With the rapid proliferation of non-English speakers on the Internet, it is becoming critical to be able to provide interactions in multiple languages. The critical issues discussed in this paper address the importance of multilingual interfaces, as well as language preferences in conducting various types of tasks. As the global economy continues to grow, technological solutions will be sought after to solve existing as well as newer issues that will arise in the future.

KEY TERMS

Business-to-Business Electronic Commerce: Any business transaction conducted between two business entities. An example is where a manufacturer buys raw material from a supplier over the Internet.

Business-to-Consumer Electronic Commerce: Any business transaction conducted through the Internet between a business and a consumer. An example includes a commercial Web site that sells products to individual customers.

Electronic Catalog: An electronic catalog is a graphical user interface that presents product and/or service information to users, typically using the World Wide Web.

Electronic Commerce: Any business transaction that is performed over the Internet.

Multilingual Interfaces: Interfaces that are written in multiple languages. These interfaces may be identical to each other or vary based on differential needs.

Semistructured Information: The type of information that is a combination of structured and unstructured information. An example of semistructured information is an HTML (hypertext markup language) page. It is structured because it uses tags to describe the content of a Web page, but it is unstructured because there is free text between two tags.

Structured Information: Information that is specific. An example is the price of a product.

Unified Content Model: As used in multilingual Web-based systems, the unified content model refers to word-for-word translation of the content from one language to another.

Unstructured Information: Information that is not well specified. An example is a free-text description of a certain product that cannot be exhaustively characterized by specific features.

ENDNOTE

Multimedia Computing Environment for Telemedical Applications

M

V.K.Murthy
University of New South Wales, Australia

E.V.Krishnamurthy
Australian National University, Australia

INTRODUCTION

Telemedicine (in short, e-medicine) is a means of delivering medical services to any place, no matter how remote, thereby removing the limitations of space and time that exists in today's health-care settings. Computers are indispensable in telemedicine, since they provide for efficient, relevant data gathering for large-scale applications. Besides providing immediate feedback of results to patients and doctors, they also can compare past patient records and evaluate relative improvement or deterioration. Further, they are readily available at any time, fatigue-free and can be more objective.

Five important application areas of telemedicine are:

1. Lifetime health care;
2. Personalized health information;
3. Tele-consultation;
4. Continuing Medical education; and
5. Context-aware Health monitoring.

For example, computers provide for multimedia imaging: ultra sound, digital X-rays, 3D spiral Cat Scanner, magnetic resonance imaging, PET scanning, and so forth, and can fuse them into a single multi-purpose image using fusion software. Adding mobility to computers enhances their role in telemedical applications considerably, especially at times of emergency since the patients, doctors, the data collecting and retrieval machines, as well as their communication links can always be on the move. Very simple, inexpensive mobile communication and computing devices can be of great help in telemedicine, as explained in the following:

- ***Low Cost Radio:*** Even the simplest of mobile devices, such as a low power radio that can transmit messages to a home computer from which medical data can be sent through telephone line and the Internet can be of great value in saving lives (Wilson et al., 2000).
- ***Personal Digital Assistants (PDA):*** The simplest of the computers, such as palmtops and PDA can assist the doctors for instant nomadic information sharing, and look for diagnosis of different diseases and treatment. PDA can help the doctors to figure out drug interactions, storing summaries of sick patients and their drug list. Further, PDA can provide for downloading suitable programs from the Web, and can be programmed for alert, sending and receiving email, jotting down pertinent points, and for storing immediately needed clinical results to carry out ward rounds. Also a hand held system can provide context-awareness to support intensive and distributed information management within a hospital setting (Munoz et al., 2003).
- ***Internet:*** The Internet is an important tool for medical professionals and will completely change the manner in which medical consultations are provided (Coiera, 1997); for further details on telehealth and telemedicine practice and their real life implementation issues, refer to Orlov and Grigoriev (2003), Jennett and Anddruchuk (2001), and Suleiman (2001).

For minor ailments, Internet-based consultations to doctors can provide prescriptions for medical/pathological examinations by laboratories. The results are then posted in the Internet for subsequent reading of the results by the concerned doctors who can prescribe medicines that can be posted on the Internet. This prescription can then be handled by a pharmacy to dispense the medicines to the concerned individual. Kim and Hwang (2001) have proposed a password controlled Internet-based medical system that brings in a variety of services to doctors, patients, pharmacists and health-care professionals. It allows people to receive medical examinations and medical advice.

BACKGROUND: TELEMEDICAL INFORMATION SERVICES

The first step in telemedicine is the telemedical diagnosis (or telediagnosis) based on information obtainable from medical images, blood, urine and other pathological test reports. Usually, for diagnostic purposes, the doctor sends a patient for such examinations. The laboratory assistant takes the required X-ray or ultrasound images or carries out pathological tests and passes these images (or readings) on to a radiologist/pathologist who then makes analysis and sends a report to a doctor. These manual actions are totally sequential and slow. This whole procedure can be made cooperative and faster, if the images and data are stored in a database and these can be simultaneously retrieved by specialists in their offices or homes to make a cooperative diagnosis (Alfano, 1997; Coiera, 1997; Ganapathy, 2001; Gomez et al., 1997; Jameson et al., 1996; Kleinholz et al., 1994; Lauterbach et al., 1997).

Principal Aims

The principal aims of e-medical informatics are to:

(i) provide online services of patient records (medical and pathological databases) to medical practitioners and radiologists;
(ii) provide primary specialist diagnosis, offer second opinion, provide pre- and post treatment advice through email;
(iii) reduce the cost of imaging equipment, delay, and increase the speed and volume of diagnosis;
(iv) aid cooperative diagnosis and provide assistance for remote surgery;
(v) provide student /resident education;
(vi) reduce professional isolation, increase collaboration; and
(vii) provide home-care.

Advantages

E-medicine offers the following advantages:

(i) Provides health care to under-served and isolated areas so that we can make a better allocation and utilisation of health resources.
(ii) Since communication cost is much cheaper than the transportation cost, patients in remote areas can outreach physicians quickly.
(iii) Increases the speed of diagnosis and treatment especially when used for teleradiology, cardiology, psychiatry.
(iv) Allows access to specialty care using time-oriented clinical data.
(v) Real-time monitoring of public health databases to prepare and respond during epidemics, biological and chemical terrorism.
(vi) Internet can provide the following support:
a. Health information;
b. Administrative infrastructure;
c. Online health records;
d. Pharmaceutical information and sales outlets; and
e. Online training for telemedical professionals.

Prerequisites

The pre-requisites for a successful implementation of a telemedical system are:

- *Infrastructure:* A suitable infrastructure of health care providers, doctors, engineers, computing specialists, communication engineers, information technology professionals and medical statisticians to analyse outcomes and suitable outreach clinics with telemedical facilities.
- *Communication Network:* Reliable, inexpensive and readily accessible communication network from outreach clinics to hospitals, doctors and patients and pathological laboratories.
- *Low-cost Computers:* Suitable low-cost hardware-software and a good communication bandwidth to transmit medical data in different modes; for example, radiological images, video images of signals and text. While using wired in or wireless mobile devices and monitors, the effect of electromagnetic interference (EMI) and radio frequency interference (RFI) on data collection and transmission, and the side-effects on patients, both physiological and psychological aspects, have to be taken care of so that improper diagnosis does not result.
- *Training Facility:* Training of personnel to provide proper maintenance of equipment and safety standards to patients.
- *Security, Reliability, Efficiency:* Reliability, Efficiency, Security, Privacy and Confidentiality in handling, storing and communicating patient information.

Economic Necessity

In densely-populated countries (e.g., India), the rate of growth in hospital beds to cope up with the increasing population is economically unsustainable and technically not viable, since the number of medical specialists also cannot grow to meet this demand (Ganapathy, 2001). The use of telemedicine avoids unnecessary strain involved in travel and associated expenses, provide immediate attention and care, can avoid hospitalization, and allow the patients to stay home enjoying family support. Chan et al. (2000) describe a real-time tertiary foetal ultrasound telemedical consultation system using standard integrated system digital network (ISDN) that operates in Queensland, Australia. This consultation system has gained acceptance from the clinicians and patients.

Aging population and rising health costs have created the need to care for more patients in their own homes. Hospitals without walls (e-hospitals or virtual hospitals) provide for continuous monitoring of patients in certain diagnostic categories. Wilson et al. (2000) describe how to build such "hospital without walls". This system uses a miniature, wearable low power radio to transmit vital and activity information to a home computer, from which data is sent by telephone line and the Internet to the concerned doctors. Thus, telemedicine and telediagnosis are economic necessities for both the developing and the developed world.

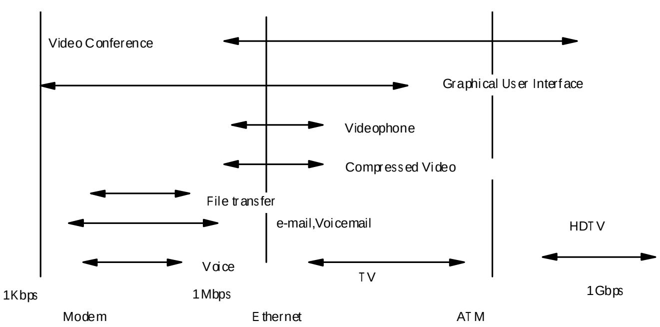
MAIN THRUST OF THE ARTICLE

The main thrust of this chapter is to describe the multimedia telediagnostic environment (MMTE), its features, and some practical MMTE systems that are currently operational.

MULTIMEDIA TELEDIAGNOSTIC ENVIRONMENT

A Mobile Multimedia Telediagnostic Environment (MMTE) permits users to work remotely on common shared resources and applications and simultaneously communicate both visually and through audio. Such an environment becomes more flexible and useful if it can work in a wireless and wired-in (integrated) environment so that the services can be provided for mobile hosts. Here, the users have interfaces of PDA or laptops interacting remotely. In this application, we need cooperation among the participants through special communication tools for conversation (Roth, 2001) and E-pointing (MacKenzie & Jusoh, 2001). The conversation can be of conference type where two or more participants are involved. The e-pointers aid each participant to point out a particular segment of an image or a video image of a signal so that each of the other participants can visualize the movements of the remote pointer. Also in telesurgery (e-surgery) where two or more operating rooms are connected by a network, live video signals may required to be transferred to other remote locations from endo-camera (camera for photographing internal organs) and operating room camera to other remote locations for consultancy. This would allow surgeons not only to see but also visualize surgical instrument movements with 3-D models in real time during the surgery.

Figure 1. Bandwidth (log scale) requirements



Pre-requisites for the Deployment of MMTE

Reliable Communication Network and Equipment

A reliable multimedia communication network that links the remote centres with hospitals is essential. The delivery of multimedia content in a timely fashion is very important. Internet provides a uniform communication medium to link users together to access or deliver multimedia information.

- Communication Bandwidth Requirements: Text requires the lowest bandwidth, while audio and video data and signals require significant increase in bandwidth. Specification of bandwidth to be used and compression techniques used are to be laid down so that the data and images that are transmitted are of diagnostic quality.
- Bandwidth Management: Bandwidth determines the information capacity of a network per unit of time. Wireless networks deliver lower bandwidth than wired network. Hence software techniques based on compression should be used. Also scheduling communication intelligently can save bandwidth. For use in telemedicine the techniques should be extremely reliable. Current cutting edge technologies are yet to develop. Bandwidth requirements along with applications are given in (approximate) logarithmic scale in Figure 1.

Three common technologies used are: (bps = bits per second; K= Kilo; M= Mega; G = Giga)

Dial up mode: Rate 28.8Kbps
T1: 1.544 Mbps; DS3: 45 Mbps

For example, standard X-ray transmission takes 30 minutes in dial-up mode, 30 seconds in T1 mode and 1 second in DS3. It is obvious that the cost goes up, as we want to increase the bandwidth to communicate voice, data and pictures. DS3 is a dedicated, private line service designed for point to point communication. This service uses fibre optic cable. One can have the option of tiered DS3 service from lower to higher bandwidth from 5 Mbps to 45 Mbps depending upon cost considerations and transmission requirements.

- Choice of Multimedia Hardware: We need a proper choice of graphics and audio equipment for quality images and audio for diagnosis.

FEATURES OF A TELEDIAGNOSTIC ENVIRONMENT

A typical cooperative telediagnostic (e-diagnostic) environment is shown in Figure 2. It consists of databases containing medical/pathological image and textual information, cooperative interaction facility, and telecommunication. Typically, its characteristics are:

Remoteness of Users

Users work remotely on common shared resources and applications and simultaneously communicate both visually and through audio. This environment becomes more flexible and useful, if it can work in an integrated (wireless and wired-in) environment so that the services can be provided for mobile hosts.

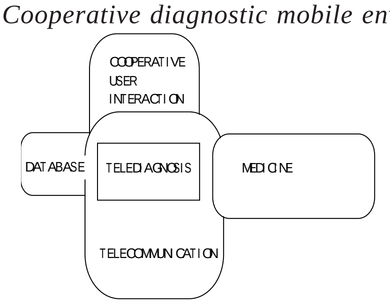
Cooperation

Many e-medicine applications require doctors, specialists and health-record officials to cooperate and discuss for particular medical treatment. Cooperation among the participants requires special communication tools for conversation, e-pointing, e-surgery.

E-pointing Facility

E-pointing is the act of moving an on-screen tracking symbol such as a cursor, by manipulating the input device. The interactive e-pointers (MacKenzie & Jusoh, 2001) aid each participant to point out a particular segment of an image or a video image of a signal so that each of the other participants can visualize the movements of the remote pointer and discuss any abnormality for diagnostic purposes.

Figure 2. Cooperative diagnostic mobile environment



Facility for Internet Link

Also users can remotely access worldwide knowledge bases/databases, download files from the Internet and browse the World Wide Web using portable and mobile devices such as laptops, palmtops and PDA.

Interoperability

Software interoperability is a key requirement in telemedicine, since different modalities of patient records are used on different platforms.

- **Security Requirements**: Security of patient data during storage and transmission are vital to safeguard confidentiality and privacy of patient information. Biometric authentication (Nanavati et al., 2002) could be an answer in dealing with patient information. Health Insurance Portability and Accountability Act (HIPAA) has devised certain security measures to handle telemedical information, see Web document of HIPAA.

FUTURE TRENDS: SOME PRACTICAL MMTE SYSTEMS

Context-aware Mobile Communicaton in Hospitals

Handheld systems can provide for context-awareness in hospitals. This can provide speedy collaboration among doctors to deal with time sensitive cases, for example, delivery, heart attacks, accidents (Munoz et al., 2003).

Presently, portable and mobile devices such as laptops and personal digital assistants (PDA) are useful for remotely accessing resources in an efficient and reliable manner and for reliable telediagnosis (Lauterbach et al., 1997; Roth, 2001). For instance, information sharing among doctors through handheld appliances are useful for transmitting small amounts of data, such as heart rate, blood pressure and other simple monitoring devices. Typical datatypes for current handheld appliances are: text, data entries, numbers, tables. None of the applications described previously can deal with multimedia data, such as audio, video which require considerable bandwidth, sufficient output devices, and a very powerful battery. Presently, multimedia data are not yet suitable for handheld appliances; they need to undergo major developments (Roth, 2001). Currently available tools, such as GyroPoint and RemotePoint (MacKenzie & Jusoh, 2001), lack accuracy and speed. The telepointer technology has yet to mature to provide reliable service for e-medicine and e-surgery. Along with the use of virtual reality, the pointer technology can be useful in teaching surgery, and for trial-error planning of operations.

Image-Guided Telemedical System

Lee (2001) describes a Java-applet based image-guided telemedicine system via the Internet for visual diagnosis of breast cancer. This system automatically indexes objects based on shape and groups them into a set of clusters. Any doctor with Internet access can use this system to analyze an image and can query about its features and obtain a satisfactory performance (http://dollar.biz.uiowa.edu/~kelly/telemedicine.html).

Software Agent based Telemedical Systems

Software agents, which are personalized, continuously running and semi-autonomous objects, can play an important role in cooperative telemedicine. Such agents can be programmed for supporting medical diagnostic intelligence and keep a watchful eye to discover patterns and react to pattern changes that usually occur in epidemics, biological and chemical terrorism.

For example, diabetes is a chronic disease with a sustained elevated glucose level. The diabetics need to be injected insulin to control the glucose level. This is quite a tedious book-keeping procedure. Real-time monitoring using agents and immediate therapy can save a life.

Also agents can help in the appropriate choice of doctors, allocation of hospitals and beds for patients. Ganguly and Ray (2000) describe a methodology for the development of software agent-based interoperable telemedicine system. This system has been illustrated using tele-electrocardiography application. Also recently, a practical agent-based approach to telemedicine has been suggested by Tian and Tianfield (2003). For medical education, this will be a very useful tool. The Foundation for Intelligent Physical Agent Architecture (FIPA, http://www.fipa.org) aims to improve agent interoperability by providing standards for protocols and languages. Also the Java 2 MicroEdition (J2ME) is targeted at PDA. These developments will provide an agent execution environment in PDA.

CONCLUSION

Cooperative telemedical informatics will have a direct impact on the rapidly changing scene of information and communication technology (including advanced communication systems) and will provide for greater interaction among doctors and radiologists and health-care professionals to integrate information quickly, efficiently and make effective decisions at all levels. Virtual e-hospital or hospital without walls will be a reality soon providing great benefit to the society.

KEY TERMS

Bandwidth Management: Determines the information capacity of a network per unit of time. Wireless networks deliver lower bandwidth than wired network. The choice of appropriate bandwidth for efficient and cost effective transmission of voice, data and pictures is called bandwidth management.

Confidentiality and Security in Telemedicine: Security and confidentiality of patient data during storage and transmission are vital to safeguard confidentiality and privacy of patient information. Biometric authentication, could be an answer in dealing with patient information. HIPAA (Health Insurance Portability and Accountability Act) has devised certain security measures to handle telemedical information (http:// www.hipaadivsory.comregs/securityoverview.htm)

Multimedia Telediagnostic Environment (MMTE): Permits users to work remotely on common shared resources and applications and simultaneously communicate both visually and through audio.

Software Agents: Personalized, continuously running and semi-autonomous objects. They can play important role in cooperative telemedicine. Such agents can be programmed for supporting medical diagnostic intelligence and keep a watchful eye to discover patterns and react to pattern changes that usually occur in epidemics, biological and chemical terrorism

Software Interoperability: Permits different software to run on different platforms with different operating systems.

Telemedicine (E-Medicine): A means of delivering medical services to any place, no matter how remote, thereby removing the limitations of space and time that exists in today's health-care settings.

Telepointers: The act of moving an on-screen tracking symbol, such as a cursor, by manipulating the input device from a remote site.

Virtual E-Hospital (or Hospital Without Walls): A telemedical facility that provides continuous monitoring of patients staying in their homes and enjoying family support and creates a psychological satisfaction to the patients that they are receiving immediate attention and care as if they are in a real hospital.

Multimedia Content Adaptation

David Knight
Brunel University, UK

Marios C Angelides
Brunel University, UK

INTRODUCTION

The previous decade has witnessed a wealth of advancements and trends in the field of communications and subsequently, multimedia access. Four main developments from the last few years have opened up the prospect for ubiquitous multimedia consumption: wireless communications and mobility, standardised multimedia content, interactive versus passive consumption and the Internet and the World Wide Web. While individual and isolated developments have produced modest boosts to this existing state of affairs, their combination and cross-fertilisation have resulted in today's complex but exciting landscape. In particular, we are beginning to see delivery of all types of data for all types of users in all types of conditions (Pereira & Burnett, 2003).

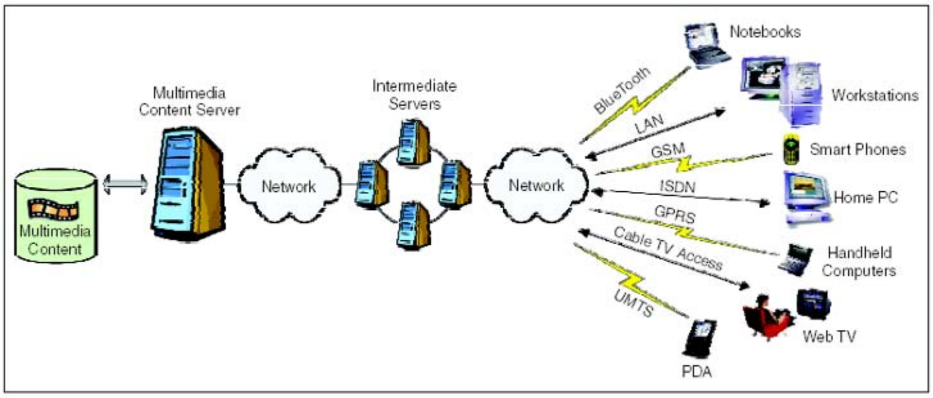
Compression, transport, and multimedia description are examples of individual technologies that are improving all the time. However, the lack of interoperable solutions across these spaces is holding back the deployment of advanced multimedia packaging and distribution applications. To enable transparent access to multimedia content, it is essential to have available not only the description of the content but also a description of its format and of the usage environment in order that content adaptation may be performed to provide the end-user with the best content experience for the content requested with the conditions available (Vetro, 2003).

In the following sections, we will look at the background of multimedia content adaptation, why do we require it and why are present solutions not adequate. We then go onto the main focus of the article, which describes the main themes of modern multimedia content adaptation, such as present day work that defines the area and overviews and descriptions of techniques used. We then look at what this research will lead to in the future and what we can expect in years to come. Finally, we conclude this article by reviewing what has been discussed.

BACKGROUND

More and more digital audio-visual content is now available online. Also more access networks are available for the same network different devices (with different resources) that are being introduced in the marketplace. Structured multimedia content (even if that structure is still limited) increasingly needs to be accessed from a diverse set of networks and terminals. The latter range (with increasing diversity) from gigabit Ethernet-connected workstations and Internet-enabled TV sets to mobile video-enabled terminals (Figure 1) (Pereira & Burnett, 2003).

Figure 1. Different terminals access multimedia content through different networks



Adaptation is becoming an increasingly important tool for resource and media management in distributed multimedia systems. Best-effort scheduling and worst-case reservation of resources are two extreme cases, neither of them well-suited to cope with large-scale, dynamic multimedia systems. The middle course can be met by a system that dynamically adapts its data, resource requirements, and processing components to achieve user satisfaction. Nevertheless, there is no agreement about questions concerning where, when, what and who should adapt (Bormans et al., 2003).

On deploying an adaptation technique, a lot of considerations have to be done with respect to how to realise the mechanism. Principally, it is always useful to make the technique as simple as possible, i.e., not to change too many layers in the application hierarchy. Changes of the system layer or the network layer are usually always quite problematic because deployment is rather difficult. Generally, one cannot say that adaptation technique *X* is the best and *Y* is the worst, as it highly depends on the application area.

The variety of delivery mechanisms to those terminals is also growing and currently these include satellite, radio broadcasting, cable, mobile, and copper using xDSL. At the end of the distribution path are the users, with different devices, preferences, locations, environments, needs, and possibly disabilities.

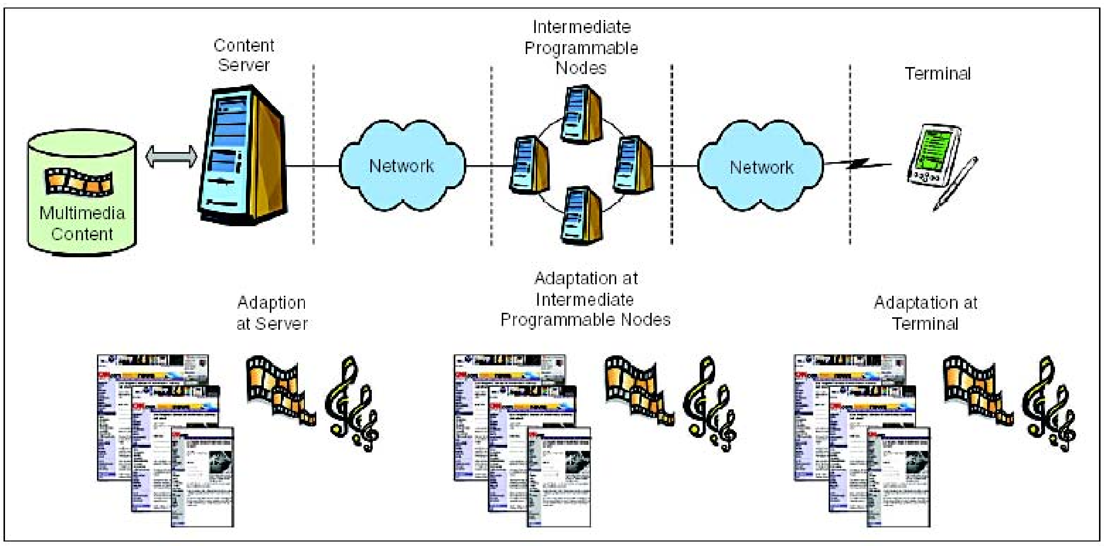
In addition the processing of the content to provide the best user experience may be performed at one location or distributed over various locations. The candidate locations are: the content server(s), any processing server(s) in the network, and the consumption terminal(s). The choice of the processing location(s) may be determined by several factors: transmission bandwidth, storage and computational capacity, acceptable latency, acceptable costs, and privacy and rights issues (see Figure 2).

Present adaptation technologies concerning content adaptation mainly focus on the adaptation of text documents. Therefore, one text document will be adapted on demand to the capabilities of different devices or applications. To fulfill this functionality the structure of the content must be separated from its presentation, i.e., the source document is structured using XML (Extensible Markup Language) and then dynamically processed to generate a presentation tailored to the available resources. One possible use case scenario will be to present the same information either on a standard Web browser or a WAP browser.

Efficient adaptation requires that the participating components know from each other and take advantage of adaptation steps done by other components, which needs standardised media, metadata, and communication. Several standardisation bodies (W3C, MPEG, and WAP) have already been established or are currently under development, which have recognised the need to create a framework that facilitates the efficient adaptation of content to the constraints and preferences of the receiving end.

MPEG-7 (ISO/IEC 15938-5:2002) provides tools for content description, whilst capability description and negotiation is provided for with CC/PP (Composite Capabilities/Preference Profiles, 2003) and UAProf (WAG User Agent Profile, 2001). MPEG-21 (ISO/IEC JTC 1/SC 29/WG 11), the "multimedia framework" includes Digital Item Adaptation (DIA), which enables standard communication of dynamic adaptation of both media resources and

Figure 2. Adaptation may be performed at different places



meta-data, enabling negotiation of device characteristics and QoS parameters. (Böszörményi et al., 2002)

In this section, the reasons for the need for interoperable and efficient multimedia content adaptation have been introduced. A number of standards groups (such as W3C, MPEG and WAP) that facilitate multimedia content adaptation by concentrating on the adaptation of associated XML-type documents have also been mentioned. The next section delves into the different technologies that help make up this exciting field.

MAIN THRUST OF THE CHAPTER

In this section we will look at the main themes found in multimedia content adaptation. We start with a look at a multimedia content adaptation architecture, a discussion on the present state of affairs regarding scalable coding and transcoding, an analysis of the effect the actual location point the adaptation takes place and a brief summary of the relevance of user profiling.

Multimedia Content Adaptation Architecture

The networking access paradigm known as Universal Multimedia Access (UMA) refers to the way in which multimedia data can be accessed by a large number of users/clients to view any desired video stream anytime and from anywhere. In the UMA framework, multimedia information is accessed from the network depending on the following three parameters: channel characteristics, device capabilities, and user preference.

Figure 3 gives an example of different presentations (to suit different capabilities such as formats, devices, networks, and user interests) of the same information.

One option for UMA is to provide different variations of the content with different quality, bit rate, media modality (e.g., audio to text), etc. The problem with this option is that it is not too efficient from the viewpoint of variation generations and storage space. On the other hand, real-time transformation of any content implies some delay for the processing and a lot of computing resources at the server (or proxy server) side. Pursuing either of these two options assumes the use of an adaptation engine. Figure 4 gives a bird's eye-view of such an adaptation engine architecture that is applicable to the adaptation of any type of content.

The architecture consists of an adaptation engine that can be located on the server, an intermediate network device such as a gateway, router, or proxy, or even on the client. This engine comprises of two logical engine modules, the adaptation decision engine and the resource adaptation engine. The adaptation decision engine receives the metadata information about the available content (context, format, and adaptation options) from the resource repository and the constraints (terminal and network capabilities, user characteristics, and preferences) from the receiving side. If there are multiple versions of the content pre-stored in the repository and one of these versions matches the constraints, then this version is selected, retrieved, and sent to the end user. However, if the available resource does not match the constraints, but can be adapted, then the adaptation decision engine determines the optimal adaptation for the given constraints and passes this decision to the resource adapta-

tion engine. The resource adaptation engine retrieves the resource from the repository, applies the selected adaptation, and sends the adapted resource to the end user.

Constraints can be grouped into four broad categories: user and natural environment characteristics, terminal capabilities, and network characteristics. The terminal and network constraints will set an upper bound on the resources that can be transmitted over the network and rendered by the terminal. Information like the network's maximum bandwidth, delay and jitter, or the terminal's resolution, buffer size, and processing power, will help the adaptation engine determine the optimal version of the resource for the given network and terminal device. As the user is the actual consumer (and judge) of the resource, user-related information, including user preferences, user demographics, usage history and natural environment, is equally important in deciding which resource should be delivered to the terminal.

The adaptation engine needs to have sufficient information about the context and the format of the multimedia resources in order to make a decision whether the resource is suitable for the user or how it should be adapted in order to offer the user the optimal context and quality. The description should therefore include information on the resource type, semantics, available adaptation options, and characteristics of the adapted versions of the resource (Panis et al., 2003).

Scalable Coding

If content is scalable, then adapting content may be done using scalable coding. This removes or alters parts of resources in such a way as to reduce their quality in order to satisfy the receiver's capabilities and needs. Currently available scaling options depend on the coding format to be used. The Holy Grail of scalable video coding is to encode the video once, and then by simply truncating certain layers or bits from the original stream, lower qualities, spatial resolutions, and/or temporal resolutions could be obtained (Vetro, 2003).

Current scalable coding schemes fall short of this goal. MPEG-4 is currently the content representation standard where the widest range of scalability mechanisms is available, notably in terms of data types, granularities, and scalability domains (Pereira & Ebrahimi, 2002).

Transcoding

This is another more complex option that typically refers to transforming the resource from one coding format into another one, i.e., decoding the resource and encoding the resource using another codec (e.g., transcode an MPEG-2 video to an MPEG-1 video). According to Sun et al. (2003), the key design goals of transcoding are to maintain the video quality during the transcoding process and to keep complexity as low as possible. Cavallaro et al. (2003) identify three main approaches to video transcoding: content-blind transcoding, semantic transcoding, and description-based transcoding:

- **Content-blind transcoding** does not perform any semantic analysis of the content prior to conversion. The choice of the output format is determined by network and appliance constraints, independent of the video content (i.e., independent of the way humans perceive visual information). The three main content-blind transcoding categories are spatial conversion, temporal conversion, and colour-depth reduction.
- **Semantic (or intramedia) transcoding** analyses the video content prior to conversion. An example of such analysis is the separation of the video content

into two classes of interest, namely foreground and background. Once this separation has been accomplished, the two classes can be coded differently to better accommodate the way humans perceive visual information, given the available network and device capabilities.

- **Description-based (or intermedia) transcoding** transforms the foreground objects extracted through semantic segmentation into quantitative descriptors. These quantitative descriptors are transmitted instead of the video content itself. In this specific case, video is transformed into descriptors so as to produce a textual output from the input video. Such textual output can be used not only for transcoding, but also for annotating the video content and for translating the visual content into speech for visually impaired users. This transformation is also referred to as cross-media adaptation.

Location of Adaptation

As well as the technologies used, the location used for multimedia content adaptation needs to be addressed. Resource delivery and adaptation can be sender-driven, receiver-driven, or network-driven.

Sender-driven proceeds to adapt resources at the sender/server node depending on the terminal and/or network capabilities received beforehand. After successful adaptation the sender transmits the adapted version of the resource to the receiver. This action requires a serious amount of computational power at the server node and goes at the expense of latency between the receiver's request and the server's delivery.

In contrast, the receiver-driven approach decides what and how to adapt at the terminal side although the real adaptation could take place somewhere else, e.g., on a proxy node. Adaptation directly at the end node could fail due to insufficient capabilities. Additionally network bandwidth will be wasted, too. Nevertheless, adaptation on terminal devices should not be strictly excluded.

The pure network-driven approach is transparent where the network, i.e., the transport system, is responsible for adaptation only. Typical use case scenarios will cover all kind of adaptation approaches described so far, i.e., resource adaptability along the delivery chain, from resource provider to resource consumer. A high-performance server node will provide some kind of pre-processing in order to facilitate easy adaptation along the delivery chain across a wide range of network and terminal devices. Network nodes such as routers or gateways will then perform so-called light-weight adaptations using segment dropping or minor editing techniques whereas proxy nodes could utilise more complex adaptation techniques. Such complex adaptation techniques include not only scaling but also transcoding and cross-media. An adaptive terminal device could perform adjustments due to user and/or usage preferences. The complexity of these adaptations to be done in terminal devices depends on its capabilities, e.g., display resolution, computational power, local storage capacity, and buffer size.

User Profiling

In order for the personalisation and adaptation of multimedia content to take place, the users' preferences, interests, usage, and environment need to be described and modelled. This is a fundamental realisation for the design of any system that aims to aid the users while navigating through large volumes of audio-visual data. The expectation is that by making use of certain aspects of the user model, one can improve the efficacy of the system and further help the user (Kobsa et al., 2001).

This section described the components needed to make up a multimedia content adaptation architecture: transcoding, scalable coding, location of adaptation, and user profiling. The next section discusses the future of multimedia content adaptation by looking at UMA, transcoding, and scalability, specifically.

FUTURE TRENDS

The major problem for multimedia content adaptation is to fix the mismatch between the content formats, the conditions of transmission networks, and the capability of receiving terminals. A mechanism for adaptation needs to be created for this purpose.

Scalable coding and transcoding are both assisting in this. It can be seen that scalable coding and transcoding should not be viewed as opposing or competing technologies. Instead, they are technologies that meet different needs regarding multimedia content adaptation and it is likely that they will coexist.

Looking to the future of video transcoding, there are still quite a number of topics that require further study. One problem is finding an optimal transcoding strategy. Given several transcoding operations that would satisfy given constraints, a means for deciding the best one in a dynamic way has yet to be determined. Another topic is the transcoding of encrypted bit streams. The problems associated with the transcoding of encrypted bit streams include breaches in security by decrypting and re-encrypting within the network, as well as computational issues (Vetro, 2003).

The inherent problem with cross-media (description-based) adaptation is in preserving the intended semantics. What are required are not the blindfolded exchange of media elements and fragments, but their substitution by semantically equivalent alternatives. Unfortunately, current multimedia authoring tools provide little support for producing annotated multimedia presentations. Richly annotated multimedia content, created using document-oriented standards, such as MPEG-7 and MPEG-21 DIA, will help facilitate sophisticated cross-modal adaptation in the future.

For the implementation of UMA, "universal," scalable, video-coding techniques are essential components. Enhancements to existing video-coding schemes, such as MPEG-4 FGS (Fine-Granular-Scalability) and entirely new schemes will help drive the UMA ideal. More efficient FGS-encoders, tests on the visual impact of variability and more improved error resilient techniques are improvements that can be made to scalable coding schemes.

While some technologies such as content scalability and transcoding are fairly well established, there are still vital technologies missing for a complete multimedia content adaptation system vision. Many of these technologies are directly related to particular usage environments. While multimedia adaptation for improved experiences is typically thought of in the context of more constrained environments (e.g., mobile terminals and networks), it is also possible that the content has to be adapted to more sophisticated environments, e.g., with three-dimensional (3-D) capabilities. Whether the adaptation processing is to be performed at the server, at the terminal, or partially at both, is something that may have to be determined case–by-case, depending on such criteria as computational power, bandwidth, interfacing conditions, and privacy issues.

CONCLUSION

The development and use of distributed multimedia applications is growing rapidly. The subsequent desire for multimedia content adaptation is leading to new demands on transcoding, scaling, and, more generally, adaptation technologies. Metadata-based standards, such as MPEG-7 and MPEG-21, which describe the semantics, structure, and the playback environment for multimedia content are breakthroughs in this area because they can assist more intelligent adaptation than has previously been possible.

A prerequisite for efficient adaptation of multimedia information is a careful analysis of the properties of different media types. Video, voice, images, and text require different adaptation algorithms. The complex nature of multimedia makes the adaptation difficult to design and implement. By mixing intelligence that combines the requirements and semantic (content) information with low-level processing, the dream of UMA could be closer than we envision.

KEY TERMS

Bit Stream: The actual data stream, which is the transmission of characters at a fixed rate of speed. No stop and start elements are used, and there are no pauses between bits of data in the stream.

Content Scalability: The removal or alteration of certain subsets of the total coded bit stream to satisfy the usage environment, whilst providing a useful representation of the original content.

Cross-Media Adaptation: Conversion of one multimedia format into another one, e.g., video to image or image to text.

Multimedia Content Adaptation: The process of adapting a multimedia resource to the usage environment. The following factors make up this usage environment: users preferences, device, network, natural environment, session mobility, adaptation QoS, and resource adaptability.

Transcoding: The process of changing one multimedia object format into another.

UMA: How users can access the same media resources with different terminal equipment and preferences.

User Modelling: In the context of adaptation, the describing/modelling of the users preferences, interests, usage, and environment.

M

Multimedia Evaluations Based on Cognitive Science Findings

Eshaa M. Alkhalifa
University of Bahrain, Bahrain

INTRODUCTION

Multi-media systems waltzed into the lives of students and educators without allowing for the time required for the development of suitable evaluation techniques. Although everyone in the field is aware that judging this type of teaching software can only come through evaluations, the work done in this regard is scarce and ill organized. Unfortunately, in many of the cases the evaluation forms were just filled in by instructors who pretended they were students when they went through the tutorial systems (Reiser et al., 1994).

BACKGROUND

In the early days, some researchers regarded the evaluation of the program's functional abilities and efficiency to be important, so they defined them as formative evaluation, and they also defined the effectiveness of the system as summative evaluation (Bloom et al., 1971; Scriven, 1967).

Others believe the evaluation of the system is unimportant, so they focused on the latter by comparing student performance in pre- and post-test questionnaires prior to and following the use of the system, learning style questionnaires that targeted their learning preferences and a subjective questionnaire that investigated whether students like the system (Kinshuk et al., 2000). Unfortunately, many of the pre- and post-tests resulted in no significant1 differences in student grades when multimedia is compared to classroom lectures or to carefully organized, well-illustrated textbooks (Pane et al., 1996). These disappointing results caused researchers to question whether or not the correct evaluation questions are being asked; for example should the test be of interactivity versus lack of interactivity, or should one compare animation with textual media (McKenna, 1995)? If Pane et al. (1996) were aware of the work done by Freyd (1987), who studied the cognitive effects of exposing subjects to a series of still images to find that they are equivalent in the reactions they elicit to being exposed to a moving picture, then perhaps they would not have asked whether animation is equivalent to a textbook with carefully set images of all stages.

Since the problem that arose is the evaluation question, researchers continued to alter it in order to recognize what should be emphasized. Tam et al. (1997) proposed a three-part evaluation procedure that includes peer review, student evaluation as well as pre- and post-testing (Tam et. al., 1997). They were not able to get rid of the pre- and post-test evaluation, as it is the primary test for how much learning was achieved, and they still got no significant differences.

At this stage, researchers recognized that evaluations did not target the appropriate level of detail, so Song et al. (2000, 2001) presented empirical support that animation helps reduce the cognitive load on the learner. They also showed that multi-media is more effective in teaching processes than in teaching conceptual definitions, while textual presentations are better at the latter. However, all this was done in very limited test domains that lacked the realistic world of an educational system. Albalooshi and Alkhalifa (2002) implemented some of these ideas in addition to offering both textual representations and animations within the same screen to students. This supports individual learning preferences while offering multi-media systems as a cognitive tool. Such a tool requires an evaluation framework that is well informed of the justification behind its design and the way its main modules interact.

A 3-DIMENTIONAL FRAMEWORK FOR EVALUATION

In the reported cases, most of the evaluated systems failed to reflect their true abilities because some aspects of the design or effects were neglected. Consequently, a complete framework of evaluation is required to take into account all issues concerning the software and the learning process. Evaluation questions can be channeled into three main dimensions of evaluation that could then be subdivided into the various methods that form possible criteria that guide the evaluation process.

Table 1. A three-dimensional framework of evaluation

1st Dimension: System Architecture

This dimension is concerned with the system's main modules, their programming complexity as well as their interactions. Evaluation within this dimension should be performed in any or all of the following methods:

- Full description of system modules and complete check of interaction.
- Expert survey of the system filled by experts or educators.
- Student evaluations to consider their perspective of the system.
- Architectural design must be based on cognitive science findings rather than chance.
- Everything else concerning the system design such as cost analysis and portability.

2nd Dimension: Educational Impact

This dimension is concerned with assessing the benefits that could be gained by students when they use the system. Classically, these are done in pre- and post-tests, and this is carried on in this framework with more attention given to detail.

- Students grouped according to their mean grade in a quiz.
- Post-tests are used to compare one group with system only and another classroom only. A third group attends the classroom lecture with the class group and does a pre-test, and then uses the system before doing a post-test for comparison with the other two.
- Questions in the pre/post-tests must be mapped to each other to test the same types of knowledge, mainly consisting of declarative and procedural knowledge.
- The tests should best be attempted with students who were never exposed to this material previously to assess their learning rate.

3rd Dimension: Affective Measures

This dimension is mainly concerned with student opinions on the user friendliness of the system and allows them to express any shortcomings in the system. This could best be done through a survey where students are allowed to add any comments they wish freely and without restraints.

The framework will be explained through a case study that was performed of a data structure tutorial system (DAST) that was developed and evaluated at the University of Bahrain (AlBalooshi & Alkhalifa, 2003). The process started with a pre-evaluation stage, where students were all given a test and then were divided into groups of equivalent mean grades. This was done to allow each group to have members of all learning levels.

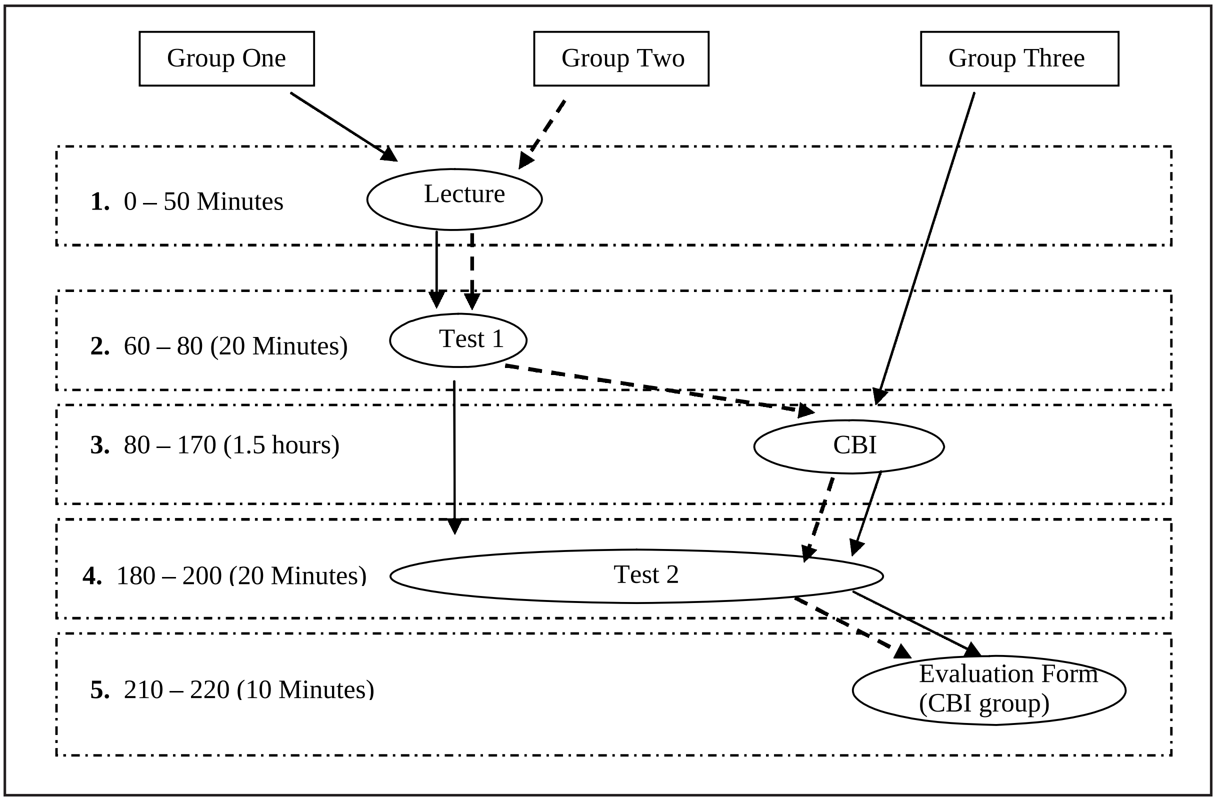
Then the pre- and post-tests were written to ensure that one set of questions mapped onto the next by altering their order while ensuring they include declarative questions that require verbalization of how students understand concepts as well as procedural questions that test if students understand how the concepts can be applied. Last but not least, a questionnaire was prepared to allow students to highlight what they regard as any weak areas or strong areas based upon their interaction with the system. The evaluation procedure for students is shown in Figure 1. Educators were also asked to fill in an evaluation form as experts.

ANALYSIS OF RESULTS

First of all, student grades were analyzed using the Analysis of Variance (ANOVA) test. This test allows the evaluation of the difference between the means by placing all the data into one number, which is F, and returning as a result one p for the null hypothesis. It will also compare the variability that is observed between conditions to the variability observed within each condition.

The statistic F is obtained as a ratio of two estimates of students' variances. If the ratio is sufficiently larger than 1, then the observed differences among the obtained means are described as being statistically significant. The term "null hypothesis" represents an investigation done between samples of the groups with the assumption that additional learning will not occur as a result of the treatment. In order to conduct a significance test, it is necessary to know the sampling distribution of F given that the significance level needed to investigate the null hypoth-

Figure 1. The evaluation procedure



esis. It must also be mentioned that the range of variation of averages is given by the standard deviation of the estimated means.

The ANOVA test did indeed show that there is a significant improvement in Group Two between the first test, which was taken after the lecture, and the second test, which was taken after using the system. However, this was not sufficient to be able to pinpoint the strengths of the system. Therefore, a more detailed analysis was done of student performance in the individual questions of test one and test two. Since the questions were mapped onto each other by design, it was easy to identify significant changes in student grades in a particular question type for students of group two who responded to similar questions before and after the use of the system. For example, a highly significant improvement with F=58 and $p<.000$ was observed in the question: "*Using an example, explain the stack concept and its possible use?*", which is an indication that the use of the system did strongly impact the student understanding of the concept of a "stack" in a functional manner.

Another point of view is to examine the scores by using the total average, which is 10.639, which can be approximated to 10.5, which can be used as a borderline. The rest of the scores can then be divided around this line. It was noticed that the average score of the third group was not high, yet 10 of the scores were above the borderline, while comparatively 6 scores were above it from the second group and only 6 of group one, which took the class only option. This shows the results of the third group, who took the CBI package alone and the second group, which had both the classroom lecture and the CBI package exposure to be close. It also underlines how much the second group improved their test results after taking the CBI and at the same time shows that the first group had not improved much only with the lecture learning. Alkhalifa (2001) tested in abstract logical context the effects of describing a state of a "*moving system*" versus describing it as a static system to find that this affects logical conclusions subjects eventually arrive at. This tutorial implemented those findings through this particular statistic, which revealed the effects of having animation in this multi-media system.

These results indicate that the use of the system may introduce a "limiting" effect that follows the initial introduction to the concepts (Albalooshi & Alkhalifa, 2002). Classroom lectures introduce students to the concepts, allowing them all the freedom to select all types of applications, which is in some ways overwhelming. The use of the system, on the other hand, produces a safe haven to test their ideas and strongly pursue the examples they can imagine, which helps them arrive at a solid procedural understanding of the concepts. It goes without saying that such a conclusion would have been impossible to make if the questions were not purposely set in the shown mapped fashion.

Additionally, students of groups two and three, who were exposed to the system, were asked to fill in an evaluation form composed of a series of questions as proposed by Caffarella (1987). They generally gave ratings of around 4 to 5 on a scale that went 0 to 6 with the highest for "The use of graphics, sound, and color contributes to the student's achievement of the objectives," and "The user can control the sequence of topics within the CBI program." The lowest score was 3.559 for "The level of difficulty is appropriate for you". Therefore, it seems that the students in general enjoyed learning through the system, although they found the level of difficulty of the concepts presented challenging.

In addition to all this, three peer experts filled in evaluation forms to rate the system from an instructor's point of view and they gave the system an average rating of 5.33 on the same scale of 0 to 6.

FINE-GRAINED EVALUATION

The evaluation framework proposed here evaluates multimedia educational software at a finer level of detail than what was previously followed. The system architecture, for example, is evaluated in terms of the cognitive assumptions on which it relies. In many cases this dimension was overlooked, as in the studies that found animation and carefully organized images to be equivalent (Byrne et al., 1999; Lawrence et al., 1994) because they were not informed of the work done to show that a sequence of images are translated as animation (Freyd, 1987). In fact, there is a difference between the two in that animation presents subjects with a cognitive tool that reduces the cognitive load they endure while learning and allows them to concentrate on the transfer of information rather than assimilating the presented material into animation (Albalooshi & Alkhalifa, 2002).

The educational impact question must also be carried out at a finer level of detail than just to report total grades for comparison. Specific questions may be designed to probe key types of learning, as was shown in the presented case study.

FUTURE TRENDS

Only through a fine-grained analysis can the true features of the system be revealed. It is this type of information that allows designers to take advantage of the opportunities offered by an educational medium that offers to transform the learning experience into a joy for both students and educators alike. Consequently, cognitive science concepts represent themselves to future research as a viable means to comprehend the learning process. This would guide the evaluative process to focus on the points of strengths and weaknesses of each system rather than assess it as a whole unit.

CONCLUSION

A three-dimensional framework is presented as a means to evaluating multimedia educational software in order to resolve the shortcomings of the current evaluation techniques. It differs from the other, in that it seeks a more fine-grained analysis while being informed through cognitive science findings. The extra detailed review reveals specific strengths of the system that may have been otherwise concealed if the comparison was done in the traditional manner. In other words, this process focuses on students' cognitive interpretations of what they are presented with rather than assuming to know how they will approach the educational content presented to them.

KEY TERMS

Cognition: The psychological result of perception, learning and reasoning.

Cognitive Load: The degree of cognitive processes required to accomplish a specific task.

Cognitive Science: The field of science concerned with cognition and includes parts of cognitive psychology, linguistics, computer science, cognitive neuroscience and philosophy of mind.

Cognitive Tool: A tool that reduces the cognitive load required by a specific task.

Declarative versus Procedural Knowledge: The verbalized form of knowledge versus the implemented form of knowledge.

Learning Style: This is the manner in which an individual acquires information.

Multimedia System: Any computer delivered electronic system that presents information through different media that may include text, sound, video computer graphics and animation.

ENDNOTE

[1] This term is defined in the Analysis of Results section.

Multimedia Information Filtering

INTRODUCTION

In the film *Minority Report* (20th Century Fox, 2002), which is set in the near future, there is a scene where a man walks into a department store and is confronted by a holographic shop assistant. The holographic shop assistant recognises the potential customer by iris-recognition technology. The holographic assistant then welcomes the man by his name and starts to inform him of offers and items that he would be interested in based on his past purchases and what other shoppers who have similar tastes have purchased. This example of future personalised shopping assistants that can help a customer find shopping goods is not too far away from becoming reality in some form or another.

Malone, Grant, Turbak, Brobst, and Cohen (1987) introduced three paradigms for information selection, *cognitive*, *economic*, and *social*, based on their work with a system they called the Information Lens. Their definition of cognitive filtering, the approach actually implemented by the Information Lens, is equivalent to the "content filter" defined earlier by Denning, and this approach is now commonly referred to as "content-based" filtering. Their most important contribution was to introduce an alternative approach that they called social (now also more commonly called collaborative) filtering. In social filtering, the representation of a document is based on annotations to that document made by prior readers of the document.

In the 1990s much work was done on collaborative filtering (CF). There were three systems that were considered to be the quintessential recommender systems. The Grouplens project (Miller, Albert, Lam, Konstan, & Riedl, 2003) initially was used for filtering items from the Usenet news domain. This later became the basis of Movielens. The Bellcore Video recommender system (Hill, Stead, Rosenstein, & Furnas, 1995), which recommended video films to users based on what they had rented before, and Ringo (Shardanand & Maes, 1995), which later was published on the Web and marketed as Firefly, used social filtering to recommend movies and music.

BACKGROUND

Filtering multimedia content is an extensive process that involves extracting and modeling semantic and structural information about the content as well as metadata (Angelides, 2003). The problem with multimedia content is that the information presented in any document is multimodal by definition. Attributes of different types of media vary considerably in the way the format of the content is stored and perceived. There is no direct way of correlating the semantic content of a video stream with that of an audio stream unless it is done manually. A content model of the spatial and temporal characteristics of the objects can be used to define the actions the objects take part in. This content model can then be filtered against a user profile to allow granular filtering of the content, allowing for effective ranking and relevancy of the documents.

Filtering has mainly been investigated in the domain of text documents. The user's preferences are used as keywords, which are used by the filters as criteria for separating the textual documents into relevant and irrelevant content. The more positive keywords contained in a document, the more relevant the document becomes. Techniques such as latent semantic indexing have found ways of interpreting the meaning of a word in different contexts to allow accurate filtering of documents using different syntax, but allow the same semantics to be recognised and understood.

Text documents adhere to the standards of the language they are written in. Trying to do the same for AV data streams, you are faced with the problem of identifying the terms in the content itself. The terms are represented as a series of objects that appear in the content, for example, a face in an image file. These terms cannot be directly related to the objects as there is no method of comparison, or if there is, it is complex to unlock. The title of the document and some information might be provided in the file description, but the actions and spatial and temporal characteristics of the objects will not be described to a sufficient level for effective analysis of relevancy.

MAIN THRUST OF ARTICLE

Information-filtering techniques have been applied to several areas including American football (Babaguchi, Kawai, & Kitahashi, 2001), digital television (Marusic & Leban, 2002), Web applications (Kohrs & Merialdo, 2000), and ubiquitous and pervasive device applications (Tseng, Lin, & Smith, 2002).

Filtering multimedia information requires different approaches depending on the domain and use of the information. There are two main types of multimedia information filtering: collaborative and content based. If the user wants a subjective analysis of content in order to find a recommendation based on their individual preference, then they use collaborative filtering, also known as social or community-based filtering. If, on the other hand, they require an objective decision to filter information from a data stream based on their information needs, then they use content-based filtering.

All of the above systems use either collaborative or content-based filtering or a combination of both (hybrid) as the techniques for recommending predictions on candidate objects. There are existing information-filtering models outside these classic techniques such as temperament-based filtering (Lin & McLeod, 2002), which looks at predicting items of interest based on temperament theory. It works on the same principle as social filtering. Unlike social filtering, the users are grouped on temperaments of the users and not on similar item selection.

Content-Based Filtering

Content-based filtering is suited to environments where the user requires items that have certain content features that they prefer. Collaborative filtering is unsuitable in this environment because it offers opinions on items that reflect preferences for that user instead of providing filtering criteria that tries to disseminate preferred content from a data stream based on a user's preference. Personalised video summaries are the perfect domain to use content-based filtering. The reason for this is that a user will be interested in certain content only within any video data stream. For example, when watching a football game, the user may only be interested in goals and free kicks. Therefore, users can state what content features and other viewing requirements they prefer and then filter the footage against those requirements.

The content-based approach to information filtering has its roots in the information retrieval (IR) community and employs many of its techniques. The most prominent example of content-based filtering is the filtering of text objects (e.g., mail messages, newsgroup postings, or Web pages) based on the words contained in their textual representations. Each object, here, text documents, is assigned one or more index terms selected to represent the best meaning of the document. These index terms are searched to locate documents related to queries expressed in words taken from the index language. The assumption underlying this form of filtering is that the "meaning" of objects and queries can be captured in specific words or phrases. A content-based filtering system selects items based on the correlation between the content of the items and the user's preferences as opposed to a collaborative filtering system that chooses items based on the correlation between people with similar preferences (van Meteren & Someren, 2000).

The main problem with content-based filtering is that it does not perform well in domains were the content of items is minimal and the content cannot be analysed easily by automatic methods of content-based retrieval (e.g., ideas and opinions). Users with eclectic tastes or who make ad hoc choices are given bad recommendations based on previous choices. For example, Dad, who usually buys classic rock CDs for himself, purchases a So Solid Crew album for his 12-year-old son. He may start getting recommendations for hardcore garage dance anthems every time he logs in. CF does not suffer this problem as it will rank on other users' recommendations of similar choices. Comparative studies have shown that collaborative-filtering recommender systems on the whole outperform content-based filtering.

Collaborative Filtering

A purely content-based approach to information filtering is limited by the process of content analysis. In some domains, until recently, the items were not amenable to any useful feature extraction with content-based filtering (such as movies, music, restaurants). Even for text documents, the representations capture only certain aspects of the content, and there are many others that would influence a user's experience, for example, in how far it matches the user's taste (Balabanovic, 2000).

Collaborative filtering is an approach to overcome this limitation. The basic concept of CF is to automate social processes such as "word of mouth." In everyday life, people rely on the recommendations from other people either by word of mouth, recommendation letters, and movie and book reviews printed in newspapers. Collaborative filtering systems assist and augment this process and help people in making decisions.

There are two main drawbacks to using collaborative filtering: the sparsity of large user-item databases and the first-rater problem (Rashid et al., 2002). Sparsity is a condition when not enough ratings are available due to an insufficient amount of users or too few ratings per user.

An example of sparsity is a travel agent Web site, which has tens of thousands of locations. Any user on the system will not have traveled to even 1% of the locations (possibly thousands of locations). If a nearest-neighbour algorithm is used, the accuracy of any recommendation will be poor as a sufficient amount of peers will not be available in the user-item database. The first-rater problem is exhibited when a new user is introduced that has not enough ratings. If no ratings have been given for an item or a new user has not expressed enough opinions, choices, or ratings, no predictions can be made due to the insufficient data available or bad recommendations will be made. In contrast, content-based schemes are less sensible to sparsity of ratings and the first-rater problem since the performance for one user relies exclusively on his or user profile and not on the number of users in the system.

Hybrid Filtering

Both content-based and collaborative filtering have disadvantages that decrease the performance and accuracy of the systems that implement them. If these methods are combined, then the drawbacks of one technique can be counteracted by the techniques of the other, and vice versa. There have been various implementations such as the following.

- By making collaborative recommendations, we can use others' experiences as a basis rather than the incomplete and imprecise content-analysis methods.
- By making content recommendations, we can deal with items unseen by others.
- By using the content profile, we make good recommendations to users even if there are no other users similar to them. We can also filter out items.
- We can make collaborative recommendations between users who have not rated any of the same items (as long as they have rated similar items).
- By utilizing group feedback, we potentially require fewer cycles to achieve the same level of personalisation.

User Profiles

In information filtering, a user's needs are translated into preference data files called user profiles. These profiles represent the users' long-term information needs (Kuflik & Shoval, 2000). The main drawbacks of using user profiles are creating a user profile for multiple domains and updating a user profile incrementally. The user profile can be populated by one or more of the following.

- *Explicit profiling*: This type of profiling allows users to let the Web site know directly what they want. Each user entering the site will fill out some kind of online form that asks questions related to a user's preferences (Eirinaki & Vazirgiannis, 2003). The problem with this method is the static nature of the user profile once it has been created. The stored preferences in the user profile cannot take into account the changing user's preferences.
- *Implicit user profiles*: This type of user profiles is created dynamically by tracking the user's behaviour pattern through automatic extraction of user preferences using some sort of software agent, for example, intelligent agents, Web crawlers, and so forth (Eirinaki & Vazirgiannis, 2003). All these usage statistics are correlated into a usage history that is an accurate interaction between the user and the system. This usage history is then analysed to produce a user profile that portrays the user's interests. The user profile can be updated every time the user starts a new session, making implicitly made profiles dynamic. The downside of this method is that the user initially will have to navigate and explore the site before enough data can be generated to produce an accurate profile.
- *Hybrid of implicit and explicit profiling*: The drawbacks of explicit and implicit profiling can be overcome by combining both methods into a hybrid. This allows the strong points of one technique to counteract the shortcomings of the other and vice versa. The hybrid method works by collecting the initial data explicitly using an online form. This explicitly created data is then updated by the implicit tracking method as the user navigates around the site. This is a more efficient method over both pure methods. In some instances, this hybrid method is reversed and the implicit tracking methods are used initially to produce a profile.
- *Stereotype profiling*: This can be achieved by data mining and analysis of usage histories over a period of visits. This provides accurate profiling for existing users with legacy data that is accurate. The disadvantage of this method is that it suffers from the same static nature as explicit profiling as the profile is created from archive data that might be obsolete, and therefore some updating might be necessary. The predefined user stereotype is a content-based user profile that has been created for a virtual user or group of users who have common usage and filtering requirements for consumption of certain material. The stereotyped profile will contain additional information about the stereotyped user such as demographic and social attributes. This additional information is then used

Table 1. Multimedia information filtering

	Description	Techniques Used	Advantages	Disadvantages	Future R&D
Information Filtering	filtering a dynamic information space using relatively stable user requirements	SDI systems recommender systems	allows user to constantly receive content they are interested in with minimal user effort	does not support ad hoc queries that are dynamic compared to the information space they are searching (information retrieval)	all of the below
Content-Based Filtering	filtering content from a data stream based on extracting content features that have been expressed in a content-based user profile	vector space model probabilistic/inference models latent semantic indexing	objective analysis of large and/or complicated (e.g., multimedia) sources of digital material without much user involvement	1. content dependent 2. hard to introduce serendipitous recommendations as approach suffers from "tunnel vision" effect	extracting semantics from the structure of the content automatically without human intervention
Collaborative Filtering	filtering items based on similarities between target user's collaborative profile and peer users/group	same as above	1. content independent 2. proves more accurate than content-based filtering for most domains of use enables introduction of serendipitous choices	1. sparsity: poor prediction capabilities when new item is introduced to database due to lack of ratings 2. new user: poor recommendations made to new users until they have enough ratings in their profiles for accurate comparison to other users	solving the sparsity and new-user problem finding other types of ratings schemes that do not use comparisons between users tastes (e.g., filtering using users temperament)
Hybrid Filtering	combines two or more filtering techniques	simple or rule based stereotype collaborative content based	to reduce weak points and promote strong points of each of the techniques used	weak points can outweigh strong points if the hybrid is created naively	using hybrid systems in domains where using one technique presents a large disadvantage/problem
User Profiles	log file containing user's preferences for consumption of content	content-based profiles collaborative profiles	1. user does not need to state preferences each and every time they use the system 2. user can maintain and update preferences with minimal effort compared to ad hoc methods	needs frequent updating or user preferences become stagnant	user profiles that are as ubiquitous and pervasive as the devices/systems that use them standardisation
Explicit User Profiles	user manually creates user profile by means of a questionnaire	questionnaires ratings	preference information gathered is usually of high quality	requires a lot of effort from user to update	collecting new user preferences that reduces user effort
Implicit User Profiles	system generates user profile from usage history of interactions between user and content	machine learning algorithms	minimal user effort required easily updateable by automatic methods	initially requires a large amount of interaction between user and content before an accurate profile is created	new machine learning algorithms for better accuracy when creating implicit user profiles
Hybrid User Profiles	combination of user profile techniques used to create a profile	explicit/implicit user profiles	to reduce weak points and promote strong points of each of the techniques used	N/A	finding effective strategies for deployment and use of hybrid profiles

to place new users to stereotyped profiles that match similar demographic and social traits. The new user without the need of any implicit or explicit tracking automatically inherits preference information.

FUTURE TRENDS

Content-based filtering in multimedia information filtering has one innate problem that researchers are trying to solve: How can we extract semantics automatically from structural content of the model? In collaborative filtering, the age-old problem of sparsity and the new-user problem are still the biggest hindrances to using this method of filtering. Sparsity is being solved presently by hybrid systems, and it appears that this will be favoured way of dealing with sparsity (Lin & McLeod, 2002). The most promising solutions appear to be collaboratively filtering, standardised content-based profiles, which allow flexibility for systems to use either pure content-based or collaborative filtering, or a hybrid of both interchangeably.

Current work on user profiles focuses on improving creation techniques such as improved machine learning algorithms that create implicit user profiles more rapidly so that they can be more reliable and accurate in a shorter amount of time. For explicit user profiling, there is the work on selecting items that increase the usefulness of initial ratings that we have already discussed. The main way forward here, though, appears to be hybrid user profiles that are initially explicitly created and then implicitly updated.

With the advent of digital television and broadband, consumers will be faced with a deluge of multimedia content available to them at home and at work. What they will require are autonomous, intelligent filtering agents and automated recommender systems that actively filter information from multiple content sources. These personalisation systems can then collaborate to produce ranked lists of recommendations for all purposes of information the user might require. The key to this kind of service is not in the implementation of these systems or the way they are designed, but rather on a standard metadata language that will allow systems to communicate without proprietary restrictions and aid in end-user transparency in the recommendation process.

CONCLUSION

In the coming years, as nearly all communication and information devices become digital, we will see the development of systems that will be able not only to recommend items of interest to us, but will be able to make minor decisions for us based on our everyday needs such as ordering basic shopping groceries or subscribing to entertainment services on an ad hoc basis. What is required is a model of the user that describes the user's preferences for a multitude of characteristics that define the user's information needs. This model can then be used to filter data and recommend information based on this complete view of the user's needs. This has been done for many years with text files using techniques such as content-based and collaborative filtering, but has always been a problem with multimedia as the content is diverse in terms of storage, analysis techniques, and presentation. In recent years, classical techniques used for text filtering have been transferred and used in the area of multimedia information filtering. New developments such as hybrid filtering and improved metadata languages have made filtering multimedia documents more reliable and closer to becoming a real-world application.

KEY TERMS

Collaborative filtering: aims at exploiting preference behaviour and qualities of other persons in speculating about the preferences of a particular individual

Content-based filtering: organizes information based on properties of the object of preference and/or the carrier of information

Hybrid filtering: a combination of filtering techniques in which the disadvantages of one type of filtering is counteracted by the advantages of another

Information filtering: filtering information from a dynamic information space based on a user's long-term information needs

Recommendation: a filtered list of alternatives (items of interest) that support a decision-making process

Recommender systems: assist and augment the transfer of recommendations between members of a community

User profile : a data log representing a model of a user that can be used to ascertain behaviour and taste preferences

Multiple Internet Technologies in In-Class Education

Mihir A. Parikh
University of Central Florida, USA

Neeraj Parolia
University of Central Florida, USA

INTRODUCTION

The Internet has a symbiotic relationship with academia. The Internet sprung from and is continually improved by academic research. In parallel, the Internet is also changing the way academia provides education and training. Most universities now disseminate administrative information to students through the Internet. However, despite this recent upsurge in the adoption of the Internet, educational institutes have yet to fully utilize the power of various Internet technologies. Other than the Web, educational institutes have largely ignored various Internet technologies, which can aid students in the learning process.

We have to go beyond the Web and leverage multiple Internet technologies to support in-class education. Alternate Internet technologies have to be integrated under a unifying framework to make classroom-based education more efficient and effective. We need to deploy a right combination of multiple Internet technologies with appropriate teaching methods and instructional material to improve education (Huang, 2001; Mahoney, 1998; Spooner et al., 1998; Sumner & Hostetler, 1999). Web-only education support has several inherent problems. We have to deploy the framework to alleviate these problems and improve learning effectiveness yielded by the new methodology.

Table 1. Classification of learning environments by Wilson (1996)

- Computer Microworld: Self-contained computer based learning environment.
- Classroom-based learning environment: Traditional educational setup involving students and teacher.
- Virtual learning environment: Telecommunications based learning environment in which students are dispersed over large geographic area.

EARLY EXPERIENCES WITH THE WEB

The Internet can provide valuable contributions to all three learning environments listed in Table 1. In the computer microworld environment, it can help distribute, maintain, and update training software and educational modules. In the classroom-based learning environment, it can help distribute course material, such as lecture notes and assignments, via course Web sites and provide e-mail-based communication between the instructor and students. In the virtual learning environment, it can replace the traditional telecommunications-based video conferencing network with a ubiquitous, multimedia network.

When the Web is used to support classroom instruction, several problems emerge. Some of these problems are listed in Table 2.

These problems create disappointment and prompt several instructors to reduce the use of the Web in their courses. To lessen these problems, off-the-shelf software products, like WebCT, TopClass, and BlackBoard, are used. However, at the time of this study, they also had their own problems such as server-based content management; they require efforts on the part of the student to check the Web site regularly and offer no support for off-line browsing. They also require reformatting of the content developed through commonly used software like Word and PowerPoint. While they do help technologically-challenged instructors to easily develop and maintain course Web sites, they do little to eradicate most of the above problems. We have to look for an alternate solution.

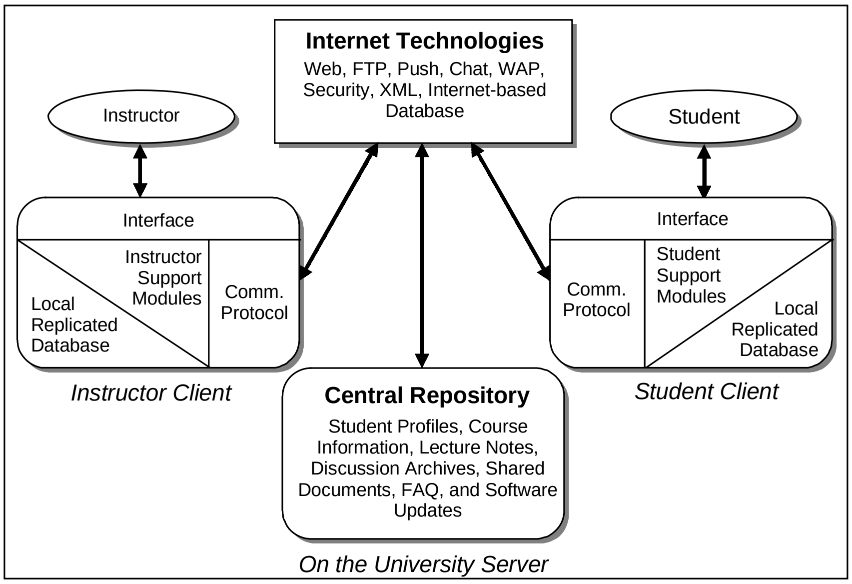
INTEGRATING INTERNET TECHNOLOGIES

The above problems relate primarily to the inherent limitations of the Web and insufficient utilization of other Internet technologies. It is easy to put documents on

Table 2. Problems with using the Web

Untimely Review of Material. The instructor regularly updates lecture notes and assignments on course Web sites, but they are not regularly reviewed by all students.	**Lack of Interactivity.** Interactivity needed for many learning activities and methods, such as group discussion, case study analysis, and real-time questions and answers are not well-developed on course Web sites.
No Confirmation Loop. The instructor does not always know who has reviewed the material and who has not.	**High Cost, No Reward.** Substantial costs are involved in developing Internet-compatible course material, in terms of time and efforts, but it brings little monetary or professional rewards for the instructor.
Wastage of Classroom Time. Significant portion of the classroom time goes in discussing and resolving technical problems.	**Varied Behavioral Response.** Some students display support for the new support technologies, while some students resist it.
Wastage of Instructor Time. The instructors usually spend substantial amount of time outside of class to develop and maintain course Web site and provide technical support to their students.	

Figure 1. Integrating multiple Internet technologies



course Web sites, but leveraging the full potential of the Internet requires integrating visual, aural, and textual material and providing nonlinear access to course material (Baer, 1998). Different Internet technologies will play an increasingly important role in the universities of the future (DosSantos & Wright, 2001).

This leads to the development and utilization of a novel, integrative model to support education (Figure 1, adapted from Parikh & Verma, 2002). This model goes beyond the Web to provide a unifying framework that can integrate and leverage various Internet technologies, such as the Web, FTP, chat, security, and Internet-based database in supporting education in the classroom-based learning environment. It has three main modules: central repository, which stores student and course-related information; instructor client, which assists the instructor in managing course information and administering the course; and student client, which assists students in accessing course information. Various Internet technologies connect these three modules and help perform information exchange task required for effective education.

NEW EDUCATION SUPPORT SYSTEM

Based on this model, a new easy-to-use education support system was developed and utilized it in eight sections of various types of courses in three semesters. It was

Table 3. Advantages of the framework

Collaborative Environment. Provides a collaborative environment, to facilitate free and easy interaction among students.	**Secure Delivery.** Enables secured delivery of course information, a significant part of which is usually an intellectual property of the instructor.
Instructor Visibility. Increases the visibility of instructors among students through synchronous and asynchronous communication.	**Mass Customization.** Using student profiles developed through the interactions with students, individual students are targeted with content customization
Confirmation Loop and Timely Feedback. Enables the instructor to track whether a student has reviewed the assigned material or not. Timely feedback is provided to the needy students.	**Ease of Use.** System modules are very simple to install and easy to use.
Increase in Efficiency. Reduces overall time spent by instructors in managing the course.	**Ease of Maintenance.** Push technology enables automatic transfer and installation on all clients without knowledge of instructors or students.
Reduced Unnecessary Meetings. Unnecessary student-instructor interactions are reduced because of FAQ and threaded discussion group databases.	**Empirical Findings.** In an empirical test, the system was found to be user friendly, to be useful, to increase convenience for students, and to provide accurate information which conformed to the needs of students in a timely manner.
Utilization of Preferred Technology. Enables the instructors to upload lecture notes and other course information in the original format.	

found that the new system was more advantageous in supporting all three types of learning activities (pre-, in, and post-class activities). The observations are in Table 3.

FUTURE TRENDS

Technology has become an integral part of learning environments. Computer hardware and software technologies provide support in computer microworld type learning environment and communications technologies provide support in the virtual learning environment. The model described previously was designed primarily for the classroom-based educational environment, but it can also be extended to the other two learning environments to simulate an interactive learning platform through synchronous and asynchronous interactivity.

On the technology front, two types of technologies are expected to have significant growth and influence in the upcoming years, peer-to-peer (p2p) technologies (e.g., Gnutella, Kazaa, etc.) and wireless combined with handheld technologies. These emerging technologies can also be utilized in the context of education under the same model discussed previously, as these technologies become omnipresent in the student community. Such technologies will involve multiple types of student client modules for various hardware types. However, all of these modules will synchronize with the single student profile stored on the central repository and replicated to all clients of the student. These technologies will further increase interactivity, facilitating the creation and sustenance of virtual communities that foster social relationships among the learners. These communities will further blur the boundaries of space and time within which education has been taking place.

Learning is not limited to the confines of academic institutions. Studies have shown that learning continues even in adulthood as individuals always adapt and learn through experiences (McCall et al., 1988). While the academic institutions are not yet at the stage of abandoning traditional degrees and adopting "learning contracts," they are preparing for the "life-long learning" as Alvin Toffler predicted. In close collaboration with corporations, they are embracing e-learning as a form of continuing education. Charles Handy (1989), a famous management guru, has foreseen that corporations would increasingly resemble universities or colleges in the years to come. We are already witnessing the beginning of this effect. U.S. corporations are spending over $60 billion annually on education with the growth of average 5% over the past decade (Prewitt, 1997). To benefit most from these efforts, going beyond the Web and leveraging all available technologies is necessary. The model discussed in this article can be the first right step in that direction.

CONCLUSION

Internet will bring about significant change in all aspects of education and training over the next decade (Aniebonam, 2000; Brandon & Hollingshead, 1999). A number of other users of Internet technologies to support university courses have suggested that they can be very effective (Jones & Rice, 2000; Stith, 2000). As the Internet is being increasingly integrated in education, it is imperative that we understand the limitations of using only one Internet technology, the Web. The Web is a powerful medium for delivering content or transferring knowledge. However, the core competency of educational institutions is developing knowledge, which can be done through intricate and robust networks and communities of students that last beyond the formal degree (Brown & Duguid, 1996). The Web falls short in this respect, probably because it is too broad and too open.

To provide more effective platform to support learning, we have to look beyond the Web. Many new Internet-based technologies have emerged recently and new ones continue to surface time and again. These technologies can provide complementary support to various educational activities that are not effectively supported by the Web. This article presented a case study of a system that integrated multiple Internet technologies, including the Web, to support learning. The system was indigenously developed with built-in flexibility to adapt to various types of courses. Further development and deployment of systems like this will provide the next frontier and drive the educational effort in the coming decades.

KEY TERMS

FTP: A protocol used to transfer files over a TCP/IP network (Internet, UNIX, etc.).

Handheld Technology: A computing device that can be easily held in one hand while the other hand is used to operate it.

Peer-to-Peer (P2P) Technology: Often referred to simply as *peer-to-peer*, or abbreviated *P2P*, a type of network in which each workstation has equivalent capabilities and responsibilities.

Push Technology: A data distribution technology in which selected data are automatically delivered into the user's computer at prescribed intervals or based on some event that occurs.

Replicated Database: A regular database in which tables, queries, and reports cannot be modified in design.

Video Conferencing: A video communications session among three or more people who are geographically separated.

Virtual Communities: A group of individuals who share a common interest via e-mail, chat rooms or newsgroups (threaded discussions). Members of a virtual community are self-subscribing.

WAP: A standard for providing cellular phones, pagers and other handheld devices with secure access to e-mail and text-based Web pages.

XML: (EXtensible Markup Language), an open standard, developed by the W3C, that involves formal syntax for adding structure and/or content information in a Web-based document. This subset of SGML defines data elements in a neutral way for easy interchange of structured data, such as mark-up tags, definitions, transmission validation, and interpretations across applications and organizations.

Music Score Watermarking

P. Nesi
University of Florence, Italy

M. Spinu
EXITECH S.r.L., Certaldo, Italy

INTRODUCTION

Music publishers, authors and/or distributors have high quantity of music scores in their archives. In classical music, the original music piece is normally kept in paper format, since its production goes back to many years ago. At present, only new light and popular music pieces are in symbolic notation formats. Light and popular music have a limited lifetime when compared with classical music pieces. The duration of the copyrights for that kind of music is about 60-80 years. Content owners are very cautious to transform their classical music pieces in digital format for e-commerce purposes, because they consider it as a highly risky process which could ultimately lose their copyright ownership. The situation is different when it comes to light and popular music, being market life shorter. According to content owners' opinion, e-commerce for music distribution cannot be accepted, unless adequate protection mechanisms are provided, as highlighted in WEDELMUSIC (www.wedelmusic.org) and MUSICNETWORK (www.interactivemusicnetwork.org). They accept to have their music protected only if it is possible to control while at the same time the users exploit content functionalities according to the established permissions and prices. To cope with these problems, mechanisms for protecting digital musical objects are used (see Table 1).

In this article, only problems and solutions for protecting and watermarking music scores are discussed.

Most music scores are still kept in paper format at publisher's archives. A first step to transform them into digital documents can be transforming them into images with a scanner. Another possible solution can be found in transforming them manually into symbolic music with a music editor. Obviously, this latter solution is very expensive, since the music has to be totally retyped. The use of very efficient Optical Music Recognition (OMR) software, similar to the Optical Character Recognition (OCR), seems to be quite unlikely in the next future. Currently, their recognition rate is close only to 90%, which makes this approach not too much reasonable when compared with retyping (www.interactivemusicnetwork.org, see assessment on the Working Group of Music Imaging).

Music images or symbolic music are obtained after music sheet digitalization. In the event of images, no further music manipulation is possible at the level of symbols. On the other hand, images can be easily viewed in any operating systems and with plenty of applications. The symbolic music gives several advantages in the score maintenance and manipulation; it allows the user to perform changes on the music, such as to justify it, change the page settings, add ornaments, accents, expressions, view single parts or the whole score, and so forth. The drawback consists in all these possible operations being performed only if the music editor is available: professional music sheets are produced by expensive and professional music editors.

It is well known that music sheets are distributed in paper format among musicians. Therefore, it seems that such digitizing process is useless. Practically speaking, Internet music sheet distribution, meaning from publishers to consumers, can only be achieved using digital formats. Distribution among users, as it occurs now with photocopies, could be made even via digital music sheets, as Napster did with audio files. Please note that on P2P (peer to peer) application there is also a quite significant

Table 1. Mechanisms for protecting digital musical objects

- encryption techniques to support any transferring of music objects;

- watermarking music sheets while they are printed from symbolic notation files.
- definition of digital rights management policies.

distribution of music scores (www.interactivemusicnetwork.org, read report on Music Distribution Models of the Working Group on Music distribution).

Whenever using digital formats, music could be converted again into paper (today musicians play music only from paper sheets).

BACKGROUND

The most relevant features for algorithms of score watermarking can be summed up into three categories (Monsignori, Nesi, & Spinu, 2003):

- *Content Requirements:*
  The embedded data may contain a simple identification code, which allows to recover the publisher and the distribution IDs simply by consulting a Web service. To this end, hiding about 100 bits is typically enough. The code can be encrypted, compressed and may include control and redundant bits to increase robustness.
- *Visual Requirements:*
  The watermark inserted in the printed music sheet has to be invisible for musicians or at least it should not bother musicians during their execution.
  The watermark has to be included in the music printed by the final user in any format if the music is available in symbolic format. Therefore, the watermark reading has not to depend on the availability of the original reference image of the music sheet.
- *Resistance Requirements:*
  The cost to remove watermark must be extremely expensive when compared to any regular purchase of the same music sheet.
  The watermark must resist against music sheet manipulation until the music printed becomes unreadable. Typically, five levels of photocopy are enough to make music unreadable or of a very bad quality.
  The watermark has to be readable when processing each single page or smaller part.

In addition, there are other parameters to be taken into account in order to analyze the technique capability.

- The amount of embedded information has a direct influence on watermark robustness. Typically, the hidden code is repeated several times in the same page; therefore, the bigger is the code, the lower is the number of times such code can be repeated, which means a decrease in the general robustness.
- Embedding strength " There is a trade-off between watermark embedding robustness and quality. Increased robustness requires a massive embedding of hidden bits. This increases music score degradation and watermark visibility.

Please note that watermarking images of scores or watermarking symbolic music lead to the same result: a watermarked music sheet. The watermarked music (symbolic or image) should be kept in some unchangeable digital file formats (like PDF) or in some formats difficult to change (PostScript), image format. The implementations of the algorithms for music watermarking in such two events are completely different (Busch, Nesi, Schmucker, & Spinu, 2002). In the first event, the watermarking is performed while the music score is printed by manipulating graphic primitives such as lines, music fonts, and so forth, and the process may generate a PostScript file or may send the information directly to the printer. In the latter case, the watermarking is performed by manipulating the B/W images.

In order to read the watermarked hidden code, the music sheet has to be scanned and the resulted image has to be elaborated with the watermark reader, to reconstruct the embedded code. The main advantages of distributing symbolic music sheets, instead of images are:

- Lower number of bytes for coding music, easier distribution, lower costs of download, and so forth;
- Higher quality of the printed music sheets, depending on the printer of the final user;
- Possibility of manipulating music notation for transposing, adding annotation, rearranging, and so forth; and
- Possibility of performing a direct music execution from symbolic format to produce MIDI or extended MIDI formats.

All of these features make the use of symbolic music more interesting for music distribution, and therefore its watermarking is very important for music protection.

APPROACHES

According to the user requirements, the printed music sheets must be produced at high resolution and quality. In appreciated music sheets, there is no noise, meaning that the information is in black and white, and therefore no space is left to hide information inside noise or in any kind of noise added-image. This means that the hidden code can be included only under the shape or in the position of music notation symbols. According to such purpose, some common elements of music sheets can be considered: staff lines, stems, note head, bar lines, and so forth.

Figure 1. Stem rotation approach

While stepping into such a direction, it is necessary to find a compromise between quality and watermark readability. Quality is very important for musicians and some minor changes could produce readability problems to musicians. They pay attention to the design of musical symbols, and any detectable variation may disturb the musician when playing. In general, the information to be hidden can be included in the changes considering both their presence and absence, for instance, coding 1 and 0 respectively. In some cases, the magnitude of the change can be used to hide more bits, for example in the orientation, the angle can be variable in order to add more bits.

Stem Rotation

The greatest problems of hiding information in the stem rotation (Busch, Rademer, Schmucker, & Wothusen, 2000) cope with the music score degradation and the low capacity in terms of hidden bits. As depicted in Figure 1, an untrained musician can identify that kind of changes in the music score. This method bothers many musicians when the music is read. In addition, the original music page is needed for watermark reading.

Beam Thickness Modification

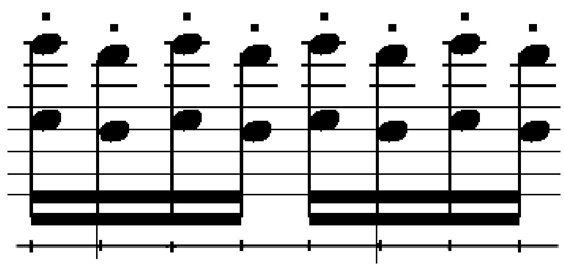
By modifying the orientation or thickness of beam lines, it is possible to hide only a few bits. Another important problem has to deal with the presence of beams which is not guaranteed in the music page. Musicians may easily detect the thickness variation when the beam is placed near a staff line. Furthermore, this method requires the original music page in order to perform the watermark reading.

Noteheads Shifting

The approach chosen by Schmucker, Busch, and Pant (2001) consists in shifting note heads (see Figure 2). The distance among notes has a musical significance. Therefore, in several cases, the approach may disturb the music reading. In Figure 2, the second chord from the left was moved to left, and musicians may detect the missed alignment of the chords. The displacement has been highlighted with the line below the staff and the gray lines. The movement of notes may generate problems when notes are marked with ornaments, accents, expressions, and so forth. In such cases, the movement becomes evident, thus creating a misalignment of notes with the markers. The idea can work things out and hide a significant code length, if there are enough noteheads in the score page.

If considering the main score, the shifted notes are quite easy to be detected by musicians reading them (according to the needs of simultaneity among parts/layers/voices), while it turns out to be quite invisible in single parts. Such a watermark is easy to be detected by musicians in regular groups of notes, provided that the distance among successive notes of the same beam is non-regular/periodic.

Figure 2. Shifting beamed notes approach



Different Fonts for the Same Music Symbol

According to this technique, different fonts for the selected music symbols are used to hide either 1 or 0, depending on the font used. This implies that the font has to be easily recognized during watermark reading. The approach was proposed for text watermarking by Maxemchuk and Low (1997).

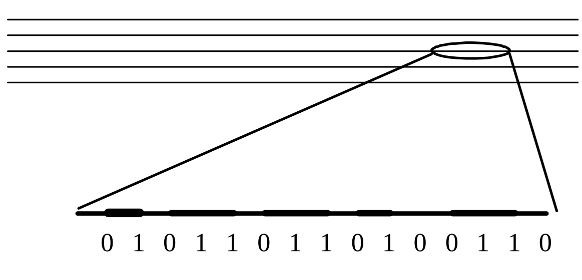
Watermarking Images of Music Sheets

The proposed methods are based on the possibility of storing information by exploiting the relationship of black and white pixels in image segments (i.e., a block) as information carrier (Funk & Schmucker, 2001). The method was elaborated upon Zhao and Koch method (1995) which is based on blocks of distinct size. The ratio of white and black pixels in certain block/area is used to embed a watermark. These areas are treated differently in the process of flipping pixels. The final idea is to embed the watermark only on the black pixels belonging to the staff lines. The fact that the pixel is on a line does not guarantee that it is on the staff line. For this purpose, only horizontal segment having a length greater than a fixed threshold was considered.

Line Thickness Modulation Approach

Figure 3 shows an example of the line modulation. It consists in modifying the lines' thickness in order to insert a binary code made up of several bits. Modulated lines can be easily noted if their presence is known, whereas they are not perceived if their presence is unknown (Monsignori, Nesi, & Spinu, 2001a, 2001b). This approach allows to hide a considerable number of bits in several instances per page, thus making the solution particularly suitable and robust to permit the watermark reading, even out of small parts of the music sheet. This approach has been used in the WEDELMUSIC Editor.

Figure 3. Staff lines thickness modification



The approach is robust with respect to staff bending, since the watermark is repeated on a large number of staff lines, and it can be read on bended lines. Moreover, a total of 108 bits can be hidden, and a certain number of CRC codes to increase the robustness has been added. This approach can be implemented only starting from the symbolic representation of music notation since the direct manipulation of staff lines on the image may introduce too much noise and produce line deformation.

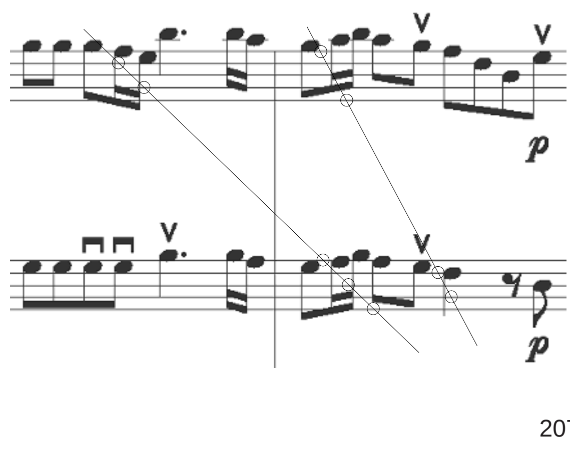
Line Mask Approach

This watermarking approach can be applied to images of music sheet or during the print out of a music score from a symbolic music notation file. The approach consists in marking some points in the music score for virtually hiding a number of lines connecting them (Monsignori et al., 2001a, 2001b). The position and the orientation of the hidden lines are used as the vehicle to hide the watermark code. In particular, the angle between the hidden line and the vertical axis has been used for hiding the information. The idea is not based on writing black lines on the music score (this may only lead up to destroy the music sheet). The points identifying the hidden line may be placed in the intersection among the hidden line and the staff lines, like it occurred with the points in Figure 4, highlighted with circles (in reality, they are interruption on the staff line). In the solution taken, groups of the lines contributing to encoding the same code start from common points. The method allows to hide a large number of bits for each page, and the code can be repeated several time increasing the robustness.

APPROACH VALIDATION

For the validation of these solutions two different phases have to be followed (Monsignori et al., 2003). First, the

Figure 4. Points chosen to be marked in the music score



validation has to be technically performed to assess the robustness against the attacks mentioned at the beginning of this article and to verify the effective coding of a large number of bits, repeated several times per page. As a second phase, the validation has to be focused on verifying the real applicability and acceptability of the solution from experts.

The experts' group has to cover the different needs: publishers, engravers, copyists, and many musicians which are the final users. Therefore, they are a very important category for the watermark validation. A specific watermark approach can be unacceptable for the musicians if the music sheet is not readable or annoying for the presence of evident changes. Typically, copyists are the most exigent. The validation has to request the assessment of a sequence of several different music score pages. Some of them are watermarked; others are not. Different levels of photocopy of the same watermarked or not watermarked music sheets have to be included. Different resolutions (dpi of the printer) of the same music sheets have also been used to assess the minimum acceptance level people involved in the validation. All music sheets were printed at the same magnitude, thus the dimension of the staff line was constant. Its value has been chosen according to that most commonly used in printed sheets.

Experts were informed about the main concepts of watermarking and not about these specific changes made in the music score. They have to perform the assessment individually, without being left with the possibility of a comparison with different pages of music and an exchange of opinions among one another.

FUTURE TRENDS AND CONCLUSIONS

As discussed in this article, the technology of music sheet watermarking is quite mature. Several algorithms have been tested and validated on real applications. The effective value of these solutions is similar to the watermark of Audio file. The presence of a specific watermark in the music sheet may be used to demonstrate the ownership of a music piece over the simple presence of textual fingerprints. In addition, the presence of the watermark can discourage people from any possible and intentional copying action of the music sheet for business purposes. The simple copying of the music sheet among friends is not prevented. The future trends of this technology are mainly in its application for monitoring the distribution of music sheets. In fact, the score watermark can be used for hiding code that can be detected during the simple distribution. This permits the content owners to set up specific services to control the data flow and thus to control and detect the passage of their digital items on the network.

KEY TERMS

Fingerprinting: Used for calling the hidden serial numbers or anything else that should allow to the copyright owner to identify which reseller broke the license agreement. It is used for the multilevel document distribution.

Fragile Watermarking: Techniques that do not guarantee the watermark presence after few document manipulations.

Image Score: An image obtained from a page of music sheet, it can include a main score or a part.

Optical Music Recognition (OMR): Optical recognition of music, transcoding of an image score to a symbolic score format by using a specific algorithm, called OMR.

Robust Copyright Marking: A term used for the techniques that assure a watermark persistence also after the original document was changed in different ways (in the case of the images: cropping, resizing, brightness modification, etc.).

Staff Line: Each single line of the music score staff. The pentagram is made of five staff lines.

Steganography: Techniques that allow secret communication, usually by embedding or hiding the secret information (called embedded data) in other, unsuspected data. Steganographic methods are based on the assumption that the existence of the covert communication is unknown and they are mainly used in secret point-to-point communication between trusting parties. As a result, steganographic methods are usually not robust, that is the hidden information cannot be recovered after data manipulation.

Symbolic Score: A representation of the music notation in symbolic, including a description of music symbols and their relationships. This can be done in some formal specific format such as Finale, Sibelius, WEDELMUSIC, HIFF, SMDL, and so forth.

Watermark: The code hidden into a digital or analog object containing an ID (identification) code or other pieces of information. The watermark is used for identifying the fields of embedded data (serial numbers, logos, etc.) that tell us who is the owner of the object or supply an ID in order to identify data connected with the digital object.

Watermarking: Process of inserting a hidden code or message into a digital or analog object. As opposed to steganography, it has the additional notion of robustness against attacks. As the name suggests, the additional data (the watermark) is added in order to protect the digital document from copyright infringements. Even if the existence of the hidden information is known, it has to be hard for an attacker to destroy the embedded watermark without destroying the data itself.

Watermark Reading: Process of extracting the watermarked code into the watermarked object.

Natural Computing

Leandro Nunes de Castro
Catholic University of Santos (UniSantos), Brazil

INTRODUCTION

There are several artifacts developed by taking inspiration from natural organisms and phenomena. For instance, Velcro was inspired by a plant burr, bullet- proof vests were inspired by spider silk, sonars were inspired by bats, airplanes were motivated by the flying of birds, and the list goes on. The observation of nature has also allowed the development of several laws and theories that describe how parts of nature work; the laws of physics are a great example – laws of thermodynamics (conservation, entropy, and absolute zero); laws of movement (Newton's laws); laws of electromagnetism (Maxwell's laws); and others. They are used to explain the trajectories, attraction and other aspects of objects.

With the advent of computing, the way humans interact with nature changed dramatically. Nowadays, we not only observe, explain and use nature as an environment for living and providing us with food, we also use nature as a source of inspiration for the development of new technologies – new computing approaches, and we use computers to simulate and/or emulate natural phenomena as well. This scenario has changed even more remarkably over the last decade when researchers realized that it is actually possible to use natural mechanisms and means as a brand new computing paradigm, which is distinct from the well-known *in silico* computation. We are in the beginning of a new age: the natural computing age!

Background

Originally, the terminology *natural computing* was used to describe only those systems that employed natural means, such as DNA or RNA strands, to perform computation. Nowadays, the terminology has broadened to encompass three major areas: *computing inspired, or motivated, by nature*; 2) *the study of natural phenomena by means of computation;* and 3) *computing with natural means*. These three branches of natural computing have one aspect in common: a strong and computer-based or computer-oriented relationship with nature. This brief overview provides a taxonomy for natural computing based on these three sub-branches and lists the most important and well-known methods of each part.

COMPUTING INSPIRED BY NATURE

The first branch of natural computing is also the oldest one. With the discovery of many principles and theories about nature and the development of its several (theoretical) models, researchers from other areas realized that these could be useful as sources of inspiration for the development of computational systems for problem solving. In particular, computer scientists, engineers and others found many works on theoretical biology that could be used for the development of novel computing approaches. Computing inspired by nature has many subareas: 1) *artificial neural networks;* 2) *evolutionary algorithms;* 3) *swarm intelligence;* 4) *artificial immune systems;* and 5) others (models based on *growth, development, culture, etc.*).

A landmark work in the branch of biologically inspired computing was the paper by McCulloch and Pitts (1943), which introduced the first mathematical model of a neuron. This neuronal model, also known as artificial neuron, gave rise to a field of investigation of its own, the so-called artificial neural networks (Bishop, 1996; Fausett, 1994; Haykin, 1999; Kohonen, 2000).

Another computing approach motivated by biology arose in the mid 1960s with the works of I. Rechenberg (1973), Schwefel (1965), Fogel (Fogel et al., 1966), and Holland (1975). These works gave rise to the field of evolutionary computation (Bäck et al., 2000a, b; Bahnzaf & Reeves, 1998; Beyer, 2001; Fogel, 1998; Goldberg, 1989; Koza, 1992; Michalewicz, 1996; Mitchell, 1998), which uses ideas from evolutionary biology to develop (evolutionary) algorithms for search and optimization.

Swarm intelligence has two main frontlines: algorithms based on the collective behavior of social insects (Bonabeau et al., 1999), and algorithms based on sociocognition (Kennedy et al., 2001). In the first case, the collective behavior of ants and other insects has led to the development of algorithms for solving combinatorial optimization and clustering problems, among others. Algorithms based on sociocognition demonstrated effectiveness in performing search on continuous spaces.

Artificial immune systems borrow ideas from the immune system and its corresponding models to design computational systems for solving complex problems (Dasgupta, 1999; de Castro & Timmis, 2002; Timmis et al., 2003). This is also a young field of research that emerged around the mid 1980s. Its application areas range from biology to robotics. The other emerging types of algorithms inspired by nature are the cultural algorithms, the simulated annealing algorithm, the systems based on growth and development, the cells and tissues models, and various others (Aarts & Korst, 1989; Kochenberger & Glover, 2003; Kumar & Bentley, 2003; Paton, 1994; Paton et al., 2003).

STUDY OF NATURAL PHENOMENA BY MEANS OF COMPUTING

Differently from computing inspired by nature, studying natural phenomena by means of computing is a synthetic approach aimed at creating patterns, forms, behaviors, and organisms that do not necessarily resemble "life-as-we-know-it". It can result in completely new phenomena never observed in nature, but that possess enough features to be qualified as "natural" or "living". For example, artificial organisms can be created that do not bear any resemblance whatsoever to any known living being on Earth. The idea is to use computers to simulate and emulate natural phenomena in a non-deterministic fashion. The study of nature by means of computing has two main branches: 1) *artificial life* (ALife); and 2) the *computational, or fractal, geometry of nature*.

As put by C. Langton in his pioneering chapter on ALife:

"Artificial Life is the study of man-made systems that exhibit behaviors characteristic of natural living systems. It complements the traditional biological sciences concerned with the analysis *of living organisms by attempting to* synthesize *life-like behaviors within computers and other artificial media. By extending the empirical foundation upon which biology is based* beyond *the carbon-chain life that has evolved on Earth, Artificial life can contribute to theoretical biology by locating* life-as-we-know-it *within the larger picture of* life-as-it-could-be.*" (Langton, 1988, p. 1)*

In summary, ALife can be defined as the synthetic or virtual approach to the study of life-like patterns (forms), behaviors, systems, and organisms (Adami, 1998; Levy, 1992).

The computational visualization of (mathematical) models of natural structures and processes results in images, animations, and interactive systems useful as scientific, research and educational tools in computer science, engineering, biosciences and many other domains. This is the core of the computational geometry of nature: how to visualize models of natural phenomena. There are several techniques that can be used with this purpose, for example, cellular automata (Ilachinski, 2001; Wolfram, 1994), particle systems (Reeves, 1983), Lindenmayer systems (Lindenmayer, 1968), iterated function systems (Barnsley, 1988; Barnsley & Demko, 1985; Hutchinson, 1981), Brownian motion (Fournier et al., 1982; Voss, 1985), and so forth.

The applications of this branch of natural computing include computer-assisted landscape architecture, design of new varieties of plants, crop yield prediction, the study of developmental and growth processes, and the modeling and synthesis (and the corresponding analysis) of an innumerable amount of natural patterns and phenomena (Flake, 2000; Mandelbrot, 1983; Peitgen et al., 1992).

COMPUTING WITH NATURAL MEANS

In 1965, G. Moore observed that there is an exponential growth in the number of transistors that can be placed in an integrated circuit. According to the "Moore's law," there is a doubling of transistors in a chip every couple of years. If this scale remains valid, by the end of this decade silicon-based computers will have reached their limits in terms of processing power. One question that remains, thus, is what kind of medium, rather than silicon, can provide an alternative for the design and implementation of a computing device?

The last decade has seen the proposal and development of several of these alternative means of computing and their corresponding computing techniques. These approaches are mostly of two types: 1) the ones based on biomolecules, and 2) the ones based on quantum bits. The approaches that use biological molecules, such as DNA and RNA strands, or membranes for computing, are usually called *molecular computing* (Calude & Pâun, 2001; Gramß et al., 2001; Pâun et al., 1998; Pâun & Cutkosky, 2002; Sienko et al., 2003). By contrast, the approaches based on quantum bits constitute what is known as *quantum computing* or *quantum computation* (Hirvensalo, 2000; Nielsen & Chuang, 2000; Pittenger, 2000).

In the first case, biomolecules are used as means to store information and techniques from molecular (genetic) and chemical engineering are used to manipulate these molecules so as to process information. Note that this approach relies on the sophistication and efficiency of the genetic engineering techniques. Quantum computing, on the other hand, stores information in quantum bits and the evolution of the "quantum computer" follows the principles of quantum mechanics.

FUTURE TRENDS

In a few decades natural computing may be pervasive in our lives. Several artifacts will have technologies based on natural computing, such as control, optimization and data mining devices. Possibly computers will involve or be based upon biomolecules or quantum bits, and the way we interact with computers may also change considerably. The amount of human expertise necessary for the use of computers may decrease in an inverse proportion to the degree of automation of our machines. But until this stage is reached, much research efforts and accomplishments still have to be made.

CONCLUSION

Natural computing is thus the terminology used to refer to three types of systems: 1) computational algorithms for problem solving developed by taking inspiration from a natural process, theory, model or mechanism; 2) computational models for the simulation and/or emulation of natural systems and processes; and 3) novel computing paradigms that use media, other than silicon, to store and process information.

Although all these branches are quite young from a scientific perspective, several of them are already being used in our everyday lives. For instance, we now have "intelligent" washing machines, games, (virtual) pets, and so forth; research on ALife and the computational geometry of nature has allowed the creation of realistic models and the simulation of several plants and animal species, has aided the study of developmental processes, and so forth; and computing with natural means has given new insights into how to complement or supplement computer technology as known nowadays.

Natural computing is highly relevant for today's computer scientists and engineers because it has offered alternative, and sometimes brand new, solutions to problems yet unsolved or poorly resolved. It has also provided us with a new way of seeing, understanding and interacting with nature. Of course there is much to come and much to do in such a broad and young field as natural computing. However, we now know for sure that this is not only a promising field of investigation; its many applications and outcomes have been affecting our lives, even if this is not perceived by most people. And the best thing is that we are only in the beginning of the natural computing age!

KEY TERMS

Analysis: The word analysis can have different meanings in different contexts. Within the natural computing domain, analysis corresponds to the investigation of a given phenomenon in order to obtain some information from it or to derive simplified computational systems (or theoretical models) that somewhat mimic the behavior of the natural system being analyzed.

Artificial Life (ALife): ALife can be defined as the synthetic or virtual approach to the study of life-like patterns (forms), behaviors, systems, and organisms, independently of the matter used for synthesis.

Computing Inspired by Nature: It embodies all approaches, mainly problem solving techniques, developed using ideas from, or inspired by, natural phenomena and/or their corresponding theoretical models. It is also sometimes referred to as computing with biological metaphors. Instead of trying to create accurate (theoretical) models, it usually results in high-level abstractions of natural phenomena.

Emergence: In the context of natural computing, an emergent phenomenon can be understood as the one whose global properties are neither possessed by, nor directly derivable from, any of its component parts. For instance, a single ant is a very simple insect with limited capabilities, but an ant colony is capable of performing complex tasks, such as nest building and organization.

Emulation: The *realization*, sometimes also called *emulation*, of a system or organism corresponds to a literal, material model that implements functions; it is a substantive functional device. Roughly speaking, a realization is judged primarily by how well it can function as an implementation of a design specification. A system or function is used to emulate or realize another, when one performs in exactly the same way as another. A typical example in computer science is the emulation of one computer by (a program running on) another computer.

Fractal Geometry: Fractal geometry is the geometry of the irregular shapes found in nature, and, in general, fractals are characterized by infinite details, infinite length, self-similarity, *fractal dimensions*, and the absence of smoothness or derivative.

Simulation: Simulations are metaphorical models that "stand for" something else, and may cover different levels of fidelity or abstraction, which can be performed by physical modeling, by writing a special-purpose computer program, or by using a more general simulation package that is probably still aimed at a particular kind of simulation. Computer simulation is pervasive in natural computing. It has been used to design problem-solving techniques that mimic the behavior of several biological phenomena, it has served to drive synthetic environments and virtual worlds, and it has been used to simulate "natural" computers.

Synthesis: Within the natural computing domain, synthesis corresponds to the act or process of developing or designing a computational system; an emulation or a simulation of a given natural phenomenon. It is usually an outcome of the analysis of the corresponding natural phenomenon.

Networks and Electronic Commerce Adoption in Small Businesses

INTRODUCTION

The adoption and diffusion of electronic commerce (e-commerce) in small businesses remains a critical area of investigation in information systems (IS) literature. A number of studies (Miles, Preece, & Baetz, 1999; Overby & Min, 2001) have suggested that in order to accommodate a technologically uncertain and globally focussed economy brought on by the advent of e-commerce, many small businesses are turning toward some form of alliance or network where the locus of the impact of change is interorganisational rather than organisational. Alliances or networks are formed entities that have a defined set of shared values, roles, responsibilities, and governance. Through involvement in such networks, small businesses not only find a ready source of technical and marketing expertise, but the very nature of the network "buffers" the impact of global market turbulence. This would suggest that belonging to a network is an important indicator of successful e-commerce adoption. However, a number of authors (Drakopoulou-Dodd, Jack, & Anderson, 2002; Dennis, 2000; McBer & Company as cited in Dennis, 2000) have found that many small businesses avoid network arrangements. Despite the widespread existence of networks, no research studies to date have formally compared networked and nonnetworked small businesses in relation to e-commerce adoption. This article presents the results of an exploratory study that aims to correct this oversight.

BACKGROUND

According to the European Commission (2003), a *small business* is defined as an organisation that employs less than 50 employees. However, apart from size, small businesses are characterised by a number of other unique features that set them apart from their larger counterparts. These are summarised in Table 1. The presence of these unique features in small businesses creates a challenging environment in which to implement new technologies. In recent years, government organisations around the world have funded projects that assist small businesses in their adoption of internet and e-commerce technologies. At a broad level, *e-commerce* involves the application of Web-based information technologies toward automating business processes, transactions, and work flows (Kalakota & Whinston, 1997). Similarly, the government-funded projects are diverse and range from establishing a simple Internet presence to building virtual business networks (for examples see Dahlstrand, 1999; Damanpour, 2001; Jeffcoate, Chappell, & Feindt, 2002; Papazafeiropoulou, Pouloudi, & Doukidis, 2002; Smith, Boocock, Loan-Clarke, & Whittaker, 2002).

Despite early predictions that small business would benefit from e-commerce adoption, recent studies (Riquelme, 2002; Roberts & Wood, 2002; Barry & Milner, 2002) have shown that it is larger businesses that have more readily adopted this technology. As a result, research studies have begun to examine more closely the processes by which small businesses make their e-commerce adoption decisions. The driving forces or reasons behind e-commerce adoption, in particular, have been investigated in some detail. A summary of the outcomes of these investigations is shown in Table 2. The driving forces can be divided into two types: external and internal. External forces include the pressures and/or influences from parties outside the organisation such as customers, suppliers, and competitors, while internal forces are perceived benefits the small business believes it will achieve through e-commerce adoption.

Unlike previous technological initiatives, e-commerce is a "disruptive" innovation that radically transforms the way a company does business. For small businesses,

Table 1. Features unique to the small business sector

Unique Features of Small Businesses	Related Literature
Small businesses are product oriented, while large business is customer oriented.	Reynolds et al. (1994)
Decision making is intuitive, not based on detailed planning.	Bunker & MacGregor (2000) Reynolds et al. (1994)
Small businesses have a strong owner influence.	Bunker & MacGregor (2000) Reynolds et al. (1994)
Small businesses are riskier than large business and have higher failure rates.	Walker (1975) Brigham & Smith (1967)
Small businesses have difficulties obtaining finances.	Gaskill & Gibbs (1994) Reynolds et al. (1994)
Planning in small businesses is informal and does not entail exhaustive study.	Tetteh & Burn (2001) Miller & Besser (2000) Reynolds et al. (1994)
Small businesses have poor record keeping.	Markland (1974)
Small businesses are more reluctant to take risks.	Walczuch, Van Braven, & Lundgren (2000) Dennis (2000)
Family values intrude in small businesses because they are often family operated.	Dennis (2000) Bunker & MacGregor (2000) Reynolds et al. (1994)
Small businesses have a strong desire for independence and tend to avoid joint business ventures.	Dennis (2000) Reynolds et al. (1994)
Small businesses have centralised management.	Bunker & MacGregor (2000)
Small businesses have a lack of technical staff and IT expertise.	Martin & Matlay (2001) Bunker & MacGregor (2000) Reynolds et al. (1994)
Small businesses do not have control over the environment and face external uncertainty.	Hill & Stewart (2000) Westhead & Storey (1996)
Small businesses make limited use of technology.	Poon & Swatman (1997) MacGregor & Bunker (1996) Abell & Limm (1996)
Small businesses have a limited market share and often operate in niche markets.	Quayle (2002) Hadjimonolis (1999) Lawrence (1997)
Small businesses rely heavily on few customers.	Reynolds et al. (1994)
Small businesses have a narrow product/service range.	Bunker & MacGregor (2000) Reynolds et al. (1994)
Small businesses have practical but narrow skills and experience.	Bunker & MacGregor (2000) Reynolds et al. (1994)

adopting e-commerce has produced both positive and negative effects. Studies by Raymond (2001) and Ritchie and Brindley (2000) found that while e-commerce adoption has eroded trading barriers, this has often come at the price of altering or eliminating commercial relationships and exposing the business to external risks. Lawrence (1997), Tetteh and Burn (2001), and Lee (2001) contend that e-commerce adoption fundamentally alters the internal procedures within small businesses. Indeed, Lee adds that the biggest challenge to a small business is not to find the best e-commerce model, but to change the mindset of the organisation itself. For those that have developed an organisation-wide strategy, these changes can lead to an increase in efficiency in the firm. For those who have not developed this strategy, this can reduce the flexibility of the business (Tetteh & Burn) and often leads to a duplication of the work effort (MacGregor, Bunker, & Waugh, 1998). These are only some of a number of studies that have examined both the benefits and disadvantages of e-commerce adoption in SMEs. A summary of these studies can be found in Table 3.

Recent studies (Keeble, Lawson, Moore, & Wilkinson, 1999; Miles et al., 1999; O'Donnell, Gilmore, Cummins, & Carson, 2001; Overby & Min, 2001) have suggested that small businesses are increasingly turning toward formal and informal alliances or networking arrangements as a mechanism to overcome the disadvantages associated with e-commerce adoption. According to Achrol and Kotler (1999, p. 148), a network is an independent coalition of task- or skill-specialised economic entities (indepen-

dent firms or autonomous organisational units) that operate without hierarchical control but is embedded by dense lateral connections, mutuality, and reciprocity, in a shared value system that defines "membership" roles and responsibilities.

Viewed as "self-designing" partnerships, networks, as suggested by Eccles and Crane (as cited in Dennis, 2000), are a dynamic arrangement evolving and adjusting to accommodate changes in the business environment. Member organisations in networks have interconnected linkages that allow more efficient movement towards predetermined objectives than would be the case if they operated as a single separate entity. The advent of e-commerce technology has given rise to a new wave of research examining the role of networks in small businesses.

Early studies of small business networks (Gibb, 1993; Ozcan, 1995) concentrated on formal networks. Indeed, Golden and Dollinger (1993) in a study of small manufacturing firms concluded that few small firms were able to function without some form of interorganisational relationship having been established. They added that these interorganisational relationships were associated with successful strategic adaptation by small businesses. Later, many small business networks took a more semi-formal approach. Local or government agencies such as small business associations and chambers of commerce provided an umbrella in the form of advisory services that assisted in legal, financial, training, or technical advice. Individual members operated formally with the umbrella organisation but could interact informally with

fellow members. Recent research (Premaratne, 2001; Rosenfeld, 1996) suggests that informal or social linkages may provide a higher and more stable flow of information and resources in the small business environment. However, a comparison of networked and nonnetworked small businesses in relation to e-commerce specifically has not been carried out to date. As a result, an exploratory study of small businesses was undertaken in Sweden to determine whether organisations belonging to a network differed from those not formally networked in terms of e-commerce adoption driving forces, benefits, and disadvantages. The results of this study are briefly presented in the next section.

E-COMMERCE ADOPTION IN NETWORKED VERSUS NONNETWORKED SMALL BUSINESSES

Based on the background literature described above, a survey was developed and administered by mail to 1,170 randomly chosen small businesses in four regional areas of Sweden: Karlstad, Filipstad, Saffle, and Arvika. Regional areas are of particular interest because of historically high unemployment rates and the loss of labour to metropolitan centres. As a result, the growth of regional businesses has been a top priority for governments worldwide, and small businesses in particular play an important role in achieving sustainable development of regional communities (Keniry et al., 2003). The adoption of technologies such as e-commerce by small businesses contributes towards the achievement of this goal. Therefore, the focus of the study was primarily on e-commerce adoption in regional small businesses.

To profile the small businesses and in line with the study by Donckels and Lambrecht (1997), respondents were asked to respond to the questions shown in Table 4. Respondents were also asked whether their business was part of a network as defined by Achrol and Kotler (1999) and whether they had adopted e-commerce in their business. Those respondents who indicated that they had adopted e-commerce were asked to rate each of the driving forces, benefits, and disadvantages (as shown in Tables 2 and 3 above) across a 5-point Likert scale (1 being very

unimportant in the decision-making process and 5 being extremely important in the decision-making process).

Responses were obtained from 339 small businesses giving a response rate of 29%. Of the 339 respondents, 148 indicated that they belonged to a network and have been termed *networked respondents*, while 191 indicated that they were not part of such an arrangement. These have been termed *nonnetworked respondents*. Table 5 provides a summary profile of the respondents.

A series of chi-square and two-tailed t-tests were performed on the data with interesting results*. Of the 339 respondents, 176 (or 52%) had adopted e-commerce, while 148 (or 43.7%) indicated that they belonged to a network. Table 6 shows a comparison of networked and nonnetworked small businesses and e-commerce adoption. While recent studies (Papazafeiropoulou et al., 2002; Riquelme, 2002; Tetteh & Burn, 2001) have concluded that adoption of e-commerce is best carried out in a networked environment, the data shown in Table 6 does not appear to support this view. It indicates that 64.9% of the

Table 6. Comparison of networked and nonnetworked small businesses and e-commerce adoption

Missing	24	14

Significance Level .004

nonnetworked respondents have adopted e-commerce, while those respondents that were part of a networked structure were, at best, equivocal where e-commerce adoption is concerned.

A number of authors (Hawkins, Winter, & Hunter, 1995; Hyland & Matlay, 1997) have noted that the adoption of e-commerce appears to be significantly linked with the size of the business. Small businesses with fewer than 10 employees (also known as microbusinesses) were less likely to adopt e-commerce than small businesses with more than 10 employees. More recently, Fallon and Moran (2000) and Smith et al. (2002) have suggested that in order to get around this problem, microbusinesses were more likely to engage in some type of formal network. The results of the Swedish study show that nonnetworked small businesses are far more likely to adopt e-commerce than those part of a network. Thus, while microbusinesses might gravitate to some form of network, this is not borne out in their patterns of adopting e-commerce. A number of authors (Donckels & Lambrecht, 1997; Keeble et al. 1999; Schindehutte & Morris, 2001) have offered market focus as an indicator of e-commerce adoption. The Swedish study shows that market focus only appears to be a significant factor for e-commerce adoption with those organisations that operate within a network structure. No significant association was found for those who have stayed outside such an arrangement.

A comparison of means showed that only two driving forces had a significant difference between the two groups of respondents (networked and nonnetworked). These were the availability of external support or assistance and improved control and follow-up. While still below the median point (3), both were rated significantly higher in the nonnetworked group than by their networked counterparts. One possible explanation for this is that sufficient technical support and business know-how exists within the networked small businesses to satisfy its members. This would tend to support the views of Foy (as cited in Dennis, 2000), Keeble et al. (1999), and Overby and Min (2001) who suggest that many small businesses seek out a network to acquire skills that are absent in their own organisations.

In contrast to the views of Achrol and Kotler (1999) and Marchewka and Towell (2000), there were no significant differences in terms of benefits of e-commerce adoption between the networked and nonnetworked respondents. One possible explanation is that in both cases, respondents expected greater benefits from e-commerce adoption than was apparent. However, in a closer examination of the disadvantages of e-commerce adoption, five of these (higher costs, increased computer/IT maintenance, duplication of work processes, reduced flexibility of work, and security) showed a significant difference between the networked and nonnetworked respondents. In all cases, the nonnetworked group found a higher level of disadvantages from these factors than did the networked group. This would tend to support the views of Achrol and Kotler (1999) and Overby and Min (2000) that difficulties dissipate through a network more readily than they might in a single stand-alone unit.

FUTURE TRENDS

The results of the Swedish study raise a number of questions concerning the nature and role of networks in the small business arena and how these impinge upon the decision making and perception of the driving forces, benefits, and disadvantages of adopting e-commerce. The implications are significant because the results raise doubts about the validity and usefulness of government initiatives to promote networks between small businesses as a means of facilitating e-commerce adoption. The study shows that there are no considerable differences between networked and nonnetworked small businesses in terms of e-commerce adoption. Consequently, government initiatives in the networking arena may not necessarily lead to any substantial outcomes.

CONCLUSION

Previous research has suggested that by entering into a networking arrangement with other organisations, a small business (and a regional small business in particular) increases its prospects of survival in a dynamic global marketplace. Furthermore, networked small businesses are able to access technical resources which are not as readily available to their nonnetworked counterparts. This would seem to imply that belonging to a network facilitates the adoption of technologies such as e-commerce. However, the research presented in this article suggests otherwise. A comparison of networked and nonnetworked small businesses in regional areas has shown that the differences between the two groups are minimal where e-commerce driving forces and benefits are concerned. However, there do appear to be noticeable differences in the disadvantages experienced following e-commerce adoption. Networked small businesses are able to absorb the negative impact of e-commerce more readily than nonnetworked ones. The research presented here, however, is by no means an exhaustive study of the relationship between networks and e-commerce adoption. Rather, it is a first step toward a more comprehensive treatment of an issue that has significant implications for the way small businesses relate to their counterparts and embrace emerging technologies.

KEY TERMS

E-Commerce/Electronic Commerce: The application of Web-based information technologies toward automating business processes, transactions, and work flows (Kalakota & Whinston, 1997).

E-Commerce Driving Forces: Conditions and/or expectations that facilitate e-commerce adoption.

E-Commerce Benefits: Tangible and intangible business advantages achieved by adopting e-commerce.

E-Commerce Disadvantages: Difficulties or problems experienced by a business following e-commerce adoption.

Microbusiness: An organisation that employs less than 10 employees.

Network: An independently formed entity that has a defined set of shared values, roles, responsibilities, and governance, and is characterised by lateral connections, mutuality, and reciprocity between the network members.

Regional Area: A geographical area located outside major metropolitan centres.

Neural Networks for Automobile Insurance Pricing

Ai Cheo Yeo
Monash University, Australia

INTRODUCTION

In highly competitive industries, customer retention has received much attention. Customer retention is an important issue, as loyal customers tend to produce greater cash flow and profits, are less sensitive to price, bring along new customers and do not require any acquisition or start-up costs.

BACKGROUND

Various techniques have been used to analyse customer retention. Eiben, Koudijs and Slisser (1998) applied genetic programming, rough set analysis, Chi-square Automatic Interaction Detection (CHAID) and logistic regression analysis to the problem of customer retention modelling, using a database of a financial company. Models created by these techniques were used to gain insights into factors influencing customer behaviour and to make predictions on customers ending their relationship with the company. Kowalczyk and Slisser (1997) used rough sets to identify key factors that influence customer retention of a mutual fund investment company. Ng, Lui and Kwah (1998) integrated various techniques such as decision-tree induction, deviation analysis and multiple concept-level association rules to form an intuitive approach to gauging customers' loyalty and predicting their likelihood of defection.

Mozer and his co-researchers (2000) explored techniques from statistical machine learning to predict churn and based on these predictions to determine what incentives should be offered to subscribers of wireless telecommunications to improve retention and maximise profitability of the carrier. The techniques included logit regression, decision trees, neural networks and boosting. Besides Mozer and his co-researchers, others have also applied neural networks to churn prediction problems. Behara and Lemmink (1994) used the neural network approach to evaluate the impact of quality improvements on a customer's decision to remain loyal to an automanufacturer's dealership. Wray and Bejou (1994) examined the factors that seem to be important in explaining customer loyalty. They found that neural networks have a better predictive power than the conventional analytic techniques such as multiple regression. Smith, Willis and Brooks (2000) also found that neural networks provided the best results for classifying insurance policy holders as likely to renew or terminate their policies compared to regression and decision tree modelling.

PREDICTING RETENTION RATES

We have also used neural networks to learn to distinguish insurance policy holders who are likely to terminate their policies from those who are likely to renew in order to predict the retention rate prior to price sensitivity analysis. Policy holders of an Australian motor insurance company are classified into 30 risk groups based on their demographic and policy information using k-means clustering (Yeo, Smith, Willis & Brooks, 2001, 2003). Neural networks are then used to model the effect of premium price change on whether a policy holder will renew or terminate his or her policy. A multilayered feedforward neural network was constructed for each of the clusters with 25 inputs and 1 output (whether the policy holder renews or terminates the contract).

Several experiments were carried out on a few clusters to determine the most appropriate number of hidden neurons and the activation function. Twenty hidden neurons and the hyperbolic tangent activation function were used for the neural networks for all the clusters. A uniform approach is preferred to enable the straightforward application of the methodology to all clusters, without the need for extensive experimentation by the company in the future. Input variables that were skewed were log transformed.

Some of the issues we encountered in using neural networks to determine the effect of premium price change on whether a policy holder will renew or terminate his or her policy were:

- Determining the threshold for classifying policy holders into those who terminate and those who renew

- Generating more homogenous models
- Clusters that had too few policy holders to train the neural networks

Determining Threshold

The neural network produces output between zero and one, which is the probability that that a policy holder will terminate his or her policy. Figure 1 shows the probability of termination of Cluster 11. A threshold value is used to decide how to categorise the output data. For example a threshold of 0.5 means that if the probability of termination is more than 0.5, then the policy will be classified as terminated. Usually the decision threshold is chosen to maximise the classification accuracy. However, in our case we are more concerned with achieving a predicted termination rate that is equal to the actual termination rate. This is because we are more concerned with the performance of the portfolio (balancing market share with profitability) rather than whether an individual will renew or terminate his or her policy. The actual termination rate for cluster 11 is 14.7%. To obtain a predicted termination rate of 14.7%, the threshold was set at 0.204 (see Figure 1). The confusion matrix for a threshold of 0.204 is shown in Table 1. The overall classification accuracy is 85.3%.

Generating more homogeneous models

The confusion matrix provides the prediction accuracy of the whole cluster. It does not tell us how a given percentage change in premium will impact termination rates. To determine how well the neural networks were able to predict termination rates for varying amounts of premium changes, the clusters were then divided into various bands of premium as follows: decrease in premiums of less than 22.5%, premium decrease between 17.5% and 22.5%, premium decrease between 12.5% and 17.5% and so on.

Figure 1. Determining the threshold value of the neural network output

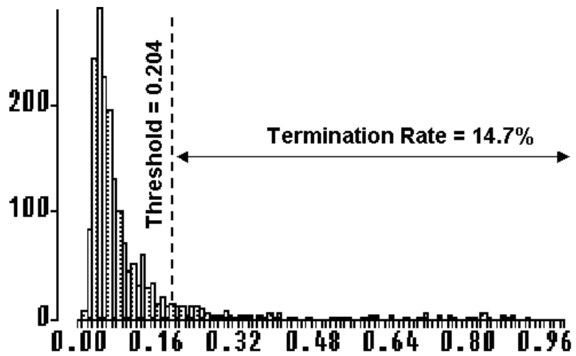

Table 1. Confusion matrix for cluster 11 with decision threshold = 0.204

	Classified as		
Actual	Terminated	Renewed	Total
Terminated	841 (50.0%)	842 (50.0%)	1,683
Renewed	845 (8.6%)	8,935 (91.4%)	9,780
Total	1,686	9,777	11,463
Overall Accuracy			85.3%

The predicted termination rates were then compared to the actual termination rates. For all the clusters the prediction accuracy of the neural networks starts to deteriorate when premium increases are between 10% and 20%. Figure 2 shows the actual and predicted termination rates for one of the clusters (Cluster 24).

In order to improve the prediction accuracy, the cluster was then split at the point when prediction accuracy starts to deteriorate. This is to isolate those policy holders with a significant increase in premium. It is believed that these policy holders behave differently due to a greater number of these policy holders who have upgraded their vehicles. Two separate neural networks were trained for each cluster. The prediction accuracy improved significantly with two neural networks as can be seen from Figure 3. The average absolute deviation decreased from 10.3% to 2.4%.

Combining Small Clusters

Some of the smaller clusters had too few policy holders to train the neural networks. We grouped the small clusters that had fewer than 7,000 policies. The criterion for grouping was similarity in risk. Risk in turn is measured by the amount of claims. Therefore the clusters were grouped according to similarity in claim cost. The maximum difference in average claim cost per policy was no more than $50. For the combined clusters, prediction ability is also improved by having two neural networks instead of one for each cluster.

PRICE SENSITIVITY ANALYSIS

Having trained neural networks for all the clusters, sensitivity analysis was then performed on the neural networks to determine the effect of premium changes on termination rates for each cluster. There are several ways of performing the sensitivity analysis:

One approach is based on systematic variation of variables (SVV). To determine the impact that a particular input variable has on the output, we need to hold all the other inputs to some fixed value and vary only the input

N

Figure 2. Prediction accuracy for one neural network model of cluster 24

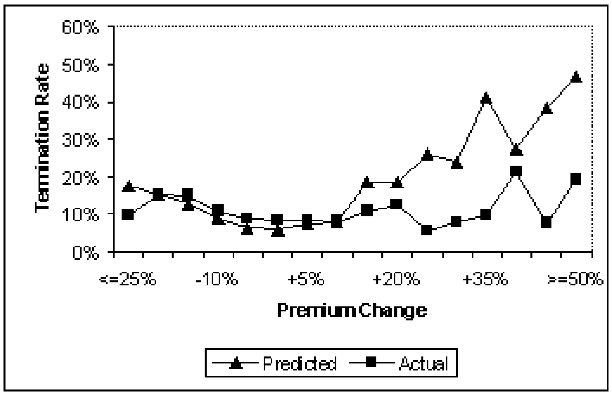

Figure 3. Prediction accuracy for two networks model of cluster 24

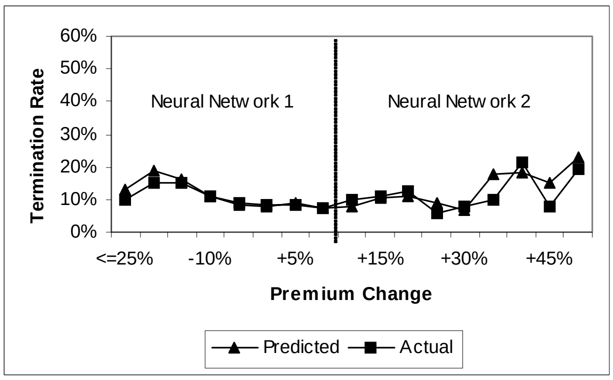

of interest while we monitor the change in outputs (Anderson, Aberg & Jacobsson, 2000; Bigus, 1996).

A more automated approach is to keep track of the error terms computed during the backpropagation step. By computing the error all the way back to the input layer, we have a measure of the degree to which each input contributes to the output error (Bigus, 1996).

The third approach is based on sequential zeroing of weights (SZW) of the connection between the input variables and the first hidden layer of the neural network (Anderson et al., 2000).

In their research, Anderson and his co-researchers (2000) found that neural networks are suitable not only for function approximation of nonlinear relationship but are also able to represent to a high degree the nature of input variables. The information generated about the variables using the SVV and SZW methods can serve as a guide to the interpretation of influence, contribution and selection of variables. We performed price sensitivity using the SVV approach by varying the premium information and holding all other inputs constant.

Table 2. Price sensitivity analysis – effect on termination rate (Cluster 24)

Scored Against	Average Change in Premium	Average Premium Amount ($)	Termination Rate
Neural Network 1	-8.3%	481	8.6%
	-3.3%	507	8.3%
	1.7%	533	9.1%
	6.7%	559	12.2%
Neural Network 2	11.7%	585	12.1%
	16.7%	612	13.2%
	21.7%	638	14.6%
	26.7%	664	16.3%
	31.7%	690	18.2%
	51.7%	795	26.9%
	71.7%	900	35.1%

Separate data sets were created from each "half" cluster with all variables remaining unchanged except the new premium and related variables (change in premium, percentage change in premium and ratio of new premium to new sum insured). For example, cluster 24 was split into two "halves"; policy holders with premium decreases or increases of less than 10% and policy holders with premium increases of more than 10%. Data sets with varying percentage changes in premium were created and scored against the trained neural networks to determine the predicted termination rates. Results of price sensitivity analysis for Cluster 24 are shown in Table 2 and Figure 4 as an example. They show that as premiums increase the termination rates also increase.

CONCLUSIONS AND FUTURE RESEARCH

We randomly selected a few clusters to carry out experiments to determine the appropriate neural network architecture for the prediction of retention rates. More experiments could be performed to find an appropriate neural network architecture for each of the clusters so that prediction accuracy could be improved. However, the insurance industry is unlikely to implement the proposed approach if it is difficult to implement. We have therefore adopted a straightforward approach that requires minimal fine tuning for specific data. While this research has been focused on premium pricing within the insurance industry, the methodology developed is quite general. In fact, the approach can be applied to any industry concerned with setting prices for products in competitive environments. This includes sectors such as retail and telecommunications.

KEY TERMS

Activation Function: Transforms the net input of a neural network into an output signal, which is transmitted to other neurons.

Association Rules: Predict the occurrence of an event based on the occurrences of another event.

Backpropagation: Method for computing the error gradient for a feedforward neural network.

Boosting: Generates multiple models or classifiers (for prediction or classification), and to derive weights to combine the predictions from those models into a single prediction or predicted classification.

Chi-Square Automatic Interaction Detection (CHAID): A decision tree technique used for classification of a data set. CHAID provides a set of rules that can be applied to a new (unclassified) data set to predict which records will have a given outcome. CHAID segments a data set by using chi square tests to create multi-way splits.

Confusion Matrix: Contains information about actual and predicted classifications done by a classification system.

Decision Trees: Tree-shaped structures that represent sets of decisions. These decisions generate rules for the classification of a dataset.

Deviation Analysis: Locates and analyses deviations from normal statistical behavior.

Genetic Programming: Search method inspired by natural selection. The basic idea is to evolve a population of "programs" candidates to the solution of a specific problem.

K-means Clustering: An algorithm that performs disjoint cluster analysis on the basis of Euclidean distances computed from variables and randomly generated initial seeds.

Logistic/Logit Regression: A technique for making predictions when the dependent variable is a dichotomy, and the independent variables are continuous and/or discrete.

Multi-Layered Feedforward Network: A layered neural network in which each layer only receives inputs from previous layers.

Multiple Concept-Level Association Rules: Extend association rules from single level to multiple levels. Database contents are associated together to the concepts, creating different abstraction levels.

Multiple Regression: A statistical technique that predicts values of one variable on the basis of two or more other variables.

Neural Network: Non-linear predictive models that learn through training and resemble biological neural networks in structure.

Neural Network Architecture: A description of the number of layers in a neural network, each layer's transfer function, the number of neurons per layer, and the connections between layers

Neuron: The basic processing element of a neural network.

Regression Analysis: A statistical technique used to find relationships between variables for the purpose of predicting future variables.

Rough Sets: Rough sets are mathematical algorithms that interpret uncertain, vague, or imprecise information.

Sequential Zeroing of Weights: A sensitivity analysis method that involves sequential zeroing of weights of the connection between the input variables and the first hidden layer of the neural network.

Statistical Machine Learning: An approach to machine intelligence that is based on statistical modeling of data.

Systematic Variation of Variables: A sensitivity analysis method whereby the input of interest is varied while holding all other inputs to some fixed value to determine the impact that particular variable has on the output.

Weights: Strength of a connection between two neurons in a neural network.

Neural Networks for Retail Sales Forecasting

G. Peter Zhang
Georgia State University, USA

INTRODUCTION

Forecasting of the future demand is central to the planning and operation of retail business at both macro and micro levels. At the organizational level, forecasts of sales are needed as the essential inputs to many decision activities in various functional areas such as marketing, sales, production/purchasing, as well as finance and accounting (Mentzer & Bienstock, 1998). Sales forecasts also provide basis for regional and national distribution and replenishment plans. The importance of accurate sales forecasts to efficient inventory management has long been recognized. In addition, accurate forecasts of retail sales can help improve retail supply chain operation, especially for larger retailers who have a significant market share. For profitable retail operations, accurate demand forecasting is crucial in organizing and planning purchasing, production, transportation, labor force, as well as after sales services.

Barksdale and Hilliard (1975) examined the relationship between retail stocks and sales at the aggregate level and found that successful inventory management depends to a large extent on the accurate forecasting of retail sales. Thall (1992) and Agrawal and Schorling (1996) also pointed out that accurate demand forecasting plays a critical role in profitable retail operations and poor forecasts would result in too many or too few stocks that directly affect revenue and competitive position of the retail business. The importance of accurate demand forecasts in successful supply chain operations and coordination has been recognized by many researchers (Chopra & Meindl, 2001; Lee et al., 1997).

Retail sales often exhibit both seasonal variations and trends. Historically, modeling and forecasting seasonal data is one of the major research efforts and many theoretical and heuristic methods have been developed in the last several decades. Different approaches have been proposed but none of them has reached consensus among researchers and practitioners. Until now, the debate has still not abated in terms of what is the best approach to handle the seasonality.

On the other hand, it is often not clear how to best model the trend pattern in a time series. In the popular Box-Jenkins approach to time series modeling, differencing is used to achieve stationarity in the mean. However, Pierce (1977) and Nelson and Plosser (1982) argue that differencing is not always an appropriate way to handle trend, and linear detrending may be more appropriate. Depending on the nature of the nonstationarity, a time series may be modeled in different ways. For example, a linear or polynomial time trend model can be used if the time series has a deterministic trend. However, if a time series exhibits a stochastic trend, the random walk model and its variations may be more appropriate.

In addition to controversial issues around the ways to model seasonal and trend time series, one of the major limitations of many traditional models is that they are essentially linear methods. In order to use them, users must specify the model form without the necessary genuine knowledge about the complex relationship in the data. This may be the reason for the mixed findings reported in the literature regarding the best way to model and forecast trend and seasonal time series.

One nonlinear model that has recently received extensive attention is the neural network model (NN). The popularity of the neural network model can be attributed to their unique capability to simulate a wide variety of underlying nonlinear behaviors. Indeed, research has provided theoretical underpinning of neural network's universal approximation ability. In addition, few assumptions about the model form are needed in applying the NN technique. Rather, the model is adaptively formed with the real data. This flexible data-driven modeling property has made NNs an attractive tool for many forecasting tasks, as data are often abundant, while the underlying data generating process is hardly known.

In this article, we provide an overview on how to effectively model and forecast consumer retail sales using neural network models. Although there are many studies on general neural network forecasting, few are specifically focused on trending or seasonal time series. In addition, controversial results have been reported in the literature. Therefore it is necessary to have a good summary of what has been done in this area and more importantly to give guidelines that can be useful for forecasting practitioners.

It is important to note that the focus of this article is on time series forecasting methods. For other types of forecasting methods used in retail sales, readers are referred to Green (1986), Smith et al. (1994), and Dominique (1998).

BACKGROUND

Neural networks are computing models for information processing. They are very useful for identifying the functional relationship or pattern in the retails sales and other time series data. The most popularly used neural network model in practice for retail sales is the feedforward multi-layer network. It is composed of several layers of basic processing units called neurons or nodes. For an in-depth coverage of NN models, readers are referred to Smith (1993) and Bishop (1995). A comprehensive review of the NNs for forecasting is given by Zhang et al. (1998).

Before it can be used for forecasting, the NN model must be built first. Neural network model building (training) involves determining the order of the network (the architecture) as well as the parameters (weights) of the model. NN training typically requires that the in-sample data be split into a training set and a validation set. The training set is used to estimate the parameters of some candidate models, among which the one that performs the best on the validation set is selected. The out-of-sample observations can be used to further test the performance of the selected model to simulate the real forecasting situations.

The standard three-layer feedforward NN can be used for time series forecasting in general and retail sales in particular. For one-step-ahead forecasting, only one output node is needed. For multiple-step forecasting, more output nodes should be employed. For time series forecasting, the most important factor in neural networks modeling is the number of input nodes, which corresponds to the number of past observations significantly auto-correlated with the future forecasts. In a seasonal time series such as the retail sales series, it is reasonable to expect that a forecasting model should capture the seasonal autocorrelation that spans at least one or two seasonal periods of, say, 12 or 24 for monthly series.

Therefore in modeling seasonal behavior, it is critical to include in the input nodes the observations separated by multiples of seasonal period. For example, for a quarterly seasonal time series, observations that are four quarters away are usually highly correlated. Although theoretically, the number of seasonal lagged observations that have autocorrelation with the future value can be high, it is fairly small in most practical situations, as empirical studies often suggest that the seasonal autoregressive order be one or at most two (Box & Jenkins, 1976).

There are many other parameters and issues that need to be carefully considered and determined in neural network model building for retail and other time series. These include data preparation, data division and sample size, network architecture in terms of number of hidden and input nodes, training algorithm, model evaluation criteria and so forth. Practical guidelines can be found in many references in the literature including Adya and Collopy (1998), Kaastra and Boyd (1996), and Zhang et al. (1998).

ISSUES AND LITERATURE REVIEW

Modeling seasonal and trend time series has been one of the main research endeavors for decades. In the early 1920s, the decomposition model along with seasonal adjustment was the major research focus due to Person's (1919) work on decomposing a seasonal time series. Different seasonal adjustment methods have been proposed and the most significant and popular one is the Census X-11 method developed by the Bureau of the Census in 1950s and 60s, which has evolved into the current X-12-ARIMA program. Because of the ad hoc nature of the seasonal adjustment methods, several model-based procedures have been developed. Among them, the work by Box and Jenkins (1976) on the seasonal ARIMA model has had a major impact on the practical applications to seasonal time series modeling. This model has performed well in many real-world applications and is still one of the most widely used seasonal forecasting methods. More recently, neural networks have been widely used as a powerful alternative to traditional time series modeling.

In neural network forecasting, little research has been done focusing on seasonal and trend time series modeling and forecasting. In fact, how to effectively model seasonal time series is a challenging task not only for the newly developed neural networks, but also for the traditional models. One popular traditional approach to dealing with seasonal data is to remove the seasonal component first before other components are estimated. Many practitioners in various forecasting applications have satisfactorily adopted this practice of seasonal adjustment. However, several recent studies have raised doubt about its appropriateness in handling seasonality. Seasonal adjustment has been found to lead into undesirable nonlinear properties, severely distorted data, and inferior forecast performance (Ghysels et al., 1996; Plosser, 1979). De Gooijer and Franses (1997) pointed out that "although seasonally adjusted data may sometimes be useful, it is typically recommended to use seasonally unadjusted data". On the other hand, mixed findings have also been reported in the limited neural network literature on seasonal forecasting. For example, Sharda and Patil (1992) found that, after examining 88 seasonal time series, NNs were able to model seasonality directly and pre-deseasonalization is not necessary. Alon et al. (2001) also found that NNs are able to "capture the dynamic nonlinear trend and seasonal patterns, as well as the interactions between them". However, Farway and Chatfield (1995) and Nelson et al. (1999), among others, found just the opposite. Their findings suggest that neural networks are not able to directly model seasonality and pre-deseasonalization of the data is necessary to improve forecasting performance.

Chu and Zhang (2003) compared the accuracy of various linear and neural network models for forecasting aggregate retail sales. Using multiple cross-validation samples, they found that the nonlinear models outperform their linear counterparts in out-of-sample forecasting, and prior seasonal adjustment of the data can significantly improve forecasting performance of the neural network model. The overall best model is the neural network built on deseasonalized time series data. While seasonal dummy variables can be useful in developing effective regression models for predicting retail sales, the performance of dummy regression models may not be robust. In addition, they found that trigonometric models are not useful in aggregate retail sales forecasting.

Zhang and Qi (2003) examined the issue of how to use neural networks more effectively in modeling and forecasting a seasonal time series with a trend component. The specific research questions they addressed are (1) whether neural networks are able to directly model different components of a seasonal and trend time series and (2) whether data pre-processing is necessary or beneficial. Instead of focusing solely on the seasonal component alone as in previous studies (e.g., Nelson et al., 1999), they took a systematic approach on the data preprocessing issue to study the relevance of detrending and deseasonalization. Using a large number of simulated and real time series, they evaluated the effect of different data preprocessing strategies on neural network forecasting performance. Results clearly show that without data pre-processing, neural networks are not able to effectively model the trend and seasonality patterns in the data, and either detrending or deseasonalization can greatly improve neural network modeling and forecasting accuracy. A combined approach of detrending and deseasonalization is found to be the most effective data preprocessing that can yield the best forecasting result. These findings are further examined and confirmed in Zhang and Qi (2002) with two monthly consumer retail sales—computer and computer software sales, and grocery store sales.

Therefore, it is recommended that data preprocessing is performed before building neural network models for retail sales data that contain seasonal and trend components. If the time series contains only the seasonal variation, deseasonalization should be the best choice. However, if both trend and seasonal fluctuations are present, a combined approach of detrending and deseasonalization should be used.

CONCLUSION

Neural networks become an important tool for retail sales forecasting. Due to the complex nature in model building, it is necessary to preprocess the data first. Several recent studies strongly suggest that for retail sales that contain both trend and seasonal variations, it is not appropriate to directly model sales time series with neural networks. Rather, both seasonal effect and trend movement can have significant effect in accurately modeling retail sales. In order to build the best neural network model, forecasters should use a combined approach of deseasonalization and detrending to remove the seasonal and trend factors first. Another benefit with both seasonality and trend removed is that more parsimonious neural networks can be constructed.

KEY TERMS

Box-Jenkins Approach: A very versatile linear approach that can model trend, seasonal, and other behaviors by using moving averages, autoregression, and difference equations.

Census II X-11: A method that systematically decomposes a time series into trend, cyclical, seasonal, and error components. It was developed by the Bureau of the Census of the Department of Commerce and is widely used in deseasonalizing economic data.

Deseasonalization: (Sometimes also called seasonal adjustment,) a process of removing seasonality from the time series. Most governmental statistics are seasonally adjusted to better reflect other components in a time series.

Detrending: A process of removing trend from the time series through either differencing of time series observations or subtracting fitted trends from actual observations.

Feedforward Neural Networks: A special type of neural networks where processing elements are arranged in layers and the information is one-directional from input layer to hidden layer(s) to output layer.

Neural Networks: Computing systems that are composed of many simple processing elements operating in parallel whose function is determined by network structure. They are used mainly to model functional relationship among many variables.

Seasonality: Periodic pattern that typically occurs within a year and repeats itself year after year. Most retail data exhibit seasonal variations that repeat year after year.

Trend: Long-term movement in a time series that represents the growth or decline over a extended period of time.

New Advancements in Image Segmentation for CBIR

Yu-Jin Zhang
Tsinghua University, Beijing, China

INTRODUCTION

The process of segmenting images is one of the most critical ones in automatic image analysis whose goal can be regarded as to find what objects are presented in images (Pavlidis, 1988). Image segmentation consists of subdividing an image into its constituent parts and extracting these parts of interest (objects). A large number of segmentation algorithms have been developed since the middle of 1960's (see survey papers and books, for example, Bovik, 2000; Fu & Mui, 1981; Lucchese & Mitra, 2001; Medioni, Lee, & Tang, 2000; Pal & Pal, 1993; Zhang, 2001), and this number continually increases from year to year in a fast rate. This number had attended, 10 years ago, the order of thousands (Zhang & Gerbrands, 1994). However, none of the proposed segmentation algorithms is generally applicable to all images, and different algorithms are not equally suitable for a particular application. Though several thousands of algorithms have been proposed, improvements for existing algorithms and developments for treating new applications are still going on.

Along with the progress of content-based image retrieval (CBIR) that searches images from a collection according to the content of images, especially with the object-based techniques, image segmentation has been involved more and more in this new research domain. By separating an image into different components and extracting the interest objects, more semantic meanings could be mined out from the image. Thus, the human intention could be fully represented and integrated into the search process. Due to the specific requirements and particular constrains of CBIR, not only have many common segmentation techniques proposed before the start of CBIR research in 1992 have been revised, but also various techniques specialized to the tasks of CBIR have been developed.

The remainder of this article is organized as follows: in the *BACKGROUND* section, image segmentation techniques are briefly summarized; and the specific requirements of CBIR to image segmentation are stated. In *MAIN THRUST*, a general trend for developing image segmentation techniques to fit the particular requirements of CBIR are discussed; some useful techniques for segmentation in the context of CBIR, such as meaningful region extractions and two-level segmentation are presented. In *FUTURE TRENDS*, some potential directions for further research are indicated. In *CONCLUSION*, several final remarks are given.

BACKGROUND

Classification of Image Segmentation Techniques

A formal mathematical-oriented definition for image segmentation can be found in Fu and Mui (1981). Generally speaking, it defines image segmentation as a process of treating every pixel in images to form non-overlap regions, each of which has certain properties different from that of others.

As many techniques for image segmentation have been proposed in the literature, the classification of segmentation algorithms becomes critical. Algorithm classification should be performed according to some suitable classification criteria; otherwise, the classification schemes might be non-consistent and/or non-complete (Fu & Mui, 1981; Pal & Pal, 1993).

Considering the classification of segmentation algorithms as a partition of a set (of algorithms) into subsets, an appropriate classification scheme should satisfy the following four conditions (Zhang, 1997; Gonzalez & Woods, 2002):

(1) Every considered algorithm must be classified into one subset.
(2) All subsets together can include all algorithms (form the whole set).
(3) Different algorithms in the same subset should have some common properties.
(4) The algorithms in different subsets should have certain distinguishable properties.

Two criteria commonly used for the classification of segmentation algorithms are based on two pairs of complementary attributes:

(1) Homogeneous property: either discontinual (inter-regions, at boundaries) or continual (intra-region);

(2) Processing strategy: either sequential (step-by-step) or parallel (simultaneous and independent).

Combining these two criteria, a classification scheme can distinguish the following four groups of segmentation algorithms (Zhang, 2001):

(1) Boundary-based sequential algorithms;
(2) Boundary-based parallel algorithms;
(3) Region-based sequential algorithms;
(4) Region-based parallel algorithms.

Recently, many new segmentation algorithms based on different theories, such as mathematical morphology, pattern recognition principle, neuron network, information theory, fuzzy logic, wavelet transform, genetic algorithms, and so forth, are proposed (Zhang 2001). All these algorithms can still be classified according to the above classification scheme.

In the context of image analysis aiming at automatically obtaining measurement data from objects, the most important criteria for judging the performance of segmentation algorithms are related to the accuracy of segmentation results, though some other criteria, such as processing complexity and efficiency as well as segmentation resolution of algorithms, are also considered (Zhang, 1996). From the accuracy point of view, the algorithms based on boundary representation and sequential strategy are often more powerful (especially for noisy images), according to their natures, than other algorithms.

Particularity of Image Segmentation in CBIR

Design of segmentation techniques for CBIR counts several new challenges. Two of them are indicated here.

In contrast to many applications of image analysis, which aim at obtaining objective measurements over objects in the images, CBIR is a somehow subjective process (Zhang, 2003). Instead of deriving accurate measures of object properties for further identification or classification, the primary concerns in CBIR are to separate required regions and to obtain more information related to the semantic of these regions.

From other side, typical image analysis applications are normally limited to particular domains, some *a priori* knowledge about the scene geometry, the sensor characteristics, lighting conditions, noise statistics, number and form of objects, and so forth, are available. Taking into consideration such kinds of information, the results of segmentation could be improved. While in CBIR using a generic database, none of these factors can be controlled; segmentation algorithms could not be specialized by taking into account this information.

Due to these particular aspects, the development of image segmentation techniques for CBIR should be guided by the purpose of segmentation in CBIR applications.

MAIN THRUST

General Ideas

With the progress in segmentation techniques, people have realized that a precise segmentation of objects in many cases is still beyond the capability of current computer techniques (Zhang, 2001). On the other hand, compared to some image analysis tasks that aim at obtaining accurate measurements from the segmented objects, the requirement for precise segmentation of objects can be somehow relaxed in the context of CBIR. As discussed previously, image retrieval is a subject-oriented process in which the precise object measurement might not be the must. In particular, for object-based image retrieval, the main purpose of segmentation here is for identifying the objects.

Several techniques taken into consideration of these particularities are proposed; some typical examples are discussed in the following.

Taking the homogeneous regions in images as the primitives (the "atomic" structures) and assuming these regions do not necessarily cover the whole images, an algorithm called perceptual region growing (PRG) has been proposed (Siebert, 1998). This algorithm combines region growing, edge detection, and perceptual organization principles together for a domain independent segmentation. The main stages of PRG consist of the following:

(1) Identify the seed pixels of each region from images;
(2) Merge adjacent pixels that have similar intensity values to these regions;
(3) Compute the gradient map of images and try to form closed boundaries with high gradient pixels;
(4) If a boundary is apparently formed, continuously growing its enclosed region to the limit of boundary.

Presuming that regions in images should integrate enough intrinsic variability to provide a better characterization of regions, an algorithm based on coarse region detection and fine description is suggested (Fauqueur & Boujemaa, 2002). The coarse determination of regions can alleviate the problems caused by over-segmentation that produces homogeneous and small regions, such as: it is hard to differentiate homogeneous regions; it is rarely that a small region to be visually salient in a scene. Since regions are detected coarsely and these regions should be more homogeneous than the whole images, finely describing the visual appearance is important to reveal even-detailed information in images, such as the granularity of color and the shades of hue.

Considering that the basis for retrieval queries would be the image semantics, the purpose of image segmentation should be to split the image into pieces for capturing a reduced and implicit portion of the full semantics (Jermyn, 2003). Thus, obtained semantics are successfully used for a psychovisual test with some interesting results that both the boundaries of regions and regions themselves are comparable in presenting the semantic meanings of images to human beings. The human visual system is quite tolerant to a number of factors, so the object extraction task can be simplified to a certain extent in this context.

Some details of two potential techniques — 1) extracting meaningful regions for object identification, and 2) two-level segmentation and matching — are described in the following as other examples.

Meaningful Region Extraction for Object Identification

The objective of image segmentation in CBIR applications is more related to the number and position of salient objects in images. So, one may only extract approximately their corresponding region, instead of to segment each object accurately (Luo et al., 2001). It is known that, during the process of visual perception and recognition, human eyes actively perform the problem-oriented and/or application-oriented selection and aggressively process the information from the visible world by moving and successfully fixating on the most informative parts of the image. These parts might not have the one-to-one correspondence to all objects, but they have some obvious common visual properties. These informative parts could be called "meaningful regions". Here, the definition of meaningful regions lies more on the general visual appearance, such as the form and position of big regions in images, while the exact boundary of region is less notable in the primary concern.

The "meaningful region" provides an effective visual representation of objects from the point of view of object identification. Though the "meaningful region" is not an exact representation of the objects, its semantic meaning could later be recovered based on some domain knowledge. On the other hand, robust extraction of "meaningful regions" could be accomplished in a relatively easy manner than accurate segmentation does. This makes the extraction of a "meaningful region" a feasible step for further object identification in CBIR using object-based techniques (Gao, Zhang, & Merzlyakov, 2000).

The general flowchart for meaningful region extraction is shown in Figure 1. First, the image to be treated is transformed or mapped into a visual feature space that combines the information of different visual features (such as HSI color features and Gabor texture features); an index of image complexity based on weighted density is used to select features for splitting images (Luo et al., 2001). Then, an unsupervised and adaptive clustering algorithm is applied to group pixels to form meaningful regions. The meaningful regions thus formed will be further identified with the help of a scene knowledge database, while those pixels that cannot form a meaningful region will be discarded. In such a way, the main object regions in images can be quickly captured, and their spatial relationship can be additionally established.

Two-level Segmentation and Matching

In CBIR applications, the search of images is based on the similarity matching between the query image and those database images. While image segmentation is first carried out, the matching will be performed between segmented regions. For generic images, as the number of objects in images are not known in advance (as indicated previously), over-segmentation (the image is divided too much in detail) and under-segmentation (the image is too coarsely divided) results are often created. Both will make the subsequent matching task less feasible (Wang & Wiederhold, 2001).

One method to solve the over-segmentation and under-segmentation problems in CBIR applications is to use a particular matching procedure to diminish the prerequisite for an accurate segmentation (Dai & Zhang, 2004). As the problem caused by over-segmentation and/or under-

Figure 1. Meaningful region extraction flowchart

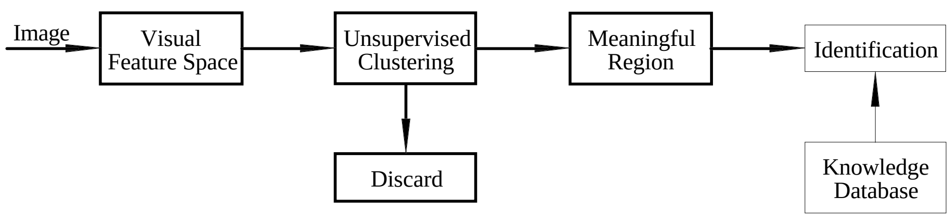

Figure 2. Two levels of segmentation results.

segmentation to the one-to-one matching can be considered as a problem of number inconsistency, the solution would be the permitting of a one-to-many or a many-to-one matching.

This adaptable matching strategy compensate for the problems caused by inaccurate segmentation. In practice, the image is first over-segmented, and then the resulted regions will be merged into under-segmented results. The over-segmented result is called detailed result and the under-segmented result is called rough result. Two groups of segmentation examples are shown in Figure 2, where for each group, the first is the original image, the second is the detailed result, and the third is the rough result.

Both over-segmented and under-segmented results are easily obtained over an exact result (Dai & Zhang, 2003). For example, the parameters in the segmentation algorithm can be biased first to perform the over-segmentation for producing detailed results. Then, by combining several regions in detailed results, a rough result corresponding to an under-segmented result can be obtained. In the retrieval process, the database images will be described based on the detailed result while the query images will be described by rough result. In other words, there are descriptions in two levels. The rough description for query images has fewer restrictions than the detailed description for database images does; this makes the query more flexible.

The similarity matching which follows the description is not computed by comparing region to region directly as the two-level description breaks the equivalence between regions in query and database images. On the other hand, the rough description of query images allows a many-to-one matching between the regions from database images and the regions from query image. This can also be considered as using the guidance of rough description for query images to group the database images with detailed descriptions. In such a way, the object matching is performed with fewer prerequisites for accurate image segmentation.

FUTURE TRENDS

To improve the performance of CBIR, different image segmentation techniques are to be enhanced:

(1) Describing objects as congruous to humans' sense as possible should be studied. As human beings are still far from knowing all of the cognitive details from the real world, how to automatically form semantic objects is a challenging task.

(2) Improving the robustness of meaningful region detection and extraction, especially with complicated images, by taking more characteristics of images into consideration.

(3) Using a more efficient feedback procedure to make the query process fast to follow the users' aspiration in the course of retrieval is an attractive research topic.

CONCLUSION

Efficient image segmentation should take into consideration the tasks that follow the segmentation step and also the goal of application in which segmentation is an indispensable stage. This has been clearly shown by the new advancements in image segmentation for CBIR. In general, further researches on image segmentation would be along the directions of improving concrete techniques for advanced image analysis and following the movements toward image understanding.

KEY TERMS

Accuracy: The agreement between the real measurement and some objective standard taken as the "ground truth." In a given measurement experimentation, the high accuracy could be achieved using correct sample design and measurement methods. An accurate measurement is also called an un-biased measurement.

Clustering: A process to group, based on some defined criteria, two or more terms together to form a large collection. In the context of image segmentation, clustering is to gather several pixels or groups of pixels with similar property to form a region.

Content-Based Image Retrieval (CBIR): A process framework for efficiently retrieving images from a collection by similarity. The retrieval relies on extracting the appropriate characteristic quantities describing the desired contents of images. In addition, suitable querying, matching, indexing and searching techniques are required.

HSI Model: A color model in which a color is described by three characteristics: hue (H), saturation (S), and intensity (I). They form a 3-D color space. HSI model is quite coherent with human perception. A closely related model is HSV model, in which value (V) takes the place of intensity.

Image Analysis: An important layer of image engineering, which is concerned with the extraction of information (by meaningful measurements with descriptive parameters) from an image (especially from interesting objects), with the goal of finding what objects (based on identification, recognition and classification) are present in the image.

Perceptual Organization: A process to group sensory primitives arising from a common underlying cause. Perceptual organization can also be defined as the ability to impose structural regularity on sensory data.

Precision: In terms of repeatability, the ability of the measurement process to duplicate the same object measurement and produce the same result. The high or low precision could be obtained is dependent upon the object of interest and in many cases could be controlled by working harder.

Segmentation Evaluation: A process to judge the performance of segmentation algorithms based on some defined quality criteria and/or ground truth in view to assess or reveal the property of algorithms in use. The inter-algorithm evaluation is also called segmentation comparison, while the intra-algorithm evaluation can be called segmentation characterization.

New Perspectives on Rewards and Knowledge Sharing

INTRODUCTION

Of the 260 responses from a survey of European multinationals, 94% believed that knowledge management requires employees to share what they know with others within the organization (Murray, 1999). Among the processes of knowledge management—creation, sharing, utilization and accumulation of knowledge—sharing is what differentiates organizational knowledge management from individual learning or knowledge acquisition.

However, the process of sharing knowledge is often unnatural to many. Individuals will not share knowledge that is regarded to be of high value and importance. In fact, the natural tendency for individuals is to hoard knowledge or look suspiciously at the knowledge of others. Thus, incentive schemes—where employees receive incentives as a form of compensation for their contributions—are common programs in many organizations. Such schemes have met their fair share of success as well as failure in the field of knowledge management. On the one hand, the carrot and stick principle used in Siemens' ShareNet project turned out to be a success (Ewing & Keenan, 2001). On the other hand, the redemption points used in Samsung Life Insurance's Knowledge Mileage Program only resulted in the increasingly selfish behavior of its employees (Hyoung & Moon, 2002).

Furthermore, despite the plethora of research on factors affecting knowledge sharing behavior, little concerns discovering effective ways to encourage individuals to voluntarily share their knowledge. Early studies on knowledge management began by trying to discover key factors pertaining to knowledge management in general, instead of knowledge sharing in particular, as summarized in Table 1. Although research on knowledge sharing started around the mid 1990s, it focused mainly on knowledge sharing at the group or organizational level in spite of the fact that knowledge itself actually originates from the individual. Even at the group or organizational level, most studies dealt with a specific knowledge type, such as best practices (Szulanski, 1996) or a specific context, such as between dispersed teams (Tsai, 2002). In addition, factors such as trust, willingness to share, information about the knowledge holder, and the level of codification of knowledge were considered in abstract. Although these factors are valuable, they require further empirical research before they could be used to explain the individual's fundamental motivation to share knowledge. Thus, this study aims to develop an understanding of the factors that support or constrain the individual's knowledge sharing behavior in the organization, with a special interest in the role of rewards. This is done according to Fishbein and Ajzen's (1975) Theory of Reasoned Action (TRA), a widely accepted social psychology model that is used to explain almost any human behavior (Ajzen & Fishbein, 1980).

BACKGROUND

Due to the fact that knowledge is a resource that is locked in the minds of humans, knowledge sharing does not occur with the sole implementation of information systems. As such, an investigation into the individual's motivation behind knowledge sharing behavior, coupled with a firm foundation in social psychology, should take precedence. Accordingly, the TRA is adopted so as to provide a well-established explanation for such volitional, rational, systematic decision logic as that of knowledge sharing.

The TRA assumes that human beings are usually rational in thinking, and would systematically use available information (Fishbein & Ajzen, 1975). In the TRA, the individual's attitude toward and subjective norm regarding a behavior jointly determine the behavioral intention that results in the individual's decision to engage in a specific behavior. In this study, we focus only on the

Table 1. Factors affecting knowledge management and knowledge sharing

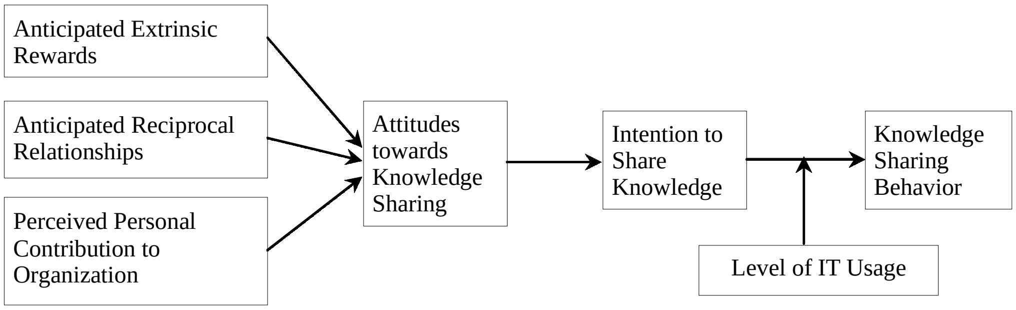
salient beliefs that affect the knowledge sharing attitude because knowledge sharing behavior is assumed to be motivated and executed mainly at the individual level. Since the TRA can be applied to almost any behavior, the nature of the beliefs operative for a particular behavior are left unspecified. Following the elicitation recommendations suggested by Fishbein and Ajzen (1975), free response interviews to elicit five to nine salient beliefs were conducted with chief knowledge officers (CKO) and chief information officers (CIO) of the subject population in April 1999. Once these salient beliefs surfaced, the research model was developed.

We propose three factors that are consistently emphasized throughout the interviews: anticipated extrinsic rewards, anticipated reciprocal relationships, and perceived personal contribution to the organization, as the antecedents of the attitudes towards knowledge sharing. According to the interdependence theory, individuals will behave according to rational self-interest. Knowledge sharing occurs when the rewards exceed the costs (Constant, Keisler & Sproull, 1994; Kelley & Thibaut, 1978), implying that anticipated extrinsic rewards will positively affect the individual's attitude. Concerning intrinsic rewards, the social exchange theory states that social exchanges entail unspecified obligations (Blau, 1967). As employees are seen to believe that their relationship with others can be improved through sharing knowledge, the anticipated reciprocal relationships positively affect the individual's attitude. In addition to these, the self-motivation theory (Deci, Connell & Ryan, 1989; Iaffaldano & Muchinsky, 1985; Schwab & Cummings, 1970) finds that feedback from others on shared knowledge can form a self-motivational factor and serve as another major determinant of the attitude toward knowledge sharing. Eisenberger and Cameron (1996) note that one's sense of competence actually increases due to the feedback concerning the quality of one's output. Employees who are able to link instances of past knowledge sharing with an understanding of how these actions contribute to others' work, and/or improvements in organizational performance are likely to develop more favorable attitudes toward knowledge sharing than employees who are unable to construct such linkages. Finally, following Fishbein and Ajzen's (1975) argument about the possibility of several external variables affecting intention to perform a behavior, we introduced an aspect of information technology (IT) into our model. Since IT is considered to be an important enabler in knowledge management (O'Dell & Grayson, 1998; Ruggles, 1998), we examined how the individual's level of IT usage affects knowledge sharing behavior.

Data were collected through the utilization of a survey. A total of 900 questionnaires were distributed in October and November 1999 to employees in 75 departments of four large government-invested organizations in South Korea. Of this total number, 861 responses were received, of which 467 were usable. We found that the anticipated reciprocal relationship provided for the individual's positive attitude towards knowledge sharing, and resulted in a positive influence of intention and behavior. However, contrary to many researchers' expectations, anticipated extrinsic rewards were found to have a negative effect on such an attitude.

Figure 1. Research model



FUTURE TRENDS

This negative correlation—which might prove important for future research—can be explained with the results of research in the pay-performance area. Kohn (1993) found that there is either no relationship or a negative relationship between rewards and performance, although many assume that people will do a better job if they are promised some form of reward. Kohn cited six reasons as to why rewards fail, three of which can also be considered within the knowledge-sharing context.

First, rewards are seen to have a punitive effect because, as compared to outright punishment, they are manipulative in nature. Not receiving an expected reward is seen to be indistinguishable from being punished. Both result in movement, but not motivation (Herzberg, 1968). Rewards are seen to destroy relationships because for any one winner, many others would feel that they have lost. When there exists a limited number of rewards, competition between employees will ensue. Second, rewards are at times used as a simpler alternative to addressing underlying issues, such as the lack of an ideal knowledge-sharing culture within the organization. The ideal culture mentioned should include providing useful feedback, social support, and room for self-determination. Third, rewards could be an undermining factor towards intrinsic motivation. Interest in knowledge sharing would decrease with an increase in one's perception of being controlled (Levinson, 1973). Employees might assume that the task at hand is not something they would want to do if they have to be bribed to do it. As such, with the increase in incentive offered, the negative perception towards the task at hand becomes greater.

Another explanation can also be found in organizational citizenship behavior literature. According to Katz and Kahn (1966), any critical voluntary behavior that is beyond the scope of one's job description is a direct result of one's identification with and internalization of individual and organizational values, rather than the involvement of any external factors. Furthermore, Constant et al. (1994) stated that experienced workers perceive the process of sharing knowledge as part of normal business activity. These workers hold a negative view of any extrinsic rewards given in return for sharing knowledge. With such strong support for the negative effect view of extrinsic rewards on the attitude towards knowledge sharing, would it be right to completely discard extrinsic rewards?

Eisenberger and Cameron (1996) found that extrinsic rewards could both positively and negatively influence motivation—knowledge sharing in this case. They find that rewards can be divided into two broad types, namely task-contingent and quality-dependent rewards. Quality-dependent rewards positively influence organization initiatives, as they do not reduce one's intrinsic motivation. In fact, due to the feedback concerning the quality of one's output, one's sense of competence actually increases. Task-contingent rewards, on the other hand, undermine any task because of their negative influence on intrinsic motivation. A possible design for such a scheme is a knowledge market where "buyers and sellers of knowledge negotiate a mutually satisfactory price for the knowledge exchanged" (Ba, Stallaert & Whinston, 2001, p. 232). In this way, the reward of individuals would be based on the usefulness of their knowledge, thus ensuring the creation of high-quality knowledge.

In addition, a reward that is less than what employees feel their performance justify could threaten their self-esteem. This is due to the fact that the self-ratings done by employees are usually higher than those done by the management. According to Meyer (1975), a common way for employees to cope with such a problem is to "downgrade the importance of the activity on which the threat is focused" (p. 44). Hence, an incentive scheme should be well-designed so as to reward individuals who are deemed deserving, as the rewarding of contributors aids in positively influencing the sharing of knowledge. Additionally, the scheme's design should discourage self-centered behavior, which is detrimental to the organization's health (Michailova & Husted, 2003); otherwise, the scheme would only produce temporary compliance, and might decrease an individual's intrinsic motivation (Deci, 1971,1972a). When intrinsic interests exist among employees for a particular task, the attachment of incentives to the performance of the task only results in the decrease of that interest (Deci, 1972b). "When pay becomes the important goal, the individual's interest tends to focus on that goal rather than on the performance of the task itself" (Meyer, 1975, p. 41), thus resulting in employees striving to increase incentives at the cost of output quality.

Furthermore and most importantly, an incentive scheme needs to be incorporated with proper organization norms (Markus, 2001). If the norms are not in place, employees will not share their knowledge even if there is in place, a comprehensive incentive scheme. According to O'Dell and Grayson (1998), "if the process of sharing and transfer is not inherently rewarding, celebrated and supported by the culture, then artificial rewards [will not] have much effect and can make people cynical" (p. 168). Husted and Michailova (2002) also stated that "unless knowledge sharing is built into the expectation of the individual and is reflected in the reward mechanism, sharing will not take place".

CONCLUSIONS

In summary, of the two views posed by past research, our recent study to discover the influence of extrinsic rewards in knowledge sharing supports the negative view. This implies that, when the management of an organization is motivated to embrace knowledge sharing but its employees are not, using incentives to influence knowledge sharing would only result in the employees placing emphasis on the incentives. This could result in the sharing of low-quality knowledge and undermine the whole knowledge-sharing effort. Furthermore, the continuous use of incentives "could actually be encouraging hoarding behavior and competitive actions, diminishing the free flow of knowledge in the organization" (Wasko & Faraj, 2000, p. 162). Therefore, extrinsic rewards should be coupled with other factors, such as organizational norms, to bring about benefits. The reconciliation of this disparity in views should provide new grounds for future research.

KEY TERMS

Explicit Knowledge: Knowledge that has been captured and codified into manuals, procedures, and rules, and is easy to disseminate (Stenmark, 2000).

Extrinsic Rewards: Incentives that are mediated outside of a person, such as praises and monetary compensation (Deci, 1972b).

Implicit Knowledge: Knowledge that can be expressed in verbal, symbolic, or written form but has yet to be expressed (Bock, Zmud, Kim, & Lee, 2003).

Intrinsic Rewards: Incentives that are mediated within a person, such as satisfaction (Deci, 1972b).

Knowledge Management System: A knowledge repository, shared knowledge base or knowledge based system, which is a class of information systems developed to support and enhance the organizational processes of knowledge creation, storage / retrieval, transfer and application (Alavi & Leidner, 2001).

Knowledge Sharing: Voluntary activities of transferring or disseminating knowledge between people or groups in an organization (Bock, Zmud, Kim & Lee, 2003).

Organizational Norm: Organization culture or climate, which consists of the shared values, beliefs and practices of the people in the organization (McDermott & O'Dell, 2001).

Tacit Knowledge: Knowledge that cannot be easily articulated, and thus only exists in people's minds, and is manifested through their actions (Stenmark, 2000).

New SQL Standard in Database Modeling

Eric Pardede
La Trobe University, Australia

J. Wenny Rahayu
La Trobe University, Australia

David Taniar
Monash University, Australia

INTRODUCTION

Relational Database (RDB) is arguably the most widely used repository for database applications. Since the 1970s, we have witnessed the relational data model, from which the RDB is originated, evolving. The progress aims to answer the increasing requirement in database applications. One of them is the requirement to deal with complex structure of real world problems. Unlike its Object-Oriented Database (OODB) counterpart, the RDB, for example, does not have facilities to store large structured objects, semi-structured data, and so forth.

The question might have been answered with the release of new version *Structured Query Language* (SQL) (Fortier, 1999; Melton, Simon, & Gray, 2001). The new SQL has provided many new features including many new data types. Since SQL is used for database definition and manipulation for relational model, the extension has enriched the modeling capability in RDB.

A problem then arises. With the existence of the new data types in the new SQL, the whole database modeling processes have changed. So far, database designers still use the conventional method for RDB design and implementation. This method can create inefficient and incorrect use of the new data types.

This work aims to show how new SQL data types affect the database modeling processes. It highlights new opportunities and new research challenges, brought by the new standard.

BACKGROUND: HISTORY OF SQL

SQL was introduced in 1970 and has emerged as the standard language for RDB (Melton, Simon, & Gray, 2001). The 1992 revision, SQL2, has been widely used by all Relational Database Management System (RDBMS) products. In 1993, an attempt to develop a new standard was started since the RDBMS vendors had enhanced their existing relational products with Object-Oriented (OO) features. The existing standard had become somewhat obsolete because it provided no support for OO features.

Many of the vendors created their own language extension of SQL to retrieve and manipulate data such as POSTQUEL (Stonebraker, 1986), Starburst (Lindsay & Haas, 1990), and so forth. These are vendor-specific languages and still there is no standard that can be used and is acceptable to all vendors. For standardization purposes, a new SQL 1999 was developed.

SQL 1999 has been characterized as “OO SQL” and it has become the foundation for several DBMS such as Oracle8. Ironically, many believe that SQL2 will still be used in the future (Elmasri & Navathe, 2002), since many researchers and practitioners still have unsettled arguments on many SQL 1999 issues.

Further, the standardization body ANSI/ISO has started to review SQL 1999 and aims to release a new SQL4 version in few more years. At the time of writing, this version is still an ongoing work and no release date has been announced (Melton, 2002). SQL4 adds some features to SQL 1999, and it also reviews its previous versions.

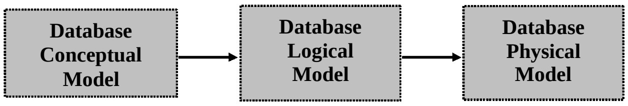
The new SQL has added some new data types to accommodate complex data structures. They are very useful to model real world problems. However, they have a big impact upon the database modeling and implementation.

DATABASE MODELING

Database modeling involves three main phases: conceptual model, logical model, and physical model (see Figure 1).

In the conceptual model level, the database designers capture the database user requirements. To model an RDB, the database designers can use many semantic data modelling such as ER, NIAM, EER, Functional Modeling, and so forth. With SQL4 data type extension, we cannot capture all features using traditional data modeling anymore.

Figure 1. Database modeling phases



The logical model links the conceptual model with the physical implementation. In RDB, this phase is started by transforming the conceptual model into logical design. It is followed by normalization, before we can come up with a set of relations that do not contain anomalies.

In traditional RDB, database designers are already familiar with the transformation methodology (Elmasri & Navathe, 2002), normalization rules (Codd, 1972), and so forth. However, this existing design was developed for simple data types. We do not know whether the old rules can be applicable to the new data types introduced in new SQL4 standard.

The physical model will be different based on how the database is implemented using DBMSs. In this phase, we are required to develop criteria in selecting DBMS. One of the most important criteria is the ability to implement all data type requirements.

For pure RDB that has simple and atomic data type, all DBMS products can be used for the implementation. These products are mainly developed based on SQL2 standard. With the existence of many new data types in SQL4, we need to search the newest DBMS version that can meet the requirement and design.

NEW SQL DATA TYPES

SQL4 classifies the data types into three main classes: predefined, constructed, and user-defined (Melton, 2002). It has few extensions from SQL 1999, but there are a large number of additional data types from SQL2, which is a pure relational model language. Figure 2 illustrates the complete data types supported by current SQL.

Predefined Data Types. Predefined or built-in data types are supported by original SQL. Even though predefined, sometimes the users are still required to determine certain parameters. They are atomic, and therefore very suitable for conventional relational model implementation.

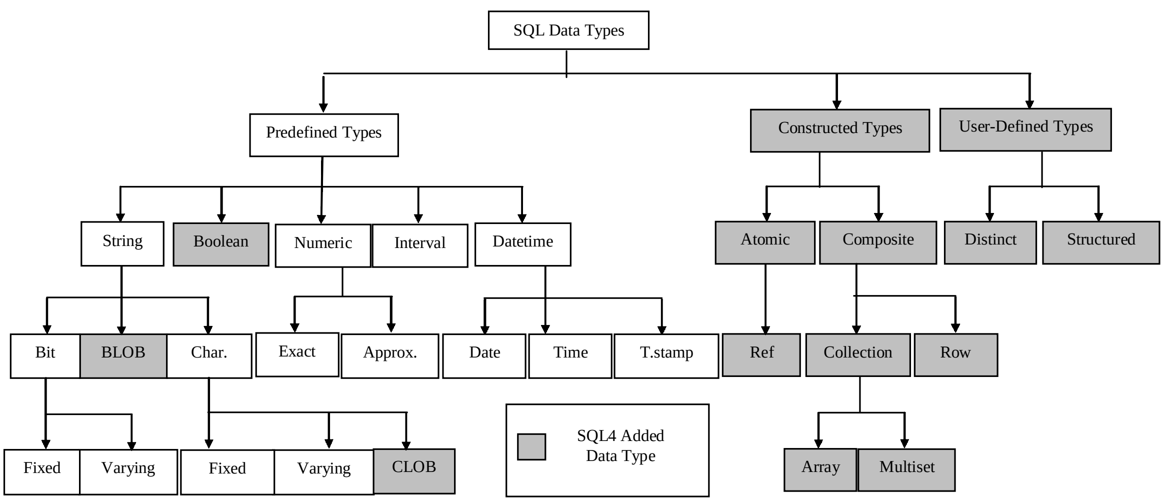
New SQL added Boolean and large object type (BLOB and CLOB). *Boolean* data type enables us to represent the true or false values instead of using a character value with permissible values "T" or "F" (Melton, Simon, & Gray, 2001). *BLOB* can hold a very large binary piece of data such as the digital representation of one's signature. *CLOB* can hold a very large, variably sized, and usually non structured group of characters such as one's resume.

Constructed Data Types. There are two categories of constructed data types: atomic and composite (Melton, 2002; Melton, Simon, & Gray, 2001). From the latest development, SQL4 supports one atomic constructed type and three composite types.

The atomic constructed data type is *REF* type. Its value can be used to address a site holding another value. The site pointed to can be another constructed data type or user-defined type in a typed table.

The first composite data type is *Row*. It contains a sequence of attribute names and their data types. Since it is defined like a flat table, a row type inside a table resembles a nested table. The next data type is *array*, which can hold composite elements of similar type with ordering semantic. Finally, *multiset* contains composite elements that can be duplicated and do not need an

Figure 2. SQL4 data types classification



ordering semantic.

User-Defined Data Types (UDT). This is the third data type provided by SQL4, and has affected the database design most significantly. Based on the number of attributes, UDT can be divided into distinct type and structured type.

Distinct type is formed by a single predefined data type. Its behaviour is different from the base type which it is derived from. The distinguished character of this type is the adherence to strong typing that guarantees correctness and intended type behaviour. *Structured* type is comprised of a number of attributes and routines. It enables users to define and to support the storage and manipulation of complex structure. Besides, structured type can be used to model richer relationships among classes such as inheritance, aggregation, and composition.

IMPACT TO DATABASE MODELING

In this section, we show how the existence of new data types by new SQL has affected the database modeling from conceptual model to the physical model or implementation. It highlights few problems, and thus, brings future research opportunities in the area.

Conceptual Model

It is widely-known that many database designers still use conventional data modeling such as ER for conceptual modeling purpose (Pfleeger, 2001). Furthermore, some even use them for non-relational model database.

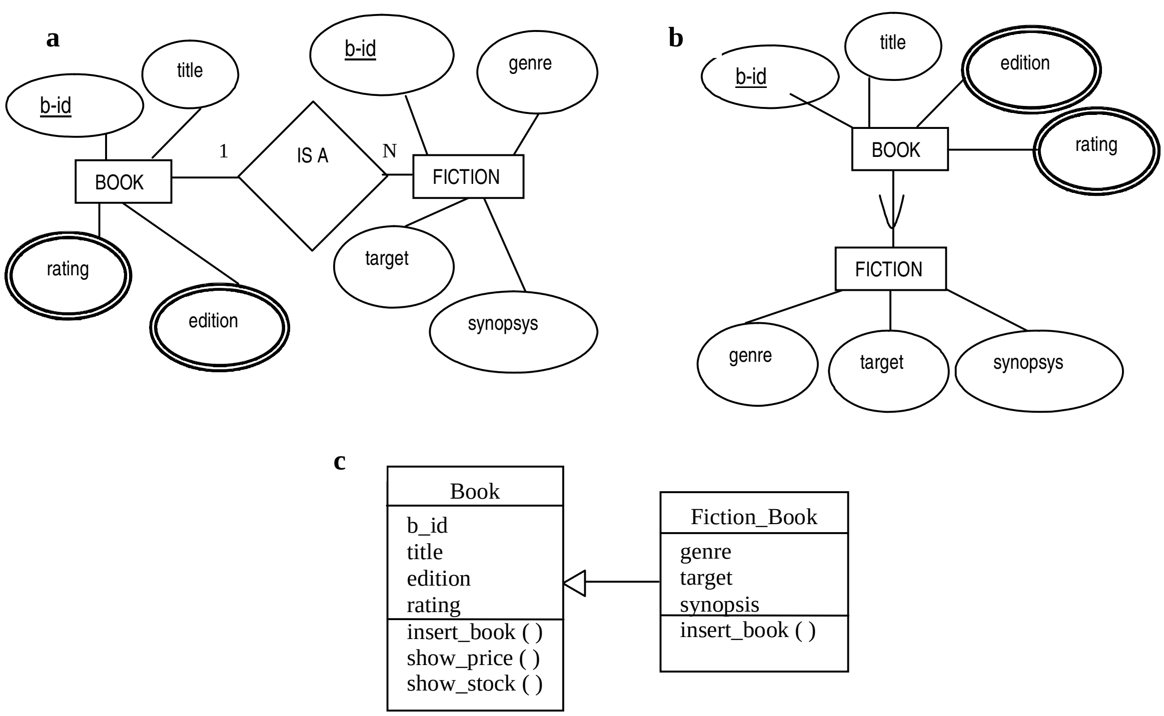
For example, we have two classes Book and Fiction (see Figure 3a) that have a simple 1:N relationship. This conceptual structure can be easily shown using traditional ER modeling. SQL4 recognizes the inheritance structure and now we want to model this relationship between Book and Fiction. Unfortunately, ER is not capable to show this relationship type.

To resolve the problem, we can use the Enhanced Entity Relationship (EER) Diagram (Elmasri & Navathe, 2002) (see Figure 3b). It can accommodate many SQL4 features, but not all of them. EER is applicable only for table or instance. Thus, it cannot include routines, which are embedded in object type.

We use Unified Modeling Language (UML) to resolve the issue (Booch, Rumbaugh, & Jacobson, 1999), since it can represent types and their routines (see Figure 3c). Nevertheless, there are many other SQL4 data type issues that cannot be captured in UML. For example, the representation of *edition* and *rating* attributes as collection types, and so forth.

This section shows that SQL4 affects the database conceptual model. We cannot use traditional data mod-

Figure 3. Conceptual modeling using ER, EER, UML



eling to capture different SQL features, including different new data types.

Logical Model

SQL4 new data types have changed the database design processes such as the transformation methodology and the normalization rules. Using conventional method will lead to an inefficient and incorrect database system. For illustration, we use SQL4 data types, written in bold, in Database Definition Language (DDL) example below.

```
CREATE TABLE Book
(b_id CHARACTER VARYING(5),
 title CHARACTER VARYING(50),
 publisher REF(Publisher_Type),
 author ROW (name CHARACTER_VARYING(20),
 city CHARACTER VARYING(15)),
 edition INTEGER ARRAY[10],
 rating INTEGER MULTISET)
```

REF type violates the conventional transformation method. Formerly, for referential integrity, we link the tables with foreign key (FK). As for the DDL example, a Publisher table is needed before the Book table can refer it. With REF type, we do not have to instantiate an object since this type can refer to an object type. The link is not done through value, but through the address.

Few problems arise with the existence of REF type, and it is a research area that can be extended further. To mention a few, problems are how to define integrity constraint toward types instead of table column, how to use REF type in different level of inheritance structure, and so forth.

Row type is not recognized in conventional model because the relation accepts only atomic values. This type was implemented as ordinary association relationship. With SQL4 row type, we can have a relation inside another relation.

The impact of row type in database design is significant. Some of the issues are: how to design a set of unique row in a tuple since we will need an attribute that take form as the row key; how to design the integrity constraint if the referring or referred attribute is actually a row attribute; how to avoid problems created by transitive, partial, or other undesired dependencies among the row attribute and simple attribute; and so forth.

Next, collection type such as array and multiset are the obvious example of how new SQL4 data types have violated the conventional design. Collection attribute violates the First Normal Form (1NF) of normalization rule (Codd, 1972) due to the existence of repeating groups. The collection would be implemented as separate tables. This practice has been followed although it has diminished the real semantic between the table and its collection attribute. With SQL4 collection types, we are able to store the repeating groups in a relation.

Collection types bring many design issues. Some of them are: how to accommodate unique collection in a tuple; how to transform different type of collection into tables; how to avoid database anomalies created by repeating groups and undesired dependencies brought by collection types; how to maintain the referential integrity if a collection is being referred, and so forth.

This brief section shows that new SQL4 standard has affected the logical model. The full research on each new type is required before we can use them with optimum benefit.

Physical Model

The physical model describes how the data is stored in the database system. The implementation should be committed to the design. For example, the DBMS must be able to

Table 1. DBMS types facilities

ORDBMS	New Data Type							
	Predefined Type		Constructed Type				User-Defined Type	
	Boolean	Large Object	REF	Row	Array	Multiset	Distinct	Structured
Informix SE	Y	Y	N	Y	List	Y	Opaque	Y
Oracle9	Y	Y	Y	Nested	Y	N	Y	Y
IBM DB2	N	Y	Y	N	N	N	Y	Y
UniSQL/X	N	Y	Y	N	List	Y	N	Y
Postgres 7.4	Y	N	N	N	Y	N	N	Y
SYBASE SQL AS 8.0.2	N	Y	N	N	N	N	N	Y

represent the level of abstraction in the design including high-level structures for complex data types and interrelationships.

One criterion of DBMS selection is the compliance with the standard. Table 1 summarizes different DBMS and whether they provide new SQL4 data types (Asiatek, 2003; IBM DB2, 2003; Informix, 2003; Oracle, 2003; Postgresql, 2003; Sybase, 2003).

The completeness of data type is an important issue on selecting DBMS. However, among the ones that facilitate the same data type, we still have to compare the pros and the cons. For example, we have to know how a DBMS implement the index for data type that requires ordering semantic such as array. In this phase, we also need to consider the query performance due to the existence of new type.

FUTURE TRENDS

With the demand of higher RDB capability, it is almost certain that SQL will add more data types in the future. These new data types will affect each database modeling phase as we have shown in this article.

The new SQL data types will enforce the DBMS vendors to comprise with the standard. If the SQL standardization body can keep up with the increasing demand of database community, the vendors will gradually reduce the use of proprietary language to the standard SQL.

Finally, richer RDB will suit more database application. Some applications that have not used RDBMS, in the future, can utilize many new data types provided by new SQL (Pardede, Rahayu & Taniar, 2003).

This article is a preliminary work to a more detailed research. For future work, one needs to investigate each database modeling phase. The processes include the conceptual data modeling, mapping, normalization, integrity constraint, implementation, and so forth, of each different data types.

CONCLUSION

New SQL standard has added many new data types for relational database. The standard impacts upon the whole phase in database modeling processes from conceptual model, logical model, to the physical model or implementation. This article shows the new data types and highlights how they have affected the database modeling processes.

KEY TERMS

Conceptual Model: A model that is concerned with the real world view and understanding of the data. It suppresses non-critical details in order to emphasize business rules and user objects.

Constructed Data Type: The data type that is formed by a number of predefined data type. This data type is also provided by the software products. The examples are LIST, ARRAY, and so forth.

Database Management System (DBMS): Software used to manage a database. It can be differentiated based on the data model such as Relational DBMS, Object-Oriented DBMS, Object-Relational DBMS, and so forth.

Database Modeling: The first step of database design, where the database designers define the data objects and their relationships to other data objects. Data modeling involves a progression from conceptual model to logical model to physical schema.

Data Type: The characteristic of a data element or a field that specifies what type of data it can hold. SQL classifies three main data types: predefined data type, constructed data type, and user-defined type.

Logical Model: Generalized formal structure in the rules of information science. For relational database, the logical model generally conforms to relational theory.

Physical Model: A logical model instantiated in a specific database management product in a specific installation.

Predefined Data Type: The primitive data type that is built-in by the software products. The examples are INTEGER, CHARACTER, and so forth.

Relational Database: A repository of data in the form of tables that have rows and columns to show the relationship between items. This database was based on relational model invented by E.F. Codd in 1970 (Codd, 1972).

Structured Query Langange (SQL): A standard interactive and programming language for getting information from and updating a database. It is developed by IBM in the mid-1970s for relational database management systems.

User-defined Type: Any data type formed by the users contained of any other data type and usually including the routines.

Newcomer Assimilation in Virtual Team Socialization

INTRODUCTION

The way we work today is being transformed. Recent technological advances, combined with more flexible job design, have helped increase the number of people working in geographically and/or temporally dispersed environments. Increasing numbers of organizations have employees who are not physically present in the traditional organizations. Hence, more employees are working on teams that seldom, if ever, meet face-to-face. These "teleworkers" have the same work responsibilities as traditional employees, but they have the added challenges of managing or operating within the dynamics of these virtual teams.

Rapid developments in communication technology and the increased globalization of organizations have also greatly accelerated the growth and importance of virtual teams in the workplace. Virtual teams are becoming more commonplace because they are more efficient, less expensive, and less difficult to organize than traditional co-located teams (Larsen & McInerney, 2002; Lurey & Raisinghani, 2001; Piccoli & Ives, 2003). Although there are apparent advantages to organizing work virtually, the challenge for new member integration lies in the fact that team members communicate primarily via electronic mail, telephone, and videoconferencing or computer conferencing. This increased dependence on mediated communication significantly alters the traditional way new members are socialized to work teams. This article addresses the challenges of virtual team socialization with regard to newcomer assimilation. Particular attention is given to newcomer encounter as embedded processes of virtual team assimilation.

Effective communication is key to organizational and team socialization. How well an individual is socialized into a team may determine his or her success within the team, as well as the success of the team in achieving its goals and objectives. Team socialization and the communication practices associated with newcomer integration have been researched extensively (e.g., Brockmann & Anthony, 2002; Lagerstrom & Anderson, 2003) since Jablin (1982) first explored the multi-layered process. Socialization occurs when a newcomer to a team acquires the knowledge, behavior, and attitudes needed to participate fully as a member of that team. Jablin (1987) framed the stages of socialization as anticipatory socialization, organizational assimilation (encounter and metamorphosis), and organizational exit. Although there is an abundance of literature on traditional organizational socialization, research on virtual team socialization is beginning to emerge (Flanagin & Waldeck, 2004; Picherit-Duthler, Long & Kohut, 2004; Ahuja & Galvin, 2003).

BACKGROUND

Organizational assimilation is perhaps the most important stage of virtual team socialization. Such assimilation concerns the process by which individuals become integrated into the culture of an organization (Jablin, 1982). This stage consists of planned and unintentional efforts by the organization to "socialize" employees, and the attempts of organizational members to modify their roles and work environment to better fit their values, attitudes, and needs. As Jablin (1987) noted through the proactive and reactive communication of expectations, organizational roles are negotiated and socially created.

Organizational encounter is a time for newcomers to learn behaviors, values, and beliefs associated with their jobs and organizations (Schein, 1988). As a result of entering a new situation, newcomers want to clarify their situational identity through their work roles (Berlew & Hall, 1966; Feldman, 1976) or through securing approval of others (Graen & Ginsburgh, 1977; Katz, 1978; Wanous, 1980). To reduce uncertainty, newcomers search for information that allows them to adjust by defining the expectations of others and orienting their behavior to the behavior of others.

The speed that virtual teams form demands that workers deal with rapid change. Although research on teamwork suggests that teams function optimally after they have worked together, virtual teams may not have the luxury of establishing working relationships over an extended period of time (e.g., Furst, Blackburn & Rosen, 1999; Mark, 2001). Thus, it is vital for newcomers to quickly establish and develop relationships with others in the work setting, especially with peers and supervisors (Jablin, 2001).

Among other things, organizational relationships provide newcomers with support that facilitates the learning process, and reduces stress and uncertainty associated with adjusting to a new work environment (Jablin, 2001). Much of the research on relationship development in the organizational encounter stage focuses on information seeking and information giving (e.g., Boyd & Taylor, 1998), learning behaviors and attitudes through exchange activities (e.g., Comer, 1991), technical or social information (Comer, 1991; Morrison, 1995), and regulative and normative information (e.g., Galvin & Ahuja, 2001). Evidence suggests that formal and informal socialization practices may affect the level of organizational commitment (Berlew & Hall, 1966; Buchanan, 1974), longevity in the organization (Katz, 1978; Wanous, 1980), and satisfaction and feelings of personal worth (Feldman, 1976).

The next section examines the three central areas of relationship building in virtual teams: peer relationships, supervisory relationships, and mentoring relationships.

Peer Relationships

Anyone who has worked on a team project is immediately concerned with the interactions they might have with their teammates. Do these individuals meet the expectations the team has of them? Are they easy to get along with? Are they competent? Peers help newcomers integrate what may appear to be disjointed pieces of information (Van Maanen, 1984), and may communicate subtle values and norms that may not be well understood by supervisors. Newcomers have more contact with coworkers, and as a consequence, more opportunities to share information with them and develop relationships (Jablin, 2001; Comer, 1991; Teboul, 1994). Sias and Cahill (1998) proposed a variety of contextual factors, including shared tasks and group cohesion (e.g., Fine, 1986), physical proximity (e.g., Griffin & Sparks, 1990), lack of supervisor consideration (Odden & Sias, 1997), and life events outside the workplace, as well as individual factors, such as perceived similarity in attitudes and beliefs as well as demographic similarity (Adkins, Ravlin & Meglino, 1996; Duck, 1994; Glaman, Jones & Rozelle, 1996; Kirchmeyer, 1995), that may affect the development of relationships with peers.

Trust is a key factor in developing close relationships. However, due to the lack of physical proximity and the reliance on communication technologies, our understanding of trust in virtual teams is different from the trust in traditional teams. Meyerson, Weick, and Kramer (1996) coined the term "swift trust" to describe how virtual teams develop a different type of trust than in traditional teams. Due to the highly interdependent task orientation of the team, newcomers develop trust more quickly. Team members are able to develop trust in relationships on the basis of shared tasks rather than on the basis of similar demographics and/or physical proximity (Jarvenpaa & Leidner, 1999).

However, swift trust is not enough to develop close peer relationships. Team members face numerous challenges including: technological mistrust by both newcomers and established members, intuitive fear of the misuse of archived communication (e.g., e-mail trails), and the difficulty of sharing personal or non-work-related issues. Thus, virtual newcomers may be unable or unwilling to take advantage of the informal organizational development that appears central to organizational socialization in traditional teams. This clearly inhibits the development of close peer relationships in virtual teams which in turn may inhibit constructive team cohesion. Similarly, opportunities to understand organizational politics are reduced. Unless the communication among team members is open, power alliances form, allowing certain behaviors to take place such as social loafing, domination, and the formation of cliques. Groups or individuals may be alienated by these behaviors and may differ in their responses based on location or functional role; but the outcome is the same—limited effectiveness of the team, low commitment, low loyalty, and mistrust. Other sources of information such as supervisors and mentors may prove more helpful in recognizing and adapting to political nuances.

Supervisor Relationships

Supervisors are important for assimilating newcomers to organizations by helping build a shared interpretive system that is reflective of assimilation (Berlew & Hall, 1966; Feldman, 1976; Graen, 1976; Kozlowski & Doherty, 1989; Ostroff & Kozlowski, 1992; Schein, 1988). Supervisors frequently communicate with the newcomers, may serve as a role model, filter and interpret formal downward-directed management messages, have positional power to administer rewards and punishments, are a central source of information related to job and organizational expectations as well as feedback on task performance, and are pivotal in the newcomer's ability to negotiate his or her role (Ben-Yoav & Hartman, 1988; Jablin, 2001). According to Staples, Hulland, and Higgins (1998), workers who learned their communication practices by modeling their managers' behaviors had greater self-efficacy, better performance, and more positive job attitudes.

The supervisor-subordinate relationship may be even more important in virtual teams than in traditional teams because of the dislocated nature of the virtual structure. The relationship is complicated by the absence of a physical communication context that characterizes most traditional teams. The supervisor's coordination of virtual team activities may be more difficult because of the distinct nature of technological feedback, the lack of robust spontaneous information exchange between supervisor-subordinate, and the obvious reduction of face-to-face verbal and nonverbal communication cues. On the other hand, some findings suggest that the assessment of team member contributions may be more accurate in virtual rather than face-to-face environments. For example, Weisband and Atwater (1999) found that ratings of liking contributed less bias to evaluations of contribution for virtual groups than face-to-face groups. Similarly, Hedlund, Ilgen, and Hollenbeck (1998) found that leaders of computer-mediated teams were better able to differentiate quality of decisions compared to leaders in face-to-face teams.

It is important for newcomers to develop professional relationships with supervisors, but because virtual teams operate within a more limited timeframe than traditional teams, close relationships leading to friendships become more difficult. This can be a significant problem because the dynamics that help teams become effective require time to develop.

Regardless of whether the supervisor is part of the team or not, the effective supervisor-subordinate relationship will depend in large part on whether the organization uses a traditional approach to managing the virtual team. In traditional teams, supervisor-subordinate relationships are often characterized by hierarchically embedded roles and responsibilities, more formalized rules, procedures, and structures (McPhee & Poole, 2001). In virtual teams, however, there is a loosening of the rules and responsibilities in the supervisor-subordinate relationship. The virtual setting reduces tangible cues that distinguish the status and/or hierarchy of the team members. Thus, the supervisor-subordinate relationships in a virtual team may rely more on co-orientation, focusing on facilitating and supporting the socialization process. Such activities are also comprised in mentoring relationships that have been recognized as important to newcomers' adjustment to socialization efforts.

Mentoring Relationships

When discussing relationship building as part of the assimilation process, mentoring relationships must be considered. Mentors help facilitate newcomer adjustment to situations by offering advice, support, and if appropriate, coaching behaviors to accomplish goals. Wigand and Boster (1991) suggest that "mentoring speeds up socialization into the work role, encourages social interaction, provides an opportunity for high-quality interpersonal interactions, and enhances identification with and commitment to the organization" (p. 16). Mentoring helps team members to generate social capital or the quality of relationships that team members form in their work environments. Due to their expanded boundaries, virtual team members have greater access to a wider range of contexts than would be available in traditional face-to-face teams. For example, Kayworth and Leidner (2002) discovered that highly effective virtual team leaders act in a mentoring role and exhibit a high degree of empathy toward other team members.

Mentoring relationships can be formal and/or informal. Formal mentoring is a "deliberative pairing of a more skilled or experienced person with a lesser skilled or experienced one, with the agreed upon goal of having the lesser skilled or experienced person grow and develop specific competencies" (Murray & Owen, 1991, p. xiv). Several scholars (e.g., Allen, McManus & Russell, 1999; Heimann & Pittenger, 1996; Seibert, 1999) acknowledge that newcomers who participate in formal mentoring relationships in traditional organizations realize greater benefits than those who do not have formal mentoring. Specifically, participation in formal mentoring increases the newcomers' understanding of various organizational issues and increases their level of organizational and job satisfaction.

Informal mentoring relationships develop naturally at the discretion of the mentor and protégé, and exist as long as the parties involved experience sufficient positive outcomes (Jablin, 2001). As opposed to formal mentoring relationships, newcomers who participate in informal mentoring relationships are privileged to information not directly associated with the job role or organizational tasks. These indirect issues include organizational power and politics, more career-related support, "inside" information about various organizational issues and its members that exists on the "grapevine," and increased social interaction outside of the job. Virtual team members who have informal mentors use more direct and less regulative and contractual communication tactics to maintain relational stability than their formal mentored peers (Burke, McKenna & McKeen, 1991; Tepper, 1995). As trust,

Table 1. Guidelines for effective virtual team assimilation

- Organizational issues
  - Develop formal mentoring programs
  - Avoid monitoring electronic communication
  - Provide archive of team history
- Supervisory issues
  - Assist in relationship building
  - Facilitate rather than manage team
  - Encourage team socialization
- Team member issues
  - Actively seek information
  - Develop swift trust based on shared tasks
  - Share personal and non-work related issues

commitment, and identification with the virtual team develops for both the newcomer and more experienced workers, informal mentoring will naturally occur. Virtual teams benefit when barriers to communication are dismantled. This is especially true for newcomers who are uncertain about their roles and the norms of their virtual team.

Recognizing the value of both formal and informal mentoring relationships suggests that virtual teams benefit from such arrangements. Acknowledging the positive impact of mentoring on newcomer assimilation in traditional teams leads us to assume that mentoring will have the same positive impact on virtual team assimilation. However, due to the structural challenges of virtual teams, organizations should consider both formal and informal mentoring programs as tools to socialize newcomers to virtual teams.

In summary, virtual teams face many challenges and issues. The socialization process of team members can become an enigma when building virtual teams. Table 1 summarizes guidelines for organizations, supervisors, and team members to successfully assimilate newcomers into virtual teams.

FUTURE TRENDS

Although we acknowledge that some aspects of virtual team assimilation are similar to traditional team assimilation, they are not identical. What may differ is the speed and the structure of the assimilation process and how newcomers learn to identify with their virtual organization. It would be prudent to explore how newcomers are socialized to use technology and communicate with colleagues and supervisors.

The importance of communication and relationships make virtual teams a challenge for organizations that want to focus more on the outcome rather than the process of producing effective teams. Organizations need to focus more on factors related to internal team processes, such as trust and commitment, rather than outcome assessments such as cost, productivity, and effectiveness.

CONCLUSION

Organizations are turning to virtual teams as a way to remain competitive in the new century's turbulent environment that is characterized by globalization, mergers and acquisitions, and a dependence on information technologies. While great attention has been given to how to provide adequate virtual team infrastructure (e.g., hardware and software), little attention has been devoted to the "human-structure." We assert that how newcomers are assimilated in virtual teams is just as important as the software chosen to accomplish work.

If done correctly, virtual team assimilation may help lead to a strong sense of loyalty and commitment to the team and the organization, which in turn may lead to greater productivity. The responsibility of virtual team socialization resides with the newcomer as well as the organization and the supervisor. Our recommendations for establishing a formal mentoring program, transforming the role of supervisor from manager to facilitator, and supporting proactive behaviors for the newcomer should be identified as high priorities in the development and maintenance of virtual teams. In sum, organizations could obtain a greater return, such as loyalty and commitment, by focusing on newcomer assimilation.

KEY TERMS

Co-Located Team: A traditional team that shares a common goal and works toward that goal in a face-to-face, same office environment.

Formal Mentoring: A deliberate pairing of a more skilled or experienced person with a lesser skilled or experienced one, with the agreed-upon goal of having the lesser skilled or experienced person grow and develop specific competencies.

Informal Mentoring: The non-assigned pairing of an experienced person who respects, guides, protects, sponsors, promotes, and teaches younger, less experienced personnel which develops naturally at the discretion of the mentor and protégé, and persists as long as the parties involved experience sufficient positive outcomes.

Organizational Assimilation: The processes by which individuals become integrated into the culture of an organization.

Organizational Encounter: A time for newcomers to learn behaviors, values, and beliefs associated with their jobs and organizations

Socialization: The acquisition of the knowledge, behavior, and attitude needed to participate fully as a member of a team.

Swift Trust: A type of trust that develops quickly on the basis of shared tasks rather than on the basis of similar demographics or physical proximity.

Virtual Team: A group of geographically and organizationally dispersed workers brought together across time and space through information and communication technologies.

Next–Generation ERP

Charles Møller
Aarhus School of Business, Denmark

INTRODUCTION

"ERP is dead - long live ERP II" is the title of a path breaking research note from Gartner Group (Bond et al., 2000). In this research note Gartner Group envision how the ERP vendors respond to market challenges and how ERP and ERP strategies evolve by 2005. Gartner Group defined ERP II as a transformation of ERP (Enterprise Resource Planning) and today the major vendors have adopted this concept in their contemporary ERP packages.

ERP (Enterprise Resource Planning) is an important concept to industry. Enterprises are increasingly implementing packaged ERP systems. A recent study confirmed that over 90% of the 500 largest Danish enterprises have adopted one or more ERP system. Further, the study found the systems to be of an average age of 2.8 years and decreasing (Møller, Kræmmergaard & Rotbøl, 2003).

ERP is a standardized software packaged designed to integrate the internal value chain of an enterprise (Klaus, Rosemann & Gable, 2000). The five major ERP vendors: (i) SAP; (ii) Oracle; (iii) Peoplesoft; (iv) SAGE; and (v) Microsoft Business Solutions control almost 50% of the ERP market (c.f. table 1) and consequently the corporate infrastructure is dominated by the design of these systems and the vendors.

According to Nah (2002) the American Production and Inventory Control Society (APICS) defines ERP as: "a method for the effective planning and controlling of all the resources needed to take, make, ship and account for customer orders in a manufacturing, distribution or service company". This definition expresses ERP as a tool but ERP is also a management vision and an agency of change and ERP has been attributed almost any good or bad that IT may bring about in business.

In the late 1990's the ERP hype was primarily motivated by companies rushing to prepare for Y2K (Calloway, 2000). Then after a short recession the adoption of ERP has continued. Davenport's sequel on enterprise systems (Davenport, 1998; Davenport, 2000; Davenport & Brooks, 2004) illustrates the changing business perspective on ERP and the ERP hype.

Davenport (1998) sums up the first wave of experiences from implementing ERP systems in a much cited paper on "putting the enterprise system into the enterprise", and points to the new potential business impact of the ERP systems. The discussion evolved over the first enthusiastic expectations, continued over a growing number of horror stories about failed or out-of-control projects, towards a renewed hype of expectations on e-business and SCM.

The ERP II concept is the software industry's perception of the new business challenges and the vision addresses the issues of e-business integration in the supply chain. ERP II is the next-generation ERP concept and in a few years from now the ERP II vision is going to be institutionalized into the infrastructure of most enterprises. This paper will portray the conceptual framework of ERP II.

BACKGROUND: EMERGENCE OF THE ERP CONCEPT

The ERP II concept may be understood by taking a closer look at the development of the ERP concept. Enterprise systems have often been explained through the historical evolution of ERP (Wortmann, 1998; Klaus, Rosemann & Gable, 2000; Chen, 2001). The concept of Enterprise Systems (ES) has evolved over almost fifty years, driven by:

Table 1. Top 5 worldwide ERP software application new license revenue market share estimates for 2002 (Source: Gartner Dataquest, June 2003)

Vendor	*2002 Market Share (%)*	*2001 Market Share (%)*
SAP AG	25.1	24.7
Oracle	7.0	7.9
PeopleSoft	6.5	7.6
SAGE	5.4	4.6
Microsoft Business Solutions	4.9	4.6
Others	51.1	50.3
Total Market Share	100.0	100.0

Table 2. Enterprise systems in retrospective

Decade	Concept	Function
50	Inventory Control Systems (ICS)	Forecast and inventory management
60	Material Requirement Planning (MRP)	Requirement calculations based on Bill-of-Material (BoM)
70	Manufacturing Resource Planning (MRP/II)	Closed-loop planning and capacity constraints
80	Computer Integrated Manufacturing (CIM)	Automation, Enterprise models
90	Enterprise Resource Planning (ERP)	Integrated processes

the changing business requirements, the new information technologies, and by the software vendor's ability to provide standardized solutions.

The fundamental structure of ERP has its origin in the fifties and in the sixties with the introduction of computers into business. The first applications were automating manual tasks such as book-keeping, invoicing and reordering. The early Inventory Control (ICS) systems and Bill of Material (BOM) processors gradually turned into the standardized Material Requirements Planning (MRP). The legacy of the IBM's early COPICS specifications can be found in the structure of the systems even today.

The development continued in the seventies and in the eighties with the MRP II and the CIM concept. During the 1970's MRP caught on like wildfire, and was fueled by the "MRP Crusade" of the American Production and Inventory Control Society (APICS). But gradually industry came to the understanding that neither of these concepts was able to meet the expectations. Even though the CIM ideas failed in many aspects the, the research, e.g. on IS development (ISD) and enterprise models provided the background for gradually integrating more areas into the scope and of the information systems (Wortmann, 2000). This development peaked in early nineties with the advent of the Enterprise Resource Planning (ERP) systems – often embodied in SAP R/3 (Bancroft, 1997) along with the other major vendors: Oracle, Peoplesoft, JD Edwards and Baan – the so called JBOPS. Although the ERP systems have other legacies like accounting, the prevailing planning and control philosophy is deeply rooted in manufacturing and in MRP.

FUTURE TRENDS: NEXT-GENERATION ERP

The ERP market experienced a hype based on the Y2K problem, but after Y2K the ERP market soured. It was doubted that traditional ERP could meet the e-business challenge (Mabert, Soni & Venkataramanan, 2001). New vendors of the "bolt-on" systems, for example, i2 Technology with SCM and Siebel with CRM emerged on the scene (Calloway, 2000) and Application Integration (EAI) became a critical issue (Evgeniou, 2002). New delivery and pricing methods such as ASP (Application Service Provider) and ERP rentals were conceived (Harell, Higgins & Ludwig, 2001) and the traditional ERP vendors were challenged.

The ERP II concept is a vision original conceived by Gartner Group in 2000. Gartner Group, who also put the name on the ERP concept, defines ERP II as, "a business strategy and a set of industry-domain-specific applications that build customer and shareholder value by enabling and optimizing enterprise and inter-enterprise, collaborative-operational and financial processes" (Bond et al., 2000).

ERP II builds on ERP and thus the concept excludes the "bolt-on" vendors like i2 or Siebel from this vision (Mello, 2001). AMR Research does not restrict their competing vision on Enterprise Commerce Management (ECM) to the ERP vendors and define ECM as, "a blueprint that enables clients to plan, manage, and maximize the critical applications, business processes and technologies they need to support employees, customers, and suppliers" (http://www.amrresearch.com/ECM). GartnerGroup has later resigned on this requirement and today ERP II is a framework which includes enterprise systems based on "Best of Breed" systems and EAI (Light, Holland & Willis, 2001) as well as "Single Vendor" solutions.

ERP II includes six elements that touch business, application and technology strategy: (i) the role of ERP II, (ii) its business domain, (iii) the functions addressed within that domain, (iv) the kinds of processes required by those functions, (v) the system architectures that can support those processes, and (vi) the way in which data is handled within those architectures. With the exception of architecture, these ERP II elements represent an expansion of traditional ERP. ERP II is essentially componentized ERP, e-business and collaboration in the supply chain (Bond et al., 2001).

Throughout the ERP industry the new philosophies of e-business was gradually incorporated into the legacy ERP systems, and system architectures were redesigned and modularized, such as what SAP did with their NetWeaver platform. Consequently the contemporary standard systems today incorporate the ERP II vision. The ERP industry survived the challenge and a recent market analysis does not render any signs of market fragmentation, but rather a consolidation. Today we see an ERP market consisting of one dominant actor, a handful of major vendors and a larger number of vendors of minor significance (also c.f. table 1).

Today all the major vendors have adopted the ERP II concept, either partly or to the full extent. The evolution has been driven by the emerging business requirements and by the possibilities offered by the new information technology exactly the same as the evolution of the ERP concept.

The new technologies are not necessarily inventions of the ERP vendors, but rather the technologies emerged as stand alone systems, and after a while they are adopted by the major vendors and then incorporated into the standard systems. For example, that happened to the application frameworks (.NET or J2EE), the databases (Oracle or MS SQL) or Decision-Support Systems (DSS). Business Intelligence (BI) is an example of an analytical DSS technology previously associated with add-ons, like Data warehouse systems based on OLAP tools, that are now integrated into to core of the standard databases. BI refers to a broad category of analytical applications that helps companies make decision based on the data in their ERP systems. Another example is the internet standards like XML, originally conceived outside the control of the major vendors but gradually adopted into the infrastructure of the ERP systems. Other examples are the Supply Chain Management (SCM) systems or the Customer Relationship Management (CRM) systems from third-party vendors like i2 or Siebel. Those third-party vendors experienced a short explosive growth, but then when the technologies are incorporated into the standard ERP system the potential business benefit increases.

There is an emerging pattern of stable generic application architectures which we choose to portray as the ERP II concept. Calloway (2000) and Weston (2003) have attempted to frame this overall development and partial aspects have further been dealt with, for example. by Wortmann (2000) and Møller (2003). The conceptual framework of ERP II illustrated in figure 1 consists of four distinct layers as exhibited in table 3: (i) the foundation layer, (ii) the process layer; (iii) the analytical layer and, (iv) the e-business layer consisting of the collaborative components.

Core Components

The foundation layer consists of the core components of ERP II. The core components shape the underlying architecture and provide a platform for the ERP II systems. ERP II does not need to be centralized or monolithic. One of the core components is the integrated database, which may be a distributed database. Another core component is the application framework likewise potential distributed. The integrated database and the application framework provide an open and distributed platform for ERP II.

Central Components

The process layer of the concept is the central components of ERP II and this layer reflects the traditional transaction based systems. ERP II is web based open and componentized. This is different from being web-enabled, and the ultimate ERP II concept may be implemented as a set of distributed web services.

Enterprise Resource Planning (ERP) is one of the central components in the ERP II conceptual framework. The backbone of ERP is the traditional ERP modules like

Table 3. Four layers of ERP II

Layer	*Components*	
Foundation	Core	Integrated Database (DB) Application Framework (AF)
Process	Central	Enterprise Resource Planning (ERP) Business Process Management (BPM)
Analytical	Corporate	Supply Chain Management (SCM) Customer Relationship Management (CRM) Supplier Relationship Management (SRM) Product Lifecycle Management (PLM) Employee Lifecycle Management (ELM) Corporate Performance Management (CPM)
Portal	Collaborative	Business-to-consumer (B2C) Business-to-business (B2B) Business-to-employee (B2E) Enterprise Application Integration (EAI)

financials, sales and distribution, logistics, manufacturing, or HR. ERP still makes up the backbone of ERP II along with the additional integrated modules aimed at new business sectors outside the manufacturing industries.

The ERP II concept is based on Business Process Management (BPM). ERP has been based on "best-practice" process reference models, but ERP II systems build on the notion of the process as the central entity and ERP II includes tools to manage processes: design (or orchestrate) processes, and to execute and to evaluate processes (Business Activity Monitoring). In ERP II redesigning processes will have effect in real-time.

The BPM component allows for ERP II to be accommodated to suit different business practices for specific business segments that otherwise would require problematic customization. ERP II further includes vertical solutions for specific segments like apparel and footwear or the public sector. Vertical solutions are sets of standardized pre-configured systems and processes with "add-ons" to match the specific requirements in , for example, a business sector.

Corporate Components

The analytical layer consists of the corporate components that extend and enhance the central ERP functions by providing decision support to manage relations and corporate issues. Corporate components are not necessarily synchronized with the integrated database and the components may easily be "add-ons" acquired by third-party vendors. The most common components such as Supply Chain Management (SCM) systems and Customer Relationship Management (CRM) systems are listed in table 3, illustrated in figure 1, and they will further be explained under the terms and definitions in the end of this paper.

In the future we can expect new breeds of corporate components. Product Lifecycle Management is already established as the R&D equivalence to ERP and Employee Lifecycle Management is emerging as an example of a people oriented component.

Collaborative Components

The e-business layer is the portal of the ERP II systems and this layer consists of a set of collaborative components. The collaborative components deal with the communication and the integration between the corporate ERP II system and actors like customer, business partners, employees, and even external systems.

The most common and generic components are listed in table 3 , illustrated in figure 1 and will further explained under the terms and definitions at the end of this paper.

CONCLUSION

ERP II is a vision of the next-generation ERP and the conceptual framework for ERP II is a generic model of the emerging architecture of the contemporary enterprise systems. ERP II is aimed at extending the reach of integration into the supply chain and the business benefits of the systems are only realized when the integration occurs (Davenport, Harris & Cantrell, 2004). Business managers will therefore need to consider their entire range of enterprise systems into a supply chain integration context, and future research will deal with inter-organizational integration based on the ERP II.

KEY TERMS

Business to Business (B2B): E-procurement systems improves the efficiency of the procurement process by automating and decentralizing the procurement process. The traditional methods of sending Request for Quotes (RFQ) documents and obtaining invoices etc. are carried out over the web through purchasing mechanisms such as auctions or other electronic marketplace functions, including catalogues.

Business to Employee (B2E): Intranets or knowledge management systems provide the employee with an updated personalized portal to the enterprise on his desktop. The perspectives of the intranet and knowledge management systems increase in the context of the ERP II concept.

Consumer to Business (B2C): E-commerce systems deals with the carrying out of commercial transactions with businesses or with individual customers by using the Internet as an electronic medium. This requires an extensive infrastructure of which the main features are a catalogue, online ordering facilities and status checking facilities.

Corporate Performance Management (CPM): Sometimes Enterprise Performance Management (EPM) is an umbrella term that describes the methodologies, metrics, processes and systems used to monitor and manage an enterprise's business performance. Thus CPM provides the managements with an overall perspective on the business.

Customer Relationship Management (CRM): Systems facilitate the managing of a broad set of functions relating to managing customers relations that primarily include the categories of customer identification process and customer service management.

Enterprise Application Integration (EAI): Extranets provide the ERP II system with a portal and a platform for integration with other systems inside or outside the corporation. EAI provides the support for automating processes across various IT platforms, systems and organizations.

Employee Lifecycle Management (ELM): The integration of all aspects of information and knowledge in relation to an employee from the hiring to the retirement from the company. ELM enables enterprises to effectively manage their portfolio of competencies.

Enterprise Resource Planning (ERP): II systems are second generation ERP systems. ERP II extends on the ERP concept (Figure 1). The ERP II vision is framed by Gartner Group and in practice defined by the contemporary systems of the major ERP vendors.

Product Lifecycle Management (PLM): Including Product Data Management (PDM) enables enterprises to bring innovative and profitable products to market more effectively, especially in the evolving e-business environment. PLM enables enterprises to harness their innovation process through effective management of the full product definition lifecycle in their extended enterprises.

Supplier Relationship Management (SRM): The vendor side analogy to CRM aimed at the effective management of the supplier base. SRM facilitates the management of the supplier relations in its entire life-cycle.

Supply Chain Management (SCM): Systems provide information that assist in planning and managing the production of goods. For instance, SCM assists in answering questions such as where the good is to be produced, from which the parts are to be procured and by when it is to be delivered.

Non–Functional Requirements and UML Stereotypes

Guadalupe Salazar-Zárate
Technical University of Catalonia, Spain

Pere Botella
Technical University of Catalonia, Spain

INTRODUCTION

In Nuseibeh and Easterbrook (2000), an overview of the field of software and systems requirements engineering is presented. Therein is highlighted some key open-research issues for the future of the Requirements Engineering (RE). Some of the major challenges mentioned there, are related with the necessity of richer models for capturing and analyzing non-functional requirements. This paper draws some possible extensions of Unified Modeling Language (UML) (Booch, G., Jacobson, I. and Rumbaugh, J., 1998) in order to include non-functional requirements.

BACKGROUND

Within the Requirements Engineering processes (e.g., domain analysis, elicitation, modeling, validation, etc.), it is common to distinguish between functional and non-functional requirements. The relevance of functional requirements has been traditionally well-covered by the existing modeling techniques, where a lot of research has been done. However, non-functional requirements (NFRs for short), quality and constraint properties, are not usually covered by these modeling techniques. On the contrary of its functional counterpart and despite the critical role they have during system development, they have received little attention in the literature as mentioned by Chung, L., Nixon, B.A., Yu, E. and Mylopoulos, J. (2000). How can we model and reason about NFRs? How can these models be integrated with those modeling techniques? These are still some of the key challenges that need more research.

Functional and non-functional aspects regarding the external system behavior involve two different ways of evaluating and/or developing a given software system. On one hand, functional aspects are directly connected to *what the system does*, for example, the basic functions that a system (or a system component) must provide. On the other hand, non-functional aspects are related with how the system behaves with respect to some observable attributes such as performance, reliability, efficiency, reusability, portability, maintainability (i.e., some software qualities). To illustrate the wide variety of issues for software quality, in Chung et al. (2000, p.160) a list of non-functional requirements can be found.

There are two basic approaches to characterize non-functional requirements: *Product-oriented* and *Process-oriented* (Chung et al., 2000). The *product-oriented approach* basically focuses on the development of a formal framework so that a software product can be evaluated in relation to the highest degree it fulfills for non-functional requirements (constraints over non-functional properties). The *process-oriented approach* uses non-functional information to guide the development of software systems. Among the works dealing with this perspective of non-functionality, those of Chung et al. (2000) are without any doubt the most complete ones. Therein a NFR framework, to deal with diverse non-functional requirements to drive the design by justifying decisions during the software development process, is described. The framework also offers structured, graphical facilities for stating, managing, and inter-relating non-functional requirements while justifying decisions and determining their impact throughout the development process.

In Cysneiros and Leite (2001a, 2001b), and Cysneiros, L.M., Leite, J.C.S.P. and Neto, J.S.M. (2001) an approach that complements the work reported in Chung et al. (2000) is presented. Strategies can be found there that are concerned with the problem of how to identify and integrate non-functional requirements with functional requirements, in a process-oriented approach and using UML.

Another important language that focuses on non-functional requirements is the Goal-oriented Requirement Language (GRL) (ITU-T, URN Focus Group, 2002b), (http://www.cs.toronto.edu/km/GRL/). The GRL graphical language is used to support goal and agent-oriented modeling and reasoning of requirements. The GRL is built on the well-established NFR Framework (used for modeling NFRs) and the agent-oriented language i* (Yu, 1997) (used for the modeling, analysis, and reengineering of organizations and business processes).

OUR APPROACH TO NON-FUNCTIONAL REQUIREMENTS AND UML

UML has today become a standard modeling language for software systems development (Object Management Group, 2001). UML offers a graphical notation to create models. However, it is mainly focused on functional aspects of the software development.

In the following approach we outline some possible extensions of UML in order to include non-functional requirements. In the works by Botella, P., Burgués, X., Franch, X., Huerta, M. and Salazar, G. (2002), and Salazar-Zárate, G, Botella, P. and Dahanajake A. (2003), more detailed considerations about this topic can be found.

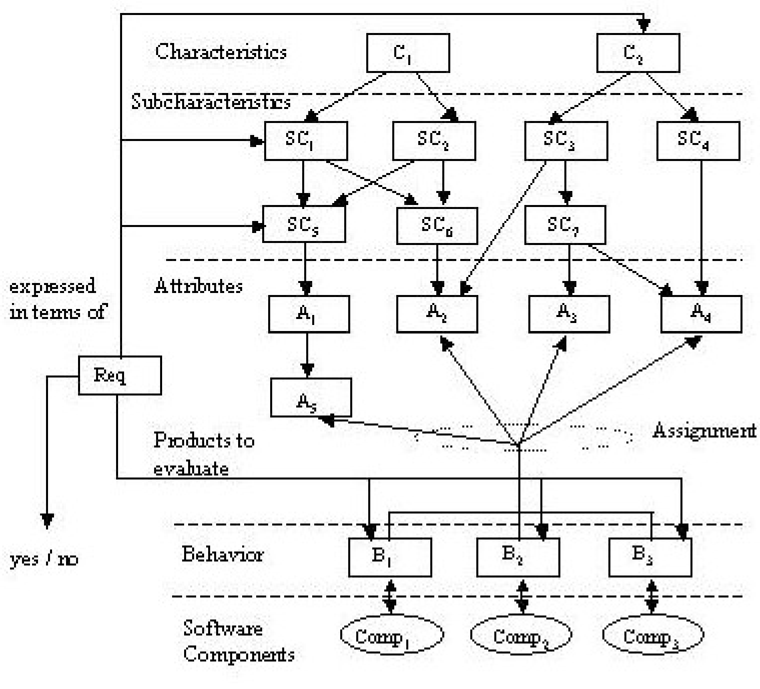
The International Standard ISO/EC 9126-1 (2001) can be used as a starting point to identify non-functional attributes of products that are potentially relevant to be modeled in a software development process. This standard provides a framework for software product quality, specifying quality characteristics to be used in the quality evaluation of software products. A *quality model* is defined by means of general *characteristics of software*, which are further refined into *subcharacteristics* in a multilevel hierarchy. In the standard, the characteristics of functionality, reliability, usability, efficiency, maintainability, and portability are being placed at the top of the hierarchy. Measurable *software attributes* appear at the bottom of the hierarchy. *Software quality metrics* allows developers to quantify up to what degree a software system meets non-functional requirements.

A language called *NoFun* (acronym for "NOn-FUNctional") is a notation that focuses on representing non-functional aspects of software systems, at the product level within the component-programming framework (Franch, 1998; Burgués & Franch, 2000; Botella et al., 2002). It is a formal language for description of software quality requirements using the ISO/IEC 9126 standard to summarize quality characteristics (see figure 1). Although the ISO/IEC 9126-1 (2001) replaces the previous version of 1991, the basic principles stay and we are still able to use the same layout therein described.

To achieve the goal of formalization within *NoFun*, three different kinds of capabilities are provided. First, there are modules for defining the different kind of concepts in the standard (characteristics, subcharacteristics and attributes). Second, values for these attributes may be given (in *behavior modules*) and bound to particular software components (i.e., the ones under evaluation). Third, additional constructions for representing quality requirements and assessment criteria are included.

In figure 1, an example of distribution of a quality model into modules is shown (extracted from Botella et al. (2002). Two characteristics defined in terms of four subcharacteristics appear in the upper part of the figure. Behavioral modules (denoted by the B_i), are abstractions of software components in the sense that they contain all the relevant information for quality evaluation. Quality requirements may be defined as restricting the values of

Figure 1. Layout of a quality model under NoFun language.



the quality entities. They are stated using operators over the quality entities, and these requirements may be categorized according to their importance (for more details see Botella et al., 2002).

In addition to those elements, an orthogonal concept is the one of refinement. Refinement allows the definition of quality models in an incremental manner, by specializing the more general ones. This kind of inheritance-like relationship is used to construct a structured representation of quality. As a result, quality models can be formulated first in a general way, and later refined in particular domains.

Using the formalizing ideas of the *NoFun* language and following a product oriented approach; we aim to extend the UML language (Booch et al., 1998) in order to capture non-functional information.

APPLYING UML STEREOTYPES FOR NFRS

Regarding non-functional information, UML offers notes to incorporate those aspects. UML notes may contain any information; and because of the different domains, types, and nature of the NF-information therein listed, specifying NF-attributes in this way may be insufficient if we want a systematic representation of the NF-information. Therefore, it is necessary to put this information in a more ordered form. One way to identify those kinds of attributes for visualizing non-functionality in UML diagrams is through the use of the layout described above with the *NoFun* language.

In order to incorporate non-functional requirements to UML, the following considerations have been devised. First, we propose to make use of stereotypes to represent the non-functionality. UML stereotypes allow us to create new kinds of building blocks that can be adapted to our specific problem. Second, those software quality characteristics and attributes defined in a layout as shown in figure 1 can be identified and some ad-hoc stereotypes can be also defined. Organizing collections of quality characteristics in this way gives us a generic language concept that can be instantiated later. There are various levels of granularity and, consequently, NF-information can be applied to a whole system, package, component or class in particular. Non-functional requirements tend to be properties of a system as a whole, but our approach attempts to be flexible in order to attach NF-information at every abstraction level, including a single component.

UML stereotypes to include non-functionality can be used in several ways:

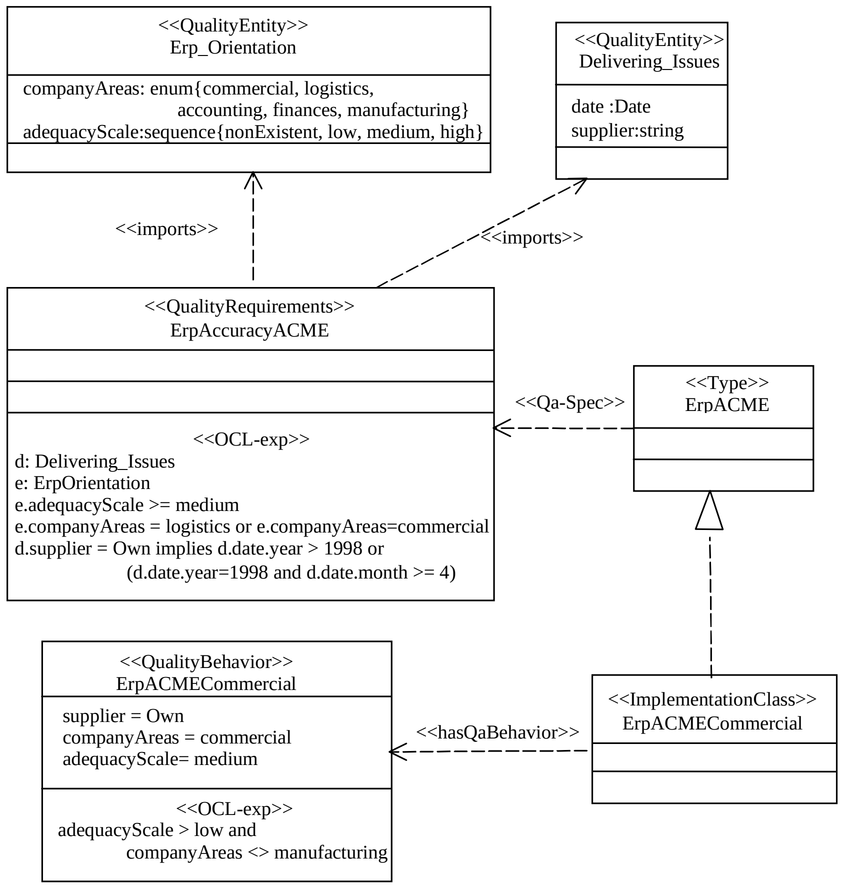
- In a *Class diagram*. At a conceptual level, one can create stereotyped classes <<NF-Entity>> to represent a specific quality characteristic. New stereotypes can be formulated and then refined into more specialized ones. In a more detailed level, the Object Constraint Language (OCL) (Warmer & Kleppe, 1999), or an adaptation of the NoFun language can be used to establish requirements in the form of constraints.
- In UML *packages*. One can group software elements under a stereotyped package, for example, to represent a collection of non-functional stereotyped classes. In this way, a framework for further design specifications is provided.
- In *Use Cases*. The non-functionalities can be seen as transformation rules causing new use cases to be added and/or the structure of the use case description to be changed or replaced so that the non-functional requirements are satisfied. New actors may also be identified in the transformation process. By adding stereotypes such as <<NF-uses>> or <<NF-extends>>, one can identify the use cases that involve non-functionalities. Constraints can be attached in a special script using OCL or NoFun.

To identify the non-functional concepts, the main idea is to use software components in an object-oriented approach. Hereafter, the software components can be seen as entities consisting in the definition of a class diagram that states both functional and non-functional characteristics. According to the analysis model proposed by Larman (1998), this approach focused initially on the conceptual model by using UML class diagrams. At a later stage, other models, such as essential use cases, system sequence diagrams (behavior), and the state diagrams, will be considered.

In a UML context, the functional requirements of the system are partially captured in a *Class Diagram* containing the classes and relationships that represents the key abstractions of the system under development. Figure 2 shows a particular case where non-functionality is applied to a whole system as represented with a single class. Following the organization described by Franch, X., Botella, P., Burgués, X. and Ribó, J.M. (1997), the functional specification part of a software system can be distinguished from its *implementation* part. In this way, it is possible to state that a specification module may have several different implementations. It is also possible to select the best implementation for a given specification according to the non-functional information. In Figure 2, it is represented by using the predefined UML stereotypes <<Type>> and <<ImplementationClass>>.

Stereotyped classes <<QualityEntity >> can be used to represent the modules for characteristics, subcharacteristics, and attributes. As a result, non-func-

Figure 2. Example showing non-functional stereotypes.



tional attributes are defined in this stereotyped class. In this way, one can create all of the stereotyped classes needed to describe the non-functionality. A kind of hierarchy between these attributes can be simulated with dependency relationships between the classes (<<imports>> indicates that the dependent class may import one or more modules of non-functional entities). In order to state constraints over the non-functional attributes, an extra compartment (titled <<OCL-exp>>) can be added to the stereotyped class.

A stereotype <<QualityRequirements>> can be declared for restricting the values of the quality entities. The stereotype <<QualityBehavior>> will define the *non-functional behavior* of a component implementation.

The use of UML stereotypes as a mechanism to incorporate non-functional elements has been outlined. It has been accomplished by describing new UML stereotypes for the class diagrams, package diagrams and use cases. In class diagrams the new stereotypes have been used to represent quality entities, in package diagrams they were used to represent collections of quality entities, and in use cases they may be applied to identify the non-functional information.

FUTURE TRENDS

The work here presented was motivated within the scope of the construction of quality models for software domains of our research group (http://www.lsi.upc.es/~gessi/). The work started by the group of Toronto (Mylopoulos, J., Chung, L. and Nixon, B.A., 1992; Chung & Nixon, 1995; Chung et al., 2000) is consolidated nowadays as a predominant research line in describing non-functional requirements. Both the UML approach of the work of Cysneiros and Leite (2001b), mentioned above, and the Goal-oriented Requirement Language (GRL) (ITU-T, URN Focus Group, 2002b) (http://www.cs.toronto.edu/km/GRL/) also mentioned before, are included under this line.

Currently there here is a project to create a language standardization to express user requirements in the scope of the telecommunications, denominated User Requirements Notation (URN) (ITU-T, URN Focus Group, 2002a), (http://www.usecasemaps.org/urn/urn-info.shtml). In this project, GRL is included for the expression of the non-functional requirements. The standardization group is mainly composed of researchers and practitioners from industry (Mitel, Nortel, KLOCwork, Rational, Telelogic, Phillips, and others) and academia (Carleton Univ. and Univ. of Ottawa for UCMs, Univ. of Toronto for GRL, and others).

CONCLUSION

Our approach presented here can be considered as a first attempt to include NFRs and distinguishing them from the FRs in the UML models and under the characteristic/subcharacteristic concepts of the standard ISO 9126-1.

Mainly using quality models (as defined by the ISO 9126-1) as a reference framework for the definition of nonfunctional requirements. As an example in Botella et al., (2003) we show the use of quality requirements based on quality models for the selection of ERP systems.

There are still many challenges to address the NFRs, and more strategies and tools are needed in order to offer alternatives to capture and analyze NFRs.

KEY TERMS:

i*: The i* modeling framework (pronounce eye-star) has been developed at the University of Toronto by Yu, Mylopoulos and Chung. It was developed for modeling and reasoning about organizational environments and their information systems (Yu, 1997, p.227)

ITU-T: The ITU Telecommunication Standardization Sector (ITU-T) is one of the three Sectors of the International Telecommunication Union (ITU). The function of ITU-T is to provide global telecommunication standards by studying technical, operating and tariff questions. The results of these studies are published as ITU-T Recommendations. (*http://www.itu.int/ITU-T/index.html*).

NFR: Non-functional requirement – in software system engineering, a software requirement that describes not what the system will do, but how the software will do it, for example, software performance requirements, software external interface requirements, software design constraints, and software quality attributes (Chung et al., 2000, p.6, based on the original given by Thayer & Dorfman, 1990).

NFR: Non-functional requirement. A property or quality that the product must have, such as an appearance, or a speed or accuracy property (Robertson & Robertson, 1999)

OCL: The Object Constraint Language is an expression language that enables one to describe constraints on object-oriented models and other object modeling artifacts (Warmer & Kleppe, 1999).

Quality evaluation: The systematic examination of the extent to which an entity is capable of fulfilling specified requirements (ISO/IEC 9126-1, 2001, p.20).

Quality Model: The set of characteristics and the relationships between them which provide the basis for specifying quality requirements and evaluating quality (ISO/IEC 9126-1, 2001, p.21).

Requirements Engineering: The branch of software engineering concerned with the real-world goals for, functions of, and constraints on software systems. It is also concerned with the relationship of these factors to precise specifications of software behavior, and to their evolution over time and across software families (Zave, 1997).

UML: The Unified Modeling Language is a standard graphical language for visualizing, specifying, constructing, and documenting the artifacts of a software-intensive system (Booch, et al., 1998).

Novel Indexing Method of Relations Between Salient Objects

Richard Chbeir
Bourgogne University, France

Kokou Yetongnon
Bourgogne University, France

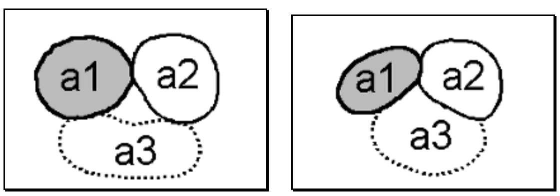
INTRODUCTION

During the last decade, a lot of work has been done in information technology in order to integrate image retrieval in the standard data processing environments (Rui, Huang & Chang, 1999; William & Grosky, 1997; Yoshitaka & Ichikawa, 1999).Relations between image objects are very frequently used to index the image-document (Peuquet, 1986). In medicine, for instance, the spatial data in surgical or radiation therapy of brain tumors are decisive because the location of a tumor has profound implications on a therapeutic decision (Chbeir, Amghar, & Flory, 2001). Hence, it is crucial to provide a precise and powerful system to express spatial relations. In the literature, three major types of spatial relations are proposed: metric (Peuquet, 1986), directional (El-kwae & Kabuka, 1999) and topological relations (Egenhofer, 1997; Egenhofer, Frank & Jackson, 1989).

In spite of all the proposed work to represent complex visual situations, several shortcomings exist in the methods of spatial relation computations. For instance, Figure 1 shows two different spatial situations of three salient objects that are described by the same spatial relations in both cases: topological relations: a1 Touch a2, a1 Touch a3, a2 Touch a3; and directional relations: a1 Above a3, a2 Above a3, a1 Left a2.

The existing systems do not have the required expressive power to represent these situations. Thus, in this article, we address this issue and propose a snapshot of our novel method that can easily compute several types of relations between salient objects with better expressions. The rest of this article is organized as follows. In the second section, we present related work in this domain. In the third section, we briefly present our method and discuss how it gives better results using spatial features. finally, conclusions and future directions are given in the fourth section.

Figure 1. Two different spatial situations



BACKGROUND

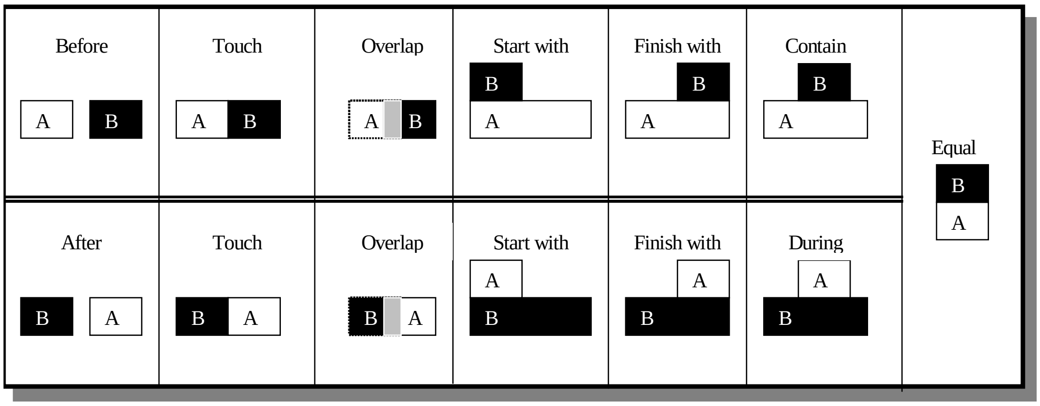
The problem of image retrieval is strongly related to image representation. The two different approaches used for the representation of images are: the metadata-based and the content-based approaches. Made with human assistance, the metadata-based representation uses alpha-numeric attributes to describe the context and/or the content of an image. The other approach for representation of images is using its low-level contents such as its color, texture, and shape (Remco & Mirela, 2000). The representations using low-level features are derived through feature extraction algorithms.

In both approaches, relations between either salient objects, shapes, points of interests, and so forth have been widely used in image indexing such as R-trees (Beckmann, 1990; Guttman, 1984), 2D-Strings (Chang & Jungert, 1991, 1997; Chang, Shi & Yan, 1987), and so forth. Temporal and spatial relations are the most used relations in image indexing.

To calculate temporal relations, two paradigms are proposed in the literature:

- The first paradigm consists of representing the time as a set of *instants:* $t_1,..t_i,..t_n$. Traditionally, only three temporal relations are possible between two objects: *before*, its symmetric relation *after*, and *equal*.
- The second paradigm considers the time as a set of intervals $[t_i, t_j]$. Allen relations (Allen, 1983) are often used to represent temporal relations between intervals. Allen proposes 13 temporal relations (Figure 2) in which six are symmetrical.

Figure 2. Allen relations



On the other hand, three major types of spatial relations are generally proposed in image representation (Egenhofer, Frank & Jackson, 1989):

- Metric relations: measure the distance between salient objects. For instance, the metric relation "far" between two objects A and B indicates that each pair of points A_i and B_j has a distance greater than a certain value δ.
- Directional relations: describe the order between two salient objects according to a direction, or the localisation of salient object inside images. In the literature, 14 directional relations are considered:
  - Strict: north, south, east, and west.
  - Mixture: north-east, north-west, south-east, and south-west.
  - Positional: left, right, up, down, front and behind.

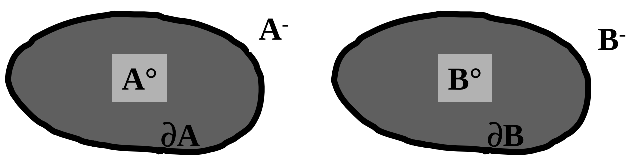
    Directional relations are *rotation variant* and there is a need to have referential base. Furthermore, directional relations do not exist in certain configurations.
- Topological relations: describe the intersection and the incidence between objects. Egenhofer (Egenhofer, 1997) has identified six basic relations: *Disjoint, Meet, Overlap, Cover, Contain, and Equal.* Topological relations present several characteristics that are *exclusive* to two objects (i.e., there is one and only one topological relation between two objects). Furthermore, topological relations have *absolute* value because of their constant existence between objects. Another interesting characteristic of topological relations is that they are transformation, translation, scaling, and zooming *invariant*.

PROPOSITION

The 9-Intersection model proposed by Egenhofer (Egenhofer, 1997; Egenhofer, Frank & Jackson, 1989) represents each shape "A" as a combination of three parts: *interior* $\mathbf{A}°$, *boundary* $\partial\mathbf{A}$ and *exterior* $\mathbf{A}^-$. The topological relations between two shapes are obtained by applying an intersection matrix between these parts (Figure 3). Each intersection is characterised by an empty ($\varnothing$) or non-empty ($\neg\varnothing$) value.

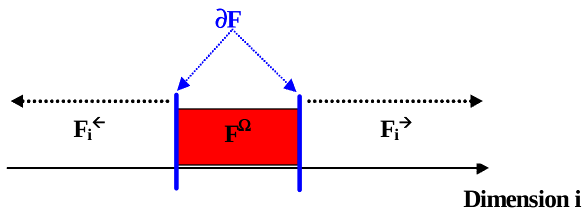
Our proposal represents an extension of this 9-Intersection model. It provides a general method for computing not only topological relations but also other types of relations such as temporal, spatial, and so forth. The idea shows that the relations are identified in function of features of shape, time, and so forth. The shape feature gives spatial relations; the time feature gives temporal relations, and so on. To identify a relation between two salient objects, we propose the use of an intersection matrix between sets of features. Let us first consider a feature F. We define its intersection sets as follows:

Figure 3. The 9-Intersection model: The topological relation between two shapes is based on the comparison of the three parts of each one.



$$R(\mathbf{A},\mathbf{B}) = \begin{pmatrix} \mathbf{A}°\cap\mathbf{B}° & \mathbf{A}°\cap\partial\mathbf{B} & \mathbf{A}°\cap\mathbf{B}^- \\ \partial\mathbf{A}\cap\mathbf{B}° & \partial\mathbf{A}\cap\partial\mathbf{B} & \partial\mathbf{A}\cap\mathbf{B}^- \\ \mathbf{A}^-\cap\mathbf{B}° & \mathbf{A}^-\cap\partial\mathbf{B} & \mathbf{A}^-\cap\mathbf{B}^- \end{pmatrix}$$

Figure 4. Intersection sets of one-dimensional feature



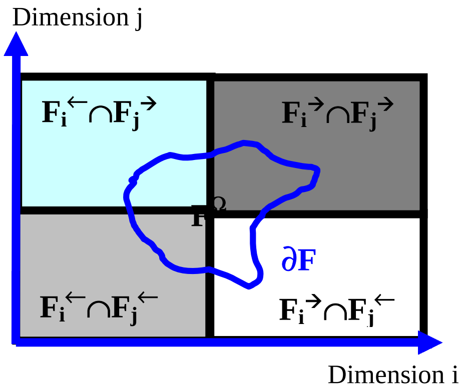
- The ***interior*** $\mathbf{F^{\Omega}}$**:** contains all elements that cover the interior or the core of F. In particular, it contains the barycenter of F. The definition of this set has a great impact on the other sets. F^{Ω} may be empty ($\emptyset$).
- The ***boundary*** **∂F:** contains all elements that allow determining the frontier of F. ∂F is never empty ($\neg\emptyset$).
- The ***exterior*** $\mathbf{F^{-}}$**:** is the complement of $F^{\Omega}\cup\partial F$. It contains at least two elements: $\perp$ (the minimum value) and ∞ (the maximum value). F^{-} can be divided into several disjoint subsets. This decomposition depends on the number of the feature dimensions. For instance, if we consider a feature of one dimension i (such as the acquisition time of an image), two intersection subsets can be defined (Figure 4):

- $\mathbf{F_i^{\leftarrow}}$ **(or inferior):** contains elements of F^{-} that do not belong to any other intersection set and inferior to ∂F elements based on i dimension.
- $\mathbf{F_i^{\rightarrow}}$ **(or superior):** contains elements of F^{-} that do not belong to any other intersection set and superior to ∂F elements based on i dimension.

If we consider a feature of two dimensions i and j (as the shape in a 2D space), we can define four intersection subsets (Figure 5):

- $\mathbf{F_i^{\leftarrow}\cap F_j^{\leftarrow}}$ **(or inferior):** contains elements of F^{-} that do not belong to any other intersection set and inferior to $\mathbf{F^{\Omega}}$ and ∂F elements based on i and j dimensions.
- $\mathbf{F_i^{\leftarrow}\cap F_j^{\rightarrow}}$**:** contains elements of F^{-} that do not belong to any other intersection set and inferior to $\mathbf{F^{\Omega}}$ and ∂F elements based on i dimension, and superior to $\mathbf{F^{\Omega}}$ and ∂F elements on the basis of j dimension.

Figure 5. Intersection sets of two-dimensional feature



- $\mathbf{F_i^{\rightarrow}\cap F_j^{\leftarrow}}$**:** contains elements of F^{-} that do not belong to any other intersection set and superior to $\mathbf{F^{\Omega}}$ and ∂F elements based on i dimension, and inferior to $\mathbf{F^{\Omega}}$ and ∂F elements on the basis of j dimension.
- $\mathbf{F_i^{\rightarrow}\cap F_j^{\rightarrow}}$ **(or superior):** contains elements of F^{-} that do not belong to any other intersection set and superior to $\mathbf{F^{\Omega}}$ and ∂F elements based on i and j dimensions.

More generally, we can determine intersection sets (2^n) of n-dimensional feature. In addition, we use a tolerance degree in the feature intersection sets definition in order to represent separations between sets. For this purpose, we use two tolerance thresholds:

- Internal threshold $\boldsymbol{\varepsilon}^{i}$ that defines the distance between F^{Ω} and ∂F,
- External threshold $\boldsymbol{\varepsilon}^{e}$ that defines the distance between subsets of F^{-}.

To calculate relation between two salient objects, we establish an intersection matrix of their corresponding feature intersection sets. Matrix cells have binary values:

- 0 whenever intersection between sets is empty,
- 1 otherwise

Figure 6. Intersection matrix of two objects A and B on the basis of two-dimensional feature

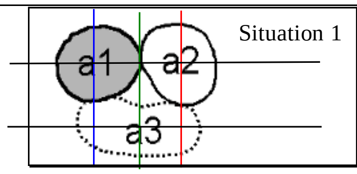
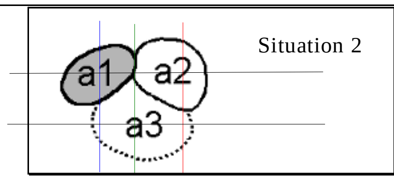
Figure 7. Identifed spatial relations using our method



$$R(a1, a2) = \begin{array}{|c|c|c|c|c|c|} \hline 0&0&1&1&0&0 \\ \hline 0&1&1&1&0&0 \\ \hline 0&0&1&0&0&0 \\ \hline 0&0&0&1&0&0 \\ \hline 1&1&0&1&1&0 \\ \hline 1&1&1&0&0&1 \\ \hline \end{array} \qquad R(a1, a3) = \begin{array}{|c|c|c|c|c|c|} \hline 0&0&0&1&0&0 \\ \hline 0&1&0&1&1&0 \\ \hline 1&1&1&1&0&0 \\ \hline 0&0&0&1&0&0 \\ \hline 0&0&0&1&1&0 \\ \hline 1&1&1&1&1&1 \\ \hline \end{array}$$



$$R'(a1, a2) = \begin{array}{|c|c|c|c|c|c|} \hline 0&0&1&1&0&0 \\ \hline 0&1&1&1&0&0 \\ \hline 0&0&1&0&0&0 \\ \hline 0&0&0&1&0&0 \\ \hline 1&1&0&1&1&0 \\ \hline 1&1&1&0&0&1 \\ \hline \end{array} \qquad R'(a1, a3) = \begin{array}{|c|c|c|c|c|c|} \hline 0&0&0&1&0&0 \\ \hline 0&1&0&1&1&0 \\ \hline 1&1&1&1&0&0 \\ \hline 0&0&0&1&0&0 \\ \hline 0&0&0&1&1&0 \\ \hline 1&1&1&0&1&1 \\ \hline \end{array}$$

For instance, for two-dimensional feature (such as the shape) of two salient objects A and B, we obtain the intersection matrix (see Figure 6).

Using our method, we are able to provide a high expression power to spatial relations that can be applied to describe images and formulate complex visual queries in several domains. For example, for Figure 1, which shows two different spatial situations between three salient objects a1, a2, and a3, our method expresses the spatial relations as shown in Figure 7. The relations R(a1, a2) and R'(a1, a2) are equal but the relations R(a1, a3) and R'(a1, a3) are clearly distinguished. Similarly, we can express relations between a2 and a3 in both situations.

Moreover, our method allows combining both directional and topological relation into one *binary* relation, which is very important for indexing purposes. There are no directional and topological relations between two salient objects but only one spatial relation. Hence, we can propose a 1D-String to index images instead of 2D-Strings (Chang, Shi & Yan, 1987).

CONCLUSION AND FUTURE TRENDS

In this article, we presented an overview of traditional relations used in image indexing. We also snapshot our method. This work aims to homogenize, reduce and optimize the representation of relations. It is not limited to spatial relations but it is also applicable to other types of relations (temporal, semantic, spatio-temporal, etc.).

However, in order to study its efficiency, our method requires more intense experiments in complex environment where a great number of feature dimensions and salient objects exist. Furthermore, we currently work on its integration in our prototype MIMS (Chbeir, Amghar & Flory, 2001) in order to improve image storage and retrieval. Future directions will address the use of these relations on video documents.

KEY TERMS

Directional Relation: Describes the order between two salient objects according to a direction, or the localization of salient object inside images. In the literature, 14 directional relations are considered:

- Strict: north, south, east, and west.
- Mixture: north-east, north-west, south-east, and south-west.
- Positional: left, right, up, down, front and behind.

Image Indexing: Consists of assigning concise and significant descriptors to an image. Objects' shapes and positions are used in several indexing approaches where image is represented as a graph or tree (R-tree, B-tree, etc.).

Metric Relation: Measures the distance between salient objects. For instance, the metric relation "far" between two objects A and B indicates that each pair of points A_i and B_j has a distance grater than a certain value d.

Multimedia Document: Represents a document containing not only textual data but also multimedia ones such as images, videos, songs, and so forth.

Salient Object: Means interesting or significant object in an image (sun, mountain, boat, etc.). Its computing changes in function of the application domain.

Spatio-temporal Relation: A combination of two spatial and temporal relations into one relation used to index video-documents and objects' evolution between two images (e.g., tumor evolution).

Topological Relation: Describes the intersection and the incidence between objects. Six basic relations have been identified in the literature: *Disjoint, Meet, Overlap, Cover, Contain,* and *Equal*.

Object Database Benchmarks

Jerôme Darmont
Universite Lumiere Lyon 2, France

INTRODUCTION

The need for performance measurement tools appeared soon after the emergence of the first Object-Oriented Database Management Systems (OODBMSs), and proved important for both designers and users (Atkinson & Maier, 1990). Performance evaluation is useful to designers to determine elements of architecture and more generally to validate or refute hypotheses regarding the actual behavior of an OODBMS. Thus, performance evaluation is an essential component in the development process of well-designed and efficient systems. Users may also employ performance evaluation, either to compare the efficiency of different technologies before selecting an OODBMS or to tune a system.

Performance evaluation by experimentation on a real system is generally referred to as benchmarking. It consists in performing a series of tests on a given OODBMS to estimate its performance in a given setting. Benchmarks are generally used to compare the global performance of OODBMSs, but they can also be exploited to illustrate the advantages of one system or another in a given situation, or to determine an optimal hardware configuration. Typically, a benchmark is constituted of two main elements: a workload model constituted of a database and a set of read and write operations to apply on this database, and a set of performance metrics.

BACKGROUND

Object Database Benchmarks Evolution

In the sphere of relational DBMSs, the Transaction Performance Processing Council (TPC) issues standard benchmarks, verifies their correct application and regularly publishes performance test results. In contrast, there is no standard benchmark for OODBMSs, even if the more popular of them, OO1, HyperModel, and OO7, can be considered as *de facto* standards.

OO1, also referred to as the "Cattell Benchmark" (Cattell, 1991), was developed early in the nineties when there was no appropriate benchmark for engineering applications such as computer aided design (CAD), computer aided manufacturing (CAM), or software engineering (SE). OO1 is a simple benchmark that is very easy to implement. A major drawback of this tool is that its workload model is too elementary to measure the elaborate traversals that are common in many types of object-oriented applications.

The HyperModel Benchmark (Anderson et al., 1990), also referred to as the Tektronix Benchmark, possesses a richer workload model than OO1. This renders it potentially more effective than OO1 in measuring the performance of engineering databases. However, this added complexity also makes HyperModel harder to implement.

OO7 (Carey, Dewitt & Naughton, 1993) reuses the structures of OO1 and HyperModel to propose a more complete benchmark and to simulate various transactions running on a diversified database. It has also been designed to be more generic than its predecessors and to correct some of their known weaknesses. However, OO7 is even harder to implement than HyperModel.

OO1, HyperModel, and OO7, though aimed at engineering applications, are often viewed as general-purpose benchmarks. However, they feature relatively simple databases and are not well suited for other types of applications such as financial, telecommunication, and multimedia applications (Tiwary, Narasayya & Levy, 1995). Hence, many benchmarks were developed to study particular domains, such as client-server architectures (Schreiber, 1994), object clustering (Bancilhon, Delobel & Kanellakis, 1992; Darmont, Petit & Schneider, 1998; Gerlhof et al., 1996), object-relational systems (Carey, Dewitt & Naughton, 1993; Lee, Kim & Kim 2000), active databases (Zimmermann & Buchmann, 1995), workflow management (Bonner, Shrufi & Rozen, 1995), CAD applications (Kempe et al., 1995), or the study of views in an object-oriented context (Kuno & Rundensteiner, 1995). A fair number of these benchmarks are more or less based on OO1, HyperModel, or OO7.

An alternative to very specific benchmarks resides in generic and tunable benchmarks such as OCB (Darmont & Schneider, 2000). The flexibility and scalability of OCB is achieved through an extensive set of parameters that helps OCB simulate the behavior of the *de facto* standards in object-oriented benchmarking. Furthermore, OCB's generic model can be implemented within an object-relational system easily and most of its operations are relevant for such a system. Hence, it can also be applied in an object-relational context with few adaptations.

Finally, OCB has been recently extended to become the Dynamic Object Evaluation Framework (DOEF), which introduces a dynamic component in the workload (He & Darmont, 2003). Changes in access patterns indeed play an important role in determining the efficiency of a system or of key performance optimization techniques such as dynamic clustering, prefetching, and buffering. However, all previous benchmarks produced static access patterns in which objects were always accessed in the same order repeatedly. In contrast, DOEF simulates access pattern changes using configurable styles of change.

Issues and Tradeoffs in Benchmarking

Gray (1993) defines four primary criteria to specify a good benchmark: (1) *relevance:* it must concern aspects of performance that appeal to the largest number of potential users; (2) *portability:* it must be reusable to test the performances of different OODBMSs; (3) *simplicity:* it must be feasible and must not require too many resources; and (4) *scalability:* it must be able to be adapted to small or large computer systems or new architectures. Table 1 summarizes the characteristics of the main existing benchmarks according to Gray's criteria. It is important to note that these four criteria are in mutual conflict. For instance, the size and complexity of a relevant workload may come in conflict with its feasibility and possibly with portability requirements. Hence, it is necessary to find the right compromise regarding given needs.

The *de facto* standards in OODBMS benchmarking all aim at being generic. However, they all incorporate database schemas that are inspired by structures used in engineering software, which finally tailors them to the study of these particular systems. Adapting these benchmarks to another domain requires some work and a derived benchmark that takes into account specific elements often needs to be designed. Hence, their relevance decreases when they are applied in other domains but engineering. A solution to this problem is to select a generic benchmark that can be tailored to meet specific needs. However, there is a price to pay. Genericity is achieved with the help of numerous parameters that are not always easy to set up. Thus, the effort in designing a specific benchmark must be compared to the parameterization complexity of a generic benchmark.

There is also another, very different, "qualitative" aspect of benchmarking that has never really been considered in published benchmarks and that is important for a user to consider when selecting an OODBMS. Atkinson et al. (1992), Banerjee and Gardner (1995), and Kempe et al. (1995) all insist on the fact that system functionality is at least as important as raw performances. Hence, criteria concerning these functionalities should be worked out.

Finally, there is an issue that is not a scientific one. Carey, Dewitt and Naughton (1993) and Carey et al. (1994) pointed out serious legal difficulties in their benchmarking effort. Indeed, OODBMS vendors are sometimes reluctant to see benchmark results published. However, designing relevant benchmarks remains an important task and should still be carried out to help researchers, software designers or users evaluate the adequacy of any prototype, system or implementation technique in a particular environment.

CONCLUSION AND FUTURE TRENDS

The development of new object database benchmarks is now scarce, mainly because the first generation of OODBMSs failed to achieve any broad commercial success. This failure is largely due to the never-ending issue of poor performance compared to relational DBMSs, which are well optimized and efficient. However, with the development of object-oriented programming both off-line and online, the need for persistent objects remains. Object-relational systems are now used more and more frequently (to store XML documents, for instance). Thus, the experience that has been accumulated when designing object-oriented database benchmarks could be reused in this context. The challenge for object store designers is now to produce efficient systems, and sound benchmarks could help them achieve this goal.

Table 1. Comparison of existing benchmarks with Gray's criteria

	Relevance	Portability	Simplicity	Scalability
OO1	– –	+ +	+ +	–
HyperModel	+	+	–	– –
OO7	+ +	+	– –	–
OCB	+ +	+	–	+ +

Strong point: +　Very strong point: ++　Weak point: –　Very weak point: – –

KEY TERMS

Benchmark: A standard program that runs on different systems to provide an accurate measure of their performance.

Database Benchmark: A benchmark specifically aimed at evaluating the performance of DBMSs or DBMS components.

Object-Oriented Database: A database system offering DBMS facilities in an object-oriented programming environment. Data are natively stored as objects.

Object-Relational Database: A database system where the relational model is extended with object-oriented concepts. Data are still stored in relational structures.

Performance Metrics: Simple or composite metrics aimed at expressing the performance of a system.

Synthetic Benchmark: A benchmark in which the workload model is artificially generated, as opposed to a real-life workload.

Workload Model: In a database benchmark, a database and a set of read and write operations to apply on this database.

Object Oriented Software Metrics

Jana Polgar
Monash University, Australia

INTRODUCTION

Software measurement is considered to be an efficient means to monitor the quality of software projects, predict cost of maintenance, assess reusability of components, provide prediction of faults in similar projects, and contribute to improvement of the software development process. This chapter surveys software metrics literature with particular focus on object-oriented metrics, and metrics for measuring code complexity. Furthermore, we provide a critical view of software metrics and their usability.

BRIEF SURVEY OF OBJECT-ORIENTED METRICS

Since 1995, the trend toward incorporating *measurement theory* into all software metrics has led to identification of scales for measures, thus providing some perspective on dimensions. The most common scale types based on measurement theory are as follows:

- *Ordinal scale*: An ordered set of categories (often used for adjustment factors in cost models based on a fixed set of scale points)
- *Interval scale*: Numerical values, where the difference between each consecutive pair of numbers is an equivalent amount, but there is no "real" zero value
- *Ratio scale*: Elements are assigned numbers such that differences and ratios between the numbers reflect differences and ratios of the attribute
- *Nominal scale*: A set of categories into which an item is classified.
- *Absolute scale*: Elements are assigned numbers such that all properties of the numbers reflect analogous properties of the attribute

Fetchke (1995) and Zuse (1994) analyzed the properties of object-oriented software metrics on the basis of measurement theory. The underlying notion of measurement theory is based on intuitive or empirical existence of relationships among objects within our Universe of Discourse. These relationships can then be formally described in a mathematically derived formal relational system. They also investigated how and under what conditions the software measures may be viewed as ordinal, ratio, nominal, and interval. They admitted that these scale types present very little meaning with regard to maintainability and "error-proneness" of the application.

The contribution of Zuse and Fetchke's work is in the introduction of specific perspectives of measures. They emphasize preciseness of definition of scales as well as definition of an attribute that is measured.

The *axiomatic approach* was proposed by Weyuker (1988). This framework is based on a set of nine axioms, as listed in Table 1.

In Weyeker's metric proposal, we observe the formalization of structural inheritance complexity metrics. Property 9 means that splitting one class into two classes can reduce the complexity. The experience supports argument by Chidamber and Kemerer (1994) that the complexity of interaction may even increase when classes are divided.

Fenton and Pfleger (1997) used the term "software metrics" to describe the following artifacts:

- A number derived, usually empirically, from a process or code [for example, lines of code (LOC) or number of function points]
- A scale of measurement (The example used in Fenton's book is nominal scale or classification.)
- An identifiable attribute used to provide specific functionality (an example is "portability" or class coupling metric)
- Theoretical or data-driven model describing a dependent variable as a function of independent variables (an example can be the functional relationship between maintenance effort and program size)

These descriptions typically lead to widespread confusion between models and their ability to predict desired software characteristics, thus their suitability in being used for estimation purposes.

The metrics of Chidamber and Kemerer, summarized in Table 2, also have foundation in measurement theory. The authors do not base their investigation on the extensive structure. The criticism by Churcher and Sheppard (1994) points to the ambiguity of some metrics, particularly WMC. Hitz and Montazeri (1996) and Fetchke (1995) showed that CBO does not use a sound empirical relation

Table 1. Weyuker's axioms

Axiom	Name	Description
1	Noncoarseness	$(\exists P)(\exists Q)(\mu(P) \neq \mu(QQ))$
2	Granularity	Let c be non-negative number. Then there is finite number of class with the complexity = c
3	Nonuniquesniss	There is distinct number of classes P and Q such that $\mu(\mathrm{P}) = \mu(\mathrm{Q})$
4	Design detail matter	$(\exists P)(\exists Q)(P \equiv Q and \mu(P) \neq \mu(Q))$
5	Monotonicity	$(\forall P)(\forall Q)(\mu(P) \leq \mu(P+Q) and \mu(Q) \leq \mu(P+Q))$
6	Non-equivalence of interaction	a) $(\exists P)(\exists Q)(\exists R)\mu(P) = \mu(Q) and \mu(P+R) \neq \mu(Q+R)$ b) $(\exists P)(\exists Q)(\exists R)\mu(P) = \mu(Q) and \mu(R+P) \neq \mu(R+Q)$
7	Interaction among statements	Not considered among objects
8	No change on renaming	If P is renaming of Q then $\mu(P) = \mu(Q)$
9	Interaction CAN increase complexity	$(\exists P)(\exists Q)(\mu(P) + \mu(Q) < \mu(P+Q))$

Table 2. Chidamber and Kemerer metrics (Chidamber, 1994)

Weighted Methods per Class **(WMC)**	$WMC = \sum_{i=1}^{n} c_i$ where c_i is the static complexity of each of the n methods
Depth of Inheritance Tree **(DIT)**	With multiple inheritance the max DIT is the length from node to the root
Number of Children **(NOC)**	Number of immediate subclasses
Coupling Between Object Classes **(CBO)**	Number of other classes to which a particular class is coupled. CBO maps the concept of coupling for a class into a measure.
The Response for a Class **(RFC)**	The size of response set for a particular class.
The lack of Cohesion metric **(LCOM)**	$LCOM = \lvert P \rvert - \lvert Q \rvert if \lvert P \rvert > \lvert Q \rvert = 0 otherwise$

system, particularly, that it is not based on the extensive structures. Furthermore, LCOM metric allows representation of equivalent cases differently, thus introducing additional error.

Coupling measures form an important group of measures in the assessment of dynamic aspects of design quality. Coupling among objects is loosely defined as the measure of the strength of the connection from one object to another. The approaches of different authors mostly differ in definition of the measured attribute—coupling among classes. Table 3 provides a summary of differences in definitions. Some of the attributes may be known only too late in development.

Two aspects impact coupling between classes: the frequency of messaging between classes (cardinality and multiplicity of objects derived from these classes) and type of coupling. The discussion in Eder and Kappel (1994) distinguishes among three types: interaction coupling, component coupling, and inheritance coupling. The degree of coupling is based on defining a partial order on the set of coupling types. The low end is described by small and explicit interrelationships, and the high end of the scale is assigned to large, complex and implicit interrelationships. The definition is subjective and requires empirical assignment of values in order to be used as a software quality indicator.

Cohesion is defined as a degree to which elements in a class belong together. The desirable property of a good design is to produce a highly cohesive classes. Comparison of different frameworks and thorough discussion can be found in Briand's work (Briand, Daly, & Wurst, 1997). Eder (Eder & Kappel, 1994) provided a comprehensive

Table 3. Comparison of attribute definition for coupling.

Attribute definition	Eder et al (Eder., 1994)	Hitz & Montazeri (Hitz, 1995)	Briand et al. (1999)
Public attribute visibility	X		
Method references attribute		X	
Method invokes method	X	X	X
Aggregation	X		X
Class type as a parameter in method signature or return type	X		X
Method's local variable is a class type	X		
A method invoked from within another method signature or return type	X		
Inheritance	X		
Method receives pointer to method			X

Source: Briand, Daly, and Wurst (1999).

framework that requires semantic analysis of classes and methods. The metrics of Chidamber define LCOM as the number of disjoint sets created by intersection of the n sets. The definition in Eq. 1 does not state how the inheritance of methods and attributes is treated with regard to method override and overload and the depth of the inheritance tree.

$$LCOM = \begin{Bmatrix} |P| - |Q|, if\ |P| > |Q| \\ 0, otherwise \end{Bmatrix} \qquad (1)$$

In Henderson-Sellers (1996), the cohesion measure is based on the number of attributes referenced by a method:

$$LCOM = \frac{\frac{1}{a}\sum_{j=1}^{a}\mu\left(A_j\right) - m}{1 - m} \qquad (2)$$

where a means number of attributes, m denotes methods, and $m(A_j)$ denotes the measure that yields 0 if each method in the class references all attributes, and 1 if each method in a class references only single attributes.

Complexity Measures

The modularized code encapsulating object interactions is characterized by class hierarchies. One of the problems in software development is that some kinds of behavior or functionality *crosscut* or are *orthogonal* to classes in many object-oriented components, and they are not easily modularized to a separate class. Examples of such behavior include the following: synchronization and concurrency, performance optimization, exception handling and event monitoring, coordination and interaction protocols, and object views. These changes in code lead to chaotic development, additional subclassing, and restructuring of the class hierarchies. They typically result in increased complexity of the code and disorder.

Cyclomatic complexity is the most widely used member of a class of static software metrics. Cyclomatic complexity as a broad measure of soundness and confidence for a program was introduced by Thomas McCabe in 1976. It measures the number of linearly independent paths through a program module. This measure provides a single ordinal number that can be compared to the complexity of other programs. Cyclomatic complexity is often referred to simply as program complexity, or as McCabe's complexity (McCabe, 1994).

Entropy-based complexity measures are based on the theory of information. The approach taken by Davis and LeBlanc (1988), who quantified the differences between *anded* and *neted* structures, is an unbiased estimate of the probability of occurrence of event m. This measurement is based on chunks of FORTRAN and COBOL code.

In 1976, Belady and Lehman elaborated on the law of increasing entropy: the entropy of a system (level of its unstructuredness) increases with time, unless specific work is executed to maintain or reduce it. An increase of entropy can result in severe complications when a project has to be modified and is generally an obstacle of maintenance.

The use of entropy as a measure of information content has been around since 1992, when it was introduced by Harrison (1992). Harrison's software complexity metric is based on empirical program entropy. A special symbol, reserved word, or a function call is considered as an operator (Zweben & Hasltead, 1979). (It is assumed that they have certain natural probability distributions.) The probability p_i of i^{th} most frequently occurring operator is defined as

$$p_i = {f_i}/{N_i} \tag{3}$$

where f_i is the number of occurrences of the i^{th} operator, and N_i is total number of nonunique operators in the program.

The entropy is defined as

$$H = -\sum_{i=1}^{Ni} p_i \log_2 p_i \tag{4}$$

Harrison's *Average Information Content Classification* (*AICC*) measure definition is shown in Eq. (5):

$$AICC = -\sum_{i=1}^{Ni} \frac{f_i}{N_i} \log_2 \frac{f_i}{N_i} \tag{5}$$

Harrison assessed the performance of these entropic metrics in two commercial applications written in C language with total number of lines of code over 130,000.

The work of Bansiya et al. (1999) introduced a similar complexity measure—*Class Definition Entropy* (*CDE*)—replacing the operators of Harrison with name strings used in a class. The assumption that all name strings represent approximately equal information is related to the possible error insertion by misusing the string. The metric has been validated on four large projects in C++, and results have been used to estimate the *Class Implementation Time Complexity* measure.

CRITICAL VIEW OF OBJECT-ORIENTED METRICS

Many metrics deal predominantly with static characteristics of code. Hitz and Montazeri (1995) clearly distinguished the difference between *static* and *dynamic class method invocation*: *number of methods invoked by a class compared to frequency of method invocation*. A metrics suite capable of capturing the dynamic behaviors of objects in regard to coupling and complexity was presented by Yacoub (Yacoub, Ammar, Hany, & Robinson, 1999). The dynamic behavior of an implementation is described by a set of scenarios. The *Export* and *Import Object Coupling* metrics are based on the percentage of message exchange between class instances (objects) to the total number of messages. The *Scenario Profiles* introduce the estimated probability of the scenario execution. The complexity metrics are aimed predominantly at assessment of stability of active objects as frequent sources of errors.

Obvious criticism of the Henderson-Sellers metrics include the typical interaction among objects, for example, treatment of inheritance, and in particular, the access to superclass attributes (private and protected) or method-to-method calls. Many metrics show dimensional inconsistencies, or their results are derived from correlative or regression analysis. As reported in Gursaran and Gurdev (2001), experienced object-oriented designers found memory management and run time errors to be more problematic and difficult to deal with.

Class size problems represent confusing effects with regard to the validity of object-oriented metrics. The confounding effect of class size has been reported by Khaled, Benlarbi, Nishith, and Shesh (2001), provoking some doubts with regard to the validity of the software metrics currently being used as early quality indicators. The relationship of high coupling factor to faults proneness seems to support the hypothesis that large class size may have a negative impact on quality and occurrence of faults.

Harrison's entropic metrics are intended to order programs according to their complexity. Because entropy provides only the ordinal position, thus restricting the way of usage, we cannot measure the "distance" between two programs.

SOME REMARKS ON OBJECT-ORIENTED METRICS

Object-oriented code is characterized by class hierarchies, which are shared structures. Often, some additional subclassing, modification to existing classes, the restructuring of the hierarchy, and changes in the visibility of attributes and sometimes even methods are made. Given these changes and possibly a lack of comprehensive documentation and time constraints, we assume that class hierarchies will become the subject of disorder and exhibit entropic tendencies in the actual code as well as in content. In some mobile agent applications, we observed that the probability that a subclass will not consistently extend the content of its superclass is increasing with the depth of hierarchy.

The entropy metrics are useful in ranking different modules and symbols with regard to their complexity. The single-valued measure of complexity is appealing as a quality indicator. However, as also discussed in Fenton's book (1997), the results may not be suitable for use in prediction models or as guidance for improving the quality of the product.

Finally, we need to establish a framework for measuring product quality by associating each metric or a set of metrics with a qualifier, such as maintainability, reusability, etc. Furthermore, for each metric, a range of threshold and "desirable" values must be established depending on application objectives and framework focus.

KEY TERMS

Axiom: This is a generally accepted proposition or principle, sanctioned by experience; a universally established principle or law that is not necessarily true.

Cohesion: This is the degree to which elements within a class are related to one another and work together to provide well-bounded behavior.

Complexity: This is the degree to which a system or component has a design or implementation that is difficult to understand and verify. The first and still classic measure of complexity is that introduced by Kolmogorov, which is the shortest computer program capable of generating a given string.

Coupling: Coupling between classes is a measure of strength of association established by the communication link between two objects.

Cyclomatic Complexity: This is a broad measure of soundness and confidence for a program. This measure was introduced by Thomas McCabe in 1976.

Information Theory: In this method, probability and ergodic theory are employed to study the statistical characteristics of data and communication systems and coding theory, which uses mainly algebraic and geometric tools to contrive efficient codes for various situations. Introduced by Claude Shannon in 1948, it was a revolutionary new probabilistic way of thinking about communication and the first truly mathematical theory of entropy.

Measurement: When measuring some attribute of a set of elements, we can go through the process of assigning numbers or other symbols to the elements in such a way that relationships of the numbers or symbols reflect relationships of the attribute being measured.

Measurement Theory: This is a branch of applied mathematics that is useful in measurement and data analysis. The fundamental idea of measurement theory is that measurements are not the same as the attribute being measured.

Object-Oriented Software Reuse in Business Systems

Daniel Brandon
Christian Brothers University, USA

INTRODUCTION

"Reuse [software] engineering is a process where a technology asset is designed and developed following architectural principles, and with the intent of being reused in the future" (Bean, 1999). "If programming has a Holy Grail, wide-spread code reuse is it with a silver bullet. While IT has made and continues to make laudable progress in our reuse, we never seem to make great strides in this area" (Grinzo, 1998). "The quest for that Holy Grail has taken many developers over many years down unproductive paths" (Bowen, 1997). This article is an overview of software reuse methods, particularly object oriented, that have been found effective in business systems over the years.

BACKGROUND

Traditional software development is characterized by many disturbing but well documented facts, including:

- Most software development projects "fail" (60%) (Williamson, 1999).
- The supply of qualified IT professionals is much less than the demand (*www.bls.gov*, 2003).
- The complexity of software is constantly increasing.
- IT needs "better," "cheaper," "faster" software development methods.

Over the years, IT theorists and practitioners have come up with a number of business and technical methods to address these problems and improve the software development process and results thereof. Most notable in this sequence of techniques are: CASE (Computer Aided Software Engineering), JAD (Joint Application Development), Prototyping, 4GL (Fourth Generation languages), and Pair/Xtreme programming. While these methods have often provided some gains, none have provided the improvements necessary to become that "silver bullet". CASE methods have allowed development organizations to build the wrong system even faster; "wrong" in the sense that requirements are not met and/or the resulting system is neither maintainable nor adaptable. JAD methods tend to waste more of everyone's time in meetings. While prototypes can help better define user requirements, the tendency (or expectation) that the prototype can be easily extended into the real system is very problematic. The use of 4GL languages only speeds up the development of the parts of the system that were easy to make anyway, while unable to address the more difficult and time consuming portions. Pair programming has some merits, but stifles creativity and uses more time and money.

The only true "solution" has been effective software reuse. Reuse of existing proven components can result in the faster development of software with higher quality. Improved quality results from both the use of previous "tried and true" components and the fact that standards (technical and business) can be built into the reusable components (Brandon, 2000). There are several types of reusable components that can address both the design and implementation process. These come in different levels of "granularity," and in both object oriented and non-object oriented flavors.

"Software reuse received much attention in the 1980s but did not catch on in a big way until the advent of object oriented languages and tools" (Anthes, 2003). In Charles Darwin's theory of species survival, it was the most adaptable species that would survive (not the smartest, strongest, or fastest). In today's fast moving business and technical world, software must be adaptable to survive and be of continuing benefit. Object oriented software offers a very high degree of adaptability. "Object technology promises a way to deliver cost-effective, high quality and flexible systems on time to the customer" (McClure, 1996). "IS shops that institute component-based software development reduce failure, embrace efficiency and augment the bottom line" (Williamson, 1999). "The bottom line is this: while it takes time for reuse to settle into an organization – and for an organization to settle on reuse – you can add increasing value throughout the process" (Barrett, 1999). We say "object technology," not just adopting an object oriented language (such as C++ or Java), since one can still build poor, non-object oriented, and non-reusable software even using a fully object oriented language.

TYPES AND APPLICATIONS OF REUSE

Radding defines several different types of reusable components (Radding, 1998), which form a type of "granularity scale":

- GUI widgets - effective, but only provide modest payback
- Server-Side components - provide significant payback but require extensive up-front design and an architectural foundation.
- Infrastructure components - generic services for transactions, messaging, and database … require extensive design and complex programming
- High-level patterns - identify components with high reuse potential
- Packaged applications - only guaranteed reuse, … may not offer the exact functionality required

An even lower level of granularity is often defined to include simple text files, which may be used in a number of code locations such as "read-me" and documentation files, "help" files, Web content, business rules, XML Schemas, test cases, and so forth. Among the most important recent developments of object oriented technologies is the emergence of design patterns and frameworks, which are intended to address the reuse of software design and architectures (Xiaoping, 2003). The reuse of "patterns" can have a higher level of effectiveness over just source code reuse. Current pattern level reuse includes such entities as a J2EE Session Façade or the .Net Model-View-Controller pattern.

Reusing code also has several key implementation areas: application evolution, multiple implementations, standards, and new applications. The reuse of code from prior applications in new applications has received the most attention. However, just as important is the reuse of code (and the technology embedded therein) within the same application.

Application Evolution

Applications must evolve even before they are completely developed, since the environment under which they operate (business, regulatory, social, political, etc.) changes during the time the software is designed and implemented. This is the traditional "requirements creep". Then after the application is successfully deployed, there is a constant need for change.

Multiple Implementations

Another key need for reusability within the same application is for multiple implementations. The most common need for multiple implementations involves customizations, internationalization, and multiple platform support. Organizations whose software must be utilized globally may have a need to present an interface to customers in the native language and socially acceptable look and feel ("localization"). The multiple platform dimension of reuse today involves an architectural choice in languages and delivery platforms.

Corporate Software Development Standards

Corporate software development standards concern both maintaining standards in all parts of an application and maintaining standards across all applications. "For a computer system to have lasting value it must exist compatibly with users and other systems in an ever-changing Information Technology (IT) world" (Brandon, 2000). As stated by Weinschenk and Yeo, "Interface designers, project managers, developers, and business units need a common set of look-and-feel guidelines to design and develop by" (Weinschenk, 1995). In the area of user interface standards alone, Appendix A of Weinschenk's book presents a list these standards; there are over 300 items (Weinschenk, 1997). Many companies today still rely on some type of printed "Standards Manuals".

EFFECTIVE SOFTWARE REUSE

Only about 15% of any information system serves a truly original purpose; the other 85% could be theoretically reused in future information systems. However, reuse rates over 40% are rare (Schach, 2004). "Programmers have been swapping code for as long as software has existed" (Anthes, 2003). Formal implementation of reuse in various forms of software reuse has been a part of IT technology since the early refinements to 3GL's (Third Generation Languages). COBOL had the "copy book" concept where common code could be kept in a separate file and used in multiple programs. Almost all modern 3GLs have this same capability, even today's Web based languages like HTML and JavaScript on the client side, and PHP (on the server side). HTML has "server side includes," JavaScript has ".js" and ".css" files, and PHP has "require" files (".inc"). Often used in conjunction with these "include" files is the procedure capability where some code is compartmentalized to perform a particular task and where code can be sent arguments and possibly also return arguments. In different 3GLs this might be called "subroutines," or in modern languages, "functions". A function "library" is a separate file of one or more functions, and depending on the language may be pre-compiled.

Object oriented methods are concerned with the design and construction of modules of code that can exhibit certain characteristics. The key characteristics are encapsulation, composition, inheritance (generalization and specialization), and polymorphism. The code modules are typically called "object types" at the design level and "classes" at the implementation level. These classes contain both form (data) and functionality (functions). Encapsulation involves public "access functions" media access to the private data of a class to preserve both data security and integrity. A class can be "composed" of other classes, and this provides one form of code reuse. A class can also be derived from another class (a more general class), and this provides another form of reuse; derived classes (more specific classes) inherit the form and functionality of their base class and can add additional form or functionality and also modify functionality; this is the polymorphism aspect.

As an example of object oriented application, consider a large GUI application that may have hundreds of windows. Suppose the corporate design is to have each window show the company name on the top left and the date/time on the top right. Later a new boss decides he wants the company name on the top right and the date/time on the top left. If the application had been written in a non-object oriented language, then we would have to go back and modify hundreds of windows. If instead we had used an environment that supported inheritance (such as C++, Java, or PHP) and had derived all our windows from a base window class, then we would only have to change the one base class. If we used only an "include file" from which to get the company name, that would allow us to easily change the company name, but not to change the place where the name appeared in the window (unless we had clairvoyantly foreseen such a possibility, and designed a name location parameter in our file).

In most organizations, software reusability is still a goal that is very elusive; as said by Bahrami, "a most difficult promise to deliver on" (Bahrami, 1999). Radding stated: "Code reuse seems to make sense, but many companies find there is so much work involved, it's not worth the effort. …In reality, large-scale software reuse is still more the exception than the rule" (Radding, 1998). Bean in "Reuse 101" states that the current decreased "hype" surrounding code reuse is likely due to three basic problems (Bean, 1999):

- Reuse is an easily misunderstood concept.
- Identifying what can be reused is a confusing process.
- Implementing reuse is seldom simple or easy to understand.

Grinzo also lists several reasons and observations on the problem of reuse (Grinzo, 1998), other than for some "difficult to implement but easy to plug-in cases" such as GUI widgets: a "nightmare of limitations and bizarre incompatibilities," performance problems, "thorny psychological issues" involving programmers' personalities, market components that are buggy and difficult to use, fear of entrapment, component size, absurd licensing restrictions, or lack of source code availability.

Schach lists and describe the impediments to reuse as:

- Too many IS professionals would rather rewrite than reuse.
- Many IS professionals are skeptical on the safety and quality of using components built for other applications.
- Reuse artifacts are not stored and cataloged in a useful manner.
- Reuse can be expensive (building a reuse process, maintaining the reuse library, and verifying the fitness of the artifact for the new application).

Some organizations try to promote software reusability by simply publishing specifications on class libraries that have been built for other in-house applications or that are available via third parties, some dictate some type of reuse, and other organizations give away some type of "bonus" for reusing the class libraries of others (Bahrami, 1999). But more often than not, these approaches typically do not result in much success.

"It's becoming clear to some who work in this field that large-scale reuse of code represents a major undertaking" (Radding, 1998). " An OO/reuse discipline entails more than creating and using class libraries. It requires *formalizing* the practice of reuse" (McClure, 1996).

There are generally two key components to formalizing an effective software reuse practice both within an application development and for new applications (Brandon, 2002). These components are:

1. Defining a specific information technology architecture within which applications would be developed and reuse would apply.
2. Defining a very specific object oriented "reuse foundation" that would be implemented within the chosen IT architecture

Once the technical issues of an architecture and a reuse foundation are addressed, then management issues need to resolved, namely: "procedures, disciplines, and tools for tracking, managing, searching, and distributing software assets" (Anthes, 2003). Procedures and disciplines have to be formulated and enforced as part of the software development management and organizational "culture". Software can be built or procured to handle the searching, tracking, cataloging, and distribution issues.

FUTURE TRENDS

Several future trends will be key to the continuing success of software reuse. The first trend is for companies to adopt the necessary management principles that foster reuse, including programming incentives. Programmers must be rewarded for reusing software, and also for producing software that can be reused.

Another trend is for software to be developed that facilitates "library" functions for reusable components. Vendors and products in this area today include: CMEE (Component Manager Enterprise Edition) from Flashline (http://www.ejbean.com 2004), Logidex byLogicLibrary, and Component Manager by Select Business Solutions (*www.selectbs.com,* 2004). International standards like UML (Unified Modeling Language) and RAS (Reusable Asset Specification) (www.rational.com, 2001) will make these tools more interoperable. As well as "library" type tools, other technologies and tools will facilitate reuse that is based on standards such as "Web services" and other messaging technologies that will let software be reused "where it sits".

Still another trend is for companies to devote programming resources specifically to developing reusable component, while other programmers use the components built by this devoted group.

CONCLUSION

"If you want reuse to succeed, you need to invest in the architecture first" (Radding, 1998). "Without an architecture, organizations will not be able to build or even to buy consistently reusable components". In terms of general IT architectures for business systems, there are historically several types, such as: central computer, file services, two or three tier client server, and two or three tier Internet (browser) based. Various transaction processing and database vendors have their own "slants" on these basic approaches, which may depend upon how business logic and the database are distributed.

Today companies are mainly interested in the last of these categories. Internet based applications are becoming the preferred way of delivering software based services within an organization (intranets), to the worldwide customer base via browsers and "net appliances" (Internet), and between businesses (extranets). Vendor independent and "open" architectures are often preferred, and the "multiple platform" dimension of reusability is handled by using server generated HTML and JavaScript (via Java or PHP programs on the server).

As has been concluded by several authors, "A reuse effort demands a solid conceptual foundation" (Barrett, 1999). One such foundation was presented in Brandon (2002). It is based on the key object oriented principles of inheritance and composition. By establishing this foundation, an organization can effectively begin to obtain significant reusability since programmers must inherit their class from one of the established classes and they must only compose their class of the established pre-built components.

KEY TERMS

Class: A program construct representing a type of thing (abstract data type) that includes a definition of both form (information or data) and functionality (methods).

Composition: A new class in an objected programming language that is composed of other classes.

Encapsulation: The ability to insulate data in a class so that both data security and integrity is improved.

Framework: A software foundation that specifies how a software system is to be built. It includes standards at all levels, both internal construction and external appearance and behavior.

Function: A programming construct where code that does a particular task is segregated from the main body of a program; the function may be sent arguments and may return arguments to the body of the program.

Implementation: The code placed inside of methods. For some languages this code is pre- compiled or interpreted.

Include: Some code stored separately from the main body of a program, so that this code can be used in many programs (or multiple places in the same program).

Inheritance: A feature of object oriented languages that allows a new class to be derived from another class (a more general class); derived classes (more specific classes) inherit the form and functionality of their base class.

Interface: The specification for a method ("what" a method does); how that function is called from another program. Interfaces are provided in source form as opposed to implementations, which are secure. This allows one to use a method without regard for "how" that method is coded. It also allows multiple implementations of the same interface.

Libraries: A group of functions and/or classes stored separately from the main body of the main program; an "include" file consisting of functions and/or classes.

Method: A function defined inside of a class.

Packages: Similar to a library, but just containing classes.

Patterns: A software library for a common business scenario. A framework may be a design framework (possibly expressed in UML [Unified Modeling Language]) or an implementation framework (possibly in C++, Java, or PHP).

Polymorphism: The ability of object oriented programs to have multiple implementations of the same method name in different classes in an inheritance tree. Derived classes can override the functionality defined in their base class.

Reuse: Reuse (software) is a process where a technology asset (such as a function or class) is designed and developed following specific standards, and with the intent of being used again.

Separation: The separation of what a method does (interface) from how the method does it (implementation).

O

Observations on Implementing Specializations within an IT Program

Erick D. Slazinski
Purdue University, USA

INTRODUCTION

With a projected 2.26 million additional jobs to fill in various computer fields by the year 2010, there are and will continue to be ample job opportunities in the computer industry. However, the computer field is far too broad for one individual to be an expert in the entire field. Therefore it may be more useful for students to have the opportunity to concentrate their studies in a specific interest area within a broader Information Technology (IT) degree.

IT educators throughout the United States (US) have paid attention to the needs and demands of the IT industry. To address the need for IT graduates with specialized skills, many of the leading universities have created programs which allow undergraduate students to specialize or focus their studies.

This chapter will discuss findings on the state of IT programs with regards to their course offerings. One area of specialization, or track, is presented as an example. It will be noted that even within a specialty area, there can be further specializations. In addition to supporting the students pursuing the specialty area, general knowledge courses must also be offered to those pursuing other specialty areas.

BACKGROUND

The Bureau of Labor Statistics reported 2.9 million computer-related jobs in 2000, with an expected 4.89 million computer jobs by the year 2010. Considering new jobs as well as replacements, over 2.26 million additional people will be needed to fill these jobs (Hecker, 2001). The fluid nature of the IT industry makes generalizations difficult. Therefore, skills are often categorized or grouped together into skill sets (or job descriptions). The most common clustering of skills has been summarized in Table 1.

Of these pathways (or specialization tracks), two of the top occupations (as predicted by the US Dept of Labor) are systems analysis and database administrators (which have been grouped in the EDC Information Support and Service Pathway). See Table 2 for a listing of the top growth occupations.

WHERE ARE THE SPECIALIZED IT PROGRAMS?

Published curriculum from the institutes who attended the Conference for IT Curriculum (CITC) II held in April of 2002 were used as the sample set. The conference attendees were primarily IT educators from around the US, who had an interest in IT curriculum issues. An IT curriculum is focused on the application of technologies to solve problems. To differentiate, a traditional Computer Science curriculum is focused on algorithm design.

Table 3 illustrates, that out of the 28 programs studied, 50% (14) had some specialization available for students. Of the 14 programs that offered specializations, 45% (6) of those offered at least a database specialization similar to our sample track.

NEED FOR A DATABASE TRACK

The same data from the Bureau of Labor Statistics (Hecker, 2001) indicates there were 106,000 jobs for database

Table 1. Summary of educational pathways

Table 2. Percentage change in employment, projected 1998-2008

Occupation	Percent change
Computer engineers	108
Computer support specialists	102
Systems analysts	94
Database administrators	77

From U.S. Dept. of Labor

administrators (DBAs) in 2000, with a projected 176,000 openings to fill by the year 2010. In addition to DBAs, there are also database professionals who specialize in database architecture and database programming.

ANATOMY OF A DATABASE TRACK

Though there are various job titles given to database activities in the workplace, such as these listed on the ITWORKS-OHIO website: Data Analyst, Database Administrator, Database Analyst, Database Developer, and Database Specialist—many others exist in the marketplace. However, based on the author's opinion, when the job descriptions are examined, one can find that there are really three, inter-related roles. Figure 1 illustrates these roles using the structure of a house as an example. The DBA (as the foundation) keeps a database available, secure, and healthy. Without the DBA, the rest of the database team could not function. The database developer (as the framing of the house) encodes the business logic in the database. Additionally the database devel-

University of Cincinnati-Clermont	NO	
USCS	NO	

oper often develops the interface layer between the system software and the database engine. Lastly, the database architect (as the roof of the house) is often a senior staff member. Typical duties include determining the amount of business logic to be encoded in the database, developing the database design (including distribution of data, data flows, etc.) and often overseeing the implementation of the database. Like the components of a house, all three roles are co-dependant and necessary. In addition to the specific duties, each member must maintain several lines of communication within the development team and organization.

The database administrator must often work with the system/network administrators when it comes to the purchasing of hardware, determining network traffic and bandwidth requirements, coordinating the use of backup devices, etc. They often work with the database architects in providing recommendations for physical implementation issues. For the database developer, they must interact with the database architect (they are implanting the design from the architect) as well as the system developers and ensure that the developers have access to the data they need while maintaining the integrity of the database. The database architect must work with the software architect. Together they determine how to partition the business logic of the system. The database architect works with the DBA in determining the best physical implementation of the supporting database. And lastly the architect often coordinates the activities of the database developers.

Based on these responsibilities and communication channels, the database track was designed to produce students prepared for these multi-faceted jobs. During the first two years of our program, all students gain a broad overview of the Information Technology field, taking introductory courses in programming, Internet technologies, architectures, telecommunications, database, and systems analysis and design

- **Introduction to Application Development:** Introduction to system development using MS Access.
- **Introduction to Computer Programming:** Application development using Visual Basic.
- **Internet Foundations and Technologies:** Web page development using XHTML.
- **Information Technology Architectures:** Explores the history, architecture, and development of the Internet and the World Wide Web.
- **Systems Software and Networking:** Introduction to data communications and Network Operating systems.
- **Programming for the Internet:** Internet application development using scripting languages.
- **Database Fundamentals:** Normalization, SQL, and application interfaces to databases.
- **Systems Analysis and Design Methods:** Introduction to information systems development.

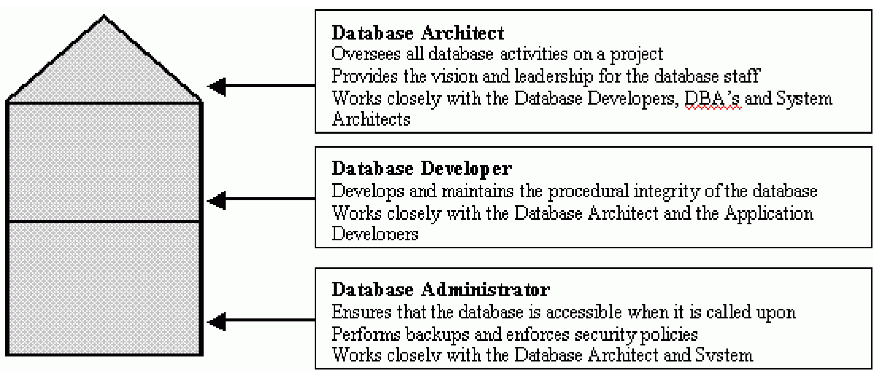
COURSES IN THE DATABASE TRACK

Students specializing in the database area must complete an additional 25 credit hours of technical courses focused on getting the database student prepared for one of the three roles described above. The progression of the courses is shown in Figure 2. Then it will be shown how these courses, in combination with other technical electives, prepare our students for future jobs.

A brief description of these database courses follows.

- **Introduction to Application Development (all students):** Introduces the development of information systems through the use of a database. Topics include business information systems, system and application development, database management

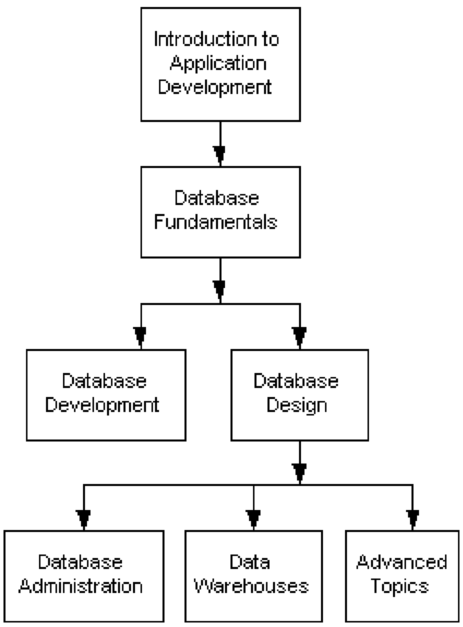
Figure 1. Database roles



systems, problem solving, logic, data types, and programming using database technology. Given a database design and application requirements, students design, construct, and test a personal computer information system.

- **Database Fundamentals (all students):** Looks at relational database concepts, including data design, modeling and normalization. Students use SQL to query, define, populate, and test a database. Expands on previous courses by accessing databases from programs and the Web, and discusses practical issues that database developers must handle.
- **Database Development:** Explores some of the programmatic extensions to SQL supported by leading Relational Database Management Systems (RDBMS) vendors. Topics include stored procedure and trigger design and implementation, query optimization to enhance performance, and data transformation to enhance interoperability of data.
- **Database Design and Implementation:** Deals with advanced design techniques and physical issues relating to enterprise-wide databases. Topics include advanced normalization, data distribution, distributed database design and replication, storage estimation and allocation, usage analysis, partitioning of very large tables, metadata analysis, data conversion, and load techniques.
- **Database Administration (elective):** Explores tools and techniques for managing an organization's database technology. Topics include database architecture, database technology installation, database creation and maintenance, RDBMS operations and troubleshooting, and database performance tuning.
- **Data Warehousing (elective):** Studies the design and implementation of data warehouses (including data marts and operational data stores) using current database technologies. Topics include data modeling for warehouses, data warehousing infrastructure and tool selection, data exploration, data synthesis and reduction, organizational metadata, and data warehouse administration.
- **Advanced Topics in Database Technology (elective):** Explores contemporary issues in the database arena. These issues may be related to new or breakthrough concepts, technologies, or techniques.

Figure 2. Database courses



Rounding Out the Students

Since database development has a significant analysis and design component, students are required to take a Systems Requirements Discovery and Modeling course, offered by our systems analysis group. Likewise many database personnel are often relegated to a distinct group with a project that has management requirements, so a Project Management course is also required. To support the further specialization into the database architect, database programmer and database administrator roles, two separate selective areas - database management selectives and database technology selectives - were defined. The students must choose a minimum of six credit hours (two courses) in each of the selective areas. The database management selectives are the elective courses listed with the database course flow in Figure 2 (above) – database administration, data warehousing and advanced topics in database management, as well as any graduate level database course offered during the student's senior year. The database technology selectives provide additional areas of exploration on topics that piqued the students' interest in their first two years. Again they are allowed to choose any two courses from the following:

- **Object-Oriented Programming:** use object-oriented programming languages (Java) in the development of modern, business applications.
- **Advanced Design Techniques:** advanced study of system design methods and techniques used by systems analysts to develop information systems.
- **Software Development Methodologies:** methodologies and practices commonly used in contemporary software development projects.

- **Enterprise Application Development:** component development and reuse, distributed object technologies, multi-tier applications.
- **Senior Software Development Project:** integrates the software development technologies and techniques taught in prior courses.
- **E-Commerce:** components of e-commerce.
- **Automatic identification and data capture:** real-time data feeds.
- Any other database management selective course(s) not already taken.

MODEL CURRICULA

At the time this chapter was written, there are at least three curricula models available from which to build from: the IEEE/ACM Computing Curricula; the EDC Academic Foundations and Pathways (EDC, 2002) and the ACM SIG ITE Curriculum Proposal. These models share more similarities than differences and selecting a model may be more a matter of preference of one set of authors over another. Considering the most mature model, the author has chosen to compare the specified database track against the IEEE / ACM Computing Curricula 2001.

The most recent IEEE / ACM Computing Curricula report, available at the ACM Web site, identifies Information Management (IM) as a knowledge area within their Computing Curricula 2001. The IM area of knowledge includes 14 components. Three are considered core, and 11 are viewed as electives. The courses in our database track provide significant coverage of the IM areas identified. Additionally, a Database Administration course that is beyond the model is offered. Table 4 shows the mapping from the IM components to our DB-track courses.

FUTURE TRENDS

For our University, the new curriculum implementing the track concept started in Fall 2001. In Spring 2003 the first cohort of Freshmen (who entered the program with the tracks in place) were required to select their track of interest. However, as news of the program's availability became known, students under the old plan of study transferred to the new plan of study. Additionally, transfer students were admitted under the new plan of study. These students plus an enthusiastic faculty caused the transition to the new course models to occur immediately after the new program (with tracks) was ratified by the University curriculum committee instead of waiting until the Spring 2003 semester.

This caused several registration issues which our counselors had to handle: multiple plans of studies; multiple course equivalencies (as courses were being brought online and retired); and pre-requisite issues. Of these the issue of tracking pre-requisites has been the most challenging because certain courses exist in multiple curriculums whose content has changed every time the curriculum has changed. Often counselors would have to

Table 4. Comparison of model curricula to database track courses

IM Knowledge Areas	DB Track
IM1: Information Models and Systems (core)	In 1st year course
IM2: Database Systems (core)	In 1st year course
IM3: Data Modeling (core)	2nd year: Database Fundamentals 3rd year: Database Design
IM4: Relational Databases (elective)	2nd year: Database Fundamentals 3rd year: Database Design
IM5: Database Query Languages (elective)	2nd year: Database Fundamentals (not OO queries)
IM6: Relational Databases Design (elective)	2nd year: Database Fundamentals 3rd year: Database Design
IM7: Transaction Processing (elective)	2nd year: Database Fundamentals 3rd year: Database Development
IM8: Distributed Databases (elective)	3rd year: Database Design 4th year Data Warehousing
IM9: Physical Database Design (elective)	3rd year: Database Design
IM10: Data Mining (elective)	4th year Data Warehousing
IM11: Information Storage and Retrieval (elective)	4th year Data Warehousing (partial)
IM12: Hypertext and Hypermedia (elective)	Candidate for 4th year Adv Topics
IM13 Multimedia Information and Systems (elective)	Candidate for 4th year Adv Topics
IM14: Digital Libraries (elective)	Candidate for 4th year Adv Topics

have professors validate that a student had the appropriate pre-requisite knowledge. This often led to questions such as "who taught this pre-requisite course?" or "did you cover this topic?"

CONCLUSION

Since the IT field is too broad to be comprised of only generalists, the IT workforce is becoming increasingly specialized. In response to this, IT educators have started offering areas of specialization or tracks that meet industry's needs. However, designing and implementing a tracked curriculum is a demanding task. The implementation costs may be higher than first estimated. If students are to get through a curriculum with multiple tracks in a reasonable time frame, the number of courses that need to be offered every semester can increase. This increase will require more resources could put a drain on other departmental offerings (such as service/graduate courses).

KEY TERMS

DBA: The title database administrator (DBA) represents an IT professional who ensures the database is accessible when it is called upon, performs maintenance activities, and enforces security policies.

IT Discipline: The ***intellectual gap*** in our educational frameworks for students who are interested in computing careers but find computer science too narrow, mathematical, and physical-science oriented, while MIS is insufficiently deep in technical content and too focused on traditional business topics and culture (Finkelstein, 2002).

Knowledge Area: Represents a particular sub-discipline that is generally recognized as a significant part of the body of knowledge that an undergraduate should know (IEEE, 2001).

Relational Database Management System (RDBMS): A suite of programs which typically manages large structured sets of persistent data, offering ad hoc query facilities to many users, which is based on the relational model developed by E.F. Codd (FOLDOC).

Selective List: A set of courses, grouped together for the purpose of filling an educational skill gap.

Systems Analysis: The design, specification, feasibility, cost, and implementation of a computer system for business (FOLDOC).

Systems Design: The approach used to specify how to create a computer system for business (FOLDOC).

Track: A series of courses designed around a topical area which is structured in a manner to efficiently develop a student's skill set.

Obstacles to SMEs for E-Adoption in the Asia Pacific Region

Sushil K. Sharma
Ball State University, USA

Nilmini Wickramasinghe
Cleveland State University, USA

INTRODUCTION

The e-commerce revolution has affected all organizations. Of particular interest is its effect on small and medium-sized enterprises (SMEs), because we can observe an interesting duality, where these companies are most likely to benefit from the opportunities afforded by e-commerce (because through e-commerce, it is possible to level the playing field), and yet they appear to be slowest in embracing many of these e-commerce possibilities. On several social and economic grounds, SMEs are of overwhelming importance in most of the Asia Pacific/Pacific region. In fact, they comprise well over 90% of all enterprises in this region and provide employment for over half of the region's workforce (Wattanapruttipaisan, 2002; APEC, 2001). Typically, the SME sector accounts for upwards of 90% of all firms outside the agricultural sector of East and Southeast Asia, and of Japan as well (Alphonso, 2001; Regnier, 2000; Tambunan, 2000; Wattanapruttipaisan, 2002; A Report Prepared for Asia Pacific Foundation, 2002).

Given the importance of SMEs to this region, it becomes crucial to understand the obstacles they are facing. First, we must understand why e-commerce adoption has been slow, if it occurs at all, for these SMEs, and then suggest changes to policy that may enable the alleviation of such obstacles, and hence, the successful embracing of e-commerce for these SMEs. What follows is a brief synopsis that serves to outline the key factors hindering SMEs' participation in e-commerce and the obstacles to SMEs for e-adoption in the Asia Pacific region.

BACKGROUND

Electronic commerce (e-commerce) succinctly stated refers to any transaction completed over a computer-mediated network that involves the transfer of ownership or rights to use goods or services (Tambunan, 2000); i.e., e-commerce can be defined as the conduct of buying, selling, and financially transacting by electronic means. E-commerce has been around for many years, particularly in the form of electronic data interchange (EDI). However, it is the Internet that is bringing it to the fore (Afuah & Tucci, 2000). The key aspect of e-commerce today is doing business over the Internet. E-commerce levels the playing field and lets small organizations compete with large organizations. The concept of e-commerce is about using the Internet to do business better and faster as well as shrinking traditional barriers of distance and time (Afuah & Tucci, 2000). Despite the downturn in the Internet economy represented by the crash of many dot-com companies, several forecasts continue to predict huge potential in global e-commerce over the next several years (Turpin et al., 1998). With an estimated 188 million users at year-end 2002, the Asia Pacific/Pacific region constitutes the world's second largest Internet market, ahead of North America (eMarketer Inc., 2002). South Korea, China, India, Singapore, Malaysia, and Indonesia are leading in ICT proliferation and e-commerce offerings as compared to other countries (Hill, 1998). ICT use is related to general economic indicators, such as gross domestic product (GDP), yet it is also affected by a wide range of other factors, including government policies, telecommunications costs, and social aspects (Beal, 2001; A Study Report on Thailand, 2001). Despite a sluggish economy in the Asia Pacific region, consumer demand for devices such as computers, mobile phones, and personal digital assistants (PDAs) has remained consistent throughout the region, and Internet usage is rising[1,2] (Debroy, 2002; UNCTAD, 2002; PricewaterhouseCoopers, 1999), yet the adoption of e-commerce by SMEs has been notably slow.

As the usage of the Internet is growing, the e-commerce and e-business initiatives in Asia Pacific are growing at a very fast rate. eMarketer projects that business-to-business (B2B) e-commerce revenues will grow to exceed $300 billion in the Asia Pacific/Pacific region by 2004 (eMarketer, 2002, www.emarketer.com). Despite such a high growth of e-commerce in Asia Pacific/Pacific and other Asia Pacific countries, the percentage of revenues generated through business-to-consumer (B2C) e-commerce transactions are still very low as compared to developed countries (Beal, 2001).

SMEs and E-Commerce

The adoption of e-commerce technologies is important for the ongoing survival of SMEs. The most significant business benefits for SMEs from the use of e-commerce are described below (Arunachalam, 1995; Sengenberger et al., 1990, Sharma et al., 2003, Afuah & Tucci, 2000):

- Better service quality—E-commerce can improve the quality of the marketing, sales, support, and procurement processes of SMEs by delivering more accurate, timelier, and more complete information to the point of sale, point of decision, or point of support. Service can also be delivered over a broader geographic and temporal base worldwide or anytime, anywhere.
- Reduced service costs—The self-service Internet-based e-commerce model is characterized by relatively low variable transaction costs, with increasing cost-effectiveness as the scale of activity increases. At higher volumes of activity, Internet commerce channels for sales and support services are likely to be low-cost channels.
- Increased revenue—Extended geographic sales channels and improved service quality may lead directly to increased market share, improved competition among brands, and greater revenue.
- Reduced time to complete a business transaction—By communicating electronically, the time required to place and confirm an order can be compressed by hours or, in some cases, days or weeks. This shortens the lead time for product delivery. As a result, it may be possible to reduce parts or finished goods inventories or receive critical products more rapidly to gain a competitive advantage.
- Reduced administrative costs—The cost of processing purchase requisitions, purchase orders, and payments can be dramatically reduced, as can invoice and bill presentation costs. The accuracy of business transactions is improved, increasing customer satisfaction; reducing transaction, auditing, and administrative expenses; as well as reducing the costs of expedited manufacturing and shipping costs to correct erroneous or late orders.
- Improved return on capital—By shortening the "product turn" and payment cycles, enterprises can reduce the amount of material requirements and the time for which funds must be committed to pay for the production of inventory, materially lowering capital requirements.
- Increased return on investment through better planning—More timely planning and information allows for more efficient acquisition and scheduling of capital equipment, reducing unit costs, increasing the return on investment, and ensuring a better match between manufacturing capacity, production, and market demand.
- Increased time devoted—SMEs now can devote more time to their products and their customers and lose less time in unproductive administrative jobs, such as time savings associated with electronic purchasing and materials management.
- Enhanced marketing—SMEs can enhance their local and international marketing efficiency through electronic catalogues and advertising through the Internet.
- Enhanced innovation capacity—SMEs can dramatically enhance their innovation capacity through technology watch, reverse and concurrent engineering, rapid prototyping, and distance manufacturing.
- Increased bidding opportunity—SMEs can bid on larger and international projects through networking with other partners worldwide and even with competitors.

OBSTACLES OR BARRIERS TO THE ADOPTION OF E-COMMERCE

The potential opportunities and benefits of e-commerce for SMEs include strengthening customer relationships, reaching new markets, optimizing business processes, reducing costs, improving business knowledge, attracting investment, and creating new products and services (APEC, 1999). Specifically, e-commerce represents an opportunity for SMEs to compensate for their traditional weaknesses in areas such as gaining access to new markets and gathering and diffusing information on a broad and international scale. Despite this, the following are the various obstacles that are experienced by Asia Pacific SMEs for their e-adoption that we have found through our research.

Lack of Awareness among SMEs about E-Commerce

This first and basic obstacle for adoption of e-commerce usage among SMEs in Asia Pacific is lack of awareness of e-commerce and the availability and access to the telecom infrastructure at a reasonable cost. This finding was confirmed by the APEC Report (2002). Many SMEs are found to be not aware of the developments taking place and the role they could play in this new marketplace. At times, the persons involved in SMEs found e-commerce literature too technical and complicated. Unless governments or other agencies simplify technical information for them, SMEs find it difficult to get involved in e-commerce concepts and implementation. Many Asia Pacific countries also found the English language a barrier, because the people involved conduct their business using local languages. The lack of awareness is closely linked to the fact that SMEs in Asia Pacific are usually slower in adopting new technologies given the often high investments necessary. Many of the Asia Pacific SMEs are also found to take less risks and to not experiment (APEC, 1999; Hall, 2002).

Lack of Critical Mass of Customers, Suppliers, and Business Partners

Another obstacle we found that was experienced by Asia Pacific SMEs is the lack of a critical mass among customers, suppliers, and business partners. The lack of a critical mass of these stakeholders is due to either ignorance or fears of a lack of security and privacy using electronic means. The e-commerce infrastructure is poor in Asia Pacific countries, and online shopping is not yet popular among the masses. Due to low use of e-commerce, there is not a large enough mass of customers and suppliers for e-commerce. This acts as a discouraging factor for SMEs to jump into the e-commerce revolution. There are not many marketplaces that could attract SMEs to take advantage (APEC, 1999). Until sufficient numbers of their main local customers or suppliers participate in online commerce activities, there is little incentive for individual SMEs to become engaged in e-commerce. In Asia Pacific countries, SMEs cited several factors contributing to low levels of customer e-commerce use, including language barriers and low levels of English fluency, lack of comfort and familiarity with e-commerce technologies, a cultural preference for more traditional trade practices involving face-to-face contact between buyer and seller, and continued preference for the use of cash in transactions. SMEs fear doing business with international marketplaces due to differing cultural backgrounds and a fear of being deceived due to lack of knowledge of new technologies.

Trust and Confidence

Lack of trust and confidence in various aspects of the electronic marketplace was identified as another main obstacle to the growth of the e-commerce market in general, and for SME engagement in e-commerce in particular. The security issue is perceived as very important across the Asia Pacific region, and the majority of SMEs have a fear of electronics. Security may not be a serious problem, but due to the low levels of technology diffusion and awareness among SMEs, it is still a psychological barrier for SMEs, as confirmed in various reports (APEC, 1999; A Report Prepared for Asia Pacific Foundation, 2002; DRPAD, **1999;** Beal, 2000; Turpin, 2000; APCTT, 2000, 2001)**.** Many of these SMEs do not have technical backgrounds and are not convinced that the technology standards, such as encryption, will protect them. Due to such perceived security fears, SMEs are not willing to use electronic payment systems. Credit cards and e-checks are naturally, then, a distant dream for many of them. Security, legal, and liability issues were frequently identified as important concerns of participating SMEs in Asia Pacific. Asia Pacific SMEs do not trust e-commerce or the technical infrastructure to support it. Trust and confidence in a sound legal framework and security standards are necessary to make e-commerce happen on a larger scale (APEC, 1999; Hall, 2002).

Confidence in Legal and Regulatory Framework

The lack of a comprehensive and acceptable legal and regulatory framework is an issue for Asia Pacific SMEs. Most of the responses indicated that SMEs want government interventions for developing an appropriate legal framework for protecting them against any frauds or disputes. Many of these Asia Pacific countries still do not have laws for electronic contracts, invoices, and other types of documentation in place. E-commerce demands several legal and liability issues to be addressed before it is widely accepted by SMEs and others in the Asia Pacific. Conducting business through electronic networks raises numerous legal questions that include the legal status and enforceability of electronic contracts, the legal jurisdiction of international e-commerce transactions, intellectual property rights and copyright protection for digital content, privacy of personal data, and validity of electronic "evidence" in legal disputes (APEC, 1999; Wade, 1990). All of these concerns about legal and liability issues are important to participating SMEs. Most of the Asia Pacific countries still do not have legal and regulatory infrastructure in place and have not addressed these issues. Unless these issues are addressed, Asia Pacific SMEs may not choose e-commerce as a medium for their businesses.

Taxation

Asia Pacific SMEs are concerned about taxation issues. Taxation processes in these countries are not transparent and are often subject to the discretion of evaluators. There are many malpractices in avoiding taxes, and SMEs do not want to have other countries' tax laws, which they anticipate could be more stringent and tough. SMEs also lack the guidance of lawyers, because many of them cannot afford the high fees necessary for sound legal advice on these matters. The application of existing taxation on commerce conducted over the Internet should be consistent with the established principles of international taxation, should be neutral with respect to other forms of commerce, should avoid inconsistent national tax jurisdictions and double taxation, and should be simple to administer and easy to understand (Hall, 1995, 2000).

Lack of Knowledge of E-Commerce

Asia Pacific SMEs lack extensive knowledge of e-commerce technologies, and that is one of the big obstacles for their participation and engagement in e-commerce. Due to lack of knowledge of e-commerce technologies, there is an internal resistance to change, and skepticism of the benefits of e-commerce among SMEs. E-commerce demands fundamental shifts in business strategies, operations, and technologies. Many participating SMEs indicated that they have limited access to information about the business models and technologies that form the basis of e-commerce success. Lack of knowledgeable staff in SMEs is also responsible for nonadoption of e-commerce. An issue often cited by participating Asia Pacific SMEs was the general lack of success stories available to demonstrate that e-commerce can be successfully implemented by firms that are similar in some way to their own. Asia Pacific SMEs do not have many success stories that could motivate other SMEs to adopt e-commerce.

Information Infrastructure Access, Quality, and Cost

Despite the cost reduction of Internet-based technology, implementing e-commerce solutions still represents a considerable and costly challenge for most SMEs in the Asia Pacific region. Large corporations with more funding, more attainable skills, and strengths in building solid business strategies could afford e-commerce deployment. But most SMEs, typically with less cash, and a shortage of information technology (IT) staff and necessary infrastructure, are not able to afford e-commerce. Insufficient access to an appropriate information infrastructure of suitable quality, and at reasonable cost, is a fundamental barrier to SME adoption and use of e-commerce in Asia Pacific (Hall, 1995). The information infrastructure required for e-commerce involves reliable telecommunications links and Internet services being available to SMEs. The level of information infrastructure to support e-commerce applications differs among the Asia Pacific countries from very poor to moderate. E-commerce applications greatly cut enterprise procurement costs and bolster the efficiency of business operations. However, low-level computerization and inferior e-commerce infrastructure reduced Internet contributions to the majority of Asia Pacific SMEs. Our research shows that although 70% of SMEs have connected with the Internet, most simply opened a home page and an e-mail address.

Payment and Delivery Systems

Although Asia Pacific's Internet players are rushing to promote e-commerce as a creative business mode for the new economy, few can break through the last-mile barriers against online purchasing. These barriers have been attributed to lack of a standard credit system and an effective express network, two critical elements for the operation of online shopping and business transaction. Credit card and off-line payment, or a combination of the two, are by far the most used means of payment. Only few SMEs (those that are technology developers) support electronic cash, electronic checks, and micropayments. Asia Pacific SMEs do not have appropriate supporting payment and distribution systems in place for the adoption of e-commerce. The majority of customers and suppliers do not use credit cards for payment in Asia Pacific countries. Therefore, the development of electronic payment systems, including the use of credit cards, is limited. A relatively low credit card penetration among consumers acts as a domestic constraint to B2C e-commerce development. In many cases, it the "mindset" that inhibits the adoption of online credit card payment. The credit card culture is not there in the society, and hence, credit card companies and consumers shy away from using credit cards for transactions. The financial network of banks and other institutions do not have their databases integrated and available online (APEC, 1999; A Report Prepared for Asia Pacific Foundation, 2002; DRPAD, **1999;** A Study Report on Thailand, 2001; Beal, 2000; Turpin, 2000; APCTT, 2000, 2001)**.**

CONCLUSION

This synopsis serves to highlight that SMEs face many obstacles with respect to e-adoption. Furthermore, we note that governments have an important role to play in encouraging SMEs to embrace e-commerce in Asia Pacific countries. SMEs in Asia Pacific countries need to be made more competitive by promoting the development and use of e-commerce. In particular, governments must address four key areas so that high e-business potential will ensue for these SMEs; namely, they must address the areas of business infrastructure, regulatory or commerce infrastructure, user infrastructure, and telecommunications infrastructure. It is only through the systematic efforts of government and policy makers to encourage e-commerce adoption by SMEs and at the same time ensure that the appropriate safeguards and controls are in place, that SMEs in the Asia Pacific region will begin to embrace e-commerce. E-commerce is critical to the long-term success and sustainability of SMEs in this region. It is imperative that the full e-business potential that e-commerce affords can be utilized and maximized.

KEY TERMS

Dot-Com: A company with operations that are entirely or primarily Internet based or, more specifically, a company with a business model that would not be possible if the Internet did not exist. Dot-coms often deliver all their services over an Internet interface, but products might be delivered through traditional channels as well. Dot-coms are often divided into two categories: those that provide products and services for consumers (B2C) and those that provide products and services to other businesses (B2B).

E-Commerce: The conduct of buying and selling products and services by businesses and consumers over the Internet. "E" simply means anything done electronically, usually via the Internet. E-commerce is the means of selling goods on the Internet, using Web pages.

SMEs: As per European Commission definition, small and medium-sized enterprises, referred as "SMEs," are defined as enterprises that have fewer than 250 employees, and have either an annual turnover not exceeding 40 million EURO, or an annual balance sheet total not exceeding 27 million EURO, as shown below.

	Medium-sized	**Small**	**Micro-enterprise**
Maximum number of employees	250	50	10
Maximum turnover (in million ECU)	40	7	—
Maximum balance sheet total (in million ECU)	27	5	—

Offshore Software Development Outsourcing

Stephen Hawk
University of Wisconsin - Parkside, USA

Kate Kaiser
Marquette University, USA

OFFSHORE SOFTWARE DEVELOPMENT OUTSOURCING EVOLUTION

Until the global economic downturn of the new millennium, demand for information technology (IT) professionals exceeded supply mostly due to specific skill sets such as integrating legacy applications with Web development, project management, telecommunications, mobile commerce, and enterprise resource planning. More firms are turning externally not only to local vendors but also to services across the globe (Carmel, 1999). Staff supplementation from domestic contractors has evolved to a sophisticated model of partnering with offshore/ nearshore software development firms. Many of these relationships evolved from a short-term project need for select skills to a long-term commitment of resources, cultural diversity efforts, and dependencies that integrate vendors as partners.

The most pervasive IT project, Year 2000 (Y2K), had constraints of skill sets, time, and budget. IT managers had to look at many alternatives for achieving compliance. Firms that planned as early as the mid-1990s had time to experiment and build new relationships. With governmental sanction and support, some countries and their business leaders recognized the competitive advantage their labor force could offer (O'Riain, 1997; Heeks, 1999; Trauth, 2000). An unusual need for services because of Y2K, economic disparity within a global workforce, and proactive efforts of some governments led to the fostering of offshore software development.

Early companies to outsource offshore were software vendors. Managing offshore development smoothly took years and a certain type of project management expertise in addition to a financial commitment from executives. The activity involved new applications and integrating software development with existing domestically built applications. The Y2K investment and intense cultural communication paid off for firms willing to work through the challenges. Not only did initial offshore projects provide a solution to the skill shortage, they also yielded substantial cost savings when compared to outsourcing the work domestically. Such factors resulted in these relationships continuing past Y2K, where some companies now regard their offshore arm as partners.

The IT outsourcing market was estimated at over US$100 billion by 2001 (Lacity and Willcocks, 2001). Although outsourced IT services can include call centers and facilities management, this discussion focuses on outsourcing software development. "Offshore" software development typically refers to engaging workers from another continent. Examples are U.S. companies using Indian contractors. "Nearshore" software development refers to vendor firms located in nearby countries often on the same continent, for example Dutch firms engaging Irish software developers. For our purposes, discussion of offshore software development issues is assumed to apply to nearshore outsourcing, since most of the issues are the same.

Most firms already have had experience supplementing their staff. Dealing with offshore firms, however, is relatively new for firms whose main business is not software development. Distance, time zones, language and cultural differences are some key issues that differentiate offshore software development from the use of domestic contractors or consultants (Carmel, 1999). Nearly 1 million IT-jobs will move offshore from the United States by 2017 (Gaudin, 2002).

The most common reasons for outsourcing are cost reduction, shortages of IT staff, reduced development time, quality of work, and internationalization (see Table 1).

APPROACHES TO OFFSHORE SOFTWARE DEVELOPMENT

The approaches taken to offshore development describe the basic features of how firms have structured their relationships with offshore software developers. The basic dimensions include the type of organization that provides offshore services, the nature of the working relationship that clients have with that organization, and whether offshore staff are on a defined project or in a staff augmentation role.

Table 1. Reasons for engaging in offshore software development

- Cost reduction - due primarily to lower wages and secondarily from tax incentives. Accounting for indirect costs, such as travel and teleconferencing, overall average savings may be close to 25% (Overby, 2001).
- Access to a global pool of talent - quicker staffing thereby enabling faster time to delivery.
- 24×7 Productivity – the global delivery model allows a "follow-the sun" approach for round-the-clock handing-off of work to developers in different time zones.
- Quality – rigorous requirements of certifications (CMM, ISO) or cultural dedication to detail and quality.
- Localization - adapting software to local requirements may be best handled by resources in or near the target location.

Type of Organization Providing Offshore Development

An important dimension for describing the relationship with foreign software developers would be the basic types of organizations with which client firms form an outsourcing arrangement. The basic options are to contract directly with an offshore IT services firm, to engage a domestic IT services firm with offshore capabilities, or to set up a wholly owned software development center in an offshore location.

- Direct contract with an offshore firm – The client firm contracts directly with the offshore software firm. This option represents a range of alternatives.

  • Long-distance contracting – the offshore firm maintains no permanent staff in the country of their clients. Clients and offshore firms use long distance communications technologies such as phone, e-mail, and short-term visits.
  • Limited presence – Offshore firms locate some staff in client countries by setting up satellite offices in one or more cities. Most of the work is performed offshore, but a local project manager and a small local team answers questions and function as liaisons to solve problems.
  • Integrated on-site – the export firm provides a mix of extensive onsite expertise to handle business and requirements analysis, system design, and project management, and coordinates with offshore staff, normally working closely with client management. As many as 70 firms from Ireland have set up subsidiaries in the U.S. with Irish government financial support (Cochran, 2001).

- Contract with a domestic IT services firm with offshore capabilities – Many domestically-based IT services firms have the ability to send work offshore. This may take the form of an IT firm that acts as an intermediary, or a firm that itself owns an offshore satellite location. Some domestic firms employ both approaches. An intermediary acts as a liaison with offshore software firms, and already has subcontracting or partnering arrangements with them. The IT services firm works with clients in much the same way as other domestic IT services firms, but differs in that it uses offshore resources for some of the software development. Intermediaries may negotiate a cut of the cost savings their clients achieve by going offshore. The advantage in giving up the full savings of dealing directly with outsourcers is that the intermediaries buffer clients from most aspects of dealing with offshore providers. For small to midsize companies new to outsourcing, brokers offer the big benefit of offshore projects—good work done more cheaply, but without cross-cultural, long–distance, vendor management headaches.

- Wholly owned Satellite – The firm operates in an offshore location to directly hire IT professionals to become its employees. This is model is almost exclusively used by companies that sell software or by companies whose products have a large software component.

Length of Relationship and Type of Project

The working relationship between clients and vendors can be described by whether the relationship is short or long term, and the type of work the vendor performs.

Relationships with an offshore IT services firms can range from a few months to many years. Short-term relationships may be a single-hit project with no plan for follow-up projects. Long-term relationships may become important business partnerships where an offshore firm is responsible for an ongoing stream of projects.

The nature of work given to offshore vendors can range from well-defined projects to relatively unstructured ones. Typical examples of well-defined projects are technical design, implementation, maintenance, or software conversion. In other cases, vendors may take on significant responsibility for project initiation, requirements determination, and project management involving new systems or major enhancements to existing systems that have strategic impact to the firm.

Carmel and Agarwal (2002) propose a four-stage model of offshore outsourcing that can be described in terms of time frame and nature of work. They describe firms moving from short-term structured engagements to longer-term structured engagements, and finally to long-term unstructured engagements as a maturation process. A company, however, may have outsourcing efforts that fall into different categories. For example an organization may engage offshore firms for both an ongoing stream of structured and unstructured projects, while at the same time evaluating other vendors, or outsourcing special needs projects on a one-time basis.

Defined Project vs. Staff Augmentation

The previous discussion of offshore development focused on contracting with the outsourcer for the delivery of a defined product. It's possible to tap some outsourcing firms as sources for augmenting staff. Companies contract outsourcing services on the basis of developer time instead of a fixed price software deliverable. Offshore staff may travel to the client's site and be managed closely by the client or may remain in the offshore location managed remotely. Offshore firms in this case have limited responsibility for managing projects.

SOFTWARE EXPORTING COUNTRIES

Table 2 lists dominant players by order of reported revenues, industry software organizations, and their Web sites. Many reports of exports are not standardized. It is not clear what is included in sales figures and who is reporting them. Even if these figures were comparable, the projection for evaluating different countries is not. Some countries are producing more software with fewer

Table 2. Information Technology Industry Organizations by Country (Enterprise Ireland promotes Irish exports, including software services.)

India	National Association of Software and Services Companies -NASSCom	www.nasscom.org
Philippines	Information Technology Association of the Philippines - ITAP	www.itaphil.org
Ireland	Enterprise Ireland*	www.enterprise-ireland.com

Canada	Information Technology Association of Canada	www.itac.ca
Mexico	AMITI - Mexican Association for the Information Technologies Industry	www.amiti.org.mx/

developers than others. The types of applications delivered may not compare. Converting a legacy customer database is not similar to customizing an enterprise system. More importantly, within a country there may be many development vendors and generalizations that are not applicable to each company.

CRITICAL ISSUES OF OFFSHORE SOFTWARE DEVELOPMENT

Challenges associated with offshore development are different than domestic development. In most cases the issues lead to creative solutions that some companies have tackled and incorporated to their advantage. Special circumstances of offshore development present factors that practitioners have found to be of special importance in achieving success.

Quality Certification

The Software Engineering Institute's Capability Maturity Model (CMM) (CM-SEI, 2002) or the International Organization for Standardization's ISO9001: 2001 standard (ISO, 2002) serves as an independent evaluation of the quality of a vendor's development processes. Certification should not be taken at face value. Investigation can clarify its meaning. When it was acquired? Was it qualified by project or by subsidiary? Who provided the evaluation? Was it self-assessed? There are a number of questions to raise.

Onsite Presence

Despite the ability to operate virtually, the tenuous nature of offshore development is optimized when face-to-face contact, handshaking, and social/professional relationships nurture the engagement. The limited presence and integrated on-site approaches address the distance resistance.

Managing Globally

The downside of being productive 24×7 is that some part of the team is often not available for real-time contact because they are not at work at the same time. Travel by someone is a necessity in almost all offshore arrangements. The nature of the relationship will dictate how many and how often, from where to where. Sometimes this may involve extended stays.

Trust and Confidence

Relationship management is the overriding success factor when minimal levels of other factors are in place. IT services firms accent their marketing on these traits. For offshore firms to be seen as important business partners and take on work beyond routine development work, clients need to have a high level of trust and confidence in the outsourcers' abilities and intentions.

Political Environment

The stability of the offshore country's government prevents some firms from exploring offshore outsourcing (Nicholson and Sahay, 2001). Israel's thriving development curtailed with the Palestinian war. The Pakistan-India border disputes caused the U. S. State Department to ban travel to India. Although firms contract with a software firm and not the country, political environment of the country can influence the feasibility of working with firms located there.

Intellectual property concerns are usually dissuaded due to protection by law. Most countries have laws that are comprehensive enough to deal with software as ownership. However, having laws in place does not mean that governments enforce them.

Cultural Awareness and Integration

Close working relationships between offshore vendors and clients from another culture may require significant time, not only for becoming aware of each others' cultures, but to integrate it in practice. Firms with close working relationships not only achieve integration in software methods and delivery but also achieve integration in social aspects of team building.

Nationalism

Organizations that hire offshore developers may have to justify why they are not hiring domestically when many people are unemployed. Issuing of U.S. H1-B visas raised concern as many Americans became unemployed. The IT community was sensitive to the impact of hiring foreigners with special skills. Although visas are no longer granted as they once were, many organizations have had to deal with the same issue that arises with offshore software development. Human rights and workers' ability to earn a living wage are not comparable to client countries' workers—but no published reports of abuse or exploitation surfaced. Offshore software development offers governments ways to gain power and enhance their standing in the world.

Capacity of the Workforce

The availability of human resources to deliver IT demand is debatable. There is mixed evidence about the ability to meet demand (Overby, 2001; Carmel and Agarwal, 2002). Determining capacity is tricky. One must not only review population numbers but the educational, telecommunications, and managerial infrastructure that allows growth.

Risk Management

The most obvious threat relates to the political environment. Because some firms perceive security breaches as more vulnerable using offshore developers, outsourcers probably take extra precaution to sell their services. Y2K and September 11th reinforced the need for business continuity planning.

Risk management can also affect selection of firms in part on the basis of location. Developing relationships with a geographically diverse portfolio of outsourcers could minimize the risk of regional political and economic disturbances.

FUTURE TRENDS

Increased Offshore Outsourcing of Higher-Level System Life Cycle Tasks

Greater experience in using offshore developers on the part of client firms coupled with the maturation of technologies and methodologies for global software delivery allow firms to outsource more high-level development and realize the benefits of outsourcing across a wider variety of IT work.

Emergence of Major Contenders to India

India has been by far the major destination for offshore software development outsourcing, with Israel and Ireland usually considered "major players." China, Philippines, and Russia are often noted as potential contenders. Outsourcing industries are emerging in a number of unexpected locations such as Viet Nam, Mexico, Ukraine, and Iran due to low entry costs.

Increasing Use of Offshore Workers by Domestic Software Firms

To remain competitive, domestic IT outsourcing firms increasingly use offshore developers either through wholly-owned development centers offshore, or by subcontracting or partnering with foreign outsourcing firms (Overby, 2001).

Increased Sensitivity to Outsourcing Domestic Jobs

Reduced employment in importing countries creates a potential for a backlash. Ensuing restrictive changes in visas for foreign workers could limit higher-level work outsourced offshore since it requires greater onsite presence.

Increased Use of Third-Party Offshore Software Development Suppliers

Rather than bear project management costs directly, more importers will engage third-part consultants to act as a buffer and minimize relationship costs

CONCLUSIONS

Offshore software development outsourcing potentially provides considerable benefits. Some businesses are in the early stages of offshore experimentation, while others have formed mature business partnerships with offshore software firms. Many businesses will outsource more IT work offshore in order to cut costs and reduce time to market in addition to the benefits of quality. An increasing share of the IT work being outsourced is found at higher levels. These forces, however, may be compensated by factors such as political agenda of domestic employment, a desire to avoid negative public relations, and visa limitations that increase the challenges for offshore firms to provide on-site staff.

KEY TERMS

Capability Maturity Model (CMM): A methodology used to evaluate an organization's software development process. The model describes a five-level evolutionary path of increasingly organized and systematically more mature processes.

Global Delivery Model: To distribute and manage software development across multiple global locations. GDM requires infrastructure, project management, cultural sensitivity, and process guidelines to support communication and coordination between locations.

Intellectual property rights: Laws and enforcement mechanisms to afford the creator of an intellectual property (e.g., software) the means of controlling how their work is used, and ensuring that the creator is properly rewarded and recognized for their work**.**

ISO 9001:2001: Provides standards used to assess an organization's ability to meet its customer's requirements and achieve customer satisfaction. Software firms use it as an alternative to CMM.

Localization: The process of adapting software to a particular language, culture, and desired local "look-and-feel". This may include local sensitivities, geographic examples, and adhering to local legal and business requirements.

Staff Augmentation: When an employee of an outsourcing firm is lent to a client company for work. Normally a staff augmentation employee works at the client's worksite with the technical direction coming from the client company.

On the Relativity of Ontological Domains and Their Specifications

E. Kapetanios
Semantic Technologies, Switzerland

INTRODUCTION

Business knowledge is considered the most valuable resource of organizations. The exchange of business knowledge within an organization as well as among different cooperating organizations is considered a major promotion of know-how and better coordination of various organization units, as well as an increase of the value of an organization itself.

In the era of "information overload" and an ever increasing "networked world," however, where the premium of business and IT is placed on communications and distributed computing and networks, semantics play a crucial role. To this extent, the usage of *semantic technology* should encourage not only *information globalism*, but also *information particularism*, in which:

- individuals or groups define, generate, and access information in ways that make sense to them,
- information is accessible across the business by integrating different and, very often, controversial points of view, and
- semantic heterogeneity is not treated as a "necessary evil," but also encouraged by the technology and solutions.

Meeting these challenges is considered a key issue in order to enable real knowledge exchange and cope with inherited diversities such as cultural differences, vaguely formulated or uncertain specifications, relativity of concept validity, and so forth. This goal becomes more crucial when, for example, advanced scientific (biology, physics, chemistry, etc.) or engineering application domains in large business settings and environments are concerned.

BACKGROUND

Knowledge models, or *ontologies*, are a necessary precondition to any semantic application (Bresciani & Fontana, 2002; Kapetanios, 2002; Kapetanios, Baer, & Groenewoud, 2003; Kapetanios, Baer, Groenewoud, Mueller, Novosad, 2004; Sugumaran & Storey, 2002). Ontologies have emerged over the last 10 years as a core technology and fundamental data model for knowledge systems.

They enable various advanced functions, for example, smart search (Andreasen, Motro, Christiansen, & Larsen, 2002), and are the foundation of the (emerging) semantic Web (Berners-Lee, Hendler, & Lassila, 2001; Davis, Fensel, D., Hendler A. J, Lieberman H., Wahlster W., & Harmelen, 2002; Fensel, Hendler, Lieberman, & Wahlster, 2002). Ontology-enabled semantic technologies show great promise for the next generation of more capable information technology solutions because they can solve some problems much more simply than before and make it possible to provide certain capabilities that have otherwise been very difficult to support.

The current state of the art, however, on representing and using ontologies has grown out of several efforts that started in the 1980s. Back then, KL-ONE was the most influential of the frame-based representation languages; it allowed for the representation of categories and instances, with inheritance of category properties, and a formal logic (Baader, Calvanese, McGuinness, Nardi, & Patel-Schneider, 2003) for expressing the meaning of properties and categories. At about the same time, rule-based systems were a promising technology. The NASA-sponsored C-Language Integrated Production System (CLIPS) became a de facto standard for building and deploying rule-based systems.

The Knowledge Interchange Format (KIF) and its accompanying translation tool Ontolingua were developed to allow knowledge to be shared among these different efforts, and provided the capability to translate knowledge bases in one representation language to another. These languages were ahead of their time. As a result, they have remained largely within academia, gaining little commercial support.

With the advent of the World Wide Web and the acceptance of XML (extended markup language) as a de facto standard for the representation of information on the Web, ontology efforts joined in. An early project at the University of Maryland produced SHOE (simple HTML [hypertext markup language] ontology extension), a system for expressing ontologies in XML and marking up Web pages with ontology-based annotations. Many of the ideas from this work made it into the World Wide Web Consortium (W3C; http://www.w3c.org) proposal for the Resource Description Framework (RDF) language (http:/

/www.w3c.org/RDF). Moreover, languages such as DAML (Defense Advanced Research Projects Agency - DARPA - or agent markup language), DAML+OIL (Ontology Inference Layer), and OWL (Web ontology language; http://www.w3c.org/2001/sw/WebOnt), which became a foundation for the W3C Web ontology language, are built on RDF.

However, the major assumption underlying all currently available ontology description formalisms and languages has been the "common view" of a conceptualization of an application domain (Berners-Lee et al., 2001; Davis et al., 2002; Fensel, Hendler, Lieberman, & Wahlster, 2002). This is also reflected in currently available ontology development tools, which are a key factor in adoption of semantic technology. Many tools are still offered as research prototypes, but many others have begun to be commercialized (they are often commercial versions of their direct research counterparts). Standard compliance and support for RDF and OWL is growing. Due to the different forms of RDF, ontology tools still do not interoperate well.

It turns out that the assumption of a common view is an unrealistic one given the ever increasing networked world, which results in a wide range of user perspectives and points of view of the same concepts within, for example, different organizational units or cultural and social environments. Information and knowledge exchange should pay tribute to these diversities in order to increase information quality and interpretability, as well as to strengthen collaboration among various user communities or organizational units and processes.

PRESENTING ONTOCONTEXT

The most outstanding difference between OntoContext and other ontology description languages and editors is twofold.

- The support of concept relativity in terms of diverse perspectives, viewpoints, natural languages, and so forth, which are reflected in both the ontology description language and the tool itself.
- Functioning as a collaborative platform and a database-driven approach reflecting concept relativity such that large-scale ontologies are enabled and shared by a wide range of end users.

Conceptulization According to Relativism

OntoContext addresses relativity and perspectiveness within an ontology in a twofold manner:

1) an ontology *external context*, such as bounding the representation of concepts to particular user environments such as natural language, roles of organization units, and so forth, and
2) an ontology *internal context*, enabling the expression of holding conditions or constraints under which concepts, business rules, and their definition, even in an agreed-upon ontology, become relevant.

Examples of an ontology internal context are given by

- the consideration of the validity of properties, value domains, or classification hierarchies under specific conditions,
- the definition of the membership of instances to classes according to the distinction between *necessary* and *sufficient* conditions,
- the definition of percentages for the membership of instances to classes,
- the definition of classes according to the distinction between prototypes and well-established properties, and
- the naming of concepts by using more than once the same name within the same ontology description name space (no unique name assumption).

As far as the database-driven availability and management of large-scale ontologies is concerned, this strengthens their practicability and usage in multiuser environments, and enables the implementation and coordination of authoring or editing facilities among various user communities, in addition to querying and sharing of business knowledge.

As far as the human-computer interaction facilities are concerned, they are addressed by a graphical user interface, which

- is free of knowledge-based formalisms and concepts,
- enables interaction with the business knowledge in more than one natural language,
- enables adaptation to particular user environments with respect to ontology external context, and
- enables the presentation of the ontology internal context issues, as stated above.

Tool Description and Architecture

The concept-relativity issues as described above are reflected in the OntoContext tool, which is an ontology development tool. However, the outstanding difference between OntoContext as an ontology development tool and other ones is

a) the human-computer interaction, and
b) the collaboration mechanism,

which both reflect the language properties of *conceptual relativism*. Therefore, the tool enables

1) specification and description of application domain semantics by novice users rather than knowledge engineers, that is, it is free of knowledge formalisms,
2) specification and description of application domain semantics by paying tribute to different perspectives and cultural differences, for example, natural languages,
3) querying and sharing of contextualized application domain semantics for better coordination and collaboration among organization units as well as among organization processes,
4) convergence of common aspects through sharing and exchange of organization and process knowledge, and
5) exporting or importing ontologies in languages such as RDF, OWL, and so forth, as proposed for the semantic Web.

These features are supported by the architectural issues of the tool, which rely on a *database-driven realization* for the needs of persistency, maintenance, and querying, as well as on the *inference services* underlying an intelligent human-computer interaction mechanism for the needs of guiding the end user for both querying and ontology specification.

Comparisons

Having said this, it is worth referring to other ontology development tools, as far as known to the author, in order to raise the major differences. The following table gives an overview of those ontology development tools with respect to some of the issues according to enabling collaboration and relativism, as described above.

As stated in Table 1, most of the currently available ontology development tools do not support collaboration. They are meant to be single-user tools and collaboration is only enabled through the exchange of ontology description files (no database for sharing of views and querying of ontologies).

It is also stated that none of these tools, even those collaborative ones, do support relativism as far as different natural languages, points of views, and user settings are concerned.

FUTURE TRENDS

Many of the issues for conceptualization according to relativism have been tried out in large- and small-scale projects in real-world applications. In particular, smart querying and semantic data collection forms, as well as concept-based search mechanisms, have been applied for a Second Opinion (Decision Support) System for querying medical guidelines, for collecting and querying multiple collections of databases as related to a Swiss national registry for clinical trials and studies for acute

Table 1. Overview of ontology development tools with respect to OntoContext's main features

Tool/Vendor	Collaboration	Natural Language	Points of View	User Bounded
Protègè 2000/Stanford USA	No/Single User	Only One	Only One	No
OilEd/U. of Manchester	No/Single User	Only One	Only One	No
OntoEdit/Ontoprise	No/Single User	Only One	Only One	No
LinkFactory Workbench/Language and Computing	Some support for collaboration	Only One	Only One	No
K-Infinity/Intelligent Views	Yes/Multiuser	Only One	Only One	No
Cerebra Construct/Network Inference	Yes/Multiuser	Only One	Only One	No

myocardial infarctions, and for querying of collected data from demining actions.

In all these application settings, external relativity has been practiced due to user-bounded validity of concepts from the underlying ontology and the application of the relevant constraints. Internal relativity has been practiced due to current states of concept descriptions such that the validity of interconnected concepts is related to that current state of concept description. This has been extensively practiced in semantic data collection forms.

For making concept descriptions, however, relative to conditions and constraints beyond those found in other ontology description languages such as OWL, which address slot or value constraints in terms of classes, a more generic constraints schema needs to be elaborated and addressed within an ontology description language. This copes with constraints as posed to class or instance definitions, adaptable value domains, and so forth.

Furthermore, in a collaborative setting for ontology specification and querying, constraints need to be addressed as first-class citizens, such that they remain consistent in large-scale ontology development. In addition, embedding of multiple viewpoints and different natural languages needs to be efficiently handled while reasoning.

CONCLUSION

The importance of increasing the value of an organization through intra- as well as interorganizational knowledge exchange and coordination of processes has been stressed many times in the past. The contribution and usage of IT, however, in such a process remained quite limited, despite the technological advantages and wide use of information technology.

Ontology-enabled semantic technologies promise to add value to business settings and environments. In particular, ontology development tools emerged recently, which put the emphasis on extrapolation of knowledge-based formalisms and provided some common view across all units or user communities. However, business settings in an ever increasing networked world with large-scale ontology development efforts forces thinking toward the accommodation of semantic heterogeneity and cultural diversity within ontologies rather than dealing with a single common view.

Sharing different perspectives and viewpoints, regardless of the user's natural language in collaborative business environments, will enable knowledge exchange and a better understanding of processes and data.

KEY TERMS

Concept-Based Search: Search over a corpus of documents or databases can proceed using a search that matches concepts rather than matching words. The value of concept-based search increases with the technical complexity of the domain of search.

Intelligent (Smart) Querying: Querying that is driven by some kind of inference engine or mechanism for refining, formulating, or completing query construction.

KL-ONE: A knowledge representation system in the late 1970s that inspired the development of a number of frame-based representation systems. These systems embraced the ideas of frames as structured descriptions, as well as the idea of differentiating between terminological and assertional aspects of knowledge representation and the central role of subsumption and classification inferences.

Knowledge Interchange Format (KIF): KIF is a language designed for use in the interchange of knowledge among disparate computer systems (created by different programmers, at different times, in different languages, and so forth). KIF is *not* intended as a primary language for interaction with human users (though it can be used for this purpose). The purpose of KIF is roughly analogous to that of Postscript. Postscript is commonly used by text and graphics formatting systems in communicating information about documents to printers.

Ontology: It is the name given to a structure of knowledge used as a means of knowledge sharing within a community. Aristotle's notion of Organon might be the earliest example of an ontology in this sense. An ontology, however, as software technology is a "data skeleton" that can be developed for a variety of data-based and knowledge-based systems. It consists of a collection of concepts and relationships between concepts. Generally, each concept is represented by a favored term (word or phrase).

Ontology Creation (Editor) Tool: A tool that enables ontology specification and creation through some collaborative authoring. It usually requires users to be trained in knowledge representation and predicate logic. They are supposed to offer a server-based environment with support for consistency checking of interconnected ontologies and a collaborative environment for model review and refinement.

OWL: It has been designed to meet the need for a Web ontology language. OWL is part of the growing stack of W3C recommendations related to the semantic Web. OWL adds more vocabulary for describing properties and classes: among others, relations between classes (e.g., disjointness), cardinality (e.g., "exactly one"), equality, richer typing of properties, characteristics of properties (e.g., symmetry), and enumerated classes.

RDF: The Resource Description Framework is a framework for representing information in the Web. The underlying structure of any expression in RDF is a collection of triples, each consisting of a subject, a predicate, and an object. A set of such triples is called an RDF graph. This can be illustrated by a node and directed-arc diagram, in which each triple is represented as a node-arc-node link (hence the term graph).

Semantic Technology: It is a software technology that allows the meaning of and associations between information to be known and processed at execution time. For a semantic technology to be truly at work within a system, there must be a knowledge model of some part of the world that is used by one or more applications at execution time.

Semantic Web: It provides a common framework that allows data to be shared and reused across application, enterprise, and community boundaries. It is a collaborative effort led by W3C with participation from a large number of researchers and industrial partners. It is based on the Resource Description Framework (RDF) and other Web ontology description languages (OWLs), which integrate a variety of applications using XML for syntax and Uniform Resource Identifiers (URIs) for naming.

SHOE: Simple HTML ontology extensions (SHOE) is a knowledge representation language that allows Web pages to be annotated with semantics.

O

One Method for Design of Narrowband Low-Pass Filters

Gordana Jovanovic-Dolecek

Javier Díaz-Carmona
National Institute of Astrophysics Optics and Electronics, INAOE and Technology Institute of Celaya (ITC), Celaya, Mexico

INTRODUCTION

Stearns and David (1996) states that "for many diverse applications, information is now most conveniently recorded, transmitted, and stored in digital form, and as a result, digital signal processing (DSP) has become an exceptionally important modern tool." Typical operation in DSP is digital filtering. Frequency selective digital filter is used to pass desired frequency components in a signal without distortion and to attenuate other frequency components (Smith, 2002; White, 2000). The pass-band is defined as the frequency range allowed to pass through the filter. The frequency band that lies within the filter stop-band is blocked by the filter and therefore eliminated from the output signal. The range of frequencies between the pass-band and the stop-band is called the transition band and for this region no filter specification is given.

Digital filters can be characterized either in terms of the frequency response or the impulse response (Diniz, da Silva, & Netto, 2000). Depending on its frequency characteristic, a digital filter is either low-pass, high-pass, band-pass or band-stop filters. A low-pass (LP) filter passes low frequency components to the output while eliminating high-frequency components. Conversely, the high-pass (HP) filter passes all high-frequency components and rejects all low-frequency components. The band-pass (BP) filter blocks both low- and high-frequency components while passing the intermediate range. The bands-stop (BS) filter eliminates the intermediate band of frequencies while passing both low- and high-frequency components.

In terms of their impulse responses, digital filters are either infinite impulse response (IIR) or finite impulse response (FIR) digital filters. Each of four types of filters (LP, HP, BP, and BS) can be designed as an FIR or an IIR filter (Grover & Deller, 1999; Ifeachor & Jervis, 2001; Oppenheim & Schafer, 1999).

The design of a digital filter is carried out in three steps (Ingle & Proakis, 1997):

- Define filter specification;
- Approximate given specification;
- Implement digital filter in hardware or software.

The topic of filter design is concerned with finding a magnitude response (or, equivalently, a gain) which meets the given specifications. These specifications are usually expressed in terms of the desired pass-band and stop-band edge frequencies w_p and w_s, the permitted deviations in the pass-band (pass-band ripple) R_p, and the desired minimum stop-band attenuation A_s, (Mitra, 2001). Here, we consider the specifications given in dB. In this case, the gain in decibels is

$$\text{Gain in dB} = 20\log_{10}\left|H(e^{j\omega})\right|. \tag{1}$$

Figure 1 illustrates a typical magnitude specification of a digital low-pass filter.

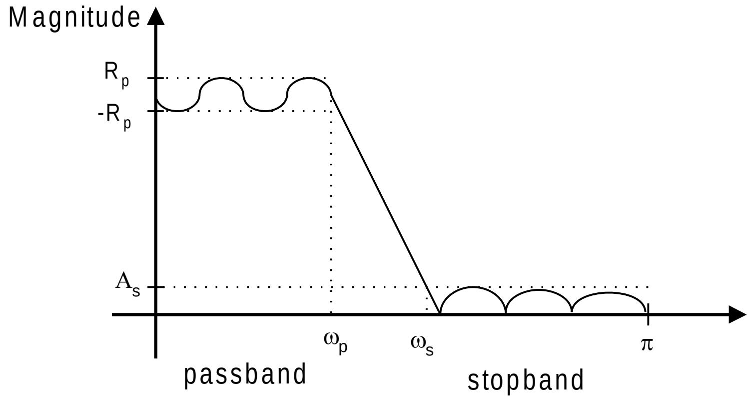
Due to their complexity, narrowband low-pass FIR filters are difficult and sometimes impossible to implement using conventional structures (Milic & Lutovac, 2002). The interpolated finite impulse response (IFIR) filter proposed by Neuvo, Cheng-Yu, and Mitra (1984) is one efficient realization for the design of narrowband FIR filters.

The IFIR filter $H(z)$ is a cascade of two filters,

$$H(z) = G(z^M)I(z), \tag{2}$$

where $G(z^M)$ is an expanded shaping or model filter, $I(z)$ is an interpolator or image suppressor, and M is the interpolator factor. In this manner, the narrowband FIR prototype filter $H(z)$ is designed using lower order filters, $G(z)$ and $I(z)$. For more details on the IFIR structure, see Neuvo, Cheng-Yu, and Mitra (1984) and Jovanovic-Dolecek (2003).

Figure 1. Low-pass filter magnitude specification



An increase in the interpolation factor results in the increase of the interpolation filter order as well as in the decrease of the shaping filter order.

The design goal in Jovanovic-Dolecek and Diaz-Carmona (2003) is to decrease the shaping filter order as much as possible, and to efficiently implement the high order interpolator filter. To do so, we propose to use a sharpening recursive running sum (RRS) as an interpolator in the IFIR structure.

BACKGROUND

Sharpening Technique

The sharpening technique, which was first proposed by Kaiser and Hamming (1984), attempts to improve both the pass-band and stop-band of a linear FIR filter by using multiple copies of the same filter based on the Amplitude Change Function (ACF). An ACF is a polynomial relationship of the form $H_0(w) = P[H(w)]$ between the amplitude responses of the overall and the prototype filters, $H_0(w)$ and $H(w)$, respectively. The improvement in the pass-band, near H=1, or in the stop-band, near H=0, depends on the order of the tangency of the ACF m and n at H=1 or H=0, respectively. The expression proposed by Kaiser and Hamming for an ACF giving the mth and nth order tangencies at H = 1 and H = 0, respectively, is given by

$$H_0 = H^{n+1} \sum_{k=0}^{m} \frac{(n+k)!}{n!\,k!}(1-H)^k$$
$$= H^{n+1} \sum_{k=0}^{m} C(n+k,k)(1-H)^k , \qquad (3)$$

where $C(n+k,k)$ is the binomial coefficient.

Hartnett and Boudreaux (1995) proposed an extension of this method by introducing the slope d of tangency at H=0 and the slope s of tangency at H=1. Samadi (2000) proposed an explicit formula for the filter sharpening polynomial.

We use the following ACF polynomials:

1) $P\left[H(\omega)\right] = 3H^2(\omega) - 2H^3(\omega); \delta = \sigma = 0; m = n = 1.$

2) $P\left[H(\omega)\right] = 6H^2(\omega) - 8H^3(\omega) + 3H^4(\omega); \delta = \sigma = 0; m = 2; n = 1.$

3) $P\left[H(\omega)\right] = 10H^2(\omega) - 20H^3(\omega)$
$+15H^4(\omega) - 4H^5(\omega); \delta = \sigma = 0; m = 3, n = 1.$

(4)

The plot of each one of these ACF is shown in Figure 2. Note that the third ACF has the best passband improvement and the smallest stopband attenuation, whereas, the first ACF has the worst pass-band improvement but the best stopband attenuation.

The three sharpening structures are presented in Figure 3, where the resulting number of multipliers per output sample (MPS) is equal to three, four and five for the first, second and third structure, respectively.

SHARPENING RRS FILTER

The simplest low-pass FIR filter is the moving-average (MA) filter. Its impulse response $g(n)$ is given by,

$$g(n) = \frac{1}{M} \sum_{k=0}^{M-1} g(n-k) . \qquad (5)$$

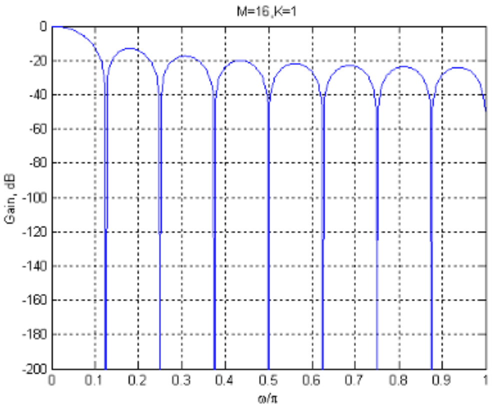
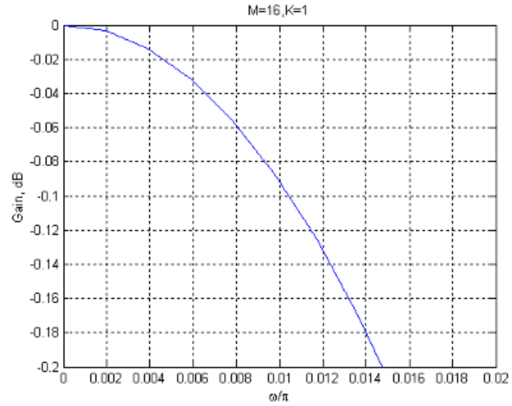
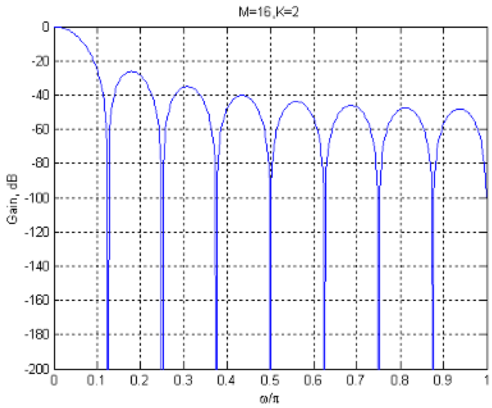
a. Overall magnitude response



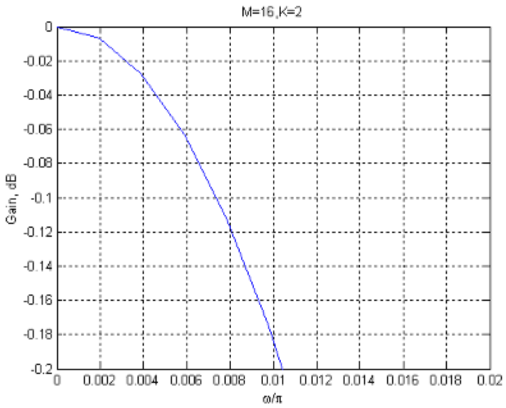
b. Pass-band zoom



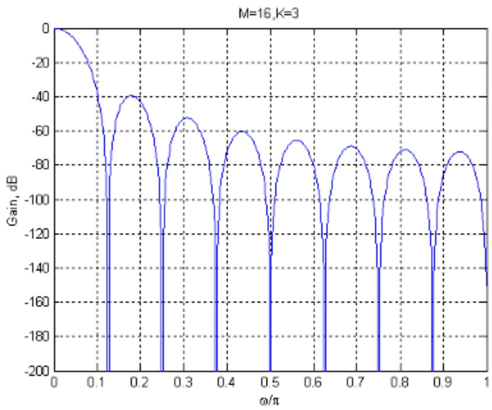
c. Overall magnitude response



d. Pass-band zoom



e. Overall magnitude response



f. Pass-band zoom

Since all impulse response coefficients are equal to 1, the filter requires no multiplications.

Its transfer function is given by

$$G(z) = \frac{1}{M}[1 + z^{-1} + ... + z^{-(M-1)}] = \frac{1}{M}\sum_{k=0}^{M-1} z^{-k} \quad . \ (6)$$

A more convenient form of the above transfer function for realization purposes is given by

$$H_{RRS}(z) = [G(z)]^K = \left[\frac{1}{M}\frac{1 - z^{-M}}{1 - z^{-1}}\right]^K, \qquad (7)$$

also known as a recursive running-sum filter (RRS) (Mitra, 2001). The scaling factor $1/M$ is needed to provide a dc gain of 0 dB, and K is the number of the cascaded sections of the filter. The magnitude response has nulls at integer multiples of $(2\pi / M)$ as shown in the following relation

$$\left|H_{RRS}(e^{j\omega})\right| = \left| \left[\frac{\sin(\omega M/2)}{M\sin(\omega/2)}\right]^K \right|. \qquad (8)$$

This characteristic provides natural alias-rejections introduced by expanding the shaping filter $G(z)$ by factor M. The stop-band attenuation is improved as a result of the increased number of stages K. Figure 4 illustrates the overall magnitude responses and the corresponding pass-band details of the RRS filter for M=16 and K=1, 2, and 3. We can notice that the characteristics have a high pass-band droop which limits the application of the RRS filters. In order to improve the characteristics we propose to use the sharpening polynomials (4). Figure 5 shows the improved magnitude responses for the RRS filter with M=16 and the cascade of 2 and 3 RRS filters using sharpening polynomials (4).

DESIGN PROCEDURE

This section describes the design of a narrowband lowpass filter using an IFIR structure, where the interpolator filter is the sharpening recursive running (RRS) filter. In order to suppress the mirror images of the expanded model filter, the RRS frequency nulls must be centered at each mirror image. This implies that the length of the RRS filter must be equal to the interpolator factor M.

The design procedure is outlined in the following steps:

1. Choose the interpolation factor M and design the model filter $G(z)$, using the specifications:

$$\omega_p^G = M\omega_p, \qquad \omega_s^G = M\omega_s,$$

$$R_p^G = \frac{R_p}{2}, \qquad A_s^G = A_s \quad , \qquad (9)$$

   where ω_p^G and ω_s^G are the pass-band and the stop-band edge frequencies, R_p^G is the maximum pass-band ripple and A_s^G is the minimum stop-band attenuation of the filter $G(z)$.
2. Design the K-stage RRS filter $I_{RRS}(z)$ of the length M.
3. Choose an ACF and apply the filter sharpening to the filter $I_{RRS}(z)$. The resulting filter is denoted as $I_{shRRS}(z)$.
4. Cascade the model filter $G(z^M)$ and the sharpening RRS filter $I_{shRRS}(z)$.
5. If the resulting stop-band filter specification A_s is not satisfied, go to Step 2 and increase the number of stages K.
6. If the pass-band filter deviation is higher than R_p go to Step 3 and change ACF.

The number of stages in the RRS filter K controls the resulting filter stop-band attenuation and the filter sharpening technique controls the filter pass-band width. The design algorithm is illustrated with following example.

Example:

A linear-phase narrowband lowpass FIR filter is designed to meet these specifications: normalized pass-band edge at w_p=0.01, normalized stop-band edge at w_s=0.015, maximum pass-band ripple R_p =0.086dB, and minimum stop-band attenuation A_s=-60 dB.

The linear-phase FIR filter designed by Parks McClellan method would have the order N=1017, which translates into 509 multiplications per output sample (MPS). Using M=18 in the IFIR structure, the orders of filters G(z) and I(z), both designed by Parks McClellan method, are 66 and 69 respectively, thereby requiring a total of 68 MPS.

By choosing the first ACF given in Equation (4), the interpolation factor M is 21, and the number of the stages of the RRS filter K is 2. The order of the model filter $G(z)$ is N_G= 57. The resulting structure is shown in Figure 4. The all-band magnitude response for the designed filter and the pass-band zoom are shown in Figure 5.

Figure 6. Resulting structure in example 1 using the first ACF

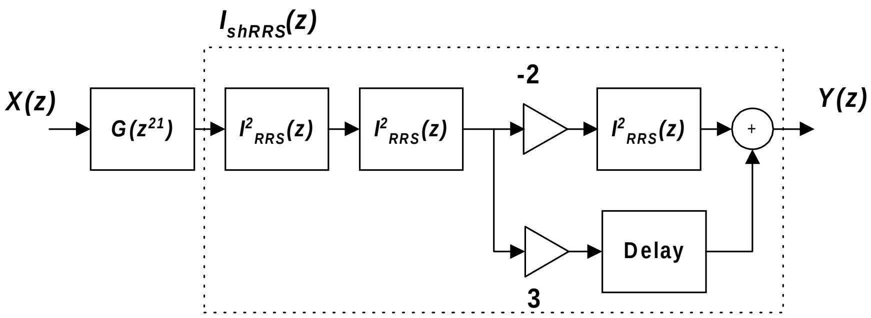

Figure 7. Magnitude response for example 1 and first ACF

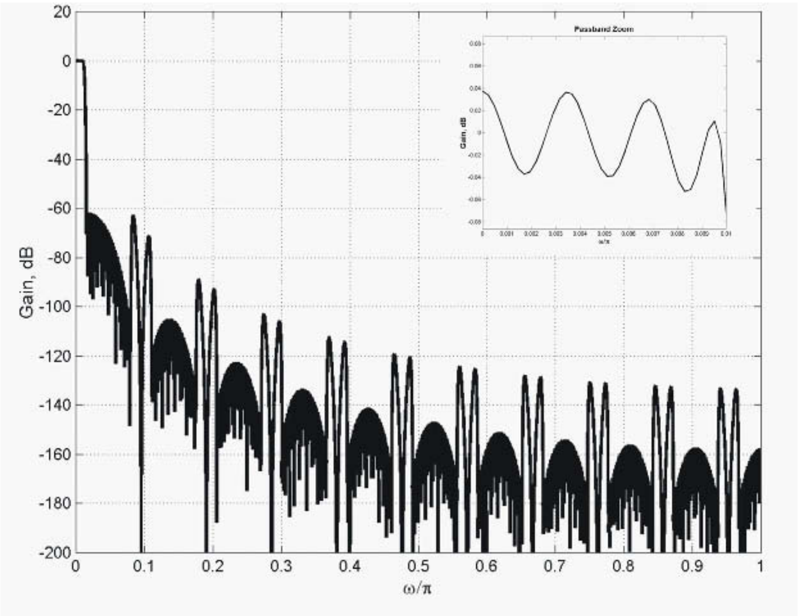

Table 1. Design parameters and number of MPS for example 1

ACF	M	N_G	L	MPS
1	21	57	2	31
2	31	40	3	24
3	37	34	4	22

If instead, the second ACF in Equation (4) is used as a sharpening filter polynomial, it would be possible to use even higher values for the interpolation factor M, such as M=31. In this case, the RRS filter has 3 stages, and the resulting order of the filter $G(z)$ is 40. A further order reduction of the filter $G(z)$ is obtained by using the third ACF in Equation (4). The interpolation factor M is then 37, and the number K of the stages of RRS filter is equal to 4. As a result, the model filter has order N_G= 34. The design parameters for all three cases and the resulting number of MPS are summarized in Table 1. Note that the number of MPS is decreased as a result of the increase in the complexity of the ACF.

FUTURE TRENDS

The use of IFIR filter design techniques is now a rather well-developed topic in the field of digital filters. Nonetheless, an analytical technique for obtaining a design employing the minimum number of filter-tap multipliers has not previously appeared and presents an important research task (Mehrnia & Willson, 2004). The future research also includes a multistage design and finding an optimal choice of the corresponding interpolation factors.

Another important issue that needs to be addressed is how to choose the sharpening polynomials (as a trade-off between the values of tangencies m and n and the number of cascaded basic RRS filters) that will yield an improved characteristic of the RRS filter and a decreased complexity of the overall design.

CONCLUSION

An overview of the design method for narrowband linear-phase FIR filter with sharp transition band is presented. The method reduces the complexity of an IFIR structure by using a high value of the interpolation factor which in turn makes the order of the model filter low.

Furthermore, the resulting high order interpolation filter is replaced by a recursive running sum (RRS) filter, which does not need any multiplications. The sharpening technique, based on the amplitude change function (ACF), improves the magnitude characteristic of the RRS filter.

Three amplitude change function (ACF) with the tangency orders $n = 1$, and $m = 1, 2, 3$, are used. As a result, the total number of multipliers per output sample is significantly decreased.

KEY TERMS

ACF: An ACF (Amplitude change function) is a polynomial relationship of the form $H_0(w) = P[H(w)]$ between the amplitude responses of the overall and the prototype filters, $H_0(w)$ and $H(w)$, respectively.

Digital Filter Design: The process of deriving the transfer function of the filter is called digital filter design. It is carried out in three steps: Definition of filter specification, Approximation of given specification, and Implementation of digital filter in hardware or software.

Expanded Filter: Expanded filter $G(z^M)$ is obtained by replacing each delay z^{-1} in the filter $G(z)$ with M delays z^M. In the time domain this is equivalent to inserting M-1 zeros between two consecutive samples of the impulse response of $G(z)$.

FIR Filter: Digital filter with finite impulse response. This filter is always stable and can be designed to have linear phase. (Filters with the symmetric impulse response). The main disadvantage is high complexity.

Frequency Selective Filters: Digital filters which pass desired frequency components in a signal without distortion and attenuate other frequency components. A low-pass (LP) filter passes low frequency components to the output while eliminating high-frequency components. Conversely, a high-pass (HP) filter passes all high-frequency components and rejects all low-frequency components. A band-pass (BP) filter blocks both low- and high-frequency components while passing the intermediate range. A bands-stop (BS) filter eliminates the intermediate band of frequencies while passing both low- and high-frequency components.

IIR Filter: Digital filter with infinite impulse response. This filter must be checked for the stability and does not have linear phase. This filter has lower complexity than its FIR counterpart.

Interpolator: The filter $I(z)$ which is used to eliminate the unwanted spectrum introduced by expansion of the model filter in an IFIR structure. For the low-pass prototype filter design, this filter is a low-pass filter with lower complexity than the prototype filter.

Model or Shaping Filter: The filter $G(z)$ in the IFIR structure which has M times higher both the pass-band and the stop-band frequencies, than the prototype filter. Since both the stop-band and the pass-band increase M fold so does their difference, that is, the transition band. As a consequence of increased transition band the order of the filter decreases, and in turn the overall complexity decreases as well.

MPS: Measure of the computational complexity of a digital filter expressed in terms of multipliers per output sample.

Pass-band: Pass-band is defined as the frequency range allowed to pass through the filter.

Passband Ripple: The permitted deviation in the pass-band.

Stop-band: The frequency band that is blocked by the filter and therefore eliminated from the output signal.

Stopband Attenuation: The desired minimum attenuation in the stopband.

Transition Band: The range of frequencies between the pass-band and the stop-band is called the transition band, and for which no filter specification is given.

One-to-One Video-Conferencing Education

INTRODUCTION

Technologies have become a critical component affecting teaching and learning effectiveness. Technologies enable informal computer-mediated interaction among instructors and students, for example, through electronic mail or bulletin boards. The Internet has changed the dynamics of teaching and learning by enabling distance direct personal tutoring, whereby a tutor (a private or personal instructor) provides personal additional instruction and attention to a student. The cost of video-conferencing using standard personal computers and off-the-shelf software involves a low set-up cost and very low usage fee (local phone charges). Its low cost can lead to a proliferation of its use. Students are no longer physically constrained in their quest for tutors. It is important to research the factors that may facilitate or hinder learning via Internet video-conferencing capabilities.

A case study was conducted, through multiple data collection methods, with two tutors and three students in Singapore. The impacts of four critical factors (system characteristics, mode characteristics, social presence, and media richness) on the effectiveness of teaching and learning were studied. This study helps to fill a gap in knowledge that arises because prior studies tend to concentrate on big virtual classroom settings.

BACKGROUND

Earlier studies on the use of information technology for education have focused on student usage of learning software, or on group interactions. For example, Sankar et al. (1997) investigated two different ways of delivering lectures with video-conferencing, without any instructor-student interaction. There are very few studies on one-to-one distance education. Graesser and Person (1994) found that the quality of student questions was correlated with grades in one-to-one tutoring sessions on mathematics. It was found that collaborative problem solving, prompt question answering, and clarity of explanation using examples contributed significantly to learning effectiveness (Graesser et al., 1995). Hume et al. (1996), studying one-to-one tutoring effectiveness, found that hints encouraged students to engage in active cognitive processes that promoted long-term retention and deeper understanding. Chi (1996) found that certain types of interaction between tutors and students, during one-to-one tutoring sessions, could produce deep learning.

The body of literature on one-to-one distance education motivates this research effort in two ways. First, like all the existing studies, this study seeks to identify factors that may enhance the effectiveness of teaching and learning in such an environment. In this study, effectiveness is measured by asking instructors to indicate their perceived ability to teach and asking students to indicate their perceived ability to learn via distance education, relative to traditional face-to-face education sessions. Second, while the results of all the existing studies alluded to the importance of communication between the tutor and the instructor, this issue has never been directly investigated. Therefore, this study focuses on identifying factors that may impact the communication process between the instructor and the student, thereby affecting distance learning effectiveness.

One-to-one distance education is examined in the context of desktop video-conferencing because the economy and prevalence of desktop video-conferencing facilities are likely to make it a dominant mode of distance education in the future (Rhodes, 2001). Table 1 presents four critical factors that can affect the success of using desktop video-conferencing facilities for education.

System Characteristics

Every desktop video-conferencing facility has both hardware and software components. A digital camera and a video card (in some products) are needed to capture images. A microphone, a sound card, and speakers are

Table 1. Factors affecting teaching and learning effectiveness

Factor	Key aspects of factor
System characteristics	Hardware, software, and bandwidth
Mode characteristics	Usefulness, challenge, attractiveness, and clarity
Social presence	Sociability, warmth, and personal focus
Media richness	Multiple cues and interactivity

needed to capture and project voices. Many windows are needed to display the captured images (of the tutor or the student), the chat window, and other applications such as Word. In addition, the software should facilitate document sharing. Bandwidth limitations on the Internet and processing speed could lead to grainy pictures and a lack of synchronization between video and audio signals (Tackett, 1995), thereby affecting teaching and learning effectiveness.

Mode Characteristics

Four key perceptual characteristics of a mode of instruction determine its effectiveness: usefulness, challenge, attractiveness, and clarity (Champness & DeAlberdi, 1981; Sankar et al., 1995). Usefulness refers to how much the mode of instruction is perceived to be appropriate for the learning task. Challenge is the extent to which the mode of instruction is able to facilitate learning of difficult concepts. Attractiveness is the extent to which the mode of instruction is perceived to be lively, exciting, and interesting. Clarity refers to the extent with which the mode of instruction is perceived to allow comprehensible communication.

Social Presence

Social presence is defined as the extent to which a communication medium allows the actual physical presence of the communicating partners to be conveyed, and how far it allows communicating parties to socialize with each other, feel the warmth of each other, and exchange messages that are personal in nature (Markus, 1994; Short et al., 1976). Short et al. (1976) rank the following five communication media in order of decreasing social presence: face-to-face, television, multi-speaker audio, telephone, and business letter. The literature suggests that desktop video-conferencing may enable people to transmit more warmth and sociability than the telephone. Video images can help people who have just met recently to become more familiar with one another (Czeck, 1995). Facial signals can allow the instructor to assess student understanding.

Media Richness

Media richness is defined as the extent to which a communication medium can facilitate shared understanding (Daft et al., 1987). Rich media enable people to overcome equivocality, the existence of different interpretations. Variables typically used to gauge media richness include multiple cues and interactivity. Trevino et al. (1987) provide this ranking, in decreasing order of media richness: face-to-face, telephone, and printed documents. Face-to-face meeting has interactivity and immediate feedback so that mutual understanding between communicating parties can be checked and differences in interpretations reconciled. This medium also carries visual, verbal, and textual cues. Printed documents have neither interactivity nor immediate feedback. Desktop video-conferencing facilities may be less rich than face-to-face meetings because interactivity may be lower (Rice, 1992). Interactivity between the instructor and the student is a critical success factor for distance education (Milhem, 1996; Millbank, 1994).

RESEARCH METHODOLOGY

A case study research approach is appropriate for examining a phenomenon in its natural setting, and it leads to in-depth answers (Yin, 2002). A prior survey with undergraduates and high school students revealed that most of them had no experience with distance education via desktop-video-conferencing facilities (Tan & Chan, 1998). Since this mode of learning was relatively new, the case study research methodology was employed. Five subjects (two tutors and three students) volunteered for this study. All the one-to-one tutoring sessions involved two individuals interacting with each other. However, the primary interest of this study was to identify factors that influence the communication efforts of an individual (tutor or student), thereby impacting his or her ability to teach or learn. Prior studies on one-to-one tutoring sessions have also focused on the perceptions of an individual, rather than the interaction between two individuals (Chi, 1996). The two tutors were undergraduates from a large university. They each had about 2 years of experience with one-to-one tuition in a traditional face-to-face context. The three students were attending high school.

Table 2. Summary of ratings

Subject	System characteristics	Method characteristics	Social presence	Media richness	Overall experience
Student Y	Fair	Fair	Poor	Poor	Poor
Student X	Neutral	Neutral	Poor	Poor	Fair
Tutor B	Neutral	Good	Fair	Neutral	Neutral
Tutor A	Fair	Good	Neutral	Neutral	Good
Student Z	Good	Excellent	Excellent	Excellent	Excellent

They had been receiving one-to-one tuition from the two tutors for a year at their respective homes. All the tutors and students had no prior experience with distance education of any kind. The topic of instruction was mathematics at a high school level.

All tuition sessions were conducted using desktop video-conferencing tools and involved a tutor and a student. All personal computers used for desktop video-conferencing tuition sessions in this study were connected to the Internet via either a local area network or a 56 kbps modem. This speed was more reflective of distance education, where students and tutors are connected through the telephones. Microsoft NetMeeting was installed to facilitate communication. A digital camera and a video card were used to capture video signals. A microphone, a sound card, and two speakers were used to capture and project voice signals. For each subject (tutor or student), data from five such desktop video-conferencing tuition sessions were collected. To preserve the realism of the natural tuition context, there was minimal control over the instructional process and materials (Yin, 2002). Multiple methods for data collection including on-site observation, computer and video recording, and interviews were used (Miles & Huberman, 1994; Yin, 2002).

DATA ANALYSES

For each case, all the data were analysed for the four main factors (system characteristics, mode characteristics, social presence, and media richness) and perceptions of effectiveness in teaching or learning. Analysis results were verified with the subjects. The subjects also contributed additional insights and highlighted issues that were of particular concern to them. Overall, two subjects were in favour of the video-conferencing tutoring, while three provided unfavorable feedback. The evidence suggests that subjects were affected by system characteristics. Those who experienced technical difficulties in starting up their systems and had more problems with visual and voice signals tended to form poorer perceptions of their tuition sessions. Although they were clearly frustrated when they encountered system problems, subjects were generally optimistic when asked to comment on the future of such applications.

The results on mode characteristics suggest that subjects tend to have better perceptions of their tuition sessions if they could understand complex concepts through these means, or if the ideas exchanged were clear enough to them. Ways to enhance exchange of complex ideas include having “some methods to decompose a complex idea into several simpler ideas before communication” as suggested by a tutor. Overall, subjects felt this mode of education had increased their interest in mathematics because it was “interesting,” “amazing” and “fun”.

Results on social presence and media richness suggest that subjects tend to form better perceptions of their tuition sessions if they could feel the presence of the other party, if they could send personal messages, or if they could get replies quickly. People who have developed shared understanding on how to work with each other through the new technology are less affected by changes in social presence and media richness (Lee, 1994). Therefore, tutors and students are likely to be able to free themselves from such restrictions if “we have enough experience with such tuition sessions”.

It is evident from Table 2 that the four factors are reasonably good predictors of success with distance education employing one-to-one desktop video-conferencing. As each of these four factors improves, the overall experience is likely to be enhanced. Specifically, the strongest discriminatory factor for success seems to be media richness, while the weakest discriminatory factor seems to be system characteristics. Given their predictive power, these four factors could serve as a basis for future research efforts on distance education involving large-scale surveys.

FUTURE TRENDS

While the use of desktop video-conferencing facilities for one-to-one tuition sessions has its limitations, it has a promising future too. The subjects have some technical and procedural suggestions on how to improve the quality of such tuition sessions in the future (see Table 3).

Future research can implement or fine-tune software tools to put in place procedural routines. Future research can also replicate this study with different topics of

Table 3. Suggestions for improvement

Category	Suggestions
Technical	▪ Use pen-based interface to draw pictures and write formulae. ▪ Replace the white board with shared document to increase shared space. ▪ The system should capture all the transmitted information for reference. ▪ Consider using ICQ instead of NetMeeting to speed up connection time. ▪ Bypass the Internet if other connections are available (e.g., direct phone).
Procedural	▪ Should speak slower with regular intervals to enhance audio quality. ▪ Close video window to improve overall transmission quality. ▪ Use multiple means to make explanation of complex concepts clearer. ▪ Solicit feedback at regular intervals. ▪ Respond quickly to suggestions or queries. ▪ Try to engage in more small talk or share jokes more frequently. ▪ Should meet face-to-face before using the technology.

instruction (e.g., languages or sciences) and different levels of instruction (e.g., middle school or college). This study has focused solely on tutors and students from Singapore but future research efforts can examine the same phenomenon in a multi-cultural context. Research has shown that culture does moderate the impact of technologies on human behavior (Tan et al., 1998), particularly since distance learning via desktop video-conferencing capabilities can match tutors and students from different cultures. Also, as network speed improves, further studies could be made to ascertain whether better speed has any significant positive effects on the other factors.

CONCLUSION

This study demonstrates the promise of desktop video-conferencing technologies as a means for conducting one-to-one distance education. Given the widespread availability of low-cost personal computers and Internet access, it is plausible that this mode of distance education may partially replace face-to-face tuition sessions. More importantly, the benefits of the technological capabilities examined in this article can extend beyond one-to-one tuition sessions to larger-scale distance education efforts. Although this study focuses on desktop video-conferencing technologies, other technologies must not be neglected. In addition to seeing each technology as a solution to an existing problem, it is also fruitful to examine how a collection of information and communication technologies may open up new and exciting possibilities for education.

Information and communication technologies have permeated many aspects of education. These technologies will continue to impact education in the future. An example of how such technologies may alter the future of education is a course on Global Project Coordination, jointly conducted by National University of Singapore, Stanford University, and Swedish Royal Institute of Technology. In this course, students from the three universities enrol in the same global class. Faculties from the three universities take turns to give weekly lectures to the entire global class via a three-way video-conferencing facility, based on real-time multicast technologies. Students also form global teams to work on large-scale projects sponsored by the industry. As part of this course, faculties and students employ a wide range of technologies to communicate with and learn from each other. The desktop videoconferencing capabilities investigated here can certainly facilitate such learning efforts by helping to breach geographical barriers among faculties and students of such a global class.

Although this article focuses on desktop video-conferencing technologies as a means for distance education, other existing and emerging technologies based on the Internet must not be neglected. In the 21st century, when information and communication technologies are likely to play a critical role in enabling effective education, knowledge accumulated on existing and emerging technologies can guide us in terms of what technologies are appropriate under what circumstances. Rather than seeing each technology as a solution to an existing problem, it is more fruitful to examine how the collection of information and communication technologies may complement each other to open up new and exciting possibilities for educating people.

KEY TERMS

Interactivity: The level of interaction among communication partners.

Media Richness: Media richness is the extent to which a communication medium can facilitate shared understanding among the communicating partners.

Mode Characteristics: Mode characteristics refer to the characteristics of a mode of instruction. The relevant characteristics identified for this study are: usefulness, challenge, attractiveness and clarity.

Microsoft NetMeeting: "NetMeeting lets you hold video conference calls, send text messages, collaborate on shared documents, and draw on an electronic whiteboard over the Internet or an intranet." (www.microsoft.com)

One-to-One Tutoring: Unlike a classroom setting with one instructor and many students, this is tuition (teaching-learning interaction) between one tutor and one student.

Social Presence: In this study, social presence refers to the extent to which a communication medium projects the physical presence of the communicating partners.

Video-Conferencing: Video-conferencing is the use of information and communications technology to allow people at different locations to hear, see and speak to one another. It often includes the sharing of documents and textual communications.

Online Academic Libraries and Distance Learning

Ardis Hanson
University of South Florida, USA

BRIEF HISTORY OF DISTANCE LEARNING

Historically, distance learning or distance education began as little more than "correspondence courses," which promised an education in one's own home as early as 1728 (Distance Learning, 2002). By the 1800s the concept of distance education could be found in England, Germany and Japan (ASHE Reader on Distance Education, 2002).

In 1933, the world's first educational television programs were broadcast from the University of Iowa and in 1982, teleconferencing began (Oregon Community Colleges for Distance Learning, 1997), often using videotaped lectures, taped-for-television programs and live programming, adding a human dimension. Students and faculty were now able to interact with each other in real time, enhancing the learning process by allowing student access to teachers across distances.

ACADEMIC DISTANCE LEARNING & THE VIRTUAL LIBRARY

Distance learning can be defined by the fact that the student and the instructor are separated by space. The issue of time is moot considering the technologies that have evolved allowing real-time access. Today, universities around the world use various methods of reaching their remote students. With the use of technology, access becomes possible, whether it is from campuses to remote sites, or to individuals located in their own homes.

The development of course instruction, delivered through a variety of distance learning methods (e.g., including Web-based synchronous and asynchronous communication, e-mail, and audio/video technology), has attracted major university participation (Burke, Levin & Hanson, 2003). These electronic learning environment initiatives increase the number of courses and undergraduate/graduate degree programs being offered without increasing the need for additional facilities.

During the 2000-2001 academic year, the NCES (National Center for Education Statistics) estimated in the United States alone there were 3,077,000 enrollments in all distance education courses offered by 2-year and 4-year institutions, with an estimated 2,876,000 enrollments in college-level, credit-granting distance education courses, with 82% of these at the undergraduate level (Watts, Lewis & Greene, 2003, p. iv). Further, the NCES reported that 55% of all 2-year and 4-year U.S. institutions offered college-level, credit-granting distance education courses, with 48% of all institutions offering undergraduate courses, and 22% of all institutions at the graduate level (ibid, p. 4). It is clear that distance education has become an increasingly important component in many colleges and universities, not only in the United States, but also worldwide.

Although educational institutions create courses and programs for distance learners, they often omit the support component that librarians and accrediting organizations consider critical. It is recommended that courses be designed to ensure that students have "reasonable and adequate access to the range of student services appropriate to support their learning" (WICHE, Western Interstate Commission for Higher Education). Further, courses should incorporate information literacy skills within the course or in class assignments to ensure skills for lifelong learning (American Library Association, 1989; Bruce, 1997).

Distance learning (DL) students are unlikely to walk into the university's library for instruction on how to use the resources, from print to electronic journals, as well as services such as electronic reserves and interlibrary loan. The elements of any successful distance-learning program must include consideration of the instructors and the students, both of whom have needs that must be examined and served.

With imaginative use of technology, libraries have created "chat" sessions, which allow 24/7 access to librarians who direct students to the resources that are available online or through interlibrary loan. In addition, librarians assist faculty in placing materials on electronic reserve so that their students can access the materials as needed. Libraries have become more willing to provide mail services and desk top delivery of electronic articles to their distance learning students and, when that is not possible, refer their students to local libraries to take advantage of the interlibrary loan system. Online tutorials have been created to help students learn how to access these resources, while other libraries have specific departments that assist their distance education students and faculty. The role of the library in this process is one of support, both for the students and the faculty.

CHANGES IN DISTANCE LIBRARIANSHIP

Of all of the "traditional" library functions, such as materials provision, electronic resources, and reciprocal borrowing available to the distance learner, there remains a significant gap in service, that of reference. Although chat lines and other 24/7 services are available, these services simply do not provide the DL student the same quality of service that the on-campus student gets when he or she consults with a librarian in person. Newer versions of distance learning course software provide external links to resources, but do not yet include reference service by e-mail and live chat sessions in their basic packages. It will be the responsibility of the library to make these services easily available and known to the distant learner, whose contact to the institution may not include information about the library and its resources. Proactive planning by the library with those who are responsible for distance education can ensure that the students are made aware of what is available for them in the library.

Recently, libraries have been looking at e-commerce business models as a functional way to serve their clientele in reference services, as today's "customers" are savvier, and businesses have become more sophisticated in responding to customers' needs. Libraries can use these models to provide the services for DLs whose level of skills has risen with the increased use of the Internet. Coffman (2001) discusses the adaptation of such business tools as customer relations management (CRM) software, such as the Virtual Reference Desk, Webline, NetAgent, and LivePerson. These programs are based upon the "call center model," which can queue and route Web queries to the next available librarian. A quick visit to the LSSI Web site (Library Systems and Services, L.L.C, *http://www.lssi.com*) allows a look into the philosophy of offering "live, real-time reference services". LSSI's "Virtual Reference Desk" allows librarians to "push" Web pages to their patrons' browser, escort patrons around the Web and search databases together, all while communicating with them by chat or phone (*www.lssi.com*). Many of these systems provide the capability to build a "knowledge base" that can track and handle a diverse range and volume of questions. These collaborative efforts, with a multitude of libraries inputting the questions asked of them and creating FAQs (frequently asked questions lists), provide another level of service for the distance learner (Wells & Hanson, 2003).

These systems have great potential, and while they show tremendous possibilities, they need more work to make them more functional for library use. Chat sessions are problematic when the patron is using his or her phone line to connect to the computer, and libraries must look to the emerging technology to find solutions to such issues to prevent becoming obsolete.

Another direction is the development of "virtual reference centers," which would not necessarily have to be located in any particular physical library. Current collaboratives among universities have created consortial reference centers accessible anywhere and anytime. The reference center librarian could direct the student to the nearest physical resource or to an online full-text database based upon the student's educational profile (e.g., university, student status, and geographic location). Although the physical library may indeed become a repository for books and physical items, the reference component may no longer be housed within that particular building.

An example of support is Toronto's Ryerson Polytechnic University (Lowe & Malinski, 2000) infrastructure, which is based upon the concept that, in order to provide effective distance education programs and resources, there must be a high level of cooperation between the university, the departments involved, and the library. At Ryerson, the Continuing Education Department studied what types of support the students needed and identified technical, administrative, and academic help as three major areas of concern. Technical help was assigned to the university's computing services; administrative help was available on the Web and through telephone access, and academic help included writing centers, study skill programs, and library services. Ryerson's philosophy encompassed the concept that synchronization of all these components would assist in making the student's experience richer and give the student a higher degree of success

The library and the distance education unit worked to provide connectivity to resources that were important to the classes being taught online or at-a-distance. It is these types of library involvement that can make distance learning an even more successful and enriching experience. When a university system, as a whole, embraces a collaboration of all its components, both the students and the university reap the rewards.

CONCLUSIONS

Distance education will only continue to grow. In order to support this educational initiative, academic libraries must establish a supporting framework and commitment to those services traditionally provided by libraries such as lending books and answering reference questions in person or by telephone, plus new services such as "live chat" and desk top delivery of articles that are unique to the virtual environment. Faculty and students in distance learning courses depend on the academic library for their resources and services, and the library must be able to deliver materials to students or assist them in finding alternate sources in a timely manner. Libraries need to be able to identify their DL students using the necessary resources to verify information. Help desks, chat rooms, e-mail programs, and live reference all contribute to the support of the distance learning programs. Since DL students may never visit a library's physical facility, it is important to provide information on how best to access the library virtually.

Faculty members also require library support for their courses. For example, materials may be scanned and placed on the Web or videos may be "streamed" for online access. In order to digitize and make these items accessible, faculty need information on the correct use of copyrighted materials. It is also advisable to put into place an action plan to implement a program for distance learning and a method for assessing that program once it is in place.

FUTURE TRENDS

As distance learning continues to flourish, research will be needed to examine the effective implementation and ongoing management of distance education. While several issues emerge as salient, such as the social aspects of communication in the networked environment, and the integrity of Web-based course resources, it is the role of libraries in support of distance education that must be considered. Although much has been written about the social isolation of distance work, recent advances in groupware technologies have enhanced an individual's ability to stay connected for both work and social exchange through the use of synchronous and asynchronous remote communication (Li, 1998; Watson, Fritz et al., 1998). However, the increased use of technology suggests that formal and extensive training on both distance technology and team communications are necessary (Venkatesh & Speier, 2000).

Libraries, often overlooked in this process, have to be far more assertive in the distance learning process. Libraries can be a center of technical and administrative help along with the traditional academic role that they have normally held. The growing DL field allows librarians to redefine their roles, and request monies for advanced technological necessary to become as "virtual" as the classes being taught. In addition, to serve the ever-increasing DL population, library education must now include the course work that will provide future librarians the training necessary to serve this ever-expanding population.

KEY TERMS

Chat: A real-time conferencing capability, which uses text by typing on the keyboard, not speaking. Generally between two or more users on a local area network (LAN), on the Internet, or via a bulletin board service (BBS).

CRM (Customer Relationship Management): This term refers to how a company interacts with its customers, gathers information about them (needs, preferences, past transactions), and shares these data within marketing, sales, and service functions.

Desk Top Delivery: Using electronic formats to send articles to users.

Distance Learning/Distance Education: Taking courses by teleconferencing or using the Internet (together with e-mail) as the primary method of communication.

Electronic Reserves: The electronic storage and transmission of course-related information distributed by local area networks (LANs) or the Internet. Also known as e-reserves; in addition to displaying items on a screen, printing to paper and saving to disk are often allowed.

Internet: A worldwide information network connecting millions of computers. Also called the Net.

Link-rot: The name given to a link that leads to a Web page or site that has either moved or no longer exists.

Next Generation Internet (NGI): Currently known as Abilene, the next generation Internet refers to the next level of protocols developed for bandwidth capacity, quality of service (QOS), and resource utilization.

Real-time: Communication that is simultaneous; see **synchronous.**

Social Aspects of Communication: A social process using language as a means of transferring information from one person to another, the generation of knowledge among individuals or groups, and creating relationships among persons.

Streaming Video: A technique for transferring data as a steady and continuous stream. A browser or plug-in can start displaying the data before the entire file has been transmitted.

Synchronous and Asynchronous Communication: Synchronous communication is when messages are exchanged during the same time interval (e.g., Instant Messenger™).

Asynchronous communication is when messages are exchanged during different time intervals (e.g., e-mail).

Virtual Library: More than just a means of collocating electronic resources (full-text materials, databases, media, and catalogues), a virtual library also provides user assistance services, such as reference, interlibrary loan, technical assistance, and so forth.

Voice over Internet Protocol (VoIP): A protocol that enables people to use the Internet as the transmission medium for telephone calls.

Web (World Wide Web): A global system of networks that allows transmission of images, documents, and multimedia using the Internet.

Online Communities and Community Building

Berlin University of Technology, Germany

INTRODUCTION

"Online community" is one of today's buzzwords. Even though superficially it is not hard to understand, the term has become somewhat vague while being extensively used within the e-commerce business. Within this article, we refer to online community as being a voluntary group of users who partake actively in a certain computer-mediated service. The term "online community" is preferred over the term "virtual community," as it denotes the character of the community more accurately: community members are interacting online as opposed to face to face. Furthermore, the term "virtual community" seems too unspecific, because it includes other communities that only exist virtually, whereas an online community in our definition is always a real community in the sense that community members know that they are part of the community.

Nevertheless, there are other reasonable definitions of online community. An early and most influencing characterization (which unfortunately utilizes the term "virtual community") was coined by Howard Rheingold (1994), who wrote: "…virtual communities are cultural aggregations that emerge when enough people bump into each other often enough in cyberspace. A virtual community is a group of people […] who exchanges words and ideas through the mediation of computer bulletin boards and networks" (p. 57). A more elaborated and technical definition of online community was given by Jenny Preece (2000), which since then, has been a benchmark for developers. She stated that an online community consists of four basic constituents (Preece, 2000, p. 3):

1. Socially interacting people striving to satisfy their own needs.
2. A shared purpose, such as interest or need that provides a reason to cooperate.
3. Policies in the form of tacit assumptions, rituals, or rules that guide the community members' behavior.
4. A technical system that works as a carrier that mediates social interaction.

Not explicitly mentioned in this characterization but nevertheless crucial for our aforementioned definition (and not in opposition to Preece's position) is voluntary engagement.

BACKGROUND

Just because everybody is now talking about them, online communities are, historically seen, neither an implication of the World Wide Web — which dates back to 1991 (Berners-Lee et al., 1992) — nor dependent on the Internet as a transport infrastructure. In fact, online communities emerged at times when ARPAnet—the predecessor of the Internet — was still restricted to military-funded institutions. They were based on computerized bulletin boards first introduced by Christensen and Suess (1978). Their system was called CBBS (computerized bulletin board system) and followed the idea of a thumbtack bulletin board hosted electronically on a computer. Other computer hobbyists were able to connect with their home computers via a dial-up modem connection and could "pin" messages to a shared "board." The first online communities developed through other participants responding to those messages, creating ongoing discussions. At that time, computer hobbyists and scientists were more or less the only ones who owned computers and modems. Therefore, most topics on CBBS were within the realm of computers, but in the long run, the discussions broaden. Within the 1980s, similar systems appeared that were now subsumed as BBS (bulletin board system). The most well known were "The Well" (Whole Earth 'Lectronic Link) and FidoNet (Rheingold, 2000).

Apparently, at the very same time, the technological and social environment was ready for online communities, as there were at least two other independent developments concerning this matter:

1. The Usenet was invented by computer science students at Duke University and the University of North Carolina, using a simple scheme by which these two computer communities could automatically exchange information via modems at regular intervals.
2. The first MUDs appeared at the University of Essex (UK) creating playful and imaginative online communities. MUDs (short for Multi-User Dungeon/Dimension/Domain) are computer-implemented versions of text-based role-playing games, in which multiple persons can take virtual identities and interact with one another. Early MUDs were adventure games played within old castles with hidden rooms, trapdoors, etc.

Nowadays, most online communities are using the Internet as carrier, and most of them are Web based, using HTTP as a protocol for transportation and the DHTML standard for presentation. But there are still communities that employ other systems and protocols, like newsreaders using NNTP and mail-groups using SMTP or IRC (Internet relay chat) based chatting systems (IRC). Some online communities even use multiple systems and protocols to communicate and cooperate.

ONLINE COMMUNITIES

The conditions in pure online communities highly differ from a computer-mediated communication situation within a company. Whereas employees in a computer-supported cooperative work (CSCW) context usually meet online as well as face-to-face, members of online communities have, as a general rule, never met each other. Working in a highly standardized company context, employees have to focus on task fulfillment within a certain time frame. Superiors evaluate their achievements, and they are accordingly paid by the company. Online communities thrive on volunteers. Usually none of the community members can be forced to do something, and there are no tangible incentives. Basic research in motivation psychology (Franken, 2001) even shows that incentives tend to be counterproductive.

Community members usually show a high degree of intrinsic motivation to participate actively in the development of an online community. It is still open to discussion where this motivation comes from. Simple rules like "It's all based on trying to maximize the potential personal benefit" seem to fail, as long as one has a simplistic concept of the term "personal benefit." As the attention-economy-debate (i.e., Aigrain, 1997; Ghosh, 1997; Goldhaber, 1997) shows that personal benefit is a complex entity if one relates it to online activities in the World Wide Web.

The likelihood of taking an active part in a community increases with the potential personal benefit that could be gained within that community. This is directly related to the quality of the contents offered. As, e.g., Utz (2000) stated, the likelihood of submitting high quality contributions increases with the quality and the manifoldness of the existing entries. Appropriate solutions of these quality assurance aspects are rating systems.

A "killer-feature" for such an application generates immediate benefit for a user as soon as he or she contributes to the community, even without anybody else contributing. In addition to such a feature, or even as a partial replacement, one can follow best practices. After analyzing numerous well-working online communities, Kollock (1999) came to the conclusion that there are basically two states of motivation: self-interest (what seems to be the common motivation found) and altruism. Self-interest as a motivational state is linked to expectation of reciprocity: people are willing to help or cooperate with others if they can expect a future quid pro quo.

A widely discussed issue in the context of community building is the so-called public goods dilemma: if people can access public goods without restriction, they tend to benefit from these goods and, therefore, from others' contributions without contributing in the same way. If, on the other hand, most members of a community are led into temptation, the public good will vanish (Kollock & Smith, 1996). The main problem is to keep the balance between the individual and common interest: an individually favorable and reasonable behavior turns out to be harmful for the others, and in the long run, disastrous for the community (Axelrod, 1984; Ostrom, 1990).

Owing to these circumstances, it is not surprising that a great deal of all online community building projects fail, even though much effort has been put into these projects due to the high profit opportunities within the field as, for instance, Hagel and Armstrong (1997) predicted.

ONLINE COMMUNITY BUILDING

Recipe-based fabrication of online communities is, at least, a bold venture if not an illusionary enterprise. Social relationships and group momentum are particularly hard to predict. As Rheingold (2000) explicated, online communities grow organically and tend to follow their own rules. Therefore, controlling efforts always have to be adjusted to the current group context. Nevertheless, some well-approved principles could be derived from findings that were discussed in the last paragraph.

According to Kollock (1999), cooperation within an online community can only be successful if individuals:

1. Can recognize each other, i.e., they are not operating anonymously within the community.
2. Have access to each others interaction history.
3. Share the presumption of a high likelihood of a future encounter within the online community.

This leads to the conclusion that online communities have to offer possibilities of creating and managing relationships by supporting continuous interaction between their members. Therefore, it is advantageous if the system has a memory, in the sense that every community member and every item stored in the system holds a personal history.

People tend to act from self-interest if they are aware that their actions have effects on their reputations: high-quality contributions, impressive knowledge, and the perception of being willing to help others enhance the prestige of the community member. Although altruism as a motivational state for taking part in an online community is less common in comparison with self-interest, it is still frequent enough to be addressed if one thinks about community building. People with altruistic motivation try to meet the needs of the group or certain group members. This motivational state can be satisfied by establishing a public space where these needs can be stated, communicated, and discussed.

Considering the public goods dilemma, it is essential to introduce a role concept to clearly communicate the borderline between being in a group and out of a group. To get full access to all group resources, one has to join the group. Several functionalities are only accessible for registered and authorized users. The commitment that is required to join the group leads to a comprehensible demarcation between members and nonmembers, who, in turn, facilitate the togetherness of the group and the identification of the members within the group. Three further selective measures address the public goods dilemma: personal presence, personal responsibility, and personal history. Anonymity and lack of continuity among the members promotes egoistic behavior. Therefore, modifying actions should be tagged with users' login names, which, in turn, should be associated with records of personal data. Tagging entries and actions with user login names makes it easy to recognize people and enhances the constitution of personal relationships and online cooperation among the community members. Seeing all modifying actions supports the actors' personal responsibility. If the system has a memory of every action, this gives a personal history to every community member, as well as to the community's artifacts. Information about past interactions of the members again increases personal responsibility, whereas information about interaction with the artifacts facilitates getting up-to-date within a new area of interest and familiarizing new members with the online community's etiquette and who-is-who.

"Content is king" is commonplace for virtually all Web-based efforts. This is notably true for online communities operating on a user-as-editors base. To implement a reasonable quality assurance system, it is crucial to apply technical as well as social means. Technically, this can be done by employing a content rating system. Employing a "tiger team" of highly motivated volunteers can, on the other hand, help the online community to start up by delivering good content. For all content producers, it has to be as easy as possible to feed new content into the system. The best way of avoiding barriers is through continuous usability testing.

Introducing dedicated and active moderators seems to be the most important step to nourish motivation of the community members. Moderators can enhance group activities and increase the efficiency of the group. They are responsible for communicating the group standards (etiquette), acting as confessors for new community members, and helping in preserving continuity. Rojo (1995) showed that an active moderator can, to some extent, compensate for the lack of active members in an online community.

As opposed to face-to-face communities, where only members can start a conversation, online communities can initiate communication. This opportunity should be brought into play by implementing change awareness functions as software agents that collect relevant information for users and present it in e-mails and personalized portal pages. An important item in using profiles for personalized services is keeping profiles up-to-date. Experience shows that interests continuously change over time. Profile setting dialogues are often accessed once and then forgotten. Thus, there is risk for personalized services to decrease subjectively in quality over time. Hence, it is important to monitor user behavior and let the agents ask from time to time if interpretations of observations of, for example, changing interests, are correct.

The open-source movement has become very successful in recruiting new developers who start their own projects or join existing software development efforts. Today, most if not all open-source software development communities use online services for cooperation. In the remainder of this section, the application of the requirements for software supporting online community building is demonstrated with examples of open-source software development communities:

- **"Killer-feature":** Open-source projects are often founded to solve an existing problem, i.e., the killer-feature is the product of the online community. When others join the project, the work becomes even more effective.

- **Recruitment:** Open-source communities produce software systems that are not only intended for use by themselves but also for external clients. These external users, i.e., users not actively involved in the open-source online community, can be made active developers that modify the source and give it back to the project. To foster this process of developer recruitment, online communities should provide transparent rules for becoming actively involved. The projects that do not seem to be hermetic have better chances of growing their developer base.
- **Transparency:** The most important possibility of gaining transparency is through a public archive of the project's mailing lists. Because it is often not easy to scan large e-mail archives, open-source communities should provide text documenting guidelines and standards.
- **Policy:** The Debian community that maintains an open-source Linux distribution is a good example of a growing community that has given itself a substantial set of roles, rules, and guidelines. They achieve transparency of their standards by publication of documents on their Web server — other projects, such as UserLinux, use a Wiki for that purpose which makes such standards more vivid and activates community members' attendance.
- **Trust:** Debian has a twofold quality assurance system. There are no anonymous additions to the system, and approved maintainers electronically sign all modifications. Bugs are reported by all users. The bug lists are available to the public.
- **Cooperation and usability:** Cvs is a configuration management software for source code trees in distributed development teams. cvs is an example of cooperation software and its usability issue: Based on rcs (revisions management for single files), it is efficient to use for everyday tasks in open-source software development.
- **Awareness:** Workflows can provide awareness. Examples include automated e-mail distribution of users' bug reports and e-mail notifications of cvs commits.

This exploration into open-source projects and their online coordination and cooperation tools reveals that a voluntary community approach works, and the infrastructures and supporting tools of these projects can be taken as a best practice reference case.

FUTURE TRENDS

Recently, the term "socialware" was proposed for software systems dedicated to enhance social relations. According to Hattori et al. (1999), socialware are systems which aim to support various social activities by means of computer networks. This is done by linking people with others, fostering communication within a community and connecting the community's information. Initially intended for CSCW systems that are used by stable communities, the socialware approach seems suitable for implementing software for online communities as well. It uses rules of interpersonal communication and transfers these structures into software. The technical concept associated with socialware is a multiagent system architecture. The CSCW functionality is achieved through coordination and cooperation of a distributed set of software entities (agents). Users of a community system have personal agents for gathering and exchanging information, visualizing contexts, and supporting decisions. Personal agents and the users they belong to are seen as personal units. Personal units interact with community agents that have the function of providing shared information and mediating communication between personal units. This approach also makes it possible to link several partially overlapping online communities.

A current development in online communities is the transformation of the virtuality of computer networks into the real world. There are different enabling technologies for mobile and ad hoc communities. An important factor is localizability in cellular phone networks or with global positioning systems (GPSs). Using the localization information as part of the application context allows for mobile communities. They are often based on asynchronous communication, like Internet online communities. An example for such a mobile community is the petrol station price comparison community. In 2000, the German Research Center for Information Technology offered car drivers a location aware service for obtaining the locations of petrol stations together with their prices, in exchange for other stations' current petrol prices.

The availability of new short-range radio networking technologies, such as Bluetooth or wireless LAN, enables new synchronous mobile communities. This gives users the ability to connect devices ad hoc (i.e., without a server infrastructure), permitting mobility and interaction. As with other Internet online communities, besides professional applications such as disaster management (Meissner et al., 2002), game playing is an important technology driver, e.g., pervasive group games are being developed (Pennanen & Keinänen, 2004) that could build up social structures in some ways comparable to online communities.

CONCLUSION

Advanced software solutions like the aforementioned socialware approach can help to build and maintain stable online communities. In the long run, though, it is not the technology, it is the people that make an online community work. The most advanced technology is neither sufficient nor, as early BBS/MUD approaches show, necessary for stable online communities. People will always make creative use of technology by using it in other ways than were originally intended by the designers. This will, once in a while, generate possibilities for new online communities.

Nevertheless, the most important factor for successful online communities is providing awareness about changes in the communities' databases to members. Awareness functions provide an understanding of the others' activities and the communities' goals and progress to relate and evaluate the users' own activities accordingly (Dourish & Bellotti, 1992).

KEY TERMS

Community Building: All activities related to building and maintaining online communities.

CSCW (Computer-Supported Cooperative Work): Software tools and technology as well as organizational structures that support groups of people (typically from different sites) working together on a common project.

Online Community: An online community is a voluntary group of active users that partake actively in a certain computer-mediated service.

Socialware: Socialware aims to support various social activities on a network. Rules of interpersonal communication are used and transferred into community software.

UaE (User-As-Editors) Approach: The community members are responsible for supplying new content and for the quality assurance of existing content, as well as for creating and maintaining the etiquette of the community.

Virtual Community: A featureless and, therefore, often misleading term usually regarded as synonymous to online community. The term "online community" is preferable, as it denotes the character of the community more accurately.

Wiki: Internet service based on HTTP and HTML providing "open editing" of Web pages with a Web browser. Hyperlinks between documents are supported with simple textual references. By default, everybody is allowed to edit all available pages.

Online Learning as a Form of Accommodation

Terence Cavanaugh
University of North Florida, USA

INTRODUCTION

An estimated three billion people, representing approximately half of the planet's population, are in some way affected by disabilities, which includes an estimated 150 million from the United States of America (Half the Planet, 2001). According to the *Twenty-Third Annual Report to Congress on the Implementation of the Individuals with Disabilities Education Act* (U.S. Department of Education, 2002a), concerning students with special needs between the ages of three and 21, the U.S. and its outlying areas are currently serving educationally more than 6,272,000 students classified as having a disability. The inclusion model, in which a special needs student participates in the "regular" classroom, has become the current classroom education standard. Today's special needs students have increasing impacts on the general education teacher as, during the past 10 years, the percentage of students with disabilities served in schools and classes with their non-disabled peers has gradually grown to over 90% in 1998 (U.S. Department of Education, 2000b). Because of the large and increasing number of special needs students, assistive educational technology is growing in importance. The population of postsecondary students with disabilities has increased over the past two decades, and currently there are approximately one million persons in postsecondary institutions who are classified as having some form of disability (U.S. Department of Education, 2000b). In 1994, approximately 45% of the adult population who reported having a disability had either attended some college or had completed a bachelor's degree or higher, as compared to only 29% in 1986 (National Center for Educational Statistics, 1999a).

BACKGROUND

Changes in the Population of Schools

While the makeup of the student population (K-20) has changed, because more students have been classified as having a disability and are now included in the general educational population, so too have the possibilities of the educational setting changed. For the 1999-2000 school year, the number of U.S. students with disabilities served was 588,300 preschool children and 5,683,707 students ages 6 through 21, representing an increase of 2.6% over the previous year (U.S. Department of Education, 2002a). Instructors now have on hand instructional tools that include forms of interactive telecommunication, such as the Internet and two-way video communication, as options for the delivery of instruction. While schools may not have been planning, designing, and creating distance learning courses and programs to meet the needs of students with disabilities, many students' needs were met through such a delivery system nonetheless. Electronic learning in and of itself is a form of instructional accommodation. Additionally, a range of assistive technology can support the student in the distance learning environment. The online class can be an assistive technology tool that students can use who would otherwise not be able to participate in a classroom for physical, health, or other reasons.

The number of students with disabilities is growing in the online education environment. A 1999 Canadian study of students with disabilities attending community colleges and universities found that an overwhelming majority of respondents (95%) indicated that they used a computer in their education situation, to the most noted reason for using the Internet was for doing research (Fichten, Asuncion, Barile, Fossey & De Simone, 2000). Thompson's (1998) summarizing report states that approximately 5% of the undergraduates at Open University of the United Kingdom have disabilities, with their population increasing at a rate of approximately 10% per year. The growth is ascribed to the convenience of home study and the ability of technology to overcome barriers to learning for students with disabilities. According to the U.S. Department of Education's (2002a) National Postsecondary Student Aid Study of 1999-2000, more than 8% of all undergraduates took at least one distance learning course, and 9.9% of those students identified themselves as having some form of disability.

Accommodations or Modifications Needed for Disabled Access

There is a difference between accommodations and modifications for students with special needs. Accommodations are considered to be provisions made in how a student accesses and/or demonstrates learning. The term accommodations focuses on changes in the instruction, or how students are expected to learn, along with changes in methods of assessment that demonstrate or document what has been learned. The use of an accommodation does not change the educational goals, standards, or objectives, the instructional level, or the content, and provides the student with equal access and equal opportunity to demonstrate his or her skills and knowledge (State of Florida, Department of State, 2000). Accommodations assist students in working around the limitations that are related to their disabilities and allow a student with a disability to participate with other students in the general curriculum program. Accommodations can be provided for: instructional methods and materials; assignments and assessments; learning environment; time demands and scheduling; and special communication systems. By comparison a modification is a change in what a student is expected to learn and demonstrate. The use of a modification for a student changes the standard, the instructional level, or the content to be learned by the student (Beech, 2000).

According to the Assistive Technology Education Network (ATEN) of Florida (2000), instructors of any classes that have students with disabilities should provide students with:

- opportunities to interact with others,
- varied models of print use,
- choices—and then wait for the student to respond,
- opportunities to communicate, and
- expectations that students will communicate, this may require the use of an alternate or augmentative form of communication.

Online instruction, especially through asynchronous Internet presentation, provides all of ATEN's requested opportunities for students. In a "traditional" course, a teacher or professor would be in a classroom, with the students sitting at tables or desks, and there would be lectures, demonstrations, possibly videos and slideshows, handouts, and readings. In an online course in an asynchronous course model, these interactions could still take place, but without the limitations of specific time and location (Picciano, 2001). In such a distance learning course, the main interactions between the student and the instructor take place using course Web pages, streaming audio and video, forums, e-mail, and online books. Assistive tools that a student with special needs may require could be more easily applied in the online environment; such assistive tools may include speech-to-text programs, environmental control devices, or assistive hearing devices. Additionally the asynchronous course design allows the students to access the information at the course Web site and learn at a time convenient to them (Barron, 1999). Within online course sections there could be forums or discussions in which students can participate, allowing each and every student the opportunity and appropriate time to develop and share responses, again without the time restrictions of the standard class period.

The Law, the IEP, and Education

Federal laws and their directives charge that each student classified as having any form of disability have an individual education plan (IEP) developed specifically for that student, that assistive technology devices and services must be considered, and that the student must be taught in the least restrictive environment (Individuals with Disabilities Education Act, 1992). The IEP will be developed by a team of people including teachers, administrators, counselors, parents, outside experts (as needed), and often the student. Distance learning can be considered an adapted form of instruction that through the use of telecommunication technology (usually the Internet) allows a student to participate in a class, meeting the classification of assistive technology. While some students with special needs may choose distance learning courses because these courses provide the necessary accommodations or educational modifications that they need in order to function in that form of "classroom," that in and of itself is not enough. It is up to educators to make sure that the accommodations and educational modifications necessary for these students to function in our classrooms exist or can be made available to these students as they need them. The educational charge extends to ensuring that distance learning classes are also accessible. These distance learning courses or situations must be designed, accommodated, or modified to allow students with special needs to be able to effectively participate.

Distance Learning and Students with Disabilities

A recent survey of seven open enrollment distance learning schools (state, public or private, or college/university) that offered Internet-based instruction may indicate trends in the current status of distance learning programs and special needs students. The distance learning population of the responding schools ran from 300 to 5,000 full- or part-time students, with an average of approximately 1,000 students. Most schools indicated that they did not have records or tracking methods for identifying students with disabilities. Schools that did identify these students indicated that special needs populations ran between 2% and 10%. With the exception of the responding university school, all the K12 distance learning schools indicated that their teachers have participated in IEPs for students. Half of the respondent schools indicated that they currently had students taking courses as part of the student's IEP, as recommended or required by the student's home school IEP team. The schools also indicated that they did not participate as IEP team members, but that the school or distance learning environment was written in as a service in the student's IEP. A consistent thread in the responses was that the distance education schools were sure that they had special needs students, but that they were not identified. When identifying their accommodations for students with special needs, all of the schools responded that they were willing to make accommodations, and the most common accommodation occurring in their programs was extending required time on tests and assignments. When questioned about the virtual school's faculty, only half of the respondents indicated that they had both counselors and exceptional education teachers on staff. Others indicated that they depended on counselors or other support personal to work with the student's home school. Interestingly, all responding virtual schools did indicate that distance learning instructors have already had, or currently have access to, training concerning accommodations for educating special needs students. Only two of the responding distance learning schools indicated that their Web-based instructional pages were compliant with either national or international accessibility guidelines, with one indicating that it was in the process of becoming so.

Hospital/Homebound Students

According to U.S. government statistics, there are more than 26,000 students classified as hospital/homebound students across the nation (U.S. Department of Education, 2002a). How these students are being served at a distance from their "home" school is a distance learning strategy question. The classic hospital/homebound program has a visiting teacher who acts as intermediary between a student's regular teacher and the student. The hospital/homebound teacher contacts the student's classroom teacher or teachers to collect assignments and directions to deliver to the hospital/homebound student, and visits the student to provide instruction and assistance. The more common approaches for hospital/homebound education are the "teleclass" phone model for secondary students and hospital/home visitation for the elementary level. In phone-based or teleclass instruction, all students taking a course dial into a common number, and a teacher provides oral instruction. Students have the opportunity to ask questions and interact through voice (G.A. Ball, personal phone communication, October 2, 2002). This instruction by phone service qualifies as a true distance learning program, as education is provided to the students through a telecommunication system. Other school systems also use online instruction, audio/videotaped instruction, and CD-ROMs, where the districts provide the needed hardware and software; some district school systems have even placed fax machines in students' homes for students to use to receive and submit assignments (C. Bishop, personal e-mail communication, January 2003).

FUTURE TRENDS

Online Education

Distance learning is a growing educational option. The numbers of both public and private distance learning intuitions are on the rise, along with the numbers of students attending. An instructional example would be the Florida Virtual School, going from 227 students in 1998 to 8,200 in 2002, an increase of 3,612% in just five years. School systems and students need flexible options to increase educational success, and using distance learning as an alternative can do that. We are already seeing experiments with asynchronous distance learning being used as an alternative for the hospital/homebound, but research still needs to be done. Virtual schools need to track the special needs students and identify effective methods that are working with them. Hospital/homebound programs need to investigate options for students who must be out of school for extended periods of time and determine the effectiveness of online skill-building education versus asynchronous module instruction of courses. Also, can distance learning assist such programs by allowing small or rural districts to band together and use common certified teachers, who are in short supply and are needed for No Child Left Behind requirements, to be shared between districts? In addition to human concerns, the future brings hardware and software issues, since most of the course management systems (CMSs) are not "disabled" accessible according to US 508 or W3C accessibility guidelines. Schools need to either create their own accessible course systems or apply pressure so that the currently available systems become compliant with access guidelines.

CONCLUSION

Distance Learning as an Accommodation

Electronic learning in and of itself is a form of accommodation, and there is also a range of assistive technology that can support the student in the distance learning environment. The online class can be an effective assistive technology tool that students can use who would otherwise not be able to participate in a classroom for physical, health, or other reasons. While distance learning may not be appropriate for every course or accommodating to every form of disability, it does provide a viable instructional option for many. As the inclusive education of all students occurs more frequently within the standard K12 classroom and through the electronic environment at the college level, it is reasonable to expect that more students with disabilities will participate in online education. While many accommodations are already available online, instructors need to insure that online courses should adhere to accessibility guidelines as proposed by state, national, or international organizations to allow all students access. These educational environments should be designed for all students, even those students who may need modifications, accommodations, and assistive technology.

KEY TERMS

Accommodations: Provisions made in how a student accesses and/or demonstrates learning. The term focuses on changes in the instruction, or how students are expected to learn, along with changes in methods of assessment that demonstrate or document what has been learned. The use of an accommodation does not change the educational goals, standards, or objectives, the instructional level, or the content, and provides the student with equal access and equal opportunity to demonstrate his or her skills and knowledge.

Assistive Technology: "…any item, piece of equipment, or product system, whether acquired commercially off the shelf, modified, or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities…." (20 U.S.C. 1401 (33)(250))

Asynchronous: Communications between the student and teacher which do not take place simultaneously.

Disabled Student: From the *U.S. Federal Register*: child/student has been evaluated as having mental retardation, a hearing impairment including deafness, a speech or language impairment, a visual impairment including blindness, serious emotional disturbance (hereafter referred to as emotional disturbance), an orthopedic impairment, autism, traumatic brain injury, an other health impairment, a specific learning disability, deaf-blindness, or multiple disabilities, and who, by reason thereof, needs special education and related services (IEP or 504).

Inclusion: A classroom design where all students should take part and attend "regular" classes. Generally, an ESE and regular education teacher work together with the same group of students, including students with disabilities and general education students. Both of the teachers share the responsibility for all of the students.

Individualized Education Program (IEP): A written statement for each child with a disability that is developed, reviewed, and revised in accordance with this section. (20 U.S.C. 1414 (d)(1)(A)) (Individuals with Disabilities Education Act, 1997)

Modification: A change in what a student is expected to learn and demonstrate. The use of a modification for a student changes the standard, the instructional level, or the content to be learned by the student.

Specific Learning Disability: Term meaning a disorder in one or more of the basic psychological processes involved in understanding or in using language, spoken or written, that may manifest itself in an imperfect ability to listen, think, speak, read, write, spell, or to do mathematical calculations, including conditions such as perceptual disabilities, brain injury, minimal brain dysfunction, dyslexia, and developmental aphasia.

Teleclass: Voice-only communications linking two or more sites. A standard method used is to connect multiple telephone lines for an audio conference through a phone bridge. A telephone bridge where the conference is established by having all of the distant sites call in to a common bridge telephone number.

Ontology-Based Query Formation and Information Retrieval

Sheng-Uei Guan
National University of Singapore, Singapore

INTRODUCTION

With the introduction of new technologies such as WAP, HSCSD, GPRS, UMTS, and Bluetooth, it is believed that the e-commerce arena will sooner or later merge its applications with handheld devices to create more opportunities for the birth of mobile commerce (m-commerce). However, m-commerce is largely unrealized to date because there still does not exist a single killer application that can attract wireless users to use wireless services. According to a recent survey by Gartner, Inc., besides the importance of coverage of wireless network and pricing issues, the wireless Internet and data services is the next crucial factor that attracts users to use wireless service. As such, there is a need to improve the data services over the wireless network. One of these services is the information retrieval service.

Most electronic product information retrieval systems are still not efficient enough to cater to the increasing needs of customers. This is especially serious in the m-commerce arena, where the bandwidth of mobile devices is low and large data would not be possible. Thus, the discovery of new information retrieval techniques is inevitable.

The main objective of this article is three-fold: 1) to research the use of ontology to assist users in shaping their product enquiries; 2) to study the use of genetic algorithms and agents in query optimization; and 3) to develop information retrieval services for the m-commerce arena. The article proposes a methodology for efficient query formation for product databases and for effective information retrieval systems, which includes the evaluation of retrieved documents to enhance the quality of results that are obtained from product searches.

This article discusses the usage of ontology to create an efficient environment for m-commerce users to form queries. The establishment of a method that combines keyword searches with using ontology to perform query formation tasks further allows a more flexible m-commerce environment for users. Also, with the use of genetic algorithms, it is hoped that query effectiveness can be achieved, at the same time saving computational time.

BACKGROUND

Definition of Ontology

In artificial intelligence, ontology is defined as a design of a conceptualization to be reused across multiple applications (Fensel, 2000; Braga, Werner & Mattosso, 2000; Hendler, 2001). A conceptualization is a set of concepts, relations, objects, and constraints that define a semantic model of some domain of interest. In other words, ontology is like the structure that describes or encodes the conceptualization in any relational aspect (McGuinness, 1998; Karp, 2000).

Literature Survey

In this section, a survey of present query formation methods and information retrieval methods will be discussed.

Unlike in e-commerce, query information using keywords alone in m-commerce is unrealistic, as mobile devices are too small and keypads are not suitable for typing. Moreover, it may be difficult for the user when vocabulary of subject is unfamiliar. Thus, relevance feedback is still the main technique for query modification.

Relevance feedback technique has been investigated for more than 20 years in various information retrieval models, such as the probabilistic model and vector space model (Boughanem, Chrisment & Tamine, 1999; Salton, 1989). It is based on randomly changing the set of query terms, as well as the weights associated with these terms, according to the document retrieved and judged during the initial search.

A lot of research (Boughanem et al., 1999; Yang & Korfhage, 1994; Kraft, Petry, Buckles & Sadasivan, 1994; Kouichi, Taketa & Nunokawa, 1999) has been done on how genetic algorithms (GAs) can be used in information retrieval. One popular approach is query restructuring, which is used to improve the efficiency and effectiveness of the queries formed. GAs actually extend the concepts of relevance feedback. The difference is that genetic algorithms use more than one query and compare the fitness among these queries. The fittest query will survive in the end. Thus, this article focuses on extending the concepts of using genetic algorithms in query restructuring.

Fitness Functions

There are a number of measures of query fitness used in previous works, namely precision and recall retrieved (Kraft et al., 1994; Salton & McGill, 1983), average search length (Losee, 1991), and average maximum parse length (Losee, 1991).

Precision is the percentage of documents retrieved that are relevant, while *recall* measures the percentage of the relevant documents retrieved (Kraft et al., 1994; Salton & McGill, 1983). These two tend to be inversely proportional, so that one is traded for another in most situations. *Average search length* is the average number of documents or text fragments examined in moving down a ranked list of documents until arriving at the average position of a relevant document (Losee, 1988, 1996). Evaluating the performance of a filtering or retrieval process with average search length provides a single number measure of performance. *Average maximum parse length* is the average (over a set of sentences) of the largest number of terms in a parse for each sentence. There are also measures that combine both average search length and average maximum parse length.

Typically, present methods had only dealt with the relevance of the document retrieved. This is reasonable but inefficient, because it is rather difficult to indicate the relevance of a document when the number of documents could be very large. This article measures the relevance of queries instead of documents retrieved. Based on this, efficiency will be improved significantly as the number of queries will be much smaller than the number of documents retrieved, which is ideal for mobile devices.

The Proposed Approaches

Both keyword- and ontology-based approaches have their advantages and disadvantages. Ontology provides the structure, context, and visual aid, while keyword provides a direct search mechanism. Both approaches are relevant for mobile commerce because they save time in browsing and searching, which is very much required by mobile users who are always on the move. Thus, by combining keyword queries with ontology, it is possible to achieve a better and more effective query formation. Before ontology terms are accessed to form the queries, there will be a keyword search to find the required ontology term. For example, "ps2" can be hidden in the node "mouse" when presented in the ontology. The user will not be able to know where "ps2" can be found intuitively without eyeballing the ontology. With the help of keyword search, the term "ps2" can be found easily.

In forming queries, there can be a high chance that the vocabulary used by the user to describe a query does not exactly match the vocabulary used by a query system (Preece, 1999). This will result in getting insufficient information. Therefore, restructuring dealing with domain ontology relationships might be useful. These relationships involve semantic links such as hyponyms and synonyms (Braga et al., 2000). Here, using synonyms is an adequate option to restructure queries because it correctly broadens the scope of search even to the extent of different languages.

When too little information is retrieved, the use of synonym or hyponym might be necessary in order to relax the constraints of the query. However, this approach has a major disadvantage. By relaxing the constraints of a query using synonym or hyponym to increase the number of documents retrieved, one could actually deface the meaning of the original query such that it could drift away from the user's intention. This concern can be alleviated by having user feedback along the process. Also, we have considered relaxing constraints step-by-step. This option can better eliminate the chances of constructing far-fetched queries from the use of genetic algorithms.

MAIN THRUST OF THE ARTICLE

Prototype Design and Implementation

Query Formation Using Ontology

Query formation will be done with the aid of tree ontology. Following the tree path will help form the requirements of a query. This allows forming a query easily. An illustration of the query formation process is shown in Figure. 1. As can be seen from this illustration, using ontology helps the user to save several steps by forming a query using the ontology path that is selected. Thus, it can be claimed that forming queries using ontology is actually more efficient than using keywords.

Combining Keywords and Ontology

The design of parallel combination is rather straightforward. Ontology does not cover everything. Thus, besides having ontology for the user to click on when forming a query, there should be some fields present for the user to fill in. When these fields are being filled in, they can replace the use of ontology either partially or completely. For a serial combination, keywords are used to look for

Figure 1. Illustration of using ontology to form queries

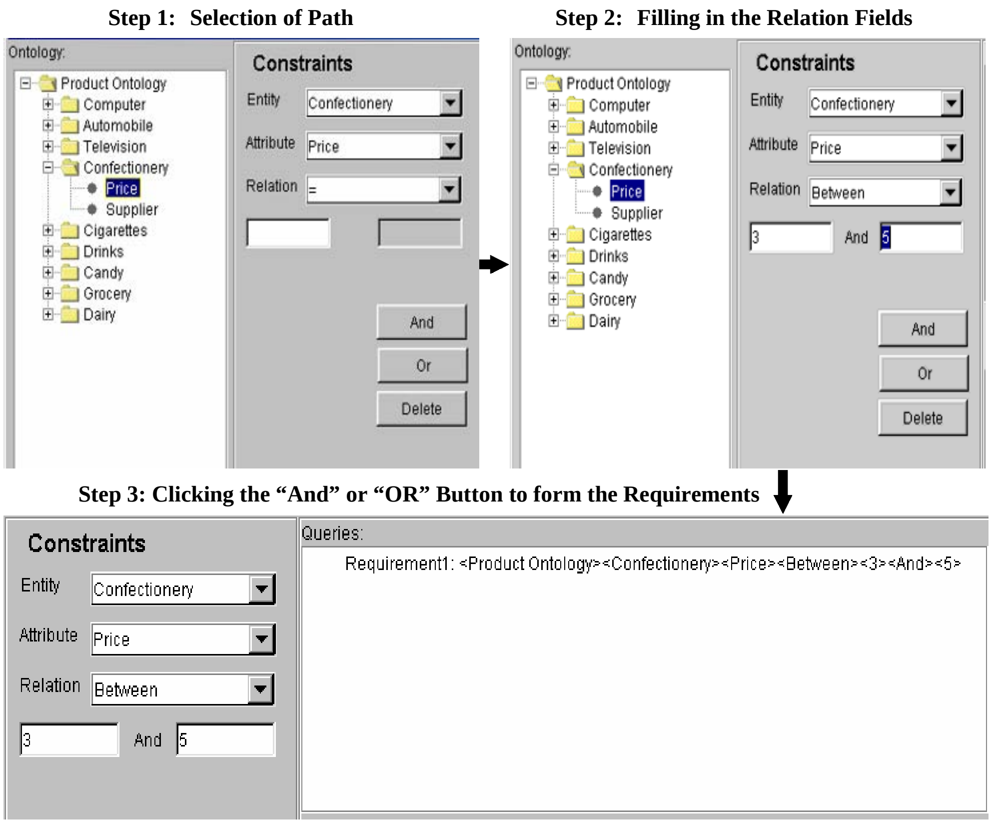

Figure 2. Illustration of the sequence of events for finding ontology terms

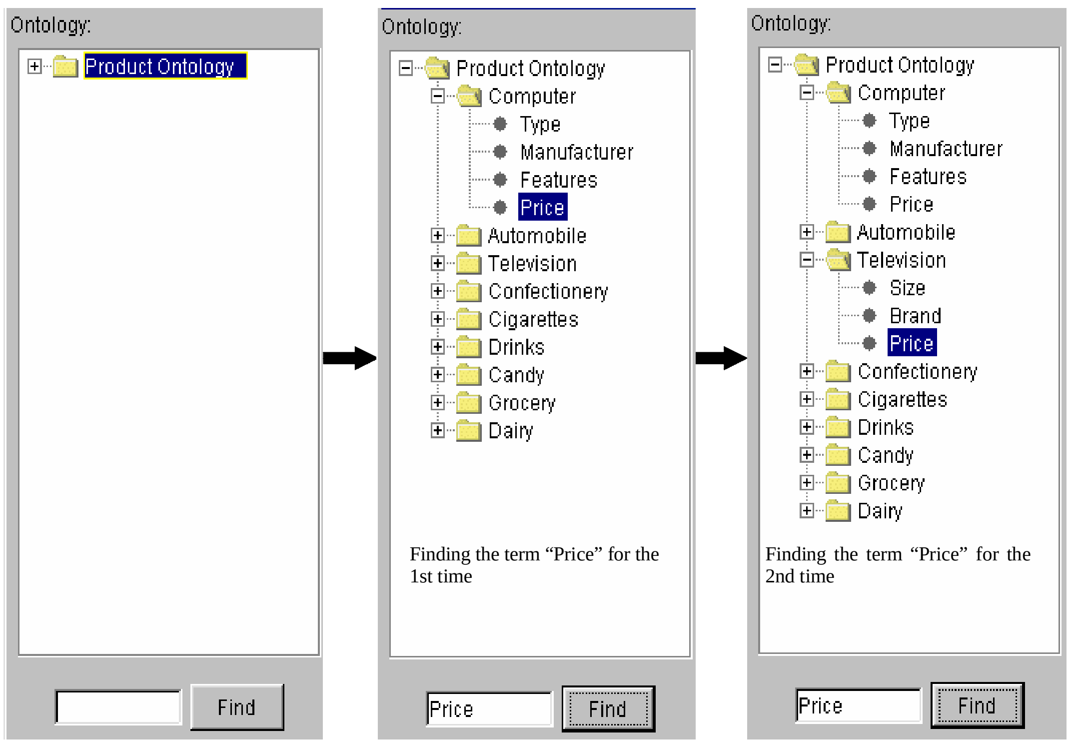

ontology terms in the ontology. This is necessary because when the ontology is too large, search for an ontology term by manual clicking becomes difficult. Thus, there would be a field that allows the user to highlight the terms in the ontology itself, as shown in Figure. 2. From this illustration, it can be seen that using keywords to search ontology terms in the ontology creates an efficient environment and context for the user.

Information Retrieval

Using the query formed by the query formation application, an application searches the databases to retrieve information. Intuitively, this application would first do a normal search before allowing the user to proceed with a genetic algorithm search. This is because a genetic algorithm search would definitely take a much longer time than a normal search because of its expensive iterations. The retrieval results are presented to the user; if he is not satisfied, he can then choose to proceed with a genetic algorithm search.

Genetic Algorithm

If the user requests the use of a genetic algorithm, the system will request some input from the user to perform genetic algorithm computation. The system then creates a population of queries from the original query. Basically, genetic algorithm will mutate the queries according to the synonyms of the terms in the ontology.

The Fitness Function

The main concern of using genetic algorithms is the design of the fitness function. In this application, three major elements are used to define the fitness function, namely the fitness of the number of documents retrieved (f_d), the fitness of the average quality of the query results (f_q), and the overall correlation for the query (f_r). The fitness of each chromosome is calculated as follows:

$$\boldsymbol{Fitness} = |f_r \cdot (f_d + f_q)|$$

| . | indicates that the fitness function is normalized to form a population distribution function.

The calculation of the value of f_d is not straightforward. Let i be the ideal number of documents specified by the user. If the user does not know the value of i, the default value will be 20. Using the value of i as the mean value, two *band pass filters*-like functions, namely the triangular and Gaussian functions, are used to create a more flexible mapping from the number of documents retrieved (*d*) to f_d. The triangular function gives a constant drop in 'gain' (decrease in fitness) from the 'center frequency' (the mean). This function is good when the user wants to give an equal amount of demerits for every document that is away from his expected or ideal number. The Gaussian function is a more robust or high-ordered 'band pass' such that its 'bandwidth' could be specified by the value of the standard deviation. Thus, this function is useful when the user wants to give heavy demerits to queries that do not fall near his expected or ideal number.

Only requirements that are specified by numerical constraints will have the value f_q. Here, it is required that the numerical values are summed up and averaged. Then, they are normalized. The signs "<" and ">" formed during the query indicate the direction in which the quality is favored.

Another interesting portion that contributes to the fitness function is the correlation of the synonyms (f_r) with the ontology terms. A value from 0 to 1 is assigned to each relation between the ontology terms and their synonyms. When a requirement is <Television><Price><<><2000>, the value or f_r will be the product of all the discrete correlations. Also, the user should be able to edit the correlation values to his preference. When there are many requirements in the query, these requirements will be linked with an "OR" or "AND" term.

Mutation and Crossover

The concept of mutation is to replace some terms with synonyms when parsing the results. Basically, the mutants are the terms that are included in each query. These terms are mutated randomly according to the synonyms so that new populations will be formed. Crossover will only interchange the different genes between two different chromosomes. A one-point crossover will be performed. This is also done randomly.

Feedback and Selection of Survival

The survivors are selected according to their overall fitness in the roulette-wheel selection manner. However, before this is done, the system will prompt for feedback from the user. The feedback will show the user some quality of each query. From this quality metric, the user may choose to kill queries that do not meet his or her requirements. Figure 3 shows a screenshot of a feedback presented to the user. If the user is satisfied with the results, he or she can choose to end the genetic algorithm by clicking on the "Stop" button. In this way, he or she can look at the retrieved results immediately.

Figure 3. Screenshot of a feedback frame

Prototype Testing and Evaluation of Genetic Algorithms

Effectiveness of the Genetic Algorithm

It is believed that the effectiveness of the genetic algorithm chosen is mainly determined by its supremacy in query effectiveness amplification. This is because its evolution power allows more retrieval results. The system was tested with a product list database. The effectiveness was measured by testing a series of queries with and without using genetic algorithms. For example, a query “<Product Ontology><Grocery><Price><<> <3>” can only retrieve nine items when a normal search is performed, but can retrieve 98 items when a genetic algorithm is performed. Table 1 shows the other results obtained by other queries.

By comparing the results shown in Table 1, it is obvious that using a genetic algorithm does, in fact, retrieve more items than using a normal search.

Effect of the Fitness Function

The fitness function in a genetic algorithm determines how well it can optimize a query. The OntoQuery system tested various fitness functions to improve the power of the genetic algorithm. The usage of triangle or Gaussian functions to evaluate the fitness for the number of documents retrieved suggested some ways to counter the “too many or too few retrieved documents” dilemma in typical search engines.

Table 1. Results showing effectiveness of GAs

Query Formed	Without GA	With GA
<Product Ontology><Drinks><Price><<><2>	25	95
<Product Ontology><Diary><Price><<><3>	3	92
<Product Ontology><Candy><Price><<><3>	13	178
<Product Ontology><Confectionery><Price><<><3>	20	248
<Product Ontology><Confectionery><Supplier> <Contains><Ho>	1	52

Efficiency of the Genetic Algorithm

Although using genetic algorithms allows a more flexible and effective platform in retrieving information, there is no doubt that they trade off efficiency due to their expensive iterations. Thus, the only study that can be made here is about their improvement over relevance feedback. In relevance feedback, query expansion is achieved by modifying a query. Similarly, genetic algorithms extend the relevance feedback techniques with an additional rule, the survival of the fittest.

In this research, the efficiency of the system is measured as follows:

$$e\ (\text{Efficiency}) \approx \frac{E}{t}$$

$$\approx \frac{D}{I}$$

where E denotes the effectiveness of the system.
t denotes the time taken for the system.
D denotes the number of relevant documents retrieved.
I denotes the number of iterations.

Efficiency is formulated as above because it is believed that the number of documents retrieved is linearly proportional to the effectiveness of the system. Also, the number of iterations is directly related to the time taken to retrieve the results.

CONCLUSION AND FUTURE WORKS

In summary, this research work investigated the OntoQuery system within an m-commerce agent framework against current query formation and information retrieval systems from extant work which were not intended for m-commerce.

The prototype implementation results showed that querying formation using an ontology approach is efficient, as it provides a friendly environment to the user using mobile devices. In addition, by combining the keyword and ontology approaches, a more efficient and effective way of forming queries could be achieved. Thus, the objective to propose efficient query formation for product databases is successful.

It was found that genetic algorithms are able to optimize queries effectively. Also, using genetic approaches, we have proposed and tested various fitness functions for searching product databases. Moreover, adding feedback to the system helps it to cater to the needs of the user more closely.

Considering typical e-commerce or m-commerce users using mobile devices for product enquiry tend to have some time constraints and they need quick response before making decisions, our work suggests a feasible approach. With the use of ontology, product enquiry can be formed easily and quickly. With the help of genetic algorithms and agents, and the technique of query optimization such as query restructuring, futile enquiries can be made productive. And finally, the use of genetic algorithms also helps improve the quality of product information retrieved.

KEY TERMS

Crossover: In genetic algorithms, it is the process of combining features of a chromosome with other chromosome(s).

Evolutionary Algorithm: An algorithm incorporating aspects of natural selection or survival of the fittest.

Fitness Function: In genetic algorithms, it is a measure of how well a chromosome can perform in certain environments (functions).

Genetic Algorithm: An evolutionary algorithm that generates each individual from some encoded form known as "chromosomes" or "genome."

Mutation: In genetic algorithms, it is defined as a change in form or qualities of chromosomes.

Ontology: Looks for semantic and ontological primitives and concepts to describe aspects or parts of "the world."

Restructuring: Replacing query terms using synonyms so that logical operators and numerical constraints can be restructured.

Roulette-Wheel Selection: A roulette wheel selects the chromosomes used in reproduction. The wheel is the fitness array, and the marble is a random unsigned integer less than the sum of all fitness in the population. To find the chromosome associated with the marble's landing place, the algorithm iterates through the fitness array; if the marble value is less than the current fitness element, the corresponding chromosome becomes a parent. Otherwise, the algorithm subtracts the current fitness value from the marble and then repeats the process with the next element in the fitness array.

Open Source Software Development Model

Luyin Zhao
Philips Research, USA

Fadi P. Deek
New Jersey Institute of Technology, USA

INTRODUCTION

The open source movement can be traced back to the hacker culture in the ’60s and ’70s. In the early 1980s, the tenet of free software for sharing was explicitly raised by Richard Stallman, who was working on developing software systems and invited others to share, contribute, and give back to the community of cooperative hackers. Stallman, together with other volunteers, established the Free Software Foundation to host GNU (Gnu’s Not Unix, a set of UNIX-compatible software system). Eric Raymond, Stallman’s collaborator, is the primary founder of the Open Source Initiative. Both communities are considered the principal drivers of open source movement.

A number of worldwide, online communities for open source development have been established since then to facilitate the development of open source software. For example, the Open Source Development Network (OSDN) is one of the largest organizations for such purpose. One of its subordinates, sourceforge.net, is hosting nearly 70,000 projects and 700,000 registered developers and users at the present time. The recent wave of sponsoring open source projects by commercial companies is another significant phenomena. Big IT players such as IBM, Sun, and HP have realized the importance and benefits to “open” their source. From other perspectives, open source applications have been expanding into various domains, including education, the Internet, office management, programming, communication, and even the medical domain. The Apache server powers half of all Web servers worldwide, far more than Microsoft and Netscape combined. Table 1 lists some typical application domains and well-known open source software.

Table 1. A list of popular open source software products

Operating system: Linux, FreeBSD
Internet: Apache Server, Mozilla
Communication: sendMail, OpenSSL
Programming: Perl, Tcl/Tk, GNU
Office: OpenOffice

BACKGROUND

With the successful delivery of many software products, the open source development model has been attracting increased interests from both practitioners and researchers. The open source development model can be characterized by its fast evolution, distributed development, and extensive user collaboration. It is a simple mean of releasing software with free source code, but one that brings a series of new social and technical challenges, including licensing, distributed development, project management, commercial adoption, and user collaboration. A number of research methods have been adopted to investigate the phenomena of open source development, including general descriptive discussion (Raymond, 1999; Hars & Ou, 2002; Cubranic & Booth, 1999; Augustin, Bressler & Smith, 2002), case studies (Mockus, Fielding & Herbsleb, 2002; Lakhani & Hippels 2003), and surveys (Zhao & Elbaum, 2003; Lakhani & Hippel, 2003). As usual, different research methods employ unique ways of investigation but have potential weaknesses. For example, case studies tend to focus on a few large open source projects such as Apache, Linux, and Mozilla, but lack of comprehensive observations on common issues for a broader spectrum of open source projects. Survey research is able to cover a large number of projects, however it may ignore details or specific issues for individual open source projects.

The open source model can dramatically affect changes in the traditional ways of software development. Table 2 lists some relevant issues that arise with open source development.

.

KEYS TO UNDERSTANDING THE OPEN SOURCE DEVELOPMENT MODEL

Despite the debates, critiques, and the evident enthusiasm regarding the Open Source Development Model, without any doubt, it is becoming a recognized paradigm that competes with the traditional methods of software development and is expected to grow in the future. To understand this phenomena, several essential attributes

Table 2. Issues that arise with the Open Source Development Model

- *Reliability:* Whether software developed under a model different from traditional carries same or higher reliability.
- *Licensing:* Licenses under which open source software products are distributed. How terms and conditions are phrased.
- *Release Management:* The rapid evolutionary open source model requires unique version control, release distribution, and management.
- *Quality Assurance:* What traditional QA methods and open-source-specific mechanisms (e.g., user contribution) are leveraged to insure quality.
- *Adoption:* How open source products are adopted by people and organizations outside of the open source community.
- *Documentation and Maintenance:* Due to the voluntary nature, attention should be paid on later development tasks such as documentation and maintenance offered to users.
- *Project Management:* Efforts are needed to keep the project stable and attract as many contributing users as possible to improve the software.
- *Collaboration Tools:* Without effective collaborative tools and environments, it is impossible to complete projects as a virtual team.

of the Open Source Development Model must be observed, including motivation to contribute, development process and quality assurance, communication methods, and user collaboration.

- *Motivations to Contribute*—It is sensible to understand the open source model by trying to understand the motivations of contributors who are willing to develop software and give it away for free. Zhao and Elbaum (2003) discovered that open source projects are started mainly for personal needs, community needs, and company needs. In a more focused study on this topic, Hars and Ou (2001) identified two types of motivations that account for people's participation in open source projects. These are internal factors that include intrinsic motivation, altruism, and community identity, and external factors that include future rewards (i.e., selling products), human capital, self-marketing, peer recognition, and personal need. Lakhani and Hippel (2003) also find that an opportunity to lead is also a motivation for developers to contribute. A recent survey study (Zhao & Deek, 2004), designed specifically for open source users, found that in user groups, most of the users are motivated to contribute by personal needs, followed by having fun and employer needs. Also, the same study verified that learning is a major benefit that users receive by contributing.
- *Communication Methods*—Open source development is a success story of collaborative development through computer-mediated virtual communities such as sourceforge.net. That is also a reason why open source projects attract contributors from all over the world. Web-based collaborative tools enable developers and users from different locations to coordinate and collaborate on development tasks. However, current collaboration environments are still largely facilitating technically oriented tasks (e.g., version control) instead of socially oriented ones (e.g., group decision making). Future trends of computer-mediated collaboration methodologies in open source development are likely to expand towards the socially oriented direction.
- *Development Process and Quality Assurance*—Unlike with traditional or commercial software development, open source projects are less formally organized in terms of following certain process models. Similarly, quality assurance activities are carried out in a less formal ways (Zhao & Elbaum, 2003). The rapid release and evolution of software raises some discussions on the analogous relationship with the eXtreme Programming model. Although there are a large variation in terms of how the evolutionary processes are managed in different projects, Zhao and Elbaum (2003) present many interesting findings relating to the lifecycles of a broad range of open source projects. For example,

43% of projects have a new release every month, around 75% of projects use configuration management tools, and when projects become more mature, the tendency of serving different users changes gradually. There is a belief, however, within the open source development community that extensive user inspection and contribution is a good remedy for the lack of formal development processes. However, we expect to see formal quality assurance activities in open source development, as more commercial IT players join in the open source community.

- *Extensive User Collaboration*—In a recent study, Zhao and Deek (2004) found that open source users are highly knowledgeable in software development at a level that is comparable to "core" developers. In other words, the projects are supported by a much larger group of experienced developers in the "background." However, this type of support occurs more often in large open source projects. The majority of open source projects are small in scale, lack sufficient user support, and are like smaller, start-up companies in the commercial world. The key for the growing of these small projects is to attract more developers and users; to achieve this goal, it is critical to understand motivations of users and use mechanisms to fulfill their needs (e.g., providing learning opportunities).

FUTURE TRENDS

There is no doubt that the open source development process is becoming more and more mature when researchers and practitioners gain deeper insights into this unique model. Future research on this topic includes attracting user contributions, providing better communication support, knowledge sharing within open source communities, overcoming language barriers, providing learning opportunities for participants, and the impact of commercial software vendor involvement.

CONCLUSION

The open source development model is an evolving effort. Participants with various skills, interests, needs, and geographic locations are able to take part and collaborate to produce powerful and free software, although there remains a host of issues to be understood and resolved by researchers and practitioners. We urge the readers to view and understand this model from four key aspects: motivation, collaboration, process, and user collaboration.

KEY TERMS

Computer-Mediated Communication: The process by which people create and exchange information using networked systems that facilitate encoding, transmitting, and decoding of messages.

Open Source: There is no universally accepted definition, but the one given by the Open Source Initiative summarized the concept as: free distribution, source code, derived works, integrity of the author's source code, no discrimination against persons or groups, no discrimination against fields of endeavor, distribution of license, license must not be specific to a product, license must not restrict other software, and license must be technology neutral.

Open Source Developer: Software developers who are core members of open source projects. They either initiated projects or joined in subsequently as major contributors.

Open Source Users: Individuals interested in open source software and willing to contribute by different means. Unlike open source developers, open source users are more heterogeneous in background, less committed to projects, but provide major impetus to software improvement.

Software Process: Methodologies offering guidelines for improving software engineering performance by requiring developers to adopt a disciplined, structured approach to building software systems.

Software Quality Assurance: Methods and approaches to ensure that a software system meets specified requirements, and customer or user needs or expectations.

User Collaboration: Voluntary collaborative efforts from users in developing open source software. The collaboration includes looking for bugs, suggesting new features, reviewing/submitting source code, documentation, and offering project administration assistance.

Optical Music Recognition with Wavelets

Susan E. George
University of South Australia, Australia

INTRODUCTION: SUPER-IMPOSED OBJECTS

The aim of optical music recognition (OMR) is to "recognise" images of music notation and capture the "meaning" of the music. When OMR is successful it will be able to automatically extract a logical representation of printed or handwritten music captured in an image. There are a variety of reasons why OMR is required. Chiefly, it is convenient for swift input of music notation and might be subsequently edited, performed, used as a search or other. There are many stages before that final high-level interpretation can be made and recognition of the primitive symbols contained in the notation is primary. One of the biggest challenges in OMR is the super-imposition of music notation symbols – notes and other – upon stave lines in the music image. This article examines a general-purpose knowledge-free method in the wavelet transform, to deal with super-imposition in images of typeset music.

Super-imposition arises when notes and other music symbols are placed upon the stave line (or staff), making "ink" of the symbol overlap with "ink" of the stave line. There are various reasons why isolating the super-imposed object is so difficult within OMR. Firstly, image capture may have introduced perturbations; stave lines in the image are rarely parallel, horizontal, equidistant, of constant thickness, or even straight. Secondly, other symbols within the music (such as beams, phrase marks and others) can be mistaken for stave lines and hence lines mis-located. Thirdly, there is only one piece of "ink" for objects that are super-imposed upon the lines and stave lines have to be extracted, leaving the symbol intact — or conversely the symbol has to be segmented from the stave line, having identified its location within the stave.

The OMR field has taken two basic approaches to dealing with super-imposed objects. These approaches are (i) the removal of stave lines and (ii) the recognition/segmentation of music symbols. Neither of these methods has met with complete success. When focusing upon the segmentation, difficulties specific to music notation arise, including (i) the variant size of symbols (e.g., phrase markings, slurs) rendering template matching inappropriate and (ii) the various ways of typesetting a particular musical sound are potentially infinite, and again template matching would not suffice for all the possibilities.

Since the 1960s there have been various approaches to dealing with super-imposed objects. All of these approaches are knowledge-based techniques, in that they are assuming some information is known about the format of music images in order to locate the stave lines or isolate symbols. Blostein and Baird (Blostein & Baird, 1992) present a critical survey of problems and approaches to music image analysis. Here we summarise some of the approaches to OMR from the initial attempts in the 1960s.

- Pruslin (1967) - remove thin horizontal lines (by thresholding the length of continuous vertical runs of pixels, assuming that a figure for "line thickness" was known)
- Prerau (1975) – remove stave lines and restore those parts that coincide with symbols (using a contour trace from the edge of each stave line to locate the start of symbols that might be placed on those lines).
- Nakamura et al. (1979) – remove stave lines using line tracker, calculating a least-squares fit for stave lines computing threshold to erase the stave lines and achieve segmentation.
- Andronico and Ciampa (1982) - remove just the exposed stave lines.
- Aoyama and Tojo (1982) – detect stave lines by using the horizontal histogram of black pixels within each block of low resolution scan lines and using a threshold to find sets of five peaks. Coarse segmentation was then undertaken, removing obvious, exposed sections of stave line by examining the vertical run-lengths involved. Fine segmentation detected black and white noteheads by searching for overlapping pixel runs.
- Mahoney (1982) - isolate symbols from stave lines, interpolating between end-points where there were gaps.
- Matsushima et al. (1985) – detect stave lines by a short bar-like filter that operated down equi-spaced columns in the image, simultaneously with the scanning process.
- Roach and Tatem (1988) – detect stave lines with a line-tracking algorithm calculating line direction and thickness at each pixel in a grey-scale image by

passing a window of appropriate proportions over the image. They have also considered the specific challenges of handwritten music.

- Brainbridge and Bell (1997) – determine presence of stave lines by following the wobble in groups of pixels and remove with heuristics.
- Lin and Bell (Lin et al., 2000) - propose colour printing and scanning technology to help deal with the issue of super-imposed objects.
- Choudhury, DiLauro et al. (2001) – remove staff lines using projection profiles, remove text by heuristics, vertical components of stems and barlines and horizontal components of note heads, recognising the remaining symbols with K-NN classifier combing the glyphs again.
- Droettboom et al. (Droettboom et al., 2002) - describe the use of classifiers for symbols recognition, providing tools for the creation of a simple heuristic classifier, a template-based image matching and a k-nearest neighbour learning classifier.

All these approaches have met with some success and various limitations. Perhaps the biggest limitation is that they are knowledge-based, requiring specific knowledge about music to isolate the symbols, or follow stave lines. Implicitly, knowledge-based techniques are constrained by the knowledge that they may draw upon. For example, a symbol finding algorithm can only find symbols that it knows about, and should a new symbol be encountered within the music notation, the recognition is likely to fail. Similarly, a stave line tracking algorithm is constrained by heuristics about how stave lines generally appear, or in what ways they may be corrupted. When knowledge is explicitly utilised, at some point, a novel input will be encountered that falls outside the scope of the knowledge-based method (this is especially the case when dealing not with "printed" documents, but handwritten ones). Hence the importance and appeal of general-purpose knowledge-free methods.

BACKGROUND: WAVELETS

Wavelets are a relatively recent mathematical approach extending some of the principles of Fourier analysis for the study of periodic signals, decomposing a signal into its component parts. Wavelet theory is well suited for complex signals, where the frequency structure changes throughout the signal (i.e., non-periodic signals). Since very few signals or images are truly periodic, wavelet techniques are ideal. Wavelets permit the signal to be viewed so that the large-scale fluctuations are emphasised (with the small detail as noise), or such that the small fluctuations are emphasised (with the larger scale fluctuations as background). Interest in wavelets is also stimulated by the fact that some wavelets may be implemented in an extremely computationally efficient manner.

The wavelet is defined by the "mother wavelet" from which other wavelets in the "family" can be generated. All members of a particular family share the same basic wavelet shape that is shifted or dilated (*i.e.*, they are made tall and skinny or short and fat). The specific parameters are translation ('b') and contraction ('a'). Members of an individual wavelet family y ^{a,b} (x) can be defined by (1):

$$\psi^{a,b}(x) = |a|^{-1/2}\,\psi\left(\frac{x-b}{a}\right) \qquad (1)$$

Equation 1 generates a one-dimensional function that can be plotted. There are a number of families of wavelets including Harr, Daubechies, Coifmanns, Mexican Hat, Meyer and Morlet. The coefficients in the wavelet transform are an important part of the wavelet expression since (combined with the generating mother wavelet) they compact the signal and can be used to approximate a function. Instead of having to store every value of the function, it is only necessary to store the coefficients, perhaps at various levels of decomposition, and from these the signal can be obtained. Two-dimensional wavelets can be applied to two-dimensional signals; that is, the wavelets are applied to images.

In terms of general image processing, wavelets decompose images into their high and low pass components in row and column-wise directions, thus filtering an image into its component parts. There are four combinations of low pass filters (H1 and H2) and high pass filters (G1 and G2) in the vertical (H1 and G1) and horizontal (H2 and G2) directions. These decompositions are typically represented in quadrant diagrams where the top left quadrant contains an approximation of the original image, the top right contains the horizontal components, the bottom left the vertical components and the bottom right the diagonal components.

When considering wavelet image decomposition, it is worth observing that the music image possesses certain properties, including: (i) the music stave lines – which present a strong horizontal component to the image signal and which are (generally) regular across the image page, (ii) other music notation symbols - which present a more vertical component and are more local perturbations within the image; wavelets are particularly useful for such local irregularities within an image, and some wavelets may be more suitable than others for the regular/irregular patterns that occur within a music image.

WAVELETS IN OMR ANALYSIS

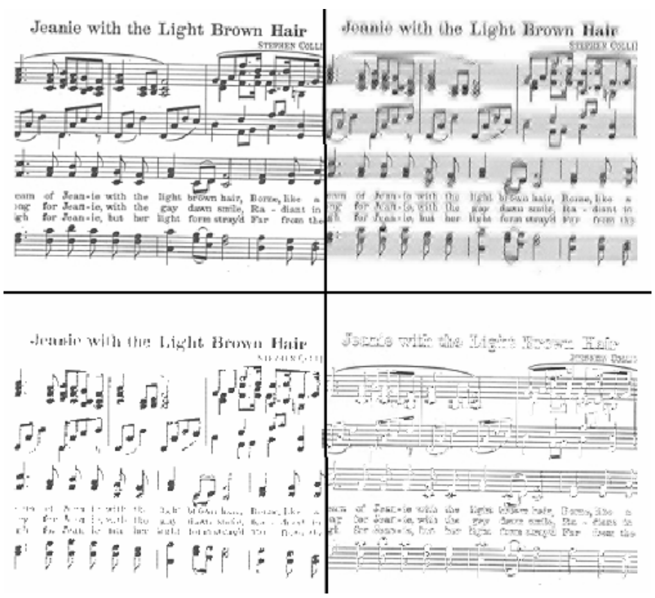
Wavelets represent a general-purpose knowledge-free method of image filtering that is capable of separating super-imposed objects. They provide a fresh (theoretical) perspective on the problem of super-imposed objects in music notation; recognising the duality of the segregation task that exists with stave line removal/symbol extraction. The wavelet provides a unified theoretical framework within which to deal with super-imposed objects in OMR.

Recent results (George, 2004) have found that they are able to segregate the super-imposed components for stave line removal and symbol segmentation, finding that the Coifmann family are most suitable for emphasising vertical image components and the Daubechies for the horizontal. Evaluation is conducted at a pixel-based level using a truth representation of the image to evaluate the accuracy with which symbols are identified.

Figure 1 illustrates a 256 x 256 binary image filtered with the Daubechies wavelet. The original image appears in the top left; the filtered image (top right) has been blurred in the horizontal direction, making the stave lines and other horizontal components less distinct. The bottom left quadrant contains the thresholded transformed image, showing how the cut-off has removed the lighter blurred pixels from the image (these are precisely the stave lines, leaving chiefly the notes in the filtered image). The bottom right quadrant illustrates the difference between the original and the thresholded transformed image, showing the areas of overlap between notes and stave lines.

One of the first questions that arise with the application of wavelet transforms to super-imposed objects within music is the question of evaluation. That is, the question of "how can we know whether a wavelet transform has been of any benefit to OMR?" Fundamental to evaluating accuracy is some target "truth representation". For images, the target representation is another image and a pixel-based measure can be made comparing the filtered image with the target, eventually attaining a sensitivity/specificity measure for how well the filtering has "diagnosed" black/white pixels in the image.

Figure 1. Example of wavelet filtering



Locating Stave Lines

We can demonstrate that stave lines can better be detected in a wavelet filtered version compared to the original image. Various music samples were captured, including: stave lines interspersed with text, small font inserted staves, incomplete staves and skewed staves, as illustrated in Figure 2. These examples present special challenges to conventional stave line finding methods.

Stave lines are located in the original image and the wavelet transform using a simple pixel histogram along the rows to locate where the peaks and troughs of black pixels are. The pixel histograms of the original and transformed image are compared. The presence of peaks in the histograms indicates where there is a strong horizontal signal in the image. Ideally, for locating stave lines there will be five such peaks close together. This characteristic peak is most clearly seen in the filtered images rather than the original images, suggesting that whatever stave line finding algorithms are used, the filtered image provides a clearer starting base. For complete details of the experiments see George (George, 2004).

Segmenting Symbols

Similarly, we can demonstrate that the wavelet can help in isolating the symbols superimposed upon the lines. Three music fragments were selected, containing a varying amount of detail across the image, as illustrated in Figure 3. From these music fragments six images were generated, capturing the image at 150, 250 and 350dpi in binary and grayscale modes. For each of these images a truth representation was constructed by hand, separating the stave lines from the music symbols that appear upon them.

The Daubechies-3 wavelet transform was applied to each of the images in turn, isolating the horizontal and vertical components of the image and the filtered image compared with the truth representation containing the segmented symbols. The results suggest that image 2 (containing just a few bars) was the easiest image to deal with since the average sensitivity was 0.65 and specificity was 0.75 over all the image capture parameters. The hardest image was image 3, with average sensitivity of

Figure 2. Examples for stave line locating

0.31 and specificity of 0.78 over the image capture parameters. However, it was determined that a pixel-based evaluation may be misleading since pixels in the filtered image may simply be shifted left or right and cause a low index in the quantification, although in reality the filtering has benefited the isolation of symbols from the horizontal components.

CONCLUSION

We have found that it is possible to provide a unified theory for dealing with super-imposed objects in OMR, since both stave line location and symbol segmentation can be addressed by the same technique – that of wavelet filtering. As a knowledge-free, general-purpose image processing technique, wavelet filtering makes it possible to emphasise certain features of the image using the image decompositions.

We observed that (i) the horizontal pixel histograms made stave lines easier to detect in the filtered image. Stave line finding algorithms may want to use the filtered image rather than the original to improve upon their results; (ii) the accuracy of detection for segmented music symbols appeared better in low resolution binary images, but this was mainly due to the amount of "ink" involved in the pixel-based accuracy evaluation (which was made between the truth representation and the filtered image). Nevertheless, filtering the image to isolate the non-stave line components emphasised a feature that was not so obvious in the original image.

At present, wavelet filtering is likely to be most practically useful as a pre-processing method to emphasise certain features of the images for conventional OMR methods. However, there is scope that it may be used in isolation as a knowledge-free OMR procedure for super-imposed objects that can isolate notation symbols from stave lines. We consider that further work is required to continue the investigation of the wavelet as a knowledge-free, general-purpose image processing technique for OMR that is able to provide a unified theory for super-imposed objects.

KEY TERMS

Knowledge-Free Image Processing: A general method of dealing with an image that does not require specific information or data. The image is simply filtered, typically uniformly, and so transformed or processed without the need for knowledge-based methods.

Optical Music Recognition (OMR): OMR is the recognition of images of music notation in such a way that the "meaning" is captured.

Stave lines/Stafflines: The five horizontal lines upon which symbols of music notation are placed.

Super-imposed Object: Super-imposition is an image processing problem that occurs in music notation as music symbols are placed upon the stave lines. Separating the symbol from the lines becomes an important task in most approaches to recognition. Approaches either attempt to remove the stave lines or segment the music symbols.

Wavelets: Wavelets are a relatively recent mathematical approach extending some of the principles of Fourier analysis for the study of periodic signals, decomposing a signal into its component parts. Wavelets permit the signal to be viewed so that the large scale fluctuations are emphasised (with the small detail as noise), or such that the small fluctuations are emphasised (with the larger scale fluctuations as background).

Organization and Management Issues in End User Computing

Jason C.H. Chen
Gonzaga University, USA

Robert W. Holt
Gonzaga University, USA

D. Bruce Sun
California State University at Long Beach, USA

INTRODUCTION

End-user computing (EUC) or as it is commonly termed, end-user development (EUD), is a concept and capability granted by advancement in technology that allows participants in a business environment to utilize information technology (IT) by developing applications of their own. Traditional methodology required a software program to be developed by trained programmers in the analysis and design stages of the systems development life cycle, where a user had to accept the program as an individual entity with unalterable characteristics. EUC/EUD now enables this person to customize the program around his/her specific demands. The framework of EUC establishes empowerment and capabilities so that anyone can develop entire information systems (IS) with little or no help from professional systems analysts or programmers, along with accessing data and creating reports (Laudon & Laudon, 2003). EUC/EUD is a topic in the IT environment that cherishes a progressive history spanning from the mid-1970's to what it as today.

BACKGROUND

During the 1970's, the concept of management information systems (MIS) began which grounded the importance of utilizing IT as a strategic implementation tool in changing business environments. The event produced a two-fold outcome where generalized perceptions about computers changed to include the relevance and effective usage of data to direct most business decisions, and technological ideology shifted from an information specific denomination to a belief towards support management. (Charr, 1988). Once support management became recognized, a paradigm occurred where decision support systems (DSS) became the focal point of MIS integration. The new paradigm conceptualized the computer as a necessary tool for the decision making process in accordance with its data storing properties.

EUC has become increasingly more available, due to the induction of less complicated programming languages, termed fourth-generation languages (4GL's), that provide users who may not have a sufficient skill and knowledge of programming expertise, to develop programs, customized to their individual needs. These specific languages signify simplicity, since most users already have an intuitive understanding of the logic and terminology. They are frequently referred to as user-friendly and nonprocedural, which determines that the languages must be given less structured instructions to achieve the same result as earlier capabilities (Charr, 1988). Their relevance to EUC is significant because earlier languages, such as assembly or procedural language, required a high level of education to interpret the meaning of codes and to produce the desired outcome with the program.

From a technology perspective, when the last three decades are crucially examined on how EUC has gained its prominence today, three defining events are attributable for this outcome (Charr, 1988). First, is the success of computer engineering to derive programs which grant users, whom are not skilled computer programmers, to manipulate and maintain the software; second, computer training is now a skill that everyone must have to enter the job market, so everyone must demonstrate proficiency in this area; third, the huge growth in the evolution of the use of computers has drastically decreased costs of hardware and software (Charr, 1988). When these three forces are evolved, it is obvious how EUC has radically gained in recognition and how progressive computer technology has grown to what we know and use today.

The computer has developed into a commodity as common as any household item, like the food processor or even the vacuum cleaner. Despite slightly higher costs, people all over the world are finding the investment increasingly beneficial. The number of things one can accomplish in the comfort of one's home, even with a little PC, is incredibly large. Hence, it is no surprise that the term EUC has earned its position in the world of computer jargon.

Management Issues of EUC

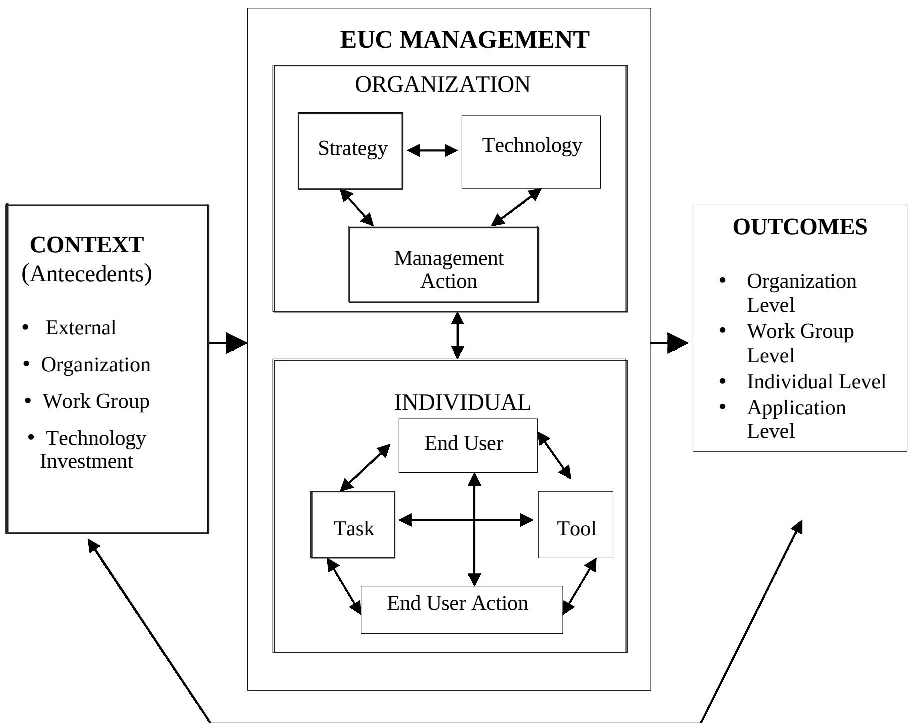
Even with the popularity of EUC, the greatest debate substantiated through this capability is: how much will a business benefit from this process, and can certain disadvantages be posed to limit the effectiveness of EUC implementation? This paper is structured to further provide a background on the evolvement of EUC, based in part on research conducted by Brancheau and Brown (1993), to establish a framework which will finally provide the necessary information and address important management issues and perspectives on EUC.

EUC Management Model

EUC can be defined as "the adoption and use of IT personnel outside the IS department to develop software applications in support of organizational tasks" (Brancheau & Brown, 1993). The content of Brancheau and Brown's study was generated from different journal articles and upon conclusion of their findings they developed a model, incorporating all of the aspects identified with EUC (see Figure 1).

The model includes three major components: antecedents (contexts), behavior (EUC management) and consequences (outcomes). EUC management is further divided into two customized sections, organizational EUC management and individual EUC management. The organizational part of the model represents the planning, organizing, staffing, directing, controlling, supporting, and coordinating functions associated with EUC management. As the model depicts, three relationships occur involving strategy, technology, and management action. Four factors are incorporated within the individual EUC management: the end user, task, tools and end-user action. The antecedents incorporate those factors pertaining to external, organization, workgroup, and technology investment activities as related to the business. Through the integration of EUC, both individual and organizational management styles, four levels of outcomes occur, organization, workgroup, individual and application (Moore & Powell, 2002). With the background pertaining to this model, we propose that four management issues should be addressed: 1) what are the characteristics associated with End-User Computing? 2) what are the necessary tools needed? 3) what are the advantages gained through EUC? and 4) what are the possible risks and security issues associated with EUC?

Figure 1. EUC Management Model



What are the Characteristics Associated with EUC?

The characteristics of the EUC can be explored in three areas: applications, development skills and prototyping. The details are explained in the following sections.

End-User Computing and Applications

Early on, EUC was identified as a spreadsheet-oriented operation, repetitively calculating large quantities of data and then later graduated to incorporate operational systems throughout entire organizations (O'Donnell & Sanders, 2003). Approximately ten years later, from the mid-1990's and beyond when graphical user interfaces and 4GL's advanced in complexity, EUC was elevated to include large database systems, known as data warehouses, and Internet Web sites (O'Donnell & Sanders, 2003). The impact was delivered throughout the EUC establishment, where individual applications can now include a variety of group applications. EUC initially began as only an inter-organizational intermediary, but it can now be able to accommodate a wider spectrum of implementations, consisting of inter-organization and organization-to-customer based systems on the Internet (O'Donnell & Sanders, 2003; Christoff, 1990).

End-User System Development Skills

It is vitally important before a DSS is designed, that the end-user is first identified by the end-user developer. The end-user's applications have to be analyzed initially, based upon what they will do with the software and the technical knowledge that they possess. This establishment will govern how complex the program will be for the end-user's and customize it to fit their individual needs. End-user developers consist of three types (from the least to the most in complexity and technical skill level): menu-level developers, command-level developers, and end-user programmers (O'Donnell & Sanders, 2003).

Prototype Development

The characteristic that defines one of EUC's unique advantages is "flexibility," which basically explains its purpose in the technical software world and is encapsulated by the implementation of prototyping. To define prototyping's specific parameters, a prototype software program must meet these qualifications: quick to create, easy of change, inexpensive to build, and inexpensive to discard (Carr, 1988; Gelbstein, 2003). Advantages of prototyping are severely weakened if any of these requirements are not successfully met.

What are the Necessary Tools Needed?

End-users must have the necessary tools available to them, so that they can develop specific software satisfying their individual needs. The categories of tools consist of three major types geared toward specific requirements within the business. The three varieties include: office productivity tools, workgroup computing tools and application development tools (Bruni & Stigliano, 2003).

The objective of office productivity tools is to enhance the productivity of individuals, by providing computer support for common office tasks. Typical with the commonalities of the business sector, these tools include all of the relevant software applications, such as word processing, database management, spreadsheets, presentation graphics and other similar programs. With a click of the mouse button, the series of functions will orchestrate, illustrating a custom application on the user's worksheet.

In the office environment, the effectiveness of groups is widely understood with workgroup computing tools to support their specific needs. Specifically, the tools "support the efforts of groups of users working on related tasks," unlike office productivity tools, which are specific to a single user (Bruni & Stigliano, 2003). Examples of tools under this category include, but are not limited to: email, group calendars, workflow systems and other similar applications, providing for effective communication, among employees.

The final division of development tools that are vital for the successful implementation of EUC in a business are application tools. Application tools consist of four types: application generators, fourth-generation languages, application development environments and scripted web pages, functioning to "develop reusable programs with which end users create custom applications" (Bruni & Stigliano, 2003). Essentially, these are the most crucial tools of the three categories, since they support the capability for the formal development and maintenance of computer-based applications, along with software problem resolution and customer support.

What are the Advantages Gained Through EUC?

In today's environment, every corporate advantage that can be gained, invites the potential for greater revenue achievement, promoting a greater capture of market share. In respect to obtaining distinct advantages, EUC encourages another important behavioral application in addition to "flexibility," by increasing a program's "usability." There are many advantages for a usable software: reduced training costs, reduced support and service costs, reduced error costs, increased productivity of users, increased customer satisfaction, and increased maintainability (Hohmann, 2003; Holsapple & Whinston, 1996).

Based on the premise of EUC that the developer is also the user, a key understanding to what the end-user ultimately wants with the product can be achieved. Once the groundwork is laid out, product development can proceed as usual, with fewer modifications and/or errors.

What are the Possible Risks and Security Issues Associated with EUC?

Potential risks are involved in a system development with its integration into the company. Four main areas are: poorly aimed systems, poorly designed and documented systems, inefficient use of organizational resources, and loss of security (O'Donnell & Sanders, 2003; McLeod & Schell, 2001). It is logical to determine how each of these risks can limit success upon inviting EUC into the business atmosphere. The purpose of EUC is to mediate the software development problems that are associated with a poorly aimed, designed, and documented computing system, to provide the ultimate end-user with certain specified capabilities (Lucas, 2000). EUC is a system to provide for that allowance of software customization and enhanced programming communication.

It is evident that in today's world, there is always technical evolution occurring, between computer security systems, increasing in complexity to counteract the continual updated attempts by software hackers to disrupt the software information. This kind of "predator & prey" relationship is an ongoing process and certainly impacts and threatens the business and the EUC software applications. What is essential to know is that the consequences of a business not having EUC software can greatly outweigh the potential security aspect that looms over all types of software programs. Only the business itself can determine that decision and judge the possible outcomes it may encounter, depending upon which decision is chosen.

Costs/Benefits Analysis of EUC

The costs of EUC are evident and intensive studies have been completed to examine and determine what these costs entail. The research conducted by James, Ang, Joo-Eng and Shaw (2003) uncovers deep concerns involved in this type of application. They discovered that users without adequate technical knowledge did not conduct activities that required a greater degree of technicality. Furthermore, due to these inadequacies, these users "expected more from the PC, viewing it as a task enhancing tool" (James et al., 2003). These findings illustrate a very essential point relating to EUC which is regardless of the software program's abilities, if the employees lack the proper expertise to tap into these aspects of the program, the benefits of EUC will never be recognized.

No matter how well designed, constructed, and tested a system or application may be, errors or bugs will inevitably occur. The systems developed by the end users must be maintained, and the end users' knowledge and skills must be updated periodically as part of the maintenance. Along with training and maintenance, the end-user system will be operational if the organization moves to the next-level programming language or update its software applications and hardware.

The benefits of EUC software and its applications are profound, giving modern businesses the distinct edge on their competitors. This provides for a greater level of independence with each employee, so that they do not have to directly rely on a software specialist to solve these problems.

One specific characteristic of EUC is that end-users may work directly with software development specialists to organize and design applications which include attributes needed in the program but allows them the "flexibility" to make any necessary manipulations in the future. This benefit substantiates in a business only having to purchase one program which will adapt to a variety of applications, saving time and money.

PERSPECTIVES ON EUC

The applications of EUC are judged at two distinct levels based on which area in the software development process is effected, either the end-user or the IS specialist. Both of these perspectives are outlined below, detailing the importance of this capability for both constituents.

The End User Perspective

In what perspective do end users view EUC? Response to the growth in EUC has been extremely positive, especially from the perspective of the common end user. From Word Processors to Database Management Systems, and from Decision Support Systems to Executive Information Systems, EUC has broken down all barriers between the layman and the computer. The dependence on computers has grown tremendously. The end user perspective is inclined towards formal as well as informal means of computation.

The IS Specialist Perspective

From this angle, EUC has also had ample support. IS specialists initially would solve the layman's problems from start to end, generating the required output on the computer. With the growth in EUC, end users began gaining independence and so the IS specialists had to adopt the job of training end users, helping them gain some control over computing functions. Information Centers have cropped up in almost all computer-using organizations, where IS specialists perform a variety of functions, from hardware and software purchasing and maintenance to end user support and training functions. It has been argued many times that EUC might be a threat to IS professionals, but upon reflection, it seems unlikely. The end user would be someone whose career focus would be something different from technology itself. He would, however, be using technology as a career and would constantly be a source of assistance to the common end user. Hence, it is important to note the role played by the IS specialist in EUC and conclude that the two categories complement, rather than oppose each other (Alter, 1999).

FUTURE TRENDS AND CONCLUSION

With the continuing growth in technology and in the capacities of the computer, the trend for the future seems to be towards more emphasis on user-friendliness and ease of handling (Morre & Powell, 2002). EUC has an extremely positive future, even considering the general technology trends - the technology connecting the information resource to the end user. In the future, organizations would be better off moving towards an investment in IT as an integral part of the organizational constitution rather than considering it a functional cost. With such an attitude developing in the business world, EUC has a bright future with many expanding horizons. This would be due to the fact that IS/IT would become such an integral part of the creation and existence of organizations, and that ultimately its role would not have to be questioned or analyzed.

As it has been described in this article, EUC has an essential application associated with software development and customization that greatly increases a businesses competitive advantage upon implementation. Specifically, it reduces a business cost in relation to the fewer number of programs that as a result need to be purchased to maintain the corporation's vitalities. It seeks to further reduce time and complexities through the provision of manipulating software applications around an employee or department's individual needs. Although providing employees with this specific type of software poses the possibility for security problems, this risk is always a given threat with all software programs. The success of EUC is weighed heavily upon many variables, and various tools have to be available to expand on all of its capabilities. EUC software development can be made more efficiently, when the software vendor can establish a close link of communication with the final end-user and specifically identify and outline their requests. Perspectives on end-user computing have certainly been well supported among both the end-users and the IS specialists, rooting its existence in present day business strategies. Although its history has evolved in less than three decades, end-user computing has established itself in the IT environment and will only further progress to ever increasing heights in the future.

KEY TERMS

Database Management System (DBMS): A software program (or group of programs) that manages and provides access to a database.

Decision Support Systems (DSS): A computer-based information systems whose purpose is the support of (not replacement) decision-making activities.

End-User Computing (EUC): Direct, hands-on use of information systems by end user whose jobs go beyond entering data into a computer or process transactions.

End-user Development: The development of information systems by end users rather than information system specialists.

Hacker A very knowledgeable computer user who uses his or her knowledge to invade other people's computer through the computer network.

Information Systems (IS): A computer-based system helps people deal with the planning for, development, management, and use of information technology tools to help them perform all tasks related to their information needs.

Information Technology (IT): A computer-based tool (hardware and software) that people use to work with information and support the information-processing needs of an organization.

Organizational Hypermedia Document Management Through Metadata

Woojong Suh
Inha University, Korea

Garp Choong Kim
Inha University, Korea

INTRODUCTION

Web business systems, the most popular application of hypermedia, typically include a lot of hypermedia documents (hyperdocuments), which are also called Web pages. These systems have been conceived as an essential instrument in obtaining various beneficial opportunities for CRM (customer relationship management), SCM (supply chain management), e-banking or e-stock trading, and so forth (Turban et al., 2004). Most companies have made a continuous effort to build such systems. As a result, today the hyperdocuments in the organizations are growing explosively.

The hyperdocuments employed for business tasks in the Web business systems may be referred to as organizational hyperdocuments (OHDs). The OHDs typically play a critical role in business, including the forms of invoices, checks, orders, and so forth. The organization's ability to adapt the OHDs rapidly to ever-changing business requirements may impact on business performance. However, the maintenance of the OHDs increasing continuously is becoming a burdensome task to many organizations; managing them is as important to economic success as is software maintenance (Brereton et al., 1998).

An approach to solve the challenge of managing OHDs is to use metadata. Metadata are generally known as data about data (or information about information). Concerning this approach, this article first reviews the previous studies and discusses perspectives desirable to manage the OHSs and then provides metadata classification and elements. Finally, this article discusses future trends and makes a conclusion.

BACKGROUND

The hyperdocument is a special type of digital document based on the interlinking of nodes such as multimedia components and sets of data elements derived from databases. For digital document, metadata have typically been employed for the access to media- and application-specific documents, such as for information discovery (Anderson & Stonebraker, 1994; Glavitsch et al., 1994; Hunter & Armstrong, 1999). Also, most of the previous studies on metadata for hyperdocuments have also been interested in information discovery from a content-oriented perspective (Lang & Burnett, 2000; Li et al., 1999; Karvounarakis & Kapidakis, 2000). Especially, a set of hyperdocument metadata, the Dublin Core (Dublin Metadata Core Element Set) (Weibel et al., 1995; Weibel & Koch, 2000), has been paid attention to as a standard for Web information resources and also focuses on the information discovery. However, besides this perspective, for the OHDs metadata, the organizational perspectives also need to be considered to satisfy various managerial needs of organizations.

First, a process-oriented perspective needs to be considered. It is also pointed out that the perspective needs to be reflected on defining metadata of corporate digital documents (Murphy, 1998). OHDs as corporate digital documents are closely related to business tasks and information for them in an organization. Generally, corporate documents are produced in undertaking an organizational process (Uijlenbroek & Sol, 1997); furthermore, most businesses are based on, or driven by, document flow (Sprague, 1995). Thus, documents and business processes may be considered simultaneously in the analysis of a corporate information system (Frank, 1997). In this context, the OHDs may affect the speed of communications to perform business process. Accordingly, the OHDs should be designed to support collaboration among workers in business processes. Also, the OHDs can be rapidly improved to fit ever-changing business requirements.

Second, the metadata for OHDs are to be considered from a technical perspective. The system resources linked to the OHDs, such as program files and data components dynamically cooperated, are a considerable part of the organizational assets. The links between such resources and OHDs are very complex. Accordingly, managing the resources and the links through metadata can result in the efficient use of the organizational asset; the metadata related to the technical components can help developers change and improve the OHDs more efficiently.

Third, in the long term, the metadata role of OHDs should be extended toward organizational memory (OM), because organizational digital documents are a major source of OM (Murphy, 1998; Sprague, 1995). The OM techniques concentrate on managing an organization's information or knowledge of the past (Stein & Zwass, 1995; Wijnhoven, 1998). The metadata for OHDs need to play a critical role in managing a variety of histories in terms of business functions, communication mechanisms, technical artifacts, and contents. The memory may provide knowledge to support various decisions for controlling communication mechanisms in a business process, linking to the previous responsible workers, or maintaining the hypermedia applications.

Considering all the perspectives discussed previously, metadata roles for OHDs can be summarized in three levels--operation, system, and organization--as shown in Table 1. In fact, we believe that these roles can also be applied to other kinds of corporate digital documents.

METADATA CLASSIFICATION AND ELEMENTS FOR OHDS

Metadata classification can be perceived as a fundamental framework for providing metadata elements. According to the our perspective on the metadata for OHDs described in the previous section, the following categories of metadata need to be considered:

- *Content-dependent Metadata*: These metadata are used to enable understanding of the content of documents. The metadata include information that depends on (i) the content directly, and (ii) semantic meanings based on the content of the document indirectly.
- *Workflow-dependent Metadata*: These metadata provide information about workflow related to an organizational hyperdocument. These metadata are concerned with process-related factors such as workers, tasks, or business rules.
- *Format-dependent Metadata*: These metadata describe information on formats related to organizational hyperdocuments as well as hypermedia components such as nodes, anchors, interface sources, and database attributes.
- *System-dependent Metadata*: These metadata provide information concerned with storage- and software-related information on system resources such as hyperdocuments, interface sources, and databases.
- *Log-dependent Metadata*: These metadata describe information on the history and the status of organizational hyperdocuments.

Content-dependent metadata are essential for discovering information in OHDs. Workflow-dependent metadata can contribute to increasing the ability to control business processes through the efficient adaptation of OHDs to ever-changing organizational requirements. Format-dependent metadata can provide an understanding of the hypermedia features in terms of structures and operational mechanisms, so that they can be useful in the technical maintenance of OHDs. System-dependent

Table 1. Metadata roles for OHDs

Level	Metadata Roles
Operation	• Easy and fast access • Increased accuracy
System	• Interoperability under heterogeneous environment • Document maintenance • Document distribution
Organization	• Increased reusability of information and knowledge resources • Increased capacity of business management • Increased organizational memory

Table 2. Metadata elements of OHDs

Classifications	Elements
Content-dependent	[Document] Title, Description, Document Domain Name, Conceptual Attribute Name [Anchor] Name [Data Node] Title [Interface-Source] Name
Workflow-dependent	Task Domain Name, Task, Agent Domain Name, Agent Object Name, Business Rule
Format-dependent	[Document] Type [Anchor] Type [Node] Type, [Data Node] Property [Interface-Source] Property [DB] Physical Attribute Type
System-dependent	[Document] File Name, H/W Name, Location Path, S/W Technology [Data Node] File Name, H/W Name, Location Path [Interface-Source] File Name, Storage, Location Path [Database] Name, H/W Name, Location Path, Table Name, Table Type, Physical Attribute Name, DBMS Name
Log-dependent	Document Number, Version Number, Loading Date, Withdrawal Date, Update Date, Update Description, Director, Operator

metadata can also play a critical role in technical maintenance by providing information on hardware and location, and software technologies applied to the hyperdocuments. This meta-information is essential for sharing and reusing system resources. Finally, log-dependent metadata may contribute to organizational memories. Thus, the metadata in this category should be specified in order to capture the history of OHDs. According to this classification, detailed metadata elements may be specified under the classification suggested in this article, as shown in Table 2.

Content-dependent classification consists of elements that enable users to understand the content of the hyperdocuments. The document domain may be in terms of content and roles. The conceptual attributes, as data items represented on a hyperdocument, are connected to a corporate database. Interface sources are primarily multimedia components such as image or animation that are represented on interfaces.

A node, an essential factor of hypermedia, has been defined as the fundamental unit of hypertext (Nielsen, 1993), fragments of information (Fluckiger, 1995), or basic information containers (Schwabe & Rossi, 1994). This article defines a node as any navigational object with hyperlinks. An object may a type of media, such as image, sound, animation, or a hyperdocument itself. Nodes may be categorized into two types from the perspective of their properties: document nodes and data nodes. Nodes are also of two types from the perspective of link directions: source and destination. The fundamental definitions for nodes are summarized in Table 3.

An interface may consist of one or more hyperdocuments. Accordingly, a document node, a hyperdocument, can be either only a part of an interface or an interface itself. From these definitions, the element of node type in format-dependent metadata may take a document node or data node as its value.

The information of a hyperdocument in terms of a process can be obtained effectively by the use of a document-based workflow concept. The workflow con-

Table 3. Types of nodes

Perspectives	Types	Descriptions
Properties	Document Node	A unit of an HTML document, which may be a whole interface or a part of it.
	Data Node	A unit of multimedia data that may be accessed from a document node.
Link Direction	Source Node	Nodes that can access a current node.
	Destination Node	Nodes that a current node can access.

cept typically includes common essential factors in terms of a unit of a work, a tool of a work, and a person for a work (Lee & Suh, 2001). In the document-based workflow approach, an OHD is regarded as a tool of a work. A task, as a work unit consisting of a workflow, may be described as operations or descriptions of human actions with a hyperdocument. An agent refers to a person who performs the task, and is expressed by hierarchical status in an organization. An agent domain can be defined as a group of agent objects having common tasks or organizational objectives. The agent domain can be typically conceived as a department of an organization. The task domain is a set of tasks corresponding to an agent domain.

The format-dependent metadata are concerned with type or properties of hyperdocuments, anchors, nodes, interface sources, and databases. The types of anchors can be static or dynamic depending their value. The definitions of these types are as follows:

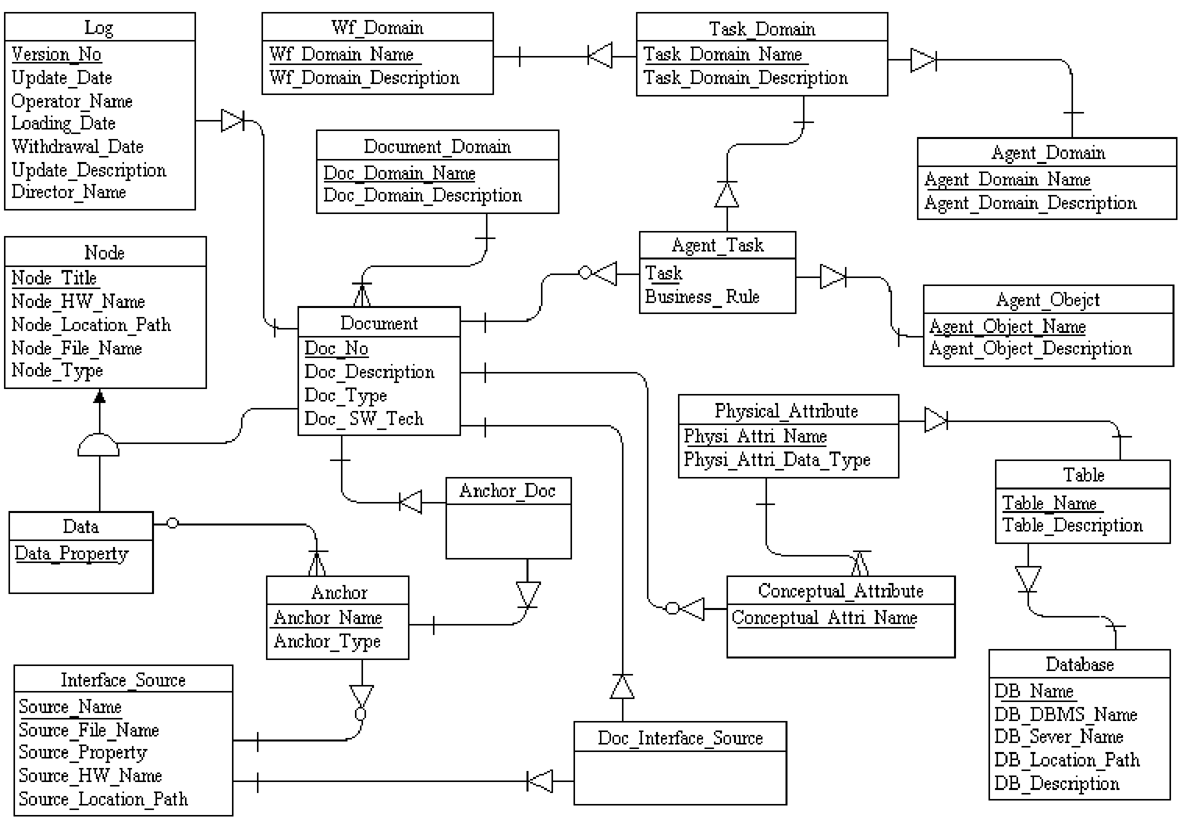
- *Static anchor:* One fixed in a hyperdocument.
- *Dynamic anchor:* One generated by data stored in a database; that is, it refers to data transformed into and represented as an anchor when the data are accessed by a hyperdocument according to any event that occurs as a function or another anchor.

The types of OHDs can be categorized into three: control, processing, and referential, according to their roles in a hypermedia application. These types are defined as follows:

- *Control Type:* Hyperdocuments that typically guide users to other hyperdocuments of processing or referential types. Homepages or index pages are examples of this type.
- *Processing Type:* Hyperdocuments that typically contain data attributes connected with a database in the style of a form.
- *Referential Type:* Hyperdocuments that provide supplementary information about work instructions, business rules, news, or products.

Properties of interface sources are multimedia properties such as images or animation. The properties of data nodes are the same as those of interface sources. The

Figure 1. Metadata DB schema of OHDs



physical attribute type of a database implies the data properties of the attribute.

System-dependent metadata focus on storage-related information. The storage-related information can be found in various applications, but they are not integrated, so it is difficult to create a synergetic effect. However, if metadata of all the components of hypermedia systems, such as hyperdocuments, data nodes, interface sources, and databases, are integrated into a repository, it is possible to manage a hypermedia system effectively. Software technology is a major factor in determining the capacity and characteristics of a system. Recently, for example, a variety of emerging software technologies, such as ASP (Active Server Page), Java scripts, Visual Basic scripts, or Perl, have had a considerable impact on the improvement of hypermedia systems. Accordingly, the information on software technologies applied to a hyperdocument may contribute to the maintenance of a hypermedia application.

Log-dependent metadata are used for tracing the history of hyperdocuments for the maintenance of their system. Although there may be log information captured automatically by an operating system or an application program, it is typically separated, so it is difficult to obtain a synergetic effect in maintenance. Furthermore, it is insufficient to maintain a hypermedia system effectively. Therefore it is necessary to capture the information about changes of hyperdocuments synthetically. Some hyperdocuments may be operated temporally, depending on their purposes. Accordingly, version- or time-related information should be managed. The loading date is a date pushing a hyperdocument into its system. The withdrawal date is a date removing a hyperdocument from the system for the expiration of its periodic role or for updating. Information on responsible operators and directors for a hyperdocument may be required for responsible management, or questions by new staff members.

The metadata elements in Table 2 can be designed as shown in Figure 1. The schema was implemented in a meta-information system for the maintenance of OHDs (Suh & Lee, 2002). The system consists of two main modules: metadata management and a supporting module. The metadata management module is responsible for metadata handling such as creating, editing, or deleting. The supporting module serves two types of functions: searching an OHD and reporting its meta-information.

FUTURE TRENDS

Concerning the challenge to cope with a flood of OHDs, today content management system (CMS) is drawing great attention; the market size of content management solutions are forecasted to grow explosively (WinterGreen Research, Inc., 2003). CMSs help organizations develop Web applications, and support content lifecycle including the following phases: creation, approval, publishing, deployment, delivery and removal. Now, CMSs are conceived as an essential infrastructure for not only developing but also maintaining Web applications; most Web projects include implementing CMSs along with Web applications. Furthermore, CMSs are often incorporated into the existing infrastructures of Web applications to support the maintenance of the applications.

The lifecycle of content is supported primarily by the engines of workflow and personalization on the basis of a repository that includes the metadata as well as actual content. The metadata are a critical component required to operate those engines and other functions of CMSs, so their importance has been addressed (Perry, 2001). In fact, current CMS solutions originate from some different backgrounds, so that the functional features and metadata schema are also different from each other. Accordingly, in the near future, the metadata standard may be required in the CMS solution industry as it has been in other application domains of information technologies so far.

CONCLUSION

Recently, many organizations have expanded their business workplaces through Web business systems. Organizational hyperdocuments (OHD), critical information resources, are growing explosively in such organizations. Accordingly, the maintenance of these documents is becoming a burdensome task. For this challenge, this article offers an approach based on metadata required from the managerial perspectives as well as content-oriented. The managerial perspectives address the adaptability of Web business systems to the ever-changing business requirements and the efficiency of developers' works. The presented metadata are expected to help manage organizational memory in the long term through implementation into a metadata-based system.

KEY TERMS

Guided Tours: A navigation type that leads users to a predefined trail of nodes without freely explorative navigation, using, for example, previous and next anchors.

HTML: HyperText Markup Language. It is markup language using tags in pairs of angle brackets, for identifying and representing the Web structure and layout through Web browsers; it is not a procedural programming language like C, Fortran, or Visual Basic.

Hyperspace: Information spaces interlinked together with hypermedia structures. Concerning World Wide Web, cyberspace is sometimes used instead of hyperspace.

META Tag: A type of HTML tags with a word, “META”. Web “spiders” read the information contained within META tags to index Web pages. The information consists of keywords and a description of its Web site.

Open Hypermedia: As a more generalized concept addressing interoperability among hypermedia services, it has the following characteristics: it should be platform independent and distributed across platforms, and users should be able to find, update, make links to, and exchange the information, unlike hypermedia titles on CD-ROM.

SGML: Standard Markup Language. Document standard from ISO (reference ISO 8897). It is a meta-language that can define document logical structure by using Document Type Definition (DTD) component. An example of document types defined using the DTD of SGML is HTML.

XML: eXtensible Markup Language. It is quite different from HTML in that XML gives document authors the ability to create their own markup. XML is flexible in creating data formats and sharing both the format and the data with other applications or trading partners, compared with HTML.

Organizing Multimedia Objects by Using Class Algebra

Daniel J. Buehrer
National Chung Cheng University, Taiwan, R.O.C.

WEB-BASED DEVELOPMENT

Web-based applications (Web services and service-oriented architectures) can be run via a Web-based browser. There are several approaches to writing such Web-based applications. A lightweight approach is suitable for hand-held devices. In this approach, a Java servlet or a JSP page (Java 2 Platform, JSP), or an ASP application (Microsoft .NET, ASP) generates HTML (Hypertext Markup Language), XHTML, or XML documents (W3C Semantic Web Activity, XHTML, XML) to be displayed by the browser. Most browsers use an anchored URLs extension (e.g., .doc, .jpg, .xml, etc.) to choose an appropriate plug-in to display the URL when it is clicked. Besides displaying text and multimedia, Web servers and/or browsers can also execute Java applets or scripting languages to read and/or change persistent data. Previously, about 98% of these data were stored in relational or object-relational databases. However, recently more of these data are being stored in XML-based documents. Often these documents have an associated "schema" declaring the nesting of tags and the types of primitive values, or an "ontology" (Everett et al., 2002, Hunter, 2003) declaring classes, attributes, and relations that are used in the document.

Databases, XML documents, and knowledge bases have traditionally been only a small part of a company's programming environment. The goal of most development environments is to use UML or entity-relation diagrams to analyze and design suitable classes, design patterns, and active objects from other existing ones. Web-based development environments (Stal, 2002) help us to find suitable classes, design patterns, and active objects on the Web, perhaps for a fee, or perhaps for a limited development time. That is, in the future, the development environment itself will be built on a distributed knowledge base.

Will there be a programming language, and will it still have explicit calls to SQL? Currently, scripting languages have their own unique means of accessing SQL databases, and the whole area of Web-based programming and multimedia networking has become quite messy (Weinstein & Gelman, 2003). Although J2EE's Container-Managed Persistency (CMP), JDO, and many object-relational development environments provide ways to hide SQL calls, security, and transactions, many applications may still choose to use the richer functionality of direct JDBC.

Web-based development environments, however, are forcing some changes in the way that persistent data are stored. Heterogeneous databases can be said to have failed to provide a sufficient platform for sharing data because of the difficulty in integrating so many SQL meta-data definitions. There was no "class hierarchy" to organize the definitions of the SQL tables, and small incompatibilities in SQL definitions often caused major headaches. Although ODBC and JDBC are now SQL standards, they permit various implementations of the meta-data, and they provide no standard way of "including" meta-data definitions from other "superclass" tables. In order to counter this lack of a class hierarchy in object-relational databases, the Semantic Web Project is proposing to use XML-based documents to share data and their declarations.

How will the Web-based development environments and their applications access Web databases? Will they access SQL, XML, or both? The answer is almost certain to be both, as well as other spreadsheets, natural language documents, and multimedia.

ISSUES IN INTEGRATING XML AND RELATIONAL DATABASES

As long as the application-tier, Web-tier or client-tier programs access the data via a standard interface, it makes little difference to the programmer if the persistent data are stored in SQL databases or XML files. This interface should take care of transactions (Ahamad & Chelliah, 2002) and security, sequencing set/get/add/remove calls from multiple users and doing load balancing and fail-over across multiple servers.

J2EE from the Java Community Process and Microsoft's .NET have the two major candidates for this programmer interface. One goal of these platforms is to hide the SQL and XML calls behind standardized set/get/add/remove calls for enterprise components. However, SQL programming and XML programming are currently fairly incompatible. There are several XML query languages for querying XML documents, and XSLT can be used to reformat XML documents. There are numerous XML schema mechanisms to enforce some type-checking, but higher-level schema mechanisms, such as RDF-Schema and OWL Ontologies (W3C RDF, OWL), are really needed before attribute and relation assignments can be strongly type-checked. OWL declarations essentially take the place of Corba IDL declarations, OMG ODL declarations, or SQL meta-data tables, by declaring ontology namespaces, a class IS-A hierarchy, attribute types and relation domains/ranges.

CLASS ALGEBRA'S ROLE

Class algebra (Buehrer, 2001; Buehrer & Chien, 2003; Buehrer & Lee, 1999; Buehrer, Tse-Wen & Chih-Ming, 2001; Buehrer, Tse-Wen, Chih-Ming & Hou, 2001; Buehrer & Wang, 2003) can serve as the theoretical basis for type-checking both OWL-based and SQL-based set/get/add/remove calls. Each SQL table is considered to be a class, and each line of the table is an object. The primary key of the object is used, along with the JNDI database service name and the table name, as a unique object identifier on the network. Each join of a foreign key to the associated primary key corresponds to a binary relation in class algebra.

For example, suppose that the user wants to find all images of Tom and his dog. One could locate Tom either by using the query @People{firstname= "Tom"} to find all people named Tom, or by following relations from his school, friends, or other objects to locate Tom. Then his pet dog(s) can be found by following the "hasPet" relation and limiting the answer to dogs. The intersection of the images containing Tom and the images containing his dog will be the images containing both Tom and his dog, as given by the query "query1@= @People{firstname= "Tom"}; query2@=query1.inImages @* (query1.hasPet @* @Dog) . inImages", where "inImages" is the relation from objects to the images that contain them and @* is the class intersection operator. These class algebra queries can be translated into SQL or XQuery, depending on where the data are stored. An interactive environment allows the user to search the IS-A hierarchy for a particular class, and then recursively constrain some of the attribute or relation ranges. The user can then combine various subqueries with Boolean operations, as given previously. The major advantage of class algebra queries is that the range is known. For example, query1 is People and query2 is Images. Therefore, all subclasses and their attributes and relations can be displayed when creating further queries. Moreover, a query may make use of the containment algorithm to optimize (Beneventano, Bergamaschi & Sartori, 2003) the processing of the query.

There are many details of the definition of class algebra that may be incompatible with various programming language typing constraints. For instance, in order to satisfy the laws of Boolean algebra, class algebra permits multiple inheritance, unlike Java and C#. Class algebra has tried to follow the Ontology Web Language, OWL, as much as possible. For example, attributes, relations, and methods are defined relative to an ontology name space rather than relative to a class. An object (or class) is permitted to be equivalent to other objects (or classes) that have different object (class) identifiers. For instance, anything known about "007" can be added to anything known about "James Bond," since they are names of the same concept (i.e., class). This facilitates sharing of equivalent objects and class definitions among organizations. The normalization process will replace such object (class) identifiers by a unique representative, and attribute and relation values will be merged together for this canonical oid (cid).

In relational algebra, the result of any operation is a relation. In class algebra, the result of any operation is a class. A class's "extent" is a DBTable, which is a collection of DBObjects. These are different from transient programming language objects, which can only be made persistent by serializing them as the value of an attribute of a DBObject. DBTables can have listeners that are guaranteed to hear updates to their contained DBObjects. The calls to get/set/add/remove DBObjects are implicitly queued as necessary to preserve ACID (atomicity, consistency, isolation, durability) properties of transactions.

A DBTable has methods for sorting, grouping, histograms, and report generation. It also has a "select" operation, which can choose a subset of objects that satisfy a given class algebra constraint, represented as a string (unlike J2EE "find" methods, which must be compiled). The constraint is first normalized to a "simplest" form. The simplest form is guaranteed to be computable in $O(n^3)$ time since it involves a simple sort of a transitive closure of Horn clauses that contain no explicit variables. A Prolog definition of the normalization process is available at *http://www.cs.ccu.edu.tw/~dan/fuzzyProlog.txt*.

As well as using the normalization procedure to optimize queries, the class "intents" (i.e., normalized constraints) are used to organize the definitions of classes into the class hierarchy. That is, the normalized class definitions are used to recognize when one class is a superclass of (i.e., contains) another, or when two class definitions are equivalent or have empty intersections.

Table 1. Advantages of semantic Web over object-relational databases

- Standardized ontology declarations are readable by both humans and computers
- Nested inclusions of classes, attributes, relations, and methods
- More compatible with UML, E-R development environments
- SQL tables become classes of class algebra
- Inter-database references use type-checked URIs
- Following a URI can be more efficient than doing a join
- Has implicit cascade deletes based on XML document nesting
- B-Tree and R-Tree indices can still be used for XML documents
- Knowledge-based rules can create implicit tables
- No limits on size of strings, integers, dollars, or floats
- Fuzzy-valued attributes, relations, and rules
- Java methods are sharable on servers and clients
- Security can use Horn clause rule-based policies

CONCLUSION

As persistent storage mechanisms become distributed across the Web, it becomes imperative that a class hierarchy mechanism be used to organize the meta-data of SQL tables. Relational algebra can be extended to class algebra to provide a theoretical basis for such a class hierarchy. This requires some changes of perspective. An SQL table then represents a collection of objects rather than a relation. Only binary relations are permitted, and these correspond to joins from foreign keys to primary keys, and vice versa for inverse relations. The JNDI name of a database service and a class (i.e., table) name can be added to a foreign key to let it represent a network-wide object identifier.

Using class algebra, a standard component get/set/add/remove interface can be used to update persistent data, whether that data reside on SQL databases, XML documents, or other files. The details regarding type-checking, security, caching, and transactions can be hidden beneath these calls.

If class algebra is integrated into the programming language, as is sometimes done with SQL, then type-checking can be done statically, as in J2EE or .NET. Otherwise, some overhead must be paid for the dynamic execution when type checking assignments or when de-serializing attribute values. The positive side of using dynamic type-checking is that there is no need for recompiling applications when new subclasses or relations are declared.

A static J2EE or .NET environment can be used to develop a class algebra service for DBTables and DBObjects, which can dynamically include other classes, relations, and methods from the network. In this approach an appropriate serialization write/read method must be called to make persistent/transient copies of attribute values of type “String”. The database then handles its own DBTable and DBObject type-checking, caching, transactions, update notifications, load-balancing, and so forth, without having to worry about any particular language’s primitive type declarations and serialization procedures.

KEY TERMS

Class Algebra: This fuzzy Boolean algebra can be used either to state necessary conditions (declarations) or sufficient conditions (queries). Because of the decidability of the containment of one class algebra expression by another, any set of class algebra expressions forms an IS-A hierarchy.

Closed World Assumption: The assumption that any goal that is not provable is false. For example, if the knowledge base cannot prove that there is a flight from Taipei to New York, then you can assume that there is no such flight. This assumption is used by most knowledge bases. For class algebra, which is decidable (i.e., membership in a class expression is either true or false for a given object), the closed world assumption corresponds to the "true-complement ~" operator. A "pseudo-complement -" operator is used in proving that something has negative evidence, but the pseudo-complemented predicates are treated like positive literals in terms of Horn clauses. The maximum proofs of positive and negative evidence produce a fuzzy interval for any class algebra expression.

Horn Clauses: A set of clauses in conjunctive normal form (i.e., a conjunction of disjunctions of literals) is a Horn set of clauses if each clause contains at most one positive predicate. That is, all literals are positive when written as Prolog clauses (Head:-Body), since the negated literals become a conjunction of positive predicates when put into the Body of the clause. When resolved with positive facts, such clauses can only result in new positive facts, and the complete set of such results is enumerable for Horn clauses, and is a unique "initial" (i.e., smallest) model for the clauses.

Initial Model: The unique set of unit consequents of a set of Horn clauses.

IS-A Hierarchy: This is a directed acyclic graph, where each node is a class, and each edge represents a "subclassOf" relationship from a class to one of its superclasses. In class algebra, the classes are labeled by normalized class algebra expressions.

Literal: A predicate or a complemented predicate.

Normalized Class Algebra Expression: A Boolean expression involving the basic class algebra predicates. The sorted leaf nodes of the non-subsumed proof trees basically form a Karnough map, which covers all assignments that could make the query true.

Subsumption: For clauses in conjunctive normal form, a clause C subsumes (i.e., contains) a clause D if there exists a substitution s such that the set of predicates of Cs are a subset of the predicates in D. The subsumed clause D may be safely deleted, as it adds nothing to the logical meaning of the conjunctive normal form in a Boolean logic.

Outsourcing Information Technology in Australia

Nicholas Beaumont
Monash University, Australia

INTRODUCTION

Outsourcing information technology (IT) has been defined as passing IT functions previously performed in-house to outside contractors (Hancox & Hackney, 2000). Outsourcing has spawned variants, especially insourcing—two departments of one organization formalizing their supply relationship.

Lonsdale and Cox (2000, pp. 445-449) summarize the history of outsourcing, noting that it substitutes for once fashionable enthusiasms for conglomeration, horizontal integration, and vertical integration. Williamson and Winter (1993) stress the role of transaction costs in all business decisions asking: Given that the market allocates resources efficiently, why do firms exist? They introduce the "asset specificity" concept; some assets have a narrow range of applications and have few or no potential buyers or sellers. The assets are inoperable without a cluster of peripheral assets, and high levels of skill and knowledge in the firm and its suppliers. There is no perfect market for such assets; investment in them is only practical in a planned environment that provides a guaranteed market for a high volume of very specific outputs and guaranteed supply of specific components.

Dealing in imperfect markets involves costs (such as identifying appropriate vendors, verifying their competence, communicating changing requirements to them, and monitoring their performances) and risks (of vendors failing or being unable to meet specifications). Deciding whether to outsource depends on comparisons of the long-term costs and risks of different modes of supply. A long-term outsourcing relationship with a trusted vendor (incorporating some price signals) may be preferable to securing supply by backward integration or developing an in-house capacity (possibly creating administrative complexity). An organization will always outsource some activities (water and electricity supply), but retain others such as strategic planning.

BACKGROUND

Outsourcing information processing (IP) functions has been facilitated by Web technologies that make it easy, quick, and cheap to transfer internal data (e.g., payroll data or delivery instructions) to a vendor. The vendor can analyze data and instantly transmit results to the client, employees' banks, and the tax office, eliminating time delay problems. Physical locations of the vendor and client are irrelevant for IP tasks; some kinds of outsourcing can be performed in low wage countries and/or a centralized facility that provides economies of scale. This is exemplified by the Asian call center and the payroll specialist whose volume (derived from many clients) allows exploitation of a high fixed-cost, low variable-cost technology and expensive expertise.

These fundamental considerations are manifest in many different motivations for outsourcing. A small organization might outsource a payroll application primarily to reduce costs by accessing economies of scale, but IT outsourcing decisions can be complex because IT applications tend to be integrated with each other and permeate the firm, touching most activities performed. The criteria used to evaluate outsourcing decisions may be multidimensional and intangible; besides cost savings (sometimes hard to ascertain), the firm must consider possible effects on customer service and its own staff; the potential advantages of access to expertise; and whether it might become uncomfortably dependent on the service provider (Kern & Willcocks, 2000) or hamper adoption to a changing environment.

THE AUSTRALIAN MARKET

In 2003, IDC (Allen & Langby, 2003) estimated that the Australian IS outsourcing market was approximately AU$3.85 billion in 2002 and would be AU$5.5B in 2007, a compound annual growth rate (CARG) of 7.4%. IT outsourcing represents "…over 10% of the total IT market and is growing faster than the total IT market." The market leaders—IBM GSA, EDS, and CSC—accounted for approximately 65-75% of the Australian IS outsourcing services market. Growth has slowed, the market is becoming more mature and competitive, clients are seeking shorter contracts and outsourcing specific tasks instead entrusting all their IT activities to a single vendor. Motivations include lower costs, higher quality, and focus on core competencies. Clients considering outsourcing were inhibited by potential loss of control, possible inability to resume running applications in-house, the complexity of protracted negotiations, loss of intellectual property, and security issues.

In 2001, Gartner predicted that (i) the value of the Australian IT services market would grow from $AU20 billion in 2001 to $AU 50 billion in 2004. (ii) By 2005, 25% of Australian organizations will not own their IT services or infrastructure, and (iii) the value of the Australian business process outsourcing market was $AU5.5 billion in 2001 and will grow to $AU15.4 billion by 2004 (Brown, 2001).

Robertson (2001) opined that "revenue from the Australian IT outsourcing market was $A1.3 billion in 1997, and projections to 2004 will push it up to $A5.3 billion, a CAGR of 16%." The increased use of IT outsourcing in Australia is exemplified by recent outsourcing decisions, some of which are listed in Table 1.

In 1998 the Australian federal government decided to force government departments to outsource their IT requirements. This initiative was a failure (Connors, 2001); the suppliers did not meet the users' requirements (wanting to apply one template to similar but distinct applications); the costs were excessive and the initiative was at least temporarily abandoned. In 1995, the South Australian state government initiated an ambitious "whole of government" 10-year/$AU1 billion IT outsourcing project with EDS. There are different views of the direct and indirect benefits of this contract to the state, but the consensus is that great effort from both parties produced marginal benefits. The more experienced state government would expect more benefit from any future outsourcing contract (Connors, 2004).

The few academic studies of Australian IT outsourcing include: Hurley and Costa (2001), a set of Australian cases; Costa (2001), an outsourcing literature review set in an Australian context; Beaumont and Costa (2002), a report on IT outsourcing; and Beaumont and Sohal (2004), a report on outsourcing in general. The author recently interviewed 10 senior executives of Australian vendors; insights from these interviews are used in this article.

REASONS FOR OUTSOURCING

Many writers have proposed research frameworks (Hancox & Hackney, 2000), criteria (Mamaghani, 2000; Smith & Rupp, 2003), and schemes for analyzing or assessing outsourcing (Bazinet, Kahn & Smith, 1998). Earl (1996) stresses the importance of considering intangible and tangible criteria in major business decisions. Some commonly cited reasons for using IT outsourcing are given in Table 2. Reasons for not using IT outsourcing and risks inherent in IT outsourcing are summarized in Table 3. Barthelemy (2001) and Barthelemy and Adsit (2003) give more details. The most common cause of outsourcing project failure is *project risk*. Problems arise when potential users of outsourcing do not carefully define their requirements, do not properly prepare for negotiations with potential vendors, or do not put enough effort into monitoring the outsourcing arrangement. An Australian contract with a call center did not specify some of the services that the client offered its customers. Another

Table 1. Some recent outsourcing contracts

Client	Vendor	Tasks Outsourced	Total Value (AU$)*	Duration (years)*
Commonwealth Bank of Australia (King, 1998)	EDS	IT	5B	10
Bank of Queensland	EDS	IT, call centers, and credit card processing	480M	10
Telstra	IBM GSA		4B	
Australian Taxation Office	EDS	IT	490M	
Five Government Agencies	CSC	IT	160M

Qantas	Oracle/ IBM GSA	IT	200M	
AMP (McFarlan & Nolan, 1995)	KAZ	IT/Insurance	70M	6
BHP-Billiton	CSC	IT	1B pa	10
South Australian Government	EDS	IT	700M	10
Westpac	EDS	IT	1B	10

Table 2. Reasons for adopting outsourcing

Reason	Comment
Reduce processing costs	By accessing economies of scale or expertise.
Focus	Outsource non-core activities and concentrate on areas of competence. Quinn and Hilmer (1994) note that identifying core activities may not be straightforward.
Access expertise	Especially in building new systems.
Avoid cultural difficulties	The IT department has anomalous working conditions.
Financial	Change from fixed to variable cost, sell assets, or manipulate accounts.
Benchmark internal operations	Get rid of an IT department that is hard to manage and/or unproductive.
Quality	Improve the IT services provided.
Resources	To meet uneven demand and/or access resources not available internally.
Risk avoidance	Avoid financial uncertainty through a fixed cost per transaction. Avoid the risks inherent in managing a project.
Ideological	The current Australian government has an ideological commitment to outsourcing, opining that the private sector is intrinsically more efficient than the public sector.

organization did not specify a reporting system in enough detail to demonstrate that the vendor was failing to deliver the sought services. Further references to reasons for and impediments to outsourcing are given in Beaumont and Costa (2002) and Beaumont and Sohal (2004).

FUTURE TRENDS

The relationship between vendor and client can (in theory) range from an arms-length and legalistic arrangement (appropriate where the vendor's performance can be unambiguously measured) to an intensely cooperative arrangement. In interviews, Australian vendors very firmly opined that taking a legalistic view would be extremely short sighted. The first contract with a client is an opportunity to demonstrate the competence and commitment prerequisite to having the contract renewed and assuming responsibility for other of the client's business processes. Clients expect to share the benefits of improving technology and exploit vendors' expertise. This reflects two of clients' primary outsourcing goals: reduced costs and access to expertise.

Australian vendors stress the importance of negotiating detailed service-level agreements (SLAs), noting that some of their clients have used specialist advice to

Table 3. Reasons for not outsourcing

Dependence	Becoming dependent on the vendor.
Confidentiality	Keep confidential data in-house.
Intellectual property	Do not give other parties access.
Loss of distinctive competencies	Outsourcing may atrophy in-house skills.
Loss of flexibility	A three-year contract may reduce the ability to adjust to changes in the environment or exploit new technology.
Personnel and change problems	Redundant IT staff may have to be dismissed or redeployed.
Information asymmetry	It is difficult for the client to determine whether the prices paid are reasonable.
Project risk	Poor methodology, negotiation, and monitoring.
Vendor incompetence	
Relationship costs	The costs of each stage of the outsourcing cycle, e.g., preparing and analyzing requirements and negotiating and monitoring vendor performance.

drive hard bargains. Comprehensive SLAs are necessary, but not sufficient, for a fruitful relationship. Competent vendor performance generates trust and ultimately "partnering" (see definitions below). Many participants in Australian outsourcing projects emphasize that negotiating and implementing outsourcing agreements is extremely stressful. A typical history tells of euphoria when protracted negotiation climaxes with signing the contract and is followed by disillusionment six months later. Usually, both parties recognize the need to repair the relationship, and more negotiations usually result in a workable relationship emerging.

Many small and medium enterprises (SMEs) retain IT departments afflicted by diseconomies of scale. Such departments find it difficult to keep current with evolving technology, tend to reinvent wheels, and are internally unpopular essentially because they do not have the skills or resources to develop and maintain the reliable systems expected and demanded by the organization. The assumption that systems should be developed in-house is too rarely examined in Australia. Although all organizations' IT systems look different, they reflect a finite number of different business processes. It would be rational for most SMEs to abandon internal systems development and either outsource IT or adopt a package such as SAP that encompasses all common business processes and can be tailored to individual firms' needs.

SURVEYS OF IT OUTSOURCING IN AUSTRALIA

Beaumont and Costa's (2002) paper on IT outsourcing in Australia was based on a survey of CFOs and CIOs, supplemented by interviews with six executives heavily involved in outsourcing. The research sought information on demographics, the kinds of activities outsourced, reasons for and obstacles to IT outsourcing, and the nature of outsourcing relationships. Some findings follow.

IT outsourcing use is not related to industry classification or organizational size. It is positively related to the size of the IT budget. The frequency of outsourcing is strongly dependent on the activity; for example, hardware maintenance is frequently outsourced, but "analysis and IT strategy" is rarely outsourced. Reasons for outsourcing are broadly consistent with findings from North America. Table 4 summarizes the results and includes a comparison with findings from a North American survey (Collins & Millen, 1995). The measurements of anticipated and actual benefits were made using a five-point Likert scale anchored by 1 (not important) and 5 (very important).

Another survey exploring Australian corporations' attitudes to outsourcing (not just IT outsourcing) was conducted in late 2001 (Beaumont & Sohal, 2004). Of the 162 responses, 93 reported outsourcing at least one as-

Table 4. Anticipated and actual objectives (ranked)

Rank based on anticipated benefits	Objective	Comparison with ranks given in Collins & Millen (1995, Table 4)	Mean (anticipated)	Mean (actual)
1	Access to skills	May be correlated with personnel cost savings (2)	2.65	2.27
2	Improved service quality	Synonymous (3)	2.48	2.06
3	Focus on core business	Synonymous (1)	2.34	1.97
4	Defined service levels	An aspect of improved quality of IS services (3)	2.34	1.89
5	Additional flexibility	Synonymous (4)	2.31	1.94
6	Access to technology	Synonymous (5)	2.25	1.98
7	Improved performance	An aspect of improved quality of IS services (3)	2.29	1.84
8	Cost savings	Reflected by personnel cost saving (2); technology cost saving (8); stabilize IS costs (7)	1.89	1.64
9	Change fixed cost basis	Not measured	1.72	1.52

pect of IT. Some aggregated responses of these 93 informants are reported here.

Table 5 gives the IT functions that were outsourced. The intensity reflects the frequency with which these functions were outsourced (a five-point scale). Clearly, development of systems and Web sites were the activities most often outsourced.

Respondents were asked to assess the benefits obtained from outsourcing (23 possible benefits were nominated). The responses were factor analyzed to obtain common themes. These common themes were, in decreasing order of importance: 1) cost savings; 2) improved performance as experienced by customers (e.g., improved user satisfaction and better service levels); 3) access to skills and technology; and 4) (surprisingly) the elimination of internal power struggles, "removal of an unsatisfactory department," and "cultural differences" were often cited.

Reluctance to outsource was primarily attributed to difficulties in ascertaining what, if any, savings could be made. Less frequently cited reasons were a fear of becoming dependent on the vendor, lack of confidence in vendors, and a fear of loss of control.

Respondents were asked how they chose vendors. The results were not amenable to factor analysis, but criteria commonly cited were: cost; proven ability ("track record"); willingness to "adapt to our business"; reputation, competence, and "understanding of our industry"; and the vendor's commitment to a long-term relationship.

OFFSHORING

Offshoring (having work outsourced to low-wage countries such as India) has become controversial in Australia and other first-world countries (Beaumont, 2004). Australian companies will be unable to ignore the opportunity to reduce the cost of systems development, data entry, and transaction processing by up to 80%. The Indian workforce is well educated with proven IT skills (McLaughlin, 2003); China, the Philippines, and perhaps New Zealand are other emerging locations. There have been calls for offshoring in Australia and the USA to be regulated to prevent IT jobs being transferred to India. Such fears were exacerbated by a Telstra vendor considering transferring some IT work to India. Several other large Australian companies have considered offshoring, some retreating because of adverse public reactions.

It is difficult for a client or governments to control where IT work gets done. Some very large organizations (Microsoft, IBM, HP) have organized their own support and software development sites in India and China. There is a bright side for Australia and perhaps New Zealand, whose citizens have high levels of education, excellent English, cultures akin to those of America and Europe, excellent technical skills, and labor costs distinctly lower than those of America. IBM and Oracle already have Australian centers supporting international activities.

Table 5. Kinds of IT outsourcing

Application	Number responding	Intensity
Development of IT applications	92	3.5
Development of Web sites	88	3.5
Security of IT	86	2.9
IT infrastructure	85	3.2
IT data center	82	2.7

CONCLUSION

The use of IT outsourcing in Australia is growing at about 10% per year. Initially adopted uncritically with some unfortunate results, it is now used more soberly in a strategic context. Establishing a fruitful outsourcing arrangement requires sustained effort from both parties; clearly written SLAs reflecting the client's objectives are a necessary, but not sufficient condition. There is a tendency to trial vendors by writing smaller, shorter term contracts for parts of the IT task and demanding demonstrated benefits before extending the relationship. Political problems may arise when cost competition forces Australian organizations to consider outsourcing IT work to third-world countries.

KEY TERMS

Backsourcing or Repatriation: Taking work that had been outsourced back in-house.

Co-Sourcing: Used instead of *outsourcing* to emphasize that the outsourcing arrangement is based on cooperation (or "partnering") between the parties. Partnering is often used to signify a highly cooperative arrangement, but Australian law only recognizes written contracts (not "a spirit of cooperation") and "de facto" relationships.

Insourcing: Formalization of the supply relationship between two departments of the same organization.

Outsourcing: "The act of transferring some of a company's recurring internal activities and decision rights to outside providers as set forth in a contract" (Greaver, 1999, p 3). Some disasters have brought outsourcing into disrepute, and arrangements have been relabeled *technology services partnerships* or *managed services contracts.*

Outsourcing Cycle: The stages of an outsourcing project: identification of a need; definition of project objectives; choice of vendor; negotiation of a Service-Level Agreement; implementation; performance monitoring; incremental modification of the agreement; and renewal or cancellation of the agreement.

Out-Tasking: The vendor provides resources (computer time or labor) and does work precisely defined by the client (Strassmann, 1997).

Service-Level Agreement: A contract defining the services to be provided by a vendor and service levels; procedures for measuring performance; payments and penalties and procedures for renegotiation.

Strategic Outsourcing: Outsourcing considered in strategic context (Quinn & Hilmer, 1994). An arrangement attractive on purely cost grounds might be rejected because it reduced the client's ability to react to a changing environment or entailed unhealthy dependence on the vendor.

Overcoming Barriers in the Planning of a Virtual Library

Ardis Hanson
University of South Florida, USA

INTRODUCTION

What is a virtual library? Gapen (1993) states:

The virtual library has been defined as the concept of remote access to the contents and services of libraries and other information resources, combining an on-site collection of current and heavily used materials in both print and electronic form, with an electronic network which provides access to, and delivery from, external worldwide library and commercial information and knowledge sources. In essence the user is provided the effect of a library which is a synergy created by bringing together technologically the resources of many, many libraries and information resources (p.1).

A decade later, the same definition holds true.

BACKGROUND

The implementation of a university-wide virtual library inevitably causes significant changes within each department across the library and campus. However, real ownership comes about only with a commitment from management to 1) educate and train staff in the new technologies and procedures, 2) manage the change process as candidly as possible, and 3) disseminate information as openly and widely as possible. Each one of these commitments is essential to the change process.

When creating a virtual library, all participants must clearly define and realize institutional commitment to the plan. To do so effectively requires an examination of the organizational and cultural change agents that will affect the implementation. The cultural constructs by which the various types of librarians and staff view the worlds of work and patron must be considered in the redesign of the current environment. Although much has been written about creating virtual libraries, very little is known about the working conditions or institutional and organizational practices that make virtual libraries most usable by library faculty and staff.

Preparing a proposal for a university-wide virtual library requires a new level of collaborative visioning, planning, and implementing among the participating departments/libraries. This process depends upon a reliable and advanced networked infrastructure and on staff, facility, and financial decisions focused on true programmatic cooperation. It is well cited in the change management literature that without commitment from administration, the belief of the individual, the team, or the organization in the relevance of the project wavers or devolves to indifference to the project. Organizational commitment to the project and, therefore, to change is a key factor in determining the success of this type of project.

COMMITMENT TO CHANGE

As libraries respond to the rapid evolution of the information environment, organizational change must occur for successful adaptation. The literature provides some insight into variables important to organizational change. An integral link exists between successful leadership, human resources, and organizational structure. If any one component has a weakness, it will negatively impact the other two. A key component to success is the ability to show flexibility and rapid response to change. This is mirrored in the qualifications necessary for staff to work effectively in a rapidly evolving environment. The literature also points to two key components in creating an effective organizational structure: 1) flattening of the existing structure and 2) development of committees that cross departmental lines.

Since open discussion of barriers is an effective strategy for implementation and adaptation of change (Beer & Eisenstat, 2000), the library as organization must be examined with a critical eye to identify strengths, weakness, ideologies, and strategic staff. Plans to resolve challenging organizational or staff problems must be devised and implemented.

Further, project outcome is shown to depend upon the behavior and resources available during the development process, and these depend upon the level of commitment. Additional factors to consider include the possibility of budgetary constraints, top management's technological non-sophistication, and the reluctance to draw up a very detailed operating plan. Finally, barriers on systems implementation included hesitation in accepting a system, lack of standard formats, and unrealistic priorities and expectations from the parties involved. These challenges are particularly true in the design of a virtual library where resources and technical standards are constantly evolving.

When identifying problems, it is essential to determine which problems are undesirable situations but impossible to correct. This allows the project team to acknowledge the problem, but not to spend too much time on it, allowing the team to focus on answers or actions to potentially correctable issues. Common problems identified include 1) the disparate geographic locations of the libraries (especially with multi-campus or departmental libraries within a university or college); 2) the lack of parity in equipment and technologies among departments within the library or among libraries; 3) budget issues; 4) staff involvement in the project; 5) difficulty in selling the virtual library as a critical library project to university administration, teaching and research faculty, and library faculty and staff; 6) unrealistic expectations by management and staff; and 7) resistance to change.

MANAGING CULTURAL CHANGE

The coming of a virtual library will significantly impact the culture of libraries. Janz and Prasarnphanich (2003, p. 353) believe that "corporate culture determines values, beliefs, and work systems that could encourage or impede learning (knowledge creation) as well as knowledge sharing." Policies, procedures, and behavior are a visible manifestation of these assumptions that most members of a culture never question or examine. The members of a culture may not even be aware of their own culture until they encounter a different one.

The cultural constructs by which the various types of librarians and staff view the worlds of work and patron should be considered in the redesign of the current environment. Very little is known about the working conditions or institutional and organizational practices that make digital libraries most usable by library faculty and staff. Most of the emphasis on users has been on the library patron or on the technology, not on the work environment of the library staff. Much of the literature discusses change at the technological level, again not at the human level. Examples include the use of Standard Generalized Markup Language (SGML) hyperlinks in bibliographic records, metadata, collection development with Internet sources, online reference services, end user electronic document delivery, electronic full-text reserves, and networked paper-less administration.

Models that make explicit connections between a focal technology (such as a digital library) and its immediate users should be used to review the ecology of social relationships with other social groups and organizations in which the technology is developed, adopted and used.

IMPLEMENTATION ISSUES

To promote ownership of the virtual library plan among the library's administration, faculty, and staff, "actions" are developed for each of the areas under design within the virtual library. At institutions that have successfully implemented a virtual library, work groups and task forces were instituted to review workflow, policies and procedures, overlap, and to create implementation plans to effect organizational change and major projects driven by the new technologies (Steele, 2000). Early virtual libraries created multi-disciplinary teams across academic disciplines and support services to implement their plans or created large groups who use phased plans covering a number of years (Anderson, 1995; Birmingham, Drabenstott, Warner, & Willis, 1994).

Alternative organization design principles replace individual job design with task design (e.g., task forces and teams). These principles are an excellent way to handle the enormity of the proposed design process. They replace "one best way" thinking with choices for organizational and technological solutions (Sarin & McDermott, 2003). Such solutions can cope with more complexity and unpredictability when people in the teams are multi-skilled and delegated more autonomy and responsibility (Hoegl, Parboteeah, & Munson, 2003; Man & Lam, 2003).

Implementing a virtual library will create cultural and organizational changes, particularly in technology and staffing. It is critical that library faculty and staff be assured of their importance and value within the new organizational structure. Staff development programs need to be made available and designed in such a way that staff members feel the new skills will enhance their ability to perform their jobs and accommodate changing work functions. Administrators and department heads need to be proactive and provide these programs to staff in an appropriate time frame. The expectation that "just-in-time" training is "good enough" is unwarranted. Often, this kind of training approach increases staff stress and decreases morale, although too much advanced training can be counterproductive as well.

As technology and a growing reliance on "virtual" materials and services increase, service points and their job functions should be analyzed. This excerpt from the USF Virtual Library Blueprint (Metz-Wiseman et al., 1996) acknowledges the importance of recognizing and managing the change process as well as emphasizing the need for staff development:

"This process of change will require creativity, a more global point of view, flexibility, and adaptability. These will be the qualities of highly valued staff.… Staff will need to understand not only their own role within the organization, but also the structure of other departments and the relationships between departments." (p.26)

Therefore, in designing a virtual library, there needs to be a more global understanding of library processes, cross training and shifting staff between departments, continuous training to remain current with technology, and time for staff to develop projects and procedures across departmental boundaries.

ROLES OF AND FOR THE LIBRARY ADMINISTRATOR

As stated earlier, any recommended actions in the implementation of a virtual library require long-term commitment by the libraries' administrations (upper- and middle-management) to their staff. Strategies to continue the change process, identified on both an individual and administrative level for professional development, include: funding for each library faculty member and staff to attend conferences, training and cross-training sessions on current library operations for staff both inside and outside the involved departments; utilization of campus training programs; an ongoing evaluation program to ensure that training is available for new technologies, workflow, and responsibilities; creation of a new technologies committee whose members are responsible for training their departments; and up-to-date documentation on policies and procedures.

Inter-institutional collaboration is difficult to define and implement, and even more difficult to implement well. Four additional infrastructure elements - attention to continuing planning, process, people, and administrative elements- are essential to a project of this kind. This becomes even more important with a conscious commitment to maintaining tradition while implementing a virtual workplace (Black & Edwards, 2000).

For administrators, the single most important factor for the success of such a system is a vision that is meaningful to the director, his or her faculty, and staff, and can be advocated within larger institutional settings as well as the library. An administrator needs to examine his or her own areas and skills so he or she can effectively foster an environment that supports the innovations in technology and services. Within a larger context, a library administrator must be confident that the larger university or college atmosphere is willing to allow him or her the opportunity to initiate collaborative, inter-institutional activities and decision-making processes. This is especially critical in today's academic environment, which requires that any large-scale initiative be integrated within the mission and core values of the university, i.e., the support of scholarship and the development and continuance of a sophisticated and individualized learning environment.

UNIVERSITY INVESTMENT

The key to this scholarly environment is the development of organizational, instructional, and informational infrastructures that 1) capitalize on the technology, and 2) reinforce the values and the identities of the institution (Heikkila & Isett, 2004). Critical technical challenges in building a virtual library include:

- parity in networking, workstation, and desktop requirements;
- a single, uncomplicated point of access for the library's electronic resources;
- standard, staff-utilized software packages;
- measurable information applications that are scalable, efficient, and interoperable;
- multiple simultaneous access with minimal down/lag time; and
- technologies and services that are user-friendly and provide privacy, security, stability, mobility, and ubiquity.

Institutions must be able to combine resources in new ways, gain additional resources, dispose of superfluous resources, and to do this repeatedly and rapidly if they are to be successful (Daniel & Wilson, 2003). Existing and planned voice, data, and image networks; institutional information systems; personal computers and workstations for students, staff, and faculty; and strategic plans for information and computing technologies at the university or college level should be considered in the creation of any virtual library plan. Conversely, the virtual library should be incorporated into university and college planning for technology and information systems. Both the library and larger administration should ensure that the virtual library is part of any extension of existing technologies and plans and future technologies used at the university. This is particularly crucial as wireless communications move into student dorms, classroom buildings, student centers, and outside space as viable a "library place" as the physical building.

FUTURE TRENDS

Three additional issues of importance are especially relevant to libraries and their user communities: content, access, and support. All three issues identified are extremely dependent upon funding. Money buys research resources (content), telecommunications infrastructure (access) necessary to deliver the content, and pays staff to run the infrastructure (support). A quick look at trends in higher education indicates that traditional funding sources remain flat or are decreasing; public and state mandates call for more accountability in the spending of state dollars; and student expectations demand more sophisticated services and greater access to data. Any virtual library plan needs to develop sustainable funding mechanisms.

It is important for library administration to make a long-term commitment to inter-institutional collaboration. The single most important factor in shared decision making is a common vision that is meaningful to the dean/director, his or her faculty, and staff. This vision must be one that is shared by the administrative staff and strenuously advocated within their individual institutional settings as well as within the larger context of the university. The role of the campus library may not be to lead the development of new information technologies, but to establish an atmosphere and a process that will promote the integration of these new technologies with each other and with the mission and core values of the university and its campuses.

CONCLUSION

The real revolution in information technology is about communication, not computation. The essential catalyst for change must be in how our cooperative efforts are communicated both internally and externally. More and more teams and groups are functioning as a community-in-practice. This type of work group evolves from three characteristics: 1) valuation of work roles, 2) the degree of participation in "peripheral" learning permitted under working conditions such as conferences, workshops, and networking opportunities, and 3) opportunities for participation in innovative implementations. Learners, according to Brown and Duguid (1991), grow through practice. "The central issue in learning is *becoming* a practitioner not learning about *practice*." As participants in an innovative "community-of-practice," work group practices are fluid and ignore many of the traditional assumptions about librarianship, librarians, and libraries. As members of the committee become more comfortable as a "community," such candidness promotes a high level of cooperation between all the committee members, despite disagreements, and can help maintain the level of commitment to the group and the project development. Consequently, organizational knowledge arises from group knowledge as well as from individual knowledge, as is also indicated by the recent literature on communities of practice (Sabherwal & Becerra-Fernandez, 2003).

KEY TERMS

Change Management: The application of many different ideas from the engineering, business, and psychology fields that focus on observable, measurable business elements. These elements, which can be changed or improved, include business strategy, processes, systems, organizational structures, and job roles.

Community-In-Practice: A term coined by Brown and Duguid (1991) regarding how groups of individuals become a team able to effectively participate in innovative implementations.

"Just-In-Time" Training (JIT): The philosophy of providing training at the exact point when one needs the knowledge/skills to perform a task or job function.

Metadata: Data that describes the content, data definition and structural representation, extent, quality, availability, status, and administration of a dataset. Examples include the MARC record in a library catalogue or information in the meta-tags of an HTML or SGML document.

Organizational Culture: A pattern of behavior, such as cross-individual behavioral consistency. For example, when people say that culture is *"the way we do things around here,"* they mean that there is a consistent way people perform tasks, solve problems, and resolve conflicts. Organizational culture is also defined as the informal values, norms, and beliefs that control how individuals and groups in an organization interact with each other and with people outside the organization.

Virtual Library: Services and resources that are provided in a digital or electronic format and accessed via a computer either in a library or remotely from another workstation.

Wireless Communications: To communicate with or send communications by wireless means, relating to radio or communication by radiotelegraphy or radiotelephony.

Packet Inter-Arrival Distributions in Computer Network Workloads

INTRODUCTION

The past decade could be classified as the "decade of connectivity"; in fact it is commonplace for computers to be connected to a LAN, which in turn is connected to a WAN, which provides an Internet connection. On an application level this connectivity allows access to data that even 5 years earlier were unavailable to the general population.

This growth has not occurred without problems, however. The number of users and the complexity/size of their applications continue to mushroom. Many networks are over- subscribed in terms of bandwidth, especially during peak usage periods. Often network growth was not planned for, and these networks suffer from poor design. Also the explosive growth has often necessitated that crisis management be employed just to keep basic applications running. Whatever the source of the problem, it is clear that proactive design and management strategies need to be employed to optimize available networking resources (Fortier & Desrochers, 1990).

BACKGROUND

Obviously, one way to increase network bandwidth is to increase the speed of the links. However, this may not always be practical due to cost or implementation time. Furthermore, this solution needs to be carefully thought out because increasing speed in one part of a network could adversely effect response time in another part of that network. Another solution would be to optimize the currently available bandwidth through programming logic. Quality of service (QOS) and reservation bandwidth (RB) are two popular methods currently being utilized. Implementation of these optimization methods is rarely simple and often requires a high degree of experimentation if they are to be effectively configured (Walker, 2000). This experimentation can have detrimental effects on a live network, often taking away resources from mission critical applications.

THE BENEFITS OF SIMULATION

Therefore, the most efficient way to ascertain the potential benefit and derive baseline configuration parameters for these optimization methods is through simulation or mathematical modeling. Simulation can be very effective in planning a network design. For example, what if network link #3 was increased to 100Mbs? Would workstations on that link experience an improvement in response time? What would happen to workstations on the other part of the total network? Another approach to ascertain if a given network will exceed its capacity is based on network calculus (Cruz, 1991; Le Boudec, 1998). In this method the characteristics (such as speed, maximum packet size, peak rate) of the network architecture are analyzed and performance bounds are defined. The goal then is to devise control/management programs (such as QOS and RB) that will keep the workload within those defined bounds. There are numerous applications of this control/management logic, such as Cruz (1995), Cruz and Tsai (1996), Firoiu, Le Boudec, Towsley and Zhang (2002), and Vojnovic and Le Boudec (2002). These control/management programs have proved very effective under a variety of circumstances, but are influenced by the packet interarrival rate as well. So therefore, if a network designer is contemplating invoking one of these options, simulation could be used to test how the option in question would improve performance on his/her system, provided an adequate method could be found to describe the distribution within that network.

Simulation has been used for many years in network design; however, the time and cost of its use have often been prohibitive. In recent years, new windows-based point and click products such as Comnet III (and its successors Network & Simscript) have eliminated the drudgery and the cost of writing simulations via a command line interface (CACI, 1998). Under Comnet III the appropriate devices are selected, connected together and their characteristics defined. There is still a limiting factor in this process: the definition of the distribution of the packet inter-arrival rates.

The theoretical model often used to describe computer networking is the Poisson. This model may have been adequate for some of the first single tier, single protocol networks. However, it lacks validity in today's hierarchically complex multi-protocol networks. In the classical Poisson process model (such as M/M/1), when the number of arrivals follows a Poisson probability distribution, then the time between arrivals (inter-arrival time) follows a decaying exponential probability distribution. A number of studies confirm that the actual inter-arrival distribution of packets is not exponential as would be expected in the classical model (Guster, Robinson & Richardson, 1999; Krzenski, 1998; Partridge, 1993; Vandolore, Babic & Jain, 1999).

The inter-arrival distribution selected can have a major impact on the results of the simulation (Guster, Safonov, Hall & Sundheim, 2003; Guster, Sohn, Robinson & Safonov, 2003). In a study by Krzenski (1999) that analyzed the simulated performance on a shared Ethernet network, 12 different inter-arrival distributions were tried within the same simulation problem. These included the gamma distribution, which is a generalization of the exponential distribution, allowing for a modal inter-arrival time (the most commonly occurring time between arrivals) to be moved out away from the very short, nearly instantaneous time occurring with the exponential distribution. Another distribution among the 12 was an integer distribution, whereby equal probabilities are assigned to different values that are equally spaced throughout the possible inter-arrival times. Among the 12 distributions, there were vast discrepancies in the results. For example, the number of collision episodes varied from 310 with a gamma distribution to 741 with an integer distribution. These results further support the need to have the correct distribution in simulations designed to provide design and management feedback about computer networks.

The frustration of the past work and the need for additional research is best summarized by Partridge (1993):

"…We still do not understand how data communication traffic behaves. After nearly a quarter of a century of data communication, researchers are still struggling to develop adequate traffic models. Yet daily we make decisions about how to configure networks and configure network devices based on inadequate models of data traffic. There is a serious need for more research work on non-Poisson queuing models."

A number of different strategies have been employed in the development of models used to describe packet inter-arrival rates (Van Slooten, 2002). Perhaps the most valid is to record all of the packet arrival times for the time period desired and use that to generate the distribution. The advantage of this strategy is accuracy, but it often requires massive amounts of data to be recorded and processed. To lessen this burden, often a representative sample from the time period is used. However, validating the sample period is often difficult, especially if the file size is not large. Known distributions have been used with limited success (Guster & Robinson, 1994, 2000; Robinson & Juckel, 2000). For simple networks exponential distributions provide some promise; however, they fail to deal with the intricacies of complex multi-protocol networks. Tabular distributions, in which one column describes the interval and a second column describes the probability of a value from that interval occurring, offer a moderate degree of accuracy, but they take time to derive and their sophistication is related to the number of rows included. Regression and ANOVA have been used in some cases, but lack the ability to describe the peaks and valleys associated with packet arrival data. Time series deals with these variations better but still lacks the sophistication needed and requires relatively complex models to even come close (Guster & Robinson, 1993). Packet trains are very effective in describing packet traffic from a single session (such as telnet), but lack the complexity to deal with multiple concurrent sessions on the same network.

FUTURE TRENDS

Two non-Poisson queuing models have offered a degree of promise. One method involves viewing the observation interval as containing several independent Poisson processes rather than as a single exponential distribution. In a study by Guster, Robinson and Richardson (1999), actual data were analyzed and shown to contain three Poisson processes of differing characteristics. During the first phase activity was increasing. During the second phase activity was decreasing. The last phase followed a classical Poisson model. For each phase, a power law process model was fit to the data, indicating the nature of the changing traffic intensity ($b>1$ – increasing intensity, $b<1$ – decreasing intensity, $b=1$ – constant intensity). These data were taken over a 24-hour period. The three phases had widely different levels of traffic intensity. In a shorter time frame, for example 10 minutes, one is less likely to see differences in intensity that dramatic. Thus, the power law process model is most appropriate for longer time frames.

A second strategy focuses on the influence any given data point has on later data points. In other words, does knowing the magnitude of the packet inter-arrival rate at any point in the time interval make it easier to predict the next inter-arrival time? Historically, there has been a tendency to apply statistical treatments such as regression, ANOVA, or time series analysis to categorize or forecast inter-arrival trends (Frieberger, 1972). These methods have proved to be limited in accuracy in modeling inter-arrival rates and require large, truly representative databases to calculate these values. Therefore, the attractiveness of methodologies such as Markov chains that use a more independent technology is apparent (Robert & Le Boudec, 1996). Specifically, a Markov chain is a tool for modeling how processes behave over time. We classify the process (in this case, the inter-arrival times of packets) into categories called "states". The assumption behind Markov Chains is that the probability for what state will be observed next depends only on the previous state. In this context, a process depends only on the most recent inter-arrival time to determine the probability of subsequent inter-arrival times increasing or decreasing

Figure 1. Frequency counts of packet inter-arrival times for ethernet data

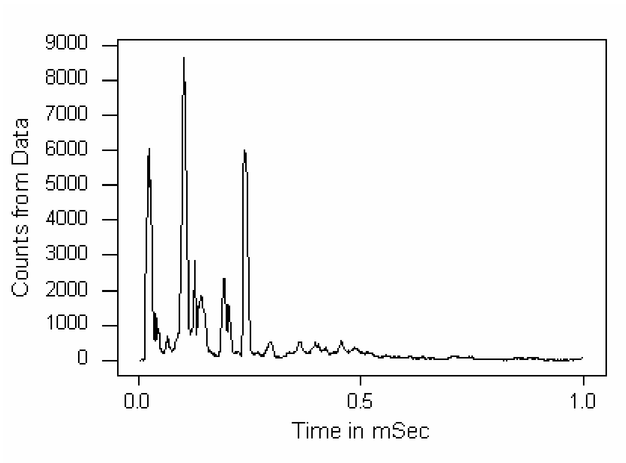

Figure 2. Density function for the actual data, the Poisson

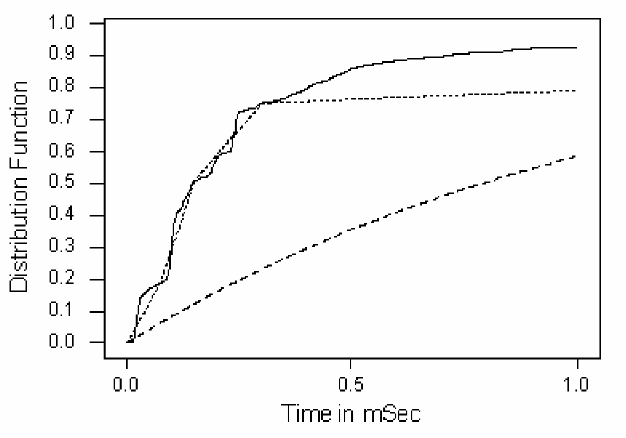


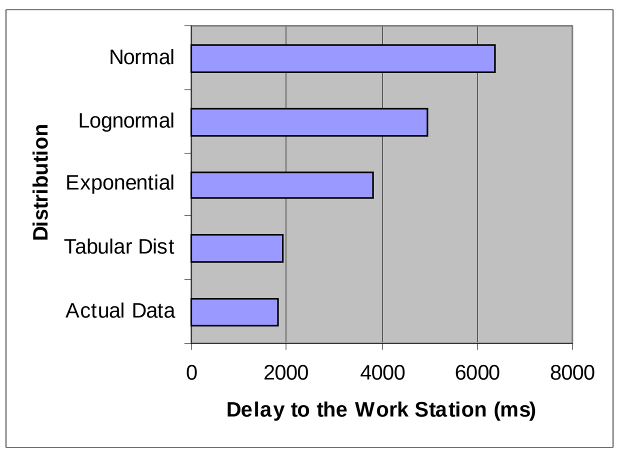
(Guster & Robinson 1994, 2000).

To provide the reader with a visual description of packet inter-arrival times from a complex multi-protocol network, a frequency plot is provided in Figure 1. It is the massive peaks and valleys from 0 to about 0.25 milliseconds that make modeling a packet distribution so difficult.

There are fairly great discrepancies in the density plots of the various distributions. For example, using the actual data from Figure 1, two attempts to model the cumulative distribution of the inter-arrival times are graphed with the actual distribution. Figure 2 depicts the actual data with the solid line, the Poisson model with long dashed line and the Markov model with the short dashed line. From the data in Figure 2 it is clear that the Markov model fits quite a bit better than the classic Poisson model.

To illustrate the effect not having the correct distribution can have on the results of a simulation, a 10-minute sample of packet traffic (packet inter-arrival times) was fed into a database inquiry simulation program. The delay in milliseconds from inquiry to response from that database was recorded. From that sample a tabular distribution was devised and placed into the same simulation and the results recorded. Then the same simulation was run three more times using exponential, lognormal and normal distributions with the appropriate means and standard deviations derived from the original 10-minute sample. The normal distribution is the classical mound shaped probability distribution used in statistical applications. The lognormal distribution is the result of exponentiating values from a normal distribution, giving a more realistic, asymmetric distribution for the inter-arrival times. Both the normal and lognormal distributions, like the gamma distribution, have modal values away from the very short, nearly instantaneous times occurring with the exponential distribution. The results are depicted in Figure 3. The tabular distribution was the closest to the actual, but a

Figure 3. Work station delay observed by varying the packet inter-arrival distribution



slight overestimate. All three of the other distributions were overestimates by quite a significant magnitude. From these results it is clear that the validity of any network simulation involving packet traffic is dependent upon using the appropriate distribution.

CONCLUSIONS

As the need to make the most of available network bandwidth increases, the importance of having valid simulation techniques available to test optimization methodologies increases. The key to this validity is an inter-arrival distribution that is truly representative of the actual data. This article explored several alternatives in selecting this distribution.

First, the actual data obviously offer the best accuracy, but is often impractical due to its massive size. Furthermore, selecting a representative sample is often challenging due to widespread variation over time exhibited by most network traffic.

Second, the exponential distribution (or any other known distribution), which according to queuing theory should be appropriate, does not fit the data well in a number of studies.

Third, the power law process has limited value in relatively short time interval studies. It does, however, offer more promise in data sets involving very large time spans.

Fourth, the Markov process has exhibited somewhat promising results. In fact, the visual plots (Figure 2) reveal a much closer fit than the Poisson model. However, Markov models have displayed limitations in the middle time range (.3-5 milliseconds), which make them far from a perfect choice (Van Slooten, 2002).

Therefore, much additional work is needed. A simple visual inspection of Figure 1 reveals the complexity of the data and subsequently the difficulty in determining a mathematical model that would truly represent them. The results exhibited by the Markov process are encouraging, and studies that examine more sophisticated Markov-related models should be encouraged.

The importance of obtaining the appropriate distribution for network traffic should not be underestimated. Without it, simulations designed to ascertain network design efficiency, network performance, and the effectiveness of software optimization techniques generate invalid results.

KEY TERMS

Inter-Arrival Distribution: The probability density function that describes likely and unlikely inter-arrival times for packets.

Inter-Arrival Time: The amount of time that elapses after the receipt of a packet until the next packet arrives.

Markov Chain: A model that determines probabilities for the next event, or "state," given the result of the previous event.

M/M/1 Model (exponential/exponential with one server): The queuing model that assumes an exponential distribution for inter-arrival times, an exponential distribution for service times, and a single server.

Packet: A finite stream of bits sent in one block with header/and trailer bits to perform routing and management functions.

Power Law Model: A generalization of the classical Poisson model, allowing for changes in the intensity of the arrivals.

Quality of Service (QOS): A method of marking certain packets for special handling to ensure high reliability or low delay.

Reservation Bandwidth: Reserving a portion of the available bandwidth for a given protocol or application, which ensures its network access will not be adversely affected by massive network traffic generated by other protocols or applications.

Parallel and Distributed Multimedia Databases

INTRODUCTION

Sensing and processing of multimedia information is one of the basic traits of human beings. The development of digital technologies and applications allows the production of huge amounts of multimedia data. The rapidly decreasing prices for hardware such as digital cameras/camcorders, sound cards and the corresponding displays led to wide distribution of multimedia-capable input and output devices in all fields of the everyday life, from home entertainment to companies and educational organisations. Thus, multimedia information in terms of digital pictures, videos, and music can be created intuitively and is affordable for a broad spectrum of users.

An important question in this context is related to the archiving of the acquired information. The old-fashioned albums with pictures from holidays, children, special occasions, and so forth are replaced by photo-CDs and DVDs. Analogously, digital videos are edited, valorised by including meta-information (occasion, place, date …) and archived on DVDs. If a particular scene, image, or sound file is needed, then one can use its memory to find the corresponding medium. This type of organisation is surely not applicable to large multimedia archives, which often exist in industrial and educational sectors and where Petabytes worth of multimedia data are produced year for year. All this information has to be systematically collected, registered, stored, organised, and classified. Therefore, in many branches professional archives for such multimedia information are established, such as document management systems, digital libraries, photo and video archives used by public authorities, corporations, broadcasting and TV companies, as well as archives for satellite and surveillance photos. The scope and spread of such systems grow day by day and lead to new demands for efficient retrieval of the archived information based on user-specific description of the sought image, video or audio.

The search for a medium similar to the given one is, due to the complexity of multimedia information, a very challenging problem and requires a number of novel mechanisms. Beside the search procedures, also methods to formulate queries, and ways to visualise the results have to be provided. Moreover, the search has to be performed efficiently in order to achieve acceptable response times for the user. Therefore, a combination of modern multimedia archives with powerful parallel and distributed architectures described in this article is mandatory for the integration of multimedia retrieval into real-world applications.

BACKGROUND

The necessity for organisation and retrieval of multimedia data led to development of a large number of prototypes and operational multimedia database management systems, which manage the multimedia data in terms of storage, annotation, and retrieval. In the early years this task was tended to by existing database management systems (DBMS) with multimedia extensions. The basis for representing and modelling multimedia data in such systems is so-called Binary Large Objects (BLOBs), which store images, video and audio sequences without any formatting and analysis done by the system. The media are saved in the current form in the database and their additional information – called meta-information – is inserted into the database tables. Typically, the file name, categories and additional key words entered by the user serve as meta-information. Once the user submits a key word about the sought media, the blocks with meta-information are searched using the existing database functions and compared with the input. In case of a key word match, the corresponding media is presented.

These extensions reflect a certain aspect of multimedia database systems, but this approach does not satisfy the requirements of multimedia archives, as the manual annotation of the media is too time-consuming and not applicable in real-world applications. Furthermore, key words are not sufficient to represent content of images or videos entirely (*An image says more than 1000 words*). Therefore, the media annotation and retrieval has to be content-based; that is, features describing the multimedia content have to be extracted automatically from the media itself and compared to the corresponding features of the sample medium. The functionality of such a multimedia database is well defined by Khoshafian and Baker, (1996):

"A multimedia database system consists of a high performance DBMS and a database with a large storage capacity, which supports and manages, in addition to alphanumerical data types, multimedia objects with respect to storage, querying, and searching."

The DBMS is already provided by traditional databases and therefore will not be discussed in the following sections. Instead, the focus is set on the mechanisms for multimedia retrieval and high-performance implementation.

MULTIMEDIA RETRIEVAL

The content-based annotation of multimedia data requires the integration of additional information, which can be classified into the following categories:

- Technical information describes details of the recording, conversion, and storage. Examples: filename, resolution, compression, frame rate.
- Extracted attributes are features that are deduced by analysing the content of the media directly. Examples: average colour or colour histograms of an image, camera motion in videos, pitch in audio files.
- Knowledge-based information links the objects, people, scenarios, and so forth detected in the media to entities in the real world.
- World-oriented information encompasses information on the producer of the media, the date and location, language, and so forth.

Technical and world-oriented information can be modelled with traditional data structures. The knowledge-based information assumes semantic analyses of the media, which is nowadays still not possible in general. However, many recent research efforts in this direction promise the applicability of semantic information in the future (Zhao & Grosky, 2002).

Most of the existing multimedia retrieval systems are specialised to work on media of a limited domain, for example news (Christel & Hauptman, 2002; Yang & Chairsorn, 2003), American football (Li & Sezan, 2002), or integrate general retrieval algorithms like face, speech or character recognition. They use features extracted from the media content to annotate and retrieve the multimedia objects, which are usually related to the colour, edge, texture, layout properties in case of images or consider object motion in case of videos or specific tone sequences for audios. Table 1 gives an overview of several prominent, specialised systems, which introduced main research retrieval concepts to the scientific community. Meanwhile, many of these systems became a part of commercial products or a part of a general multimedia archive. A survey is provided in Venters and Cooper (2000).

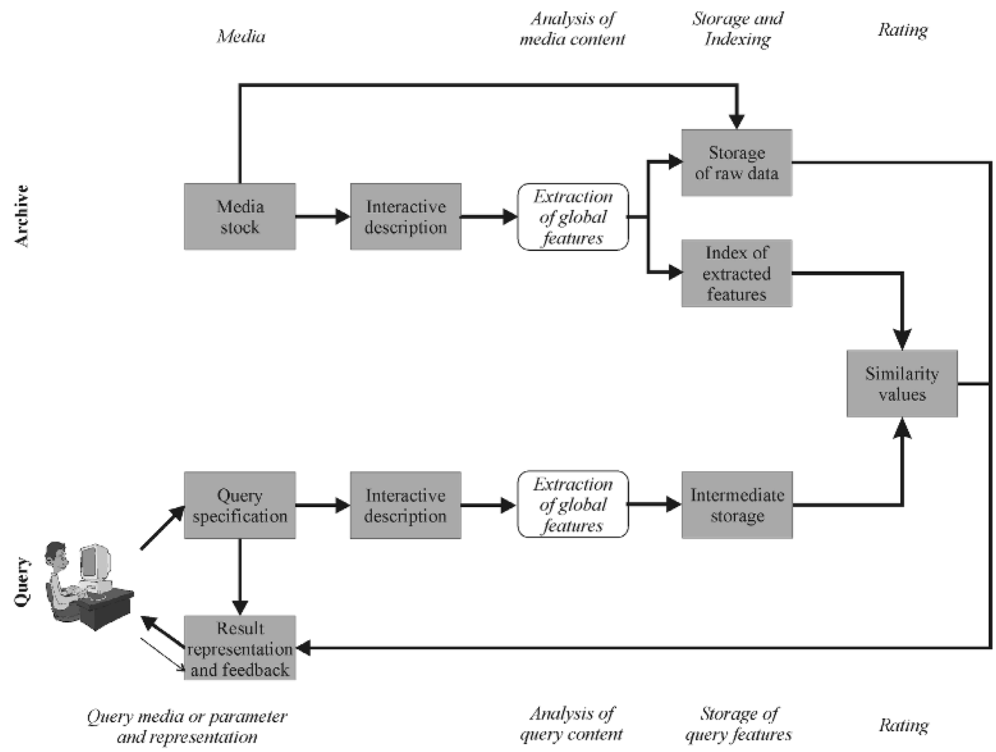
In the following, the retrieval workflow for multimedia data will be depicted by considering images as an example. The user has a specific image in mind and starts a query for this specific image or for similar samples. The user can for example browse the data set or give a suitable key word. However, for content-based similarity search, sophisticated interfaces are necessary:

- Query by pictorial example: the user supplies the system with a complete sample image, which is similar to the sought one.
- Query by painting: the user sketches the looked-for image with a few drawing tools (Rajendran & Chang, 2000).
- Selection from standards: lists of sample instances – called standards – can be offered for individual features.
- Image montage: the image is composed of single parts similar to a mosaic.

Table 1. Prominent examples for image, video and audio databases.

- Image databases
  - Qbic (Flickner, Sawhney et al., 1995)
  - Photobook (Pentland, Picard & Sclaroff, 1994)
  - Surfimage (Nastar, Mitschke et al., 1998)
- Audio databases
  - VARIATIONS (Dunn & Mayer, 1999)
  - MUSART (Birmingham, Dannenberg et al., 2001)
- Video databases
  - VideoQ (Chang, Chen et al., 1998)
  - Virage Video Engine (Hampapur, Gupta et al., 1997)
  - CueVideo (Ponceleon, Srinivasan et al., 1998)

Figure 1. General retrieval workflow



All approaches have individual advantages as well as shortcomings; thus a suitable selection depends on the domain. However, the query by pictorial example is one of the most often applied methods since it provides the greatest degree of flexibility.

In the next step the query image is compared to all archived images in the database based on the extracted features. Each feature emphasises one or more aspects of the image, usually related to colour, texture and layout. These features are extracted off-line (at creation time) for the archived images and online (at query time) for the given sample image. Thus, after the analytical phase, the images are represented by consistent feature vectors, which can be directly compared using similarity metrics or functions. For this purpose well-known metrics such as the (weighted) Euclidian Distance or specially developed and adapted metrics like Earth Mover Distance can be applied (Rubner & Tomasi, 2000).

The result of this comparison is a similarity value for the query and the analysed image. The process is repeated for all *n* images in the database, resulting in a similarity ranking. The first *k* entries, *k* being a user-defined constant, represent the *k* best hits, whose raw data are then displayed. Figure 1 describes the global workflow.

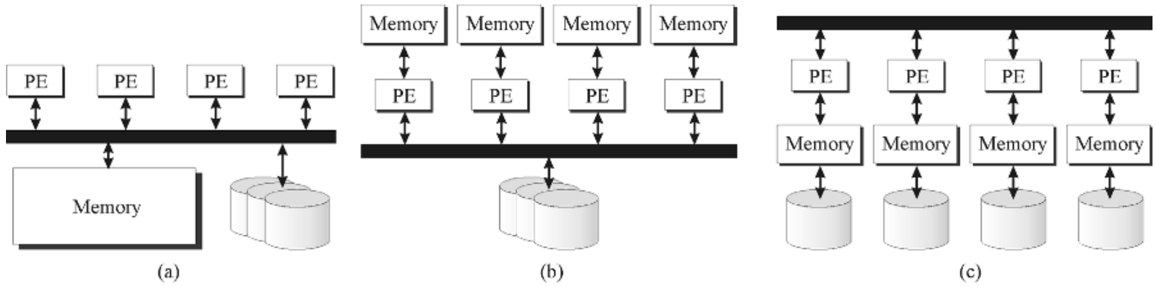
The comparison process can be accelerated by using index structures. These contain a-priori extracted features and are organised in a way that the comparisons can be focused to a certain area around the query. A novel approach and an overview of often-applied index structures are provided in Tuncel and Ferhatosmanoglu (2002). A survey of specialised retrieval techniques is provided for example in Rui (1999).

HIGH-PERFORMANCE COMPUTING FOR MULTIMEDIA RETRIEVAL

The database architecture – software and hardware – is decisive for the efficiency and thus for the usability of a multimedia archive. Because of their high storage and computing requirements, multimedia databases belong to those applications which rapidly hit the limits of the existing technology.

The widespread client/server architectures are – in their usual form – not fit for multimedia database implementations. Firstly, a centralised organisation of a media server requires immense storage and computation resources. With a growing number of user queries and data

Figure 2. Classification of parallel architectures: a) shared everything; b) shared disk; c) shared nothing



to be organised, such a centralised system will quickly reach the borders of its capabilities and the quality of service is no longer fully sustainable.

One possible solution for this problem is offered by distributed and parallel architectures, where multiple processing elements (PEs) work cooperatively on an efficient solution of a large problem. The data and the programs are spread over several nodes, so that the processing is accelerated (parallel processing) or the path to the user is shortened (distributed processing, e.g., video-on-demand servers).

There are many possible ways for the organisation of such architecture; the well-known are shared everything, shared disk, and shared everything architectures shown in Figure 2.

Due to the shared utilisation of the hard disks, buses, and memory in case of shared disk and shared everything architecture respectively, the data throughput in these architectures is rather low and the response time long. Experimental measurements executed in Bretschneider, Geisler and Kao (2002) showed that shared nothing architectures – in particular cluster-based systems – with an appropriate data distribution across the multiple nodes are most suitable for the realisation of an efficient multimedia retrieval. A node is defined as an entity consisting of a PE, a memory, a storage resource, and a network adapter.

The database running on this architecture can be denoted as a parallel and distributed database: The data are distributed over all nodes, but logically combined in a single entity, making it look like a single database system from the outside. The only difference noticeable to the user is the performance improvement of the system, which results from utilising the parallelism in the computer network. Further characteristics concern the optimisation of queries, controlling parallelism, recovery, integrity, and security. All these aspects are already well defined for conventional database systems, and have been analysed in detail. However, the possibility of a geographically separated data distribution introduces new constraints and requires additional communication and synchronisation mechanisms. The problems grow more complex when heterogeneous computer architectures, long processing times per data set – as in multimedia applications –, hardware and software failures, and so forth have to be considered.

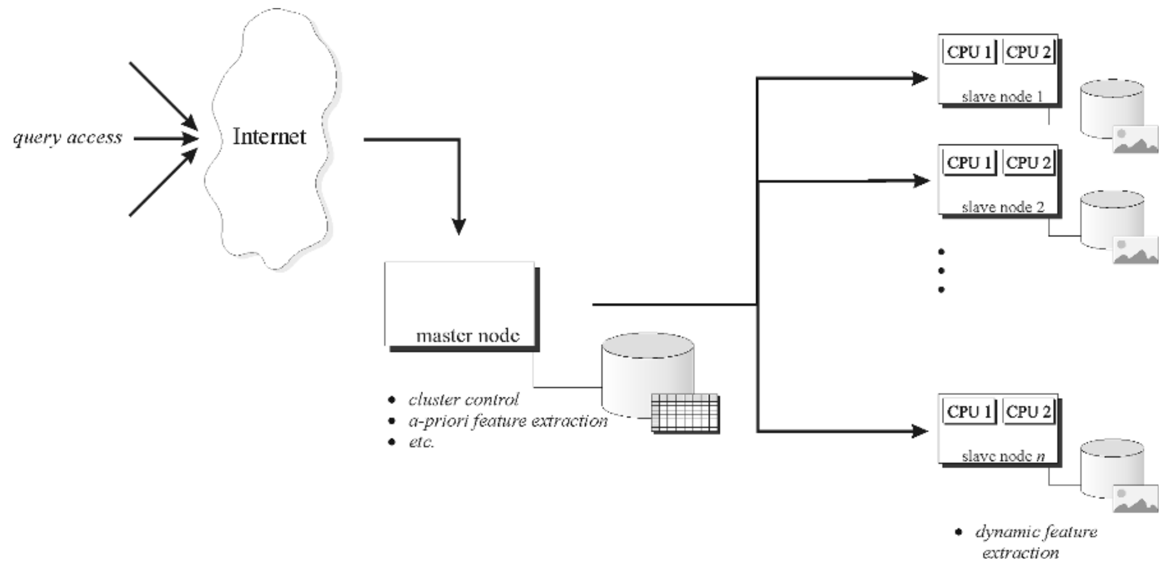
As already noted, the data distribution is a crucial efficiency aspect and has to fulfil numerous, sometimes even conflicting requirements: The data needed by an operation should – if possible – all be on one node (*data locality*). On the other hand, as many operations as possible should be processed in parallel, that is, the data should be distributed evenly among all available nodes. A drawback of the broad distribution is given by the time-consuming data transfer between the individual nodes, which affects the performance significantly. Thus a general distribution is not applicable; hence it has to be tailored for the current application. One possible solution will be presented in the following by considering the cluster-based multimedia database Cairo as an example (Kao & Stapel, 2001).

The general Cairo architecture shown in Figure 3 consists of:

- Query stations host the Web-based user interfaces for the access to the database and for the visualisation of the retrieval results.
- Master node controls the cluster, receives the query requests and broadcasts the algorithms, search parameters, the sample media, features, and so forth to the compute nodes. Furthermore, it unifies the intermediate results of the compute nodes and produces the final list with the best hits.
- Compute nodes perform the image processing and comparisons. Each of these nodes contains at least one partition and executes all operations with the data stored on the local devices. The computed intermediate results are sent to the master node.

The distribution of the media stock across the individual cluster nodes is created according to the following requirements:

Figure 3. Schematic of the Cairo cluster architecture



- Similar storage sizes of the partitions and thus an even distribution of the media across the individual nodes,
- Computation reduction for the retrieval, and
- Minimising the communication between the cluster nodes.

Cairo uses a content-independent, size-based strategy for the available media stock that creates a set of partitions $P = P_1 \cup P_2 \cup \ldots \cup P_n$ where $P_i \cap P_j = \emptyset$ and size(P_i) $\approx$ size(P_j) for all i,j, i$\neq$j. The current image under investigation is assigned to the node with the least storage space used. This process is repeated until all images are distributed to the partitions.

The processing of a partition P_i is executed per media instance. The individual operations are independent of one another, so the order of execution is irrelevant. This initial partitioning makes it possible for all nodes to have uniform processing times, assuming a homogenous, dedicated execution platform. The management overhead depends on the operator applied and the structure of the partial results. However, this time is usually neglectable, compared to the media processing times.

The advantage of a static distribution is that expensive computations and data transfers are not necessary during runtime and the partitioning can be manually optimised and adapted to a given application. On the other hand, short-term reactions to variable workloads among the nodes are not possible. A dynamic distribution of the data is done during runtime and considers the current workload of the nodes, as well as the number and the structure of pending queries. Idle times can be minimised by continuously re-distributing the data, and increasing the total throughput. Unfortunately, the long communication time for multimedia data often eliminates all performance advantages gained through the parallel processing.

After the partitions are created, these are distributed evenly over the cluster nodes, allowing parallel retrieval by executing the same operations on all nodes with the local media subset. The implementation is based on the following components:

- Transaction manager encompasses the analysis of the transformations to be executed and the order of the operations.
- Distribution manager receives a list of algorithms to be executed and a set of media instances as input. Then the programs for the analysis and comparison are compiled and sent to the computing managers.
- Computing manager controls the execution of the extraction algorithms with the local data. The process runs on each cluster node and supervises the communication with the master node.
- Result manager: The data partitioning in disjoint subsets results in a sub-ranking per node that need to be unified by the result manager.
- Update manager realises the media insertion in the database. The raw data are transformed in a uniform format and tagged with a unique identifier. All procedures for feature extraction are then applied. Finally, the cluster node, on whose hard disk the raw data are to be stored, is determined.

The described organisation was successfully implemented and evaluated in real-world scenarios. The minimised communication between the nodes allows a nearly full utilisation of the available compute resources and leads to a linear speedup; that is, the response time is shortened by a factor equal to the number of included nodes.

Other performance relevant parts of a multimedia database system are still the subject of research. Examples are given by the disk scheduler for multimedia storage (Huang & Huang, 2004) and scheduling for broadcasting videos and audios (Yoshihisa & Tsukamoto, 2003).

FUTURE TRENDS

Despite the immense development of multimedia in recent years, the efficient organisation and retrieval of multimedia data still remains a large scientific challenge. The growing number of multimedia data and new applications fields are the driving forces.

The consideration of semantic information is necessary to realise a human-like retrieval approach for images, video and audio and to integrate multimedia components in the semantic Web for ubiquitous access. Furthermore, the current restriction of the most databases to a single media type will be eliminated by methods for multimodal retrieval. For example, the editor of a newscast needs access to videos from news agencies, images from photographs, audios files from radio and text from newspaper articles. Merging the information into a single database requires methods to classify all these media instances and measure the content-based similarity between them. Speech recognition for example can be used to compare audio or video files with textual information. Multimodal access accommodates different user profiles or device capabilities and can help to receive improved query results.

Not only different media types but also media data from different providers have to be merged to create a large distributed multimedia warehouse or a multimedia grid. MPEG-21 is designed for the content description and digital rights management. Load balancing, data distribution and quality of service considerations are necessary to achieve high performance and consumer satisfaction in a very heterogeneous environment. Finally, the multimedia information has to be accessible for mobile devices using standards such as UMTS.

CONCLUSION

Traditional databases offer a search for certain media instance based on describing key words. The main invention of multimedia databases is the possibility to search directly on the media content. However, this time-consuming process has to be performed in parallel to achieve acceptable response times. The cluster architecture scales well even for a high number of processing elements, but if and only if the underlying data partitioning strategy is suitable for the given application.

Further research is needed to give the user feedback on how to improve the query and how to supply the system with feedback about the relevance of delivered results. A further aspect is the improvement of the database design, especially data distribution in parallel environments. Furthermore, advanced methods for semantic content description have to be exploited.

KEY TERMS

A-Priori Feature Extraction: Analysis and description of the media content at the time of insertion in the database. The gained information is stored in a database and enables content-based retrieval of the corresponding media object without actually accessing the latter.

Cluster: Parallel architecture that contains multiple "standard" computers connected via a high performance network that work together to solve the problem.

Dynamic Feature Extraction: Analysis and description of the media content at the time of querying the database. The information is computed on demand and discarded after the query was processed.

Feature Vector: Data that describe the content of the corresponding multimedia object. The elements of the feature vector represent the extracted descriptive information with respect to the utilised analysis.

Load Balancing: Techniques to distribute the tasks over the single processors in parallel systems in a way that idle time is minimized.

Multimedia Database (after Khoshafian & Baker): A multimedia database system consists of a high performance database management system and a database with a large storage capacity, which supports and manages, in addition to alphanumerical data types, multimedia objects with respect to storage, querying, and searching (Khoshafian & Baker, 1996).

Quality of Service (QoS): The collective term for all demands on the recording and the replaying procedures, which refer to generating and maintaining a continuous data stream.

Query by Example/Sketch/Humming: Methods to formulate queries in multimedia databases. The user provides an example media file and the result of the database system is a set of similar media files. If no example is available the user can draw a sketch or hum a melody.

Retrieval: Accessing stored information from the database.

Personal Information Privacy and Internet Technology

Edward J. Szewczak
Canisius College, USA

INTRODUCTION

Concerns about the collection of personal information by Internet technology and the possibility of misuse of that information are a primary reason why people limit their use of the Internet and are even limiting the success of e-commerce (Szewczak, 2004). Various uses of technology that collect and/or disseminate personal information include corporate and government databases, e-mail, wireless communications, clickstream tracking, hardware and software watermarks, and biometric devices. The main challenge to personal information privacy is the surreptitious monitoring of user behavior on the Internet without the user's consent and the possible misuse of the collected information resulting in financial and personal harm to the user. Our focus is primarily on Internet use in the United States of America, though clearly the technology is global in nature and poses challenges and issues for societies around the world.

PERSONAL INFORMATION AND INTERNET USE

The results of a 1998 survey conducted by Louis Harris & Associates, Inc. revealed that worries about protecting personal information ranked as the top reason people generally are avoiding the Web (Hammonds, 1998). A survey by NFO Interactive (*www.nfoi.com*) found that the safekeeping of online consumer personal information was the main reason people chose not to shop online. The misuse of credit card data for activities such as identity theft is a major concern (*Consumer Reports*, 2003).

Some recent events serve to confirm these concerns. Italian Privacy Commissioner Stefano Rodota ordered Infostrada to temporarily shut down its free ISP service because it required users to disclose their age, health status, sexual habits and political, labor and religious preferences in order to qualify for the service. Infostrada said that the information was required for marketing purposes (*http://www.privacytimes.com/NewWebstories/oxymoron_prv_2_23.htm)*. Failed Internet companies such as Boo.com, Toysmart.com and CraftShop.com have either sold or have tried to sell customer data that may include phone numbers, credit card numbers, home address and statistics on shopping habits, even though they had previously met Internet privacy monitor Truste's criteria for safeguarding customer information privacy. The rationale for the selling was to appease creditors (Sandoval, 2000). The Foundation for Taxpayer and Consumer Rights purchased the Social Security numbers and home addresses of the CIA director and the U.S. Attorney General on the Internet for $26 (Kerr, 2003).

WHAT IS PRIVACY?

In his excellent study on privacy in the information age, Cate (1997) adopted the definition of privacy as "the claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others" (Westin, 1967, p. 7). Westin/Cate's definition is interesting because it allows for flexibility in discussing privacy within the context of the Internet. Whereas many people worry about divulging personal information electronically, other people seem more than willing to give it away, trading their personal information for personal benefits such as free shipping and coupons (Kuchinskas, 2000). Personalized service is the main benefit. A Web site can save a shopper time and money by storing and recalling a user's tastes and buying habits (Baig, Spepanek & Gross, 1999). ISPs are willing to allow Web users cheaper access to the Internet provided the users are amenable to having their online behavior tracked for marketing purposes by specialized software (Angwin, 2000). Spyware installs itself on computers when users download programs, and then tracks each click the user makes (Hagerty & Berman, 2003).

TECHNOLOGICAL CHALLENGES TO PRIVACY

Government regulators and enforcement officials have to consider a host of technological challenges to personal information privacy on the Internet.

Corporate and Government Databases

The practice of gathering personal information about customers and citizens by corporations and governments is well established. Software is available that is dedicated to analyzing data collected by company Web sites, direct-mail operations, customer service, retail stores, and field sales. Web analysis and marketing software enable Web companies to take data about customers stored in large databases and offer these customers merchandise based on past buying behavior, either actual or inferred. It also enables targeted marketing to individuals using e-mail. Governments routinely collect personal information from official records of births, deaths, marriages, divorces, property sales, business licenses, legal proceedings, and driving records. Many of the databases containing this information are going online (Bott, 2000). MGM Mirage's online gambling business is aided by online screening programs wherein a bettor's location is determined using Internet mapping software and personal details checked against six external databases (King, 2003).

The deregulation of the financial services industry has made it possible for banks, insurance companies, and investment companies to begin working together to offer various financial products to consumers. Personal financial information that was kept separate before deregulation can now be aggregated. In fact the ability to mine customer data is one of the driving forces behind the creation of large financial conglomerates. Services can be offered to customers based on their information profiles. Large credit bureaus such as Equifax and Trans Union have traditionally been a source of information about a person's credit worthiness. Their databases contain information such as a person's age, address, and occupation. Credit bureaus have begun to sell personal information to retailers and other businesses (*Consumer Reports,* 2000a).

Like personal financial information, medical information is for most people a very private matter. Despite this fact, there is a wealth of personal medical data in government and institutional databases. As *Consumer Reports* (2000b, p. 23) notes:

The federal government maintains electronic files of hundreds of millions of Medicare claims. And every state aggregates medical data on its inhabitants, including registries of births, deaths, immunizations, and communicable diseases. But most states go much further. Thirty-seven mandate collection of electronic records of every hospital discharge. Thirty-nine maintain registries of every newly diagnosed case of cancer. Most of these databases are available to any member of the public who asks for them and can operate the database software required to read and manipulate them.

Much of personal health information that is available to the public is volunteered by individuals themselves, by responding to 800 numbers, coupon offers, rebate offers and Web site registration. Much of the information is included in commercial databases like Behavior-Bank sponsored by Experian, one of the world's largest direct-mail database companies. This information is sold to clients interested in categories of health problems, such as bladder control or high cholesterol.

E-mail

E-mail accounts for 70% of all network traffic, yet only 10% of it is protected by security measures. Thus it is susceptible to tampering and snooping (Armstrong, 2000; Weingarten & Weingarten, 2002). In many companies, employee e-mail communications are routinely monitored. Despite the fact that most companies had policies alerting employees that they were subject to monitoring, 25% surveyed had fired employees based on evidence collected during monitoring (Seglin, 2000). Hackers can also be a problem. Programs can be surreptitiously installed that monitor a user's keystrokes. The keystrokes can be sent across the Internet to a computer that logs everything that is typed for later use (Glass, 2000).

Employees' invasion of privacy claims have not been upheld in the United States courts, which argue that, since employers own the computer equipment, they can do whatever they want with it (McCarthy, 2000).

Wireless Communications

Wireless advertising poses a host of challenges for privacy advocates. Wireless service providers know customers' names, cell phone numbers, home and/or office addresses, and the location from where a customer is calling as well as the number a customer is calling. Each phone has a unique identifier that can be used to record where in the physical world someone travels while using the cell phone (Petersen, 2000). The Federal Communications Commission requires cell phone service providers to be able to identify the location of a caller who dials 911, the emergency number. Since a cell phone service provider can track the location of a 911 call, it can track the location of any other call as well.

Clickstream Tracking

Tracking employee behavior on the Internet has become common practice. Software programs have been specifically designed to monitor when employees use the Internet and which sites they visit (McCarthy, 1999b).

Internet companies monitor Internet user behavior by a number of means, primarily to gather data about shopping and buying preferences with a view toward developing "user profiles". These technological means include capturing and examining environment variables, cache memory, and cookies (*http://www.cnil.fr/traces*).Environment variables contain data about a user's system configuration and site last visited. These variables include a user's domain name, system address, IP (Internet Protocol) address, operating system version, browser version, and URL of the last site visited. These data are transmitted with each packet of data transmitted to an Internet server, where they are extracted by a CGI (Common Gateway Interface) script (program). This capturing of data happens without the user's explicit consent.

Cache memory is a commonly available technology that was developed to improve file download time and maximize network performance. When a user requests access to a Web site, the browser checks a directory on the user's hard drive to see if the Web page had been loaded previously. If not, it records the page on the user's hard disk and displays it on the screen. The next time the same request is made, the browser reads the page from the hard disk and saves network resources by not requiring an additional server transmission. The cache memory is not hidden and may be accessed by an outside observer using another computer, thereby revealing the sites that have been visited.

Cookies are text files created by a Web server and stored on a user's hard disk. A cookie is a set of fields that a user's computer and a server exchange during a transaction. The server may change or suppress the contents of a cookie it has created. Web servers work with ad placement companies that resell advertising space from popular sites. These companies maintain large databases in which are recorded details about who looks at which pages. When a user connects to a Web site, the browser checks the cookies on the hard drive. If a cookie matches the site's URL, the browser uploads the cookie to the Web site. With the information contained in the cookie, the site can run programs that personalize site offerings and/or track the user's activity while online.

Hardware and Software Watermarks

Hardware and software identifiers (watermarks) can also be used to identify individual users.

In 2000 Intel Corporation announced it would include a unique Processor Serial Number (PSN) in its new Pentium III microprocessor chips. The rationale for the PSN was that it was to be used for authentication purposes in e-commerce insofar as the PSN would be linked to a person's real-world identity. Though Intel later decided not to include a PSN in its chips, the possibility of a privacy challenge was evident (*http://www.bigbrotherinside.org*).

Every Ethernet card used in computer communications has its own MAC (Medium Access Control) address, a 48-bit number sent in the header of every message frame. As the Ethernet standard evolves into a wide-area communications protocol, this identifier may become of increasing concern to Internet users intent on protecting their privacy (Dornan, 2000).

Microsoft Corporation includes a unique numeric identifier into every copy of its Office program. When a Microsoft Office document is created, it is watermarked with this unique identifier (*http://www.forbes.com/Forbes/99/1129/6413182s1.htm*).

Biometric Devices

Various devices are available that identify people through scans of their faces, hands, fingers, eyes, or voice. Biometric devices create a statistical profile by assessing a number of biological characteristics. Using biometrics it is possible to scan millions of faces and other characteristics into a computer database. Privacy advocates object to the fact that much of the measurement taking happens without the knowledge or explicit cooperation of a subject, which can lead to abuses of the technology (Stepanek, 2000). However, seven states have chosen to use Viisage Technology's facial recognition systems to lessen identify theft. Scientists working for the U.S. Commerce Department's National Institute of Standards and Technology have recommended that a combination of fingerprint and facial technologies be used to secure U.S. borders (Armstrong, 2003).

FUTURE TRENDS

The issue of personal information privacy and the Internet continues to be debated within the community of Internet users. Privacy is a social issue, generally speaking. How the personal information privacy debate is ultimately resolved will be decided by the values inherent in a society. Since the position of the privacy advocates differs so markedly from the position of the technology growth advocates, and since privacy issues have been addressed in court and precedents established in state and common law, it seems likely that the personal information privacy debate will be resolved in the world's legislatures and resulting laws enforced in the courts (Lessig, 1999). The U.S. has seen the passage of the Health Insurance Portability and Accountability Act that prohibits unauthorized disclosures of personal medical information, punishable by a fine up to $250,000 and 10 years in jail (Lueck, 2003). Other nations will have to adopt their own measures to ensure the privacy of their citizens' personal information. Since the Internet is a global technology, perhaps a global effort will be needed to adequately address these issues.

CONCLUSION

Various uses of technology that collect and/or disseminate personal information include corporate and government databases, e-mail, wireless communications, clickstream tracking, hardware and software watermarks, and biometric devices. Clearly the challenges to personal information privacy posed by the various forms of Internet technology are not the result of the technology itself. Rather it is the uses of the technology that pose the threat to the integrity of personal information privacy. In particular, the surreptitious monitoring of user behavior without the user's consent and the possible misuse of the collected information pose the biggest threats. The various nations of the world must come to grip with these challenges in their own way, perhaps working in unison. Otherwise the personal information privacy of their citizens will be continuously at risk.

KEY TERMS

Biometrics: The use of technological devices to identify people through scans of their faces, hands, fingers, eyes or voice.

Cache Memory: A technology developed to reduce file download time and maximize network performance.

Clickstream Tracking: The use of software to monitor when people use the Internet and what sites they visit.

Cookies: Text files created by a Web server and stored on a user's hard disk that contain data about which Web sites have been visited.

Environment Variables: System variables whose values contain data about a user's system configuration and Web site last visited.

Identity Theft: The stealing and use of a person's identity through the acquisition of personal information without that person's knowledge or permission.

Personal Information: Information about, or peculiar to, a certain person or individual.

Privacy: The claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others (Westin).

Spyware: Software that installs itself on computers when programs are downloaded and that tracks each user click, usually without the user's knowledge or permission.

Personal Internet Usage and Quality of Worklife

Pruthikrai Mahatanankoon
Illinois State University, USA

INTRODUCTION

The management of Internet usage in the workplace is becoming one of most important productivity concerns of the modern workplaces. Through proper use of Internet technology, organizations reap the benefits of efficient communication and information sharing among employees, managers, and organizations' customers. The Internet is an essential necessity, as global business expansion requires networked organizations that can understand and predict future market trends, analyze competitors' movements, and identify vital environmental factors that could be affecting their competitive position. For this reason the Internet has provided many added benefits for organizations, and modern workplaces have equipped their employees with access to the Internet and provided individual e-mail accounts.

Not until recently, Internet usage in the workplace has received a negative view from the business community. The issue of employees spending their work time on personal activities is not new to management. In some ways, spending time on personal telephone conversations, taking longer break times, or chatting with colleagues in the office is similar to personal Internet usage. Unfortunately, publicized cases of Internet abuse in the workplace, such as pornography, employee harassment, information leakage, and software piracy, have generated different and increasingly more serious ethical, legal, and productivity concerns for many organizations.

A study conducted in the year 2000 by NFO Interactive indicated that one out of three employees spends at least 2.5 hours of work time per week on non-work-related Internet surfing. Recent online industry studies suggest that such Internet usage in the workplace costs U.S. organizations approximately $1 billion annually in lost productivity (Foster, 2001). When Internet usage policy (IUP) or broad communication regarding proper Internet usage between employees and management does not work, stronger practical solutions are implemented to handle Internet abuse, such as reprimanding employees, deploying Internet monitoring and filtering software to restrict non-work-related Web site access, even restricting the hours of access. Although these strategies have shown improvement in employees' productivity and reduction in occurrences of Internet abuses, a thorough understanding of their impact on employees' job satisfaction and quality of work life still requires further investigation.

Evidence shows that Internet filtering and monitoring tools have led to employee dissatisfaction and other productivity debates. Urbaczewski and Jessup (2002) suggest that employee motivation generally plays a significant role in productivity, performance, and satisfaction in the workplace, but employee dissatisfaction increases with any type of organizational monitoring, including Internet monitoring. Management finds it difficult to maintain a workable balance between proper behavioral controls and employee empowerment. Because both stringent control and little control generally lead to abuse, management of Internet usage in the workplace requires developing a balance of human resource strategies with individual psychological considerations to maintain and improve employee satisfaction and well-being overall. To identify the appropriate balance, it is important to understand and examine the various Internet usage behaviors.

BACKGROUND OF INTERNET USAGES BEHAVIORS

The literature related to non-work-related Internet usage in the workplace can be classified into three categories: pathological, personal, and abusive. Influenced by various individual and social psychological aspects, each category deserves a research area of its own, involving different sets of determinants and consequences related to each behavioral category.

Pathological Internet Usage (PIU) involves excessive Internet usage from people who use the Internet as a means of coping with their personal problems or current personal difficulties (David, 2001). Psychology literature defines any extensive usage of the Internet where users have no control over their behaviors as "Internet addiction" (Greenfield, 1999; Young, 1998a). Internet addiction is currently being viewed as similar to substance abuse or a gambling addiction (Young, 1998b). PIU causes a specified number of psychological symptoms, such as altered moods, denial of responsibilities, guilt, and craving (Morahan-Martin & Schumacher, 2000). Brenner (1997) claims that Internet addicts have a higher tolerance level, withdrawal symptoms, and craving for the Internet as compared to normal Internet users. However, the addictive symptoms happen only to a minority of obsessive and/or compulsive users (Griffiths, 2000). In general workplace settings, occurrences of PIU or Internet addition are atypical; organizations can deal with problem employees specifically. Research finds that normal employees utilize the Internet for its usefulness, information content, ease of use, and communication (Stevens, Williams & Smith, 2000), whether the access is work-related or not.

Personal Web Usage in the Workplace (PWU) is defined as voluntary online Web behaviors during working time where employees use any of the organization's Internet resources for activities outside current customary job/work requirements (Anandarajan & Simmers, 2002). These activities include any leisure and/or personal use of the Internet at work; for example, using the Internet to escape from work by spending work time on the Internet searching for news and entertainment information, shopping online, booking personal vacations, and using a personal e-mail account to send messages to friends and family (Mahatanankoon, Anandarajan & Igbaria, 2004). In some cases, personal Web usage is also now referred to as cyberloafing (Lim, 2002), cyberslacking, or Internet abuse (Anandarajan, 2002; Young & Case, 2004).

Internet abuse is a general term often used mostly by practitioners; it refers to any wrongful or improper use of the Internet in the workplace. Behaviors related to Internet abuse are often more severe in nature, such as viewing pornography, harassing other employees, downloading illegal software, moonlighting, playing online games, online chatting, and so forth.

Although *Internet abuse* and *pathological Internet usage* lead to lost productivity, wasted or overused network bandwidth, and other possible legal liabilities, low to moderate non-work-related usage may in fact lead to positive consequences. There are studies suggesting that some *personal Web usage* in the workplace can be a healthy recipe for a productive work life. In fact, satisfied and productive employees frequently use the Internet (Stanton, 2002). Restricting online recreational activities may prevent employees from using the Internet to its full potential. Therefore, organizations should take actions both to empower and educate employees about the balance between work and play (Oravec, 2002). Others recommend organizations should not restrict personal Web browsing and take the necessary training steps to "facilitate the transfer of learning from the play domain to work-related tasks" (Belanger & Van Slyke, 2002, p. 65). Table 1 summarizes the possible benefits and potential drawbacks of *personal Web usage* at work.

ENHANCING QUALITY OF WORK LIFE

As evidence encourages low to moderate non-work-related behaviors in the workplace, managers and practitioners are left with new issues to maintain an effective workplace Internet management strategy. The solutions deal more or less with understanding the relationship between employees' well-being and employee job performance, and filtering out Web sites that could potentially lead to unproductive employees or legal liabilities.

Because personal Web usage in the workplace may influence the well-being of motivated employees, organizations must take precautions against the restriction of PWU. In some cases, employee training or education, together with effective communication between management and employees, can reduce the impact of Internet abuse. Too much PWU or too little PWU leads to Internet abuse (Anandarajan, 2002). When Internet monitoring is necessary to enforce appropriate social norms, an organizational Internet usage policy (IUP) should be based on maintaining employee job performance without lowering the positive quality of work life. Management can thus create a healthy workforce through use of an "*adaptive Internet monitoring and filtering policy* (AIMF)" (refer to Figure 1).

Adaptive strategy implies that in order to improve employee well-being, organizations should allocate time for PWU when employees have performed up to management expectations or their job requirements. The Adaptive Internet Monitoring and Filtering policy (AIMF) requires a reciprocal sense of respect and fulfillment of an organizational and employee psychological contract. Employees themselves need to have self-discipline and a strong work ethic. In some cases, changing employee behaviors requires organizational support and commitment that is established through Internet training, education, and peer influence. Organizations must also take employees' personal needs and job characteristics into consideration, including the organizational culture, the technological infrastructure, and individual employee roles and statuses. These factors dictate the amount of Internet usage activities performed by each employee. However, the purposes of using the Internet and its usage norms (whether at home or at work) are indeed "co-evolving" (Kraut & Kiesler, 2003), so it is difficult for organizations to examine the relationships between various non-work-related Internet activities, and any individual and organizatonal outcomes.

Management must decide on the tradeoffs between employee job satisfaction, job performance, and organizational liability. In other words, performing certain PWU

Table 1. Benefits and drawbacks of personal Web usage in the workplace

Benefits	Drawbacks
• Increase job satisfaction • Reduce stress • Increase job performance • Increase employee empowerment and learning • Improve social integration and collaboration	• Productivity loss, both for organizations and employees • Wasted network bandwidth • Possible legal liability • Information leakage • Overpaid employees; lost wages

activities can increase an employee's job satisfaction by amplifying their *intrinsic* demands and increase job performance by reducing stress; however, such behaviors can also lead to higher organizational risks and operating costs. One recommended strategy is to examine each PWU activity based on job satisfaction and job performance dimensions (Mahatanankoon & Igbaria, 2004). Figure 2 shows a 2x2 workplace Internet monitoring and filtering decision grid.

The grid has two dimensions: employee well-being and job performance. Employee well-being is related to job satisfaction, intrinsic motivation, and the quality of work life. Job performance involves job productivity, extrinsic motivation, and efficiency and effectiveness at work. Different PWU activities influence the two dimensions distinctly, suggesting possible actions that organizations can employ when deciding which PWU activities should be permitted and which activities should be restricted. Organizations should permit PWU activities that fall within Area 1 (high well-being/high performance) and strongly restrict activities in Area 4 (low well-being/low performance). Examples of PWU in Area 1 include learning about educational training classes related to work, visiting professional Web sites, reading current news/events to fulfill an employee's career or promotional goals, and searching for new business tools (Anandarajan, Devine & Simmers, 2004), including activities related to personal e-commerce (Mahatanankoon & Igbaria, 2004). However, PWU activities in Area 4 fall into Internet abuse categories, such as visiting pornography sites, downloading music or illegal software, online chatting, or playing games online. These activities should be strictly monitored and restricted, as they create lower employee work performance and job satisfaction, as well as increase organizational legal liabilities.

PWU activities in Area 2 (low well-being/high performance) and Area 3 (high well-being/low performance) fall into gray areas. The trade-offs between performance and job satisfaction should be based on management judgment (Mahatanankoon & Igbaria, 2004). In other words, an Internet monitoring/filtering policy should rely on general norms, cultural fits, and the objectives of each organization. The productive use of the Internet in the workplace falls within Area 2, including those uses commonly related to work, such as accessing organizational intranet/extranet sites; sending and sharing information with coworkers; visiting customers, suppliers, and/or competitors' Web sites, and so forth. To the contrary, Internet usages in Area 3 are generally related to leisure and recreational activities, which tend to reduce stress but do not have a direct impact on job performance - for example, using personal Web-based e-mails for personal communication with friends and family, surfing the Internet without any purpose, exploring personal hobbies and interests, reading general news and sport scores, and so forth. Taking the AIMF perspective, as activities

Figure 1. Adaptive Internet monitoring and filtering policy

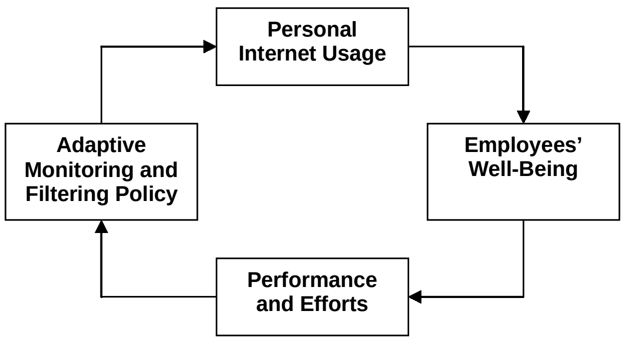

Figure 2. Workplace Internet monitoring and filtering decision grid

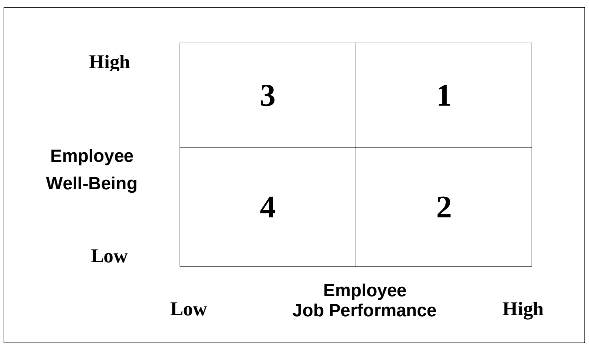

in Area 2 (low well-being/high performance) intensify, organizations should be ready to permit Area 1 (high well-being/high performance) and Area 3 (high well-being/low performance) activities to expand.

FUTURE RESEARCH

Monitoring strategy should align with organizational culture (Urbaczewski, 2004). Earlier research into the area of "junk computing" can be related to PWU. Junk computing refers to the use of organizational information technology that does not align with organizational goals (Guthrie & Gray, 1996). According to the definition, examples of junk computing are games, personal work, junk reporting, excessive unproductive computer work, and excessive e-mails. The new challenge for Internet-enabled workplaces is to find the right balance between work and play. Future studies need to examine:

- positive/negative relationships between various non-work-related Internet activities and job satisfaction or work performance;
- suitable attitudinal changes that enhance work/play ethics of employees;
- technological strategies to use to identify problem employees, and the proper tactics to reprimand valued employees;
- the moderating effects of cultural differences on non-work-related behaviors; and
- possible determinants that can lead to a different spectrum of Internet behaviors.

CONCLUSION

The Internet has been become one of the most technological necessary tools in today's workplace. The broad scope of its usefulness and ease of use make the Internet most beneficial to employee daily work activities as well as other personal activities. This article identifies the impact of personal Internet usage on employee job satisfaction and performance, and recommends several strategies that management can implement to increase employee well-being. Balancing strategies - such as a workplace Internet monitoring and filtering decision grid, and an adaptive Internet monitoring and filtering policy - will help researchers and practitioners to better understand the Internet usage patterns of employees and assist them in implementing better Internet usage policies that fit the workplace environment, employees' personal agendas, and management goals.

KEY TERMS

Cyberloafing: Any voluntary act of employees using their organization's Internet access during office hours to surf non-work-related Web sites for non-work purposes, and access non-work-related e-mail.

Internet Abuse: Any wrongful or improper use of the Internet in the workplace.

Internet Filtering and Monitoring Software: Software tools used for reducing occurrences of Internet abuse by blocking inappropriate Web sites and identifying frequently visited Web sites.

Internet Usage Policy (IUP): An organizational policy handed down to employees that governs the use of the Internet in a specific workplace. The goals of an IUP, if properly written and implemented, are to help organizations communicate proper Internet usage behaviors, lessen employees' perceived expectation of privacy, and reduce costly litigation that may occur from the use of Internet monitoring and filtering software.

Junk Computing: The use of organizational information technology that does not align with organizational goals.

Pathological Internet Use (PIU): Excessive Internet usage from people who use the Internet as a means of coping with their personal problems or current personal difficulties.

Personal Web Usage in the Workplace (PWU): Voluntary online Web behaviors during work time where employees use any of the organizations' resources for activities outside current customary job/work requirements.

Quality of Work Life: Workplace hygiene factors that support the well-being and job satisfaction of employees.

Perturbations, Accuracy and Robustness in Neural Networks

Cesare Alippi

Giovanni Vanini
Politecnico Di Milano, Italy

INTRODUCTION

A robustness analysis for neural networks, namely the evaluation of the effects induced by perturbations affecting the network weights, is a relevant theoretical aspect since weights characterise the "knowledge space" of the neural model and, hence, its inner nature.

In this direction, a study of the evolution of the network's weights over training time (training perturbations) allows the researcher for shedding light on the mechanism behind the generation of the knowledge space. Conversely, the analysis of a specific knowledge space (fixed configuration for weights) provides hints about the relationship between knowledge space and accuracy. This aspect is particularly relevant in recurrent neural networks, where even small modifications of the weight values are critical to performance (e.g., think of the stability of an intelligent controller comprising a neural network and issues, leading to robust control).

Robustness analysis must also be taken into account when implementing a neural network (or the intelligent computational system) in a physical device or in intelligent wireless sensor networks. Behavioral perturbations affecting the weights of a neural network abstract uncertainties such as finite precision representations, fluctuations of the parameters representing the weights in analog solutions (e.g., associated with the production process of a physical component), aging effects or more complex and subtle uncertainties in mixed implementations.

In this article, we suggest a robustness/sensitivity analysis in the large, that is, without assuming constraints on the size or nature of the perturbation; as such, the small perturbation hypothesis becomes only a sub-case of the theory. The suggested sensitivity/robustness analysis can be applied to all neural network models (including recurrent neural models) involved in system identification, control signal/image processing and automation-based applications without any restriction to study the relationship between perturbations affecting the knowledge space and the induced accuracy loss.

ROBUSTNESS ANALYSIS: THE STATE OF THE ART

The sensitivity/robustness issue has been widely addressed in the neural network community with a particular focus on specific neural topologies. In particular, when the neural network is composed of linear units, the relationship between perturbations and the induced performance loss can be obtained in a closed form (Alippi & Briozzo, 1998). Conversely, when the neural topology is non-linear we have either to assume the small perturbation hypothesis or particular assumptions about the stochastic nature of the neural computation, for example, see Alippi and Briozzo (1998), Pichè (1995), and Alippi (2002b); unfortunately, such hypotheses are not always satisfied in real applications. Another classic approach requires expanding the neural computation with Taylor around the nominal value of the trained weights. A subsequent linearized analysis follows which allows the researcher for solving the sensitivity issue problem (Pichè, 1995). This last approach has been widely used in the implementation design of neural networks where the small perturbation hypothesis abstracts small errors introduced by finite precision representations of the weights (Dundar & Rose, 1995; Holt & Hwang, 1993). Again, the validity of the analysis depends on the validity of the small perturbation hypothesis.

Differently, other authors avoid the small perturbation assumption by focusing the attention on very specific neural network topologies and/or by introducing particular assumptions regarding the distribution of perturbations, internal neural variables and inputs as done for Madalines neural networks (Stevenson, Winter, & Widrow, 1990; Alippi, Piuri, & Sami, 1995).

Some other authors tackle the robustness issue differently by suggesting techniques leading to neural networks with improved robustness ability by acting on the learning phase (e.g., see Alippi, 1999) or by introducing modular redundancy (Edwards & Murray, 1998); though, no robustness indexes are suggested there.

A ROBUSTNESS ANALYSIS IN THE LARGE

In the following, we consider a generic neural network implementing the $\hat{y}(x) = f(\hat{\theta}, x)$ function where $\hat{\theta}$ is the weight vector of the trained neural network.

In several neural models, and in particular in those related to system identification and control, the relationship between the inputs and the output of the system is captured by considering a regression vector φ, which contains a limited time-window of actual and past inputs, outputs, and, possibly, predicted outputs. Of particular interest are those models which can be represented by means of the model structures $\hat{y}(t) = f(\varphi)$ where function $f(\cdot)$ is a regression-type neural network, characterised by N_φ inputs, N_h non-linear hidden units and a single effective linear/non-linear output (Hassoun, 1995; Hertz, Krogh, & Palmer, 1991; Ljung, 1987; Ljung, Sjoberg, & Hjalmarsson, 1996).

The presence of a dynamic in the data can be modelled by a suitable number of delay elements which may affect inputs (time history on external inputs *u(t)*) system outputs (time history on $y(t)$) on predicted outputs (time history on $\hat{y}(t)$) or residuals (time history on $e(t) = \hat{y}(t) - y(t)$). Where it is needed, $y(t)$, $\hat{y}(t)$ and $e(t)$ are vectorial entities, a component for each independent distinct variable.

Several neural model structures have been suggested in the literature, which basically differ in the regression vector; examples are the NARMAX structures which can be obtained by considering both past inputs and outputs:

$$\varphi = [u(t), u(t-1), \cdots, u(t-n_u), y(t-1), \cdots, \\ y(t-n_y), ..., e(t-1), \cdots, e(t-n_e)]$$

and the NOE ones which process only the past inputs and

$$\varphi = [u(t), u(t-1), \cdots, u(t-n_u), \hat{y}(t-1), \cdots, \hat{y}(t-n_y)].$$

Static neural networks, such as classifiers, can be obtained by simply considering external inputs

$$\varphi = [u(t), u(t-1), \cdots, u(t-n_u)].$$

We denote by $\hat{y}_\Delta(x) = f_\Delta(\hat{\theta}, \Delta, x)$ the mathematical description of the perturbed computation and by $\Delta \in D \subseteq \Re^p$ a generic p-dimensional perturbation vector, a component for each independent perturbation affecting the network weights of model $\hat{y}(x)$. The perturbation space D is characterised in stochastic terms by providing the probability density function pdf_D.

To measure the discrepancy between $\hat{y}_\Delta(x)$ and $y(x)$ or $\hat{y}(x)$ we consider a generic loss function $U(\Delta)$. A common example for U is the mean square error (MSE) loss function

$$U(\Delta) = \frac{1}{N_x} \sum_{i=1}^{Nx} (y(x_i) - \hat{y}_\Delta(x_i))^2 \tag{1}$$

but a generic Lebesgue measurable loss function with respect to D can be taken into account (Jech, 1978). The formalization of the impact of perturbation on the performance function can be simply derived as:

Definition: Robustness Index

We say that a neural network is robust at level $\bar{\gamma}$ in D, when the robustness index $\bar{\gamma}$ is the minimum positive value for which

$$U(\Delta) \le \bar{\gamma}, \forall \Delta \in D. \tag{2}$$

Immediately, from the definition of robustness index, we have that a generic neural network NN1 is more robust than another NN2 iff $\bar{\gamma}_1 < \bar{\gamma}_2$; the property holds independently from the topology of the two neural networks.

The main problem related to the determination of the robustness index $\bar{\gamma}$ is that we have to compute $U(\Delta), \forall \Delta \in D$ if we wish a tight bound. The $\bar{\gamma}$-identification problem is, therefore, intractable from a computational point of view if we relax all assumptions made in the literature as we do. To deal with the computational aspect we associate a dual probabilistic problem to (2):

Robustness Index: Dual Problem

We say that a neural network is robust at level $\bar{\gamma}$ in D with confidence η when $\bar{\gamma}$ is the minimum positive value for which

$$\Pr(U(\Delta) \le \bar{\gamma}) \ge \eta \quad \text{holds} \quad \forall \Delta \in D. \tag{3}$$

The probabilistic problem is weaker than the deterministic one since it tolerates the existence of a set of perturbations (whose measure according to Lebesgue is 1-η) for which $u(\Delta) > \bar{\gamma}$. In other words, not more than 100η% of perturbations $\Delta \in D$ will generate a loss in performance larger than $\bar{\gamma}$. Probabilistic and deterministic problems

P

are "close" to each other when we choose, as we do, $\eta \to 1$.

The non-linearity with respect to Δ and the lack of a priori assumptions regarding the neural network do not allow computing (2) in a closed form for the general perturbation case. The analysis, which would imply testing $U(\Delta)$ in correspondence with a continuous perturbation space, can be solved by resorting to probability according to the dual problem and by applying randomized algorithms (Alippi, 2002a; Bai, Tempo, & Fu, 1997; Tempo & Dabbene, 1999; Vidyasagar, 1996; Vidyasagar, 1998) to solve the robustness/sensitivity problem.

RANDOMIZED ALGORITHMS AND PERTURBATION ANALYSIS

In the following, we denote by $p_\gamma = \{U(\Delta) \le \gamma\}$ the probability that the loss in performance associated with perturbations in D is below a given (but arbitrary) value γ.

Probability p_γ is unknown, it cannot be computed in a form for a generic U function and neural network topology, and its evaluation requires exploration of the whole perturbation space D. Anyway, the unknown probability p_γ can be estimated by sampling D with N independent and identically distributed samples Δ_i (intuitively a sufficiently large random sample explores the space); extraction must be carried out according to the pdf of the perturbation. For each sample Δ_i we then generate the triplet

$$\{\Delta_i, U(\Delta_i), I(\Delta_i)\}, i = 1, N \qquad \text{where}$$

$$I(\Delta_i) = \begin{cases} 1 \text{ if } U(\Delta_i) \le \gamma \\ 0 \text{ if } U(\Delta_i) > \gamma \end{cases}. \tag{4}$$

The true probability p_γ can now be simply estimated by means of the frequency as

$$\hat{p}_N = \frac{1}{N}\sum_{i=1}^{N} I(\Delta_i). \tag{5}$$

Of course, when N tends to infinity, $\hat{p}_N$ somehow converges to p_γ. By introducing an accuracy degree ε on the difference $|p_\gamma - \hat{p}_N|$ and a confidence level $1-\delta$ (which requests that the $|p_\gamma - \hat{p}_N| \le \varepsilon$ inequality is satisfied at least with probability $1-\delta$), our problem can be formalized by requiring that the inequality

$$\Pr\{|p_\gamma - \hat{p}_N| \le \varepsilon\} \ge 1-\delta \tag{6}$$

is satisfied $\forall \gamma \ge 0$. In other words (6) states that the true probability and its estimates must be very close (they may differ not more than ε) and that the statement must be true with high probability. Of course, we wish to control the accuracy and the confidence degrees of (6) by allowing the user to choose the most appropriate values for the particular need. Finally, by extracting a number of samples from D according to the Chernoff (1952) bound

$$N \ge \frac{\ln \frac{2}{\delta}}{2\varepsilon^2}, \tag{7}$$

we have that $\Pr\{|p_\gamma - \hat{p}_N| \le \varepsilon\} \ge 1-\delta$ holds for $\forall \gamma \ge 0, \forall \delta, \varepsilon \in [0,1]$

As an example, by considering a 5% in accuracy and 99% in confidence we have to extract 1060 samples from D; with such choice we can approximate p_γ with $\hat{p}_N$ introducing the maximum error 0.05 ($\hat{p}_N - 0.05 \le p_\gamma \le \hat{p}_N + 0.05$) and the inequality holds at least with probability 0.99.

The Chernoff bound grants that the dual probabilistic problem related to the identification of the robustness index $\bar{\gamma}$ can be solved with a polynomial complexity algorithm in the accuracy and the confidence degrees independently from the number of weights of the neural model network. In fact, from (6) if accuracy ε and confidence δ are small enough we can confuse p_γ and $\hat{p}_N$ by committing a small error. As a consequence, the dual probabilistic problem requiring $p_\gamma \ge \eta$ becomes $\hat{p}_N \ge \eta$. We surely assume ε and δ to be small enough in subsequent derivations.

The final algorithm, which allows for testing the robustness degree $\bar{\gamma}$ of a generic neural network, can be summed up as:

1. Select ε and δ sufficiently small to have enough accuracy and confidence;
2. Extract from D, according to its pdf, a number of perturbations N as suggested by (7);
3. Generate the indicator function $I(\Delta)$ and generate the estimate $\hat{p}_N = \hat{p}_N(\gamma)$ according to (5); and
4. Select the minimum value γ_η from the $\hat{p}_N = \hat{p}_N(\gamma)$ function so that $\hat{p}_N(\gamma_\eta) = 1$ is satisfied $\forall \gamma \ge \gamma_\eta$. γ_η is the estimate of the robustness index $\bar{\gamma}$.

Note that with a simple algorithm, we are able to estimate in polynomial time the robustness degree $\bar{\gamma}$ of a generic neural network. The accuracy in estimating $\bar{\gamma}$ can be made arbitrarily good by considering a larger number of samples as suggested by the Chernoff's bound.

SOME EXPERIMENTAL RESULTS

To shed light on how the methodology can be used to test the robustness of a neural network, we focus the attention on a regression-type experiment. In particular, we consider the simple error-free function

$$y = -x \cdot \sin(x^2) + \frac{e^{-0.23 \cdot x}}{1+x^4}, \quad x \in [-3,3]$$

and we approximate it with a regression-type neural network having 10 hidden units. Learning is then perfected with a Levenberg-Marquardt training algorithm (Hassoun, 1995).

We then wish to test the robustness of the trained neural network in the large, that is, by not assuming the small perturbation hypothesis. Perturbations affecting weights and biases of the neural network are defined in a perturbation space subject to a uniform distribution. In particular, a perturbation Δ_i affecting a generic weight w_i must be intended as a relative perturbation with respect to the weight magnitude according to the multiplicative perturbation model $w_{i,p} = w_i(1+\Delta_i)$, $\forall i = 1, n$ (e.g., see Edwards & Murray, 1998). As such, a t% perturbation implies that Δ_i is drawn from a symmetrical uniform distribution of extremes $\left[-\frac{t}{100}, \frac{t}{100}\right]$; a 5% perturbation affecting weights and biases composing vector $\hat{\theta}$ hence requires that each weight/bias is affected by an independent perturbation extracted from the $[-0.05, 0.05]$ interval and applied to the nominal value according to the multiplicative perturbation model. By applying the algorithm suggested in the previous section, we determine the $\hat{p}_\gamma = \hat{p}_\gamma(\gamma)$ functions corresponding to the 1%, 3%, 5%, 10%, 30% perturbations. Results are given in Figure 1 where we considered $\varepsilon = 0.02, \delta = 0.01$ leading to N=6624.

From its definition, $\bar{\gamma}$ is the smallest value for which $\hat{p}_\gamma = 1$, $\gamma \geq \bar{\gamma}$; in the figure, if we consider the 5% perturbation case, $\bar{\gamma}$ assumes a value around 7. We observe that by increasing the strength of perturbation (i.e., by enlarging the extremes of the uniform distribution characterizing the pdf of D) γ increases. In fact, stronger perturbations have a worse impact on the performance loss function since the error-affected neural network diverges from the error-free one. Conversely, we see that small perturbations, for example, the 1% one, induce a very small loss in performance since the robustness index γ_η is very small.

Another interesting use of the suggested methodology allows the neural network designer to test different neural models and identify, for instance, the most robust one.

To this end, we consider a set of performance-equivalent neural networks, each of which able to solve the application with a performance tolerable by the user. All neural networks are characterized by a different topological complexity (number of hidden units).

The $\hat{p}_\gamma = \hat{p}_\gamma(\gamma)$ curves parameterized in the number of hidden units are given in Figure 2 in the case of 1% perturbation. We see that by increasing the number of hidden units $\bar{\gamma}$ decreases. We immediately realize that neural networks with a reduced number of hidden units are, for this application, less robust than the ones possessing more degrees of freedom. For this application large networks provide, in a way, a sort of spatial redundancy: information characterizing the knowledge space of the neural networks is distributed over more degrees of freedom.

It should be clear, anyway, that robustness is a property of the identified neural model and strongly depends on the neural network complexity, the envisaged training algorithm, the training starting point and the training data samples. Hence, for a generic application, it is not possible to assert that by increasing the network complexity (i.e., by increasing the number of hidden units) we improve the robustness of the obtained model.

Figure 1: $\hat{p}_\gamma$ as a function of γ for the 10 hidden units neural network

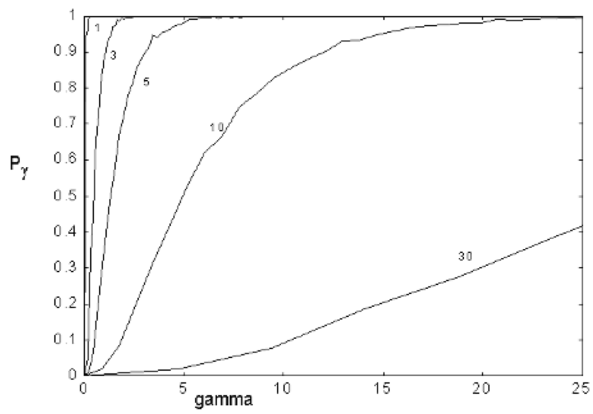

Figure 2: $\hat{p}_\gamma$ over γ and parameterized in the number of hidden unit

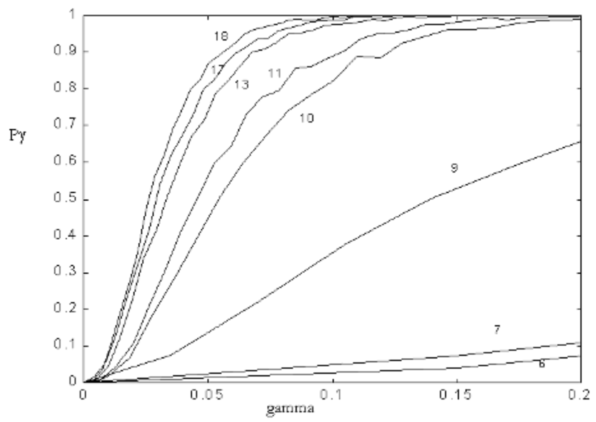

CONCLUSION

A robustness analysis in the large, i.e., by not assuming any hypothesis about the perturbation strength, can be addressed for a generic neural network model and accuracy loss figure of merit by resorting to randomization. In reality, the robustness analysis is even more general and can be considered for any Lebesgue-measurable computation (basically, all functions involved in signal/image processing are Lebesgue-measurable).

Hence, by considering trained neural networks, we can easily estimate the effects induced by perturbations affecting a generic neural network by considering a probabilistic approach. The robustness index, which can be used to investigate the relationships between knowledge space and neural network accuracy, can be computed with an effective poly-time algorithm which spouses Monte Carlo and learning theories sampling methods.

KEY TERMS

Knowledge Space: The space defined by the neural network weights.

NARMAX: Nonlinear auto regressive moving average with external inputs model. The dynamic model receives past input, output and prediction error values to estimate the current output.

Neural Network Weights: The free parameters of the neural model.

NOE: Nonlinear output error model. The dynamic model receives past input and predicted output values to estimate the current output.

Perturbation: A behavioral entity affecting the weights of a neural network.

Poly-Time Algorithm: An algorithm whose complexity evolves polynomially with respect to the envisaged complexity parameter.

Regression-Type Neural Network: A neural network with one hidden layer and a unique linear output neuron used to approximate a mathematical function.

Robustness: A property possessed by a system. A system is robust with respect to a perturbation when the perturbation effect on the system performance is tolerable according to a predefined threshold.

Randomized Algorithms: A probabilistic sampling technique for exploring a space combining learning theories and Monte Carlo approaches.

Small Perturbation Hypothesis: The strength of the envisaged perturbations is small enough to guarantee effectiveness for a linearized sensitivity analysis.

Wireless Sensor Network: A network of distributed sensors linked by a wireless connection.

Policy Frameworks for Secure Electronic Business

Andreas Mitrakas
Ubizen, Belgium

INTRODUCTION

Terms conveyed by means of policy in electronic business have become a common way to express permissions and limitations in online transactions. Doctrine and standards have contributed to determining policy frameworks and making them mandatory in certain areas such as electronic signatures. A typical example of limitations conveyed through policy in electronic signatures includes certificate policies that Certification Authorities (CAs) typically make available to subscribers and relying parties. Trade partners might also use policies to convey limitations to the way electronic signatures are accepted within specific business frameworks. Examples of transaction constraints might include limitations in roles undertaken to carry out an action in a given context, which can be introduced by means of attribute certificates. Relying parties might also use signature policies to denote the conditions for the validation and verification of electronic signatures they accept. Furthermore, signature policies might contain additional transaction-specific limitations in validating an electronic signature addressed to end users. Large-scale transactions that involve the processing of electronic signatures in a mass scale within diverse applications rely on policies to convey signature-related information and limitations in a transaction. As legally binding statements, policies are used to convey *trust* in electronic business. Extending further the use of policy in transaction environments can enhance security, legal safety, and transparency in a transaction. Additional improvements are required, however, in order to render applicable terms that are conveyed through policy and enforce them unambiguously in a transaction. The remainder of this article discusses common concepts of policies and certain applications thereof.

BACKGROUND

An early example of a transaction framework is open EDI (Electronic Data Interchange) that aims at using openly available structured data formats and is delivered over open networks. While the main goal of open EDI has been to enable short-term or *ad hoc* commercial transactions among organisations (Kalakota & Whinson, 1996), it has also aimed at lowering the entry barriers of establishing structured data links between trading partners by minimising the need for bilateral framework agreements, known as interchange agreements. One specific requirement of open EDI is to set up the operational and contract framework within which a transaction is carried out. Automating the process of negotiating and executing agreements regarding the legal and technical conditions for open EDI can significantly lower the entry barriers, especially for non-recurrent transactions (Mitrakas, 2000).

Building on the model for open EDI, the Business Collaboration Framework is a set of specifications and guides, the centre of which is the UN/CEFACT; it aims at further lowering the entry barriers of electronic commerce based on structured data formats. The need for flexibility and versatility to loosely coupled applications and communication on the Internet has led to the emergence of Web services. A Web service is a collection of protocols and standards that are used to exchange data between applications. While applications can be written in various languages and run on various platforms, they can use Web services to exchange data over the Internet.

In Web services, using open standards ensures interoperability. These standards also include formal descriptions of models of business procedures to specify classes of business transactions that all serve the same goal. A trade procedure stipulates the actions, the parties, the order, and the timing constraints on performing actions (Lee, 1996). In complex business situations, transaction scenarios typically might belong to a different trade partner that each one owns a piece of that scenario. Associating a scenario with a trade partner often requires electronic signatures. When a trade partner signs with an electronic signature, she might validate or approve of the way that individual procedural components might operate within a transaction. The signatory of an electronic document or a transaction procedure depends on the performance of complex and often opaque-to-the-end-user systems.

Trust in the transaction procedures and the provision of services is a requirement that ensures that the signatory eventually adheres to transparent contract terms that cannot be repudiated (Mitrakas, 2003). Policy is seen as a way to formalise a transaction by highlighting those aspects of a transaction that are essential to the end user (Mitrakas, 2004). The immediate effect of using policies to convey limitations is that the party that relies on a signed transaction adheres to the limitations of that policy. Policy is, therefore, used to convey limitations to a large number of users in a way that makes a transaction enforceable. While these limitations are mostly meaningful at the operational or technical level of the transaction, they often have a binding legal effect and are used to convey contractual terms. Although these terms are not necessarily legal by nature, they are likely to have a binding effect. Sometimes they can be more far reaching by constraining relying parties that validate electronic signatures. Limitations might be mandated by law or merely by agreement, as in the case of limitations of qualified signatures according to European Directive 1999/93/EC on a common framework for electronic signatures (ETSI TS 101 456).

POLICY CONSTRAINTS IN ELECTRONIC BUSINESS

Electronic signatures have been seen as a lynchpin of trust in electronic transactions. The subject matter of current electronic signature regulation addresses the requirements on the legal recognition of electronic signatures used for non-repudiation and authentication (Adams & Lloyd, 1999). Non-repudiation is addressed in both technical standards such as X.509 and legislation. Non-repudiation addresses the requirement for electronic signing in a transaction in such a way that an uncontested link to the declaration of will of the signatory is established. Non-repudiation is the attribute of a communication that protects against a successful dispute of its origin, submission, delivery, or content (Ford & Baum, 2001). From a business perspective non-repudiation can be seen as a service that provides a high level of assurance on information being genuine and non-refutable (Pfleeger, 2000). From a legal perspective non-repudiation, in the meaning of the Directive 1999/93/EC on a common framework on electronic signatures, has been coined by the term, *qualified signature*, which is often used to describe an electronic signature that uses a secure signature creation device and is supported by a qualified certificate. A qualified signature is defined in the annexes of the directive and is granted the same legal effect as hand-written signatures where law requires them in the transactions.

Policies aim at invoking trust in transactions to ensure transparency and a spread of risk among the transacting parties. Policies are unilateral declarations of will that complement transaction frameworks based on private law. Policies can be seen as guidelines that relate to the technical organizational and legal aspects of a transaction, and they are rendered enforceable by means of an agreement that binds the transacting parties.

In Public Key Infrastructure (PKI), a CA typically uses policy in the form of a certification practice statement (CPS) to convey legally binding limitations to certificate users, being subscribers and relying parties. A CPS is a statement of the practices that a CA employs in issuing certificates (ABA, 1996). A CPS is a comprehensive treatment of how the CA makes its services available and delimiting the domain of providing electronic signature services to subscribers and relying parties. A certificate policy (CP) is sometimes used with a CPS to address the certification objectives of the CA implementation. While the CPS is typically seen as answering "how" security objectives are met, the CP is the document that sets these objectives (ABA, 2001). A CP and a CPS are used to convey information needed to subscribers and parties relying on electronic signatures, in order to assess the level of trustworthiness of a certificate that supports an electronic signature. By providing detailed information on security and procedures required in managing the life cycle of a certificate, policies become of paramount importance in transactions. Sometimes, a PKI Disclosure Statement (PDS) distils certain important policy aspects and services the purpose of notice and conspicuousness of communicating applicable terms (ABA, 2001). The Internet Engineering Task Force (IETF) has specified a model framework for certificate policies (RFC 3647).

Assessing the validity of electronic signatures is yet another requirement of the end user, most importantly, the relying parties. A signature policy describes the scope and usage of such electronic signature with a view to address the operational conditions of a given transaction context (ETSI TR 102 041). A signature policy is a set of rules under which an electronic signature can be created and determined to be valid (ETSI TS 101 733). A signature policy determines the validation conditions of an electronic signature within a given context. A context may include a business transaction, a legal regime, a role assumed by the signing party, and so forth. In a broader perspective, a signature policy can be seen as a means to invoke trust and convey information in electronic commerce by defining appropriately indicated trust conditions.

In signature policies it is also desirable to include additional elements of information associated with certain aspects of general terms and conditions to relate with the scope of the performed action as it applies in the transaction at hand (Mitrakas, 2004). A signature policy might, therefore, include content that relates it to the general conditions prevailing in a transaction, the discreet elements of a transaction procedure as provided by the various parties involved in building a transaction, as well as the prevailing certificate policy (ETSI TS 102 041).

Trade parties might use transaction constraints to designate roles or other attributes undertaken to carry out an action within a transaction framework. Attribute certificates are used to convey such role constraints and are used to indicate a role, a function, or a transaction type constraint. Attribute policies are used to convey limitations associated with the use and life cycle of such attributes (ETSI TS 101 058).

Processing signed electronic invoices is an application area of using policies. By means of a signature policy, the recipient of an invoice might mandate a specific signature format and associated validation rules. The sender of the invoice might require that signing an invoice might only be carried out under a certain role; therefore, an attribute certificate issued under a specific attribute policy might be mandated. This attribute policy complements the certification practice statement that the issuer of electronic certificates makes available. It is expected that certificate policies shall influence the requirements to make a signature policy binding (Mitrakas, 2003).

BINDING POLICIES IN ELECTRONIC BUSINESS

Communicating and rendering policies binding has been an issue of significant importance in electronic transactions. Inherent limitations in the space available for digital certificates dictate that policies are often conveyed and used in a transaction by incorporating them by reference (Wu, 1998). Incorporation by reference is to make one message part of another message by identifying the message to be incorporated, providing information that enables the receiving party to access and obtain the incorporated message in its entirety, expressing the intention that it be part of the other message (ABA, 1996). The incorporation of policies for electronic signatures into the agreement between signatory and recipient can take place by referencing the intent to use such policy in transactions. When the recipient accepts the signed document of the signatory, he implicitly agrees on the conditions of the underlying signature policy. In practice, incorporating policy into the agreement between signatory and recipient can also be effected by:

- Referring to a policy in a parties' agreement that explicitly refers to such policy.
- Accepting a signed document and implicitly agreeing on the conditions of the underlying policy, although this option might be more restrictive in case of a dispute.

An issue arises with regard to how and under which conditions a particular policy framework can be incorporated into an agreement of a signatory in a way that binds a relying party, regardless of its capacity to act as consumer or business partner. Incorporation of contract terms into consumer contracts and incorporation of contract terms into business contracts follow different rules. Incorporation by reference in a business contract is comparatively straightforward, whereas in a consumer contract stricter rules have to be followed as mandated by consumer protection regulations. Limitations to the enforceability of legal terms that are conveyed by means of policy are applied as a result of consumer protection legislation. In Europe, consumer protection legislation includes the Council Directive 93/13/EC on unfair terms in consumer contracts, Directive 97/7/EC on the protection consumers in distance transactions, and Directive 1999/44/EEC on certain aspects of the sale of consumer goods and associated guarantees (Hoernle, Sutter & Walden, 2002). In an effort to proactively implement these legal requirements, service providers strive to set up specific consumer protection frameworks (GlobalSign, 2004).

Sometimes the scope of the underlying certificate policy frameworks is to equip the transacting parties with the ability to use a certificate as evidence in a court of law. It is necessary to also provide transacting parties with assurance that allows a certificate to be admitted in legal proceedings and that it provides binding evidence against the parties involved in it, including the CA, the subscriber, and relying parties (Reed, 2000). Qualified electronic signatures in the meaning of Directive 1999/93/EC establish a rebuttable presumption that reverses the burden of proof. In other words the court may at first admit a signature that claims to be qualified as an equivalent of a handwritten signature. The counter-party is allowed to prove that such signature does not meet the requirements for qualified signatures, and could therefore be insecure for signing documents requiring a handwritten signature (UNCITRAL, 2000). To further answer the question of admissibility, it is necessary to examine the admissibility of electronic data as evidence in court, which is a matter that has been addressed in Directive 2000/31/EC on electronic commerce. Consequently, electronic data can be admitted as evidence as long as certain warranties are provided with regard to the production and retention of such data. In assessing the reliability of a certificate, a Court will have to examine the possibility of a certificate being the product of erroneous or fraudulent issuance, and if is not, the Court should proclaim it as sufficient evidence against the parties involved within the boundaries of conveyed and binding policy.

FUTURE TRENDS

While case law is expected to determine and enhance the conditions of admissibility and evidential value of policy in transactions based on electronic signatures, additional technological features such as the use of object identifiers (OIDs) and hashing are expected to further enhance the certainty required to accept policies. Remarkably, to date there has been little done to address in a common manner the practical aspects of identifying individual policies and distinguishing among the versions thereof. Additionally, mapping and reconciling policy frameworks in overlapping transactions also threaten transactions, which are based on the use and acceptance of varying terms. A typical hard case might involve for example overlapping policy conditions, which apply to certificates issued by different CAs. The situation is exacerbated if those CAs do not have the means to recognise one another, while they issue certificates that can be used in the same transaction frameworks (ETSI TS 102 231). Although such certificates may well be complementary to a transaction framework, the varying assurance levels they provide might threaten the reliability of the transaction framework as a whole. The immediate risk for the transacting parties can be an unwarranted transaction environment that threatens to render otherwise legitimate practices unenforceable. Reconciling the methods used across various electronic signing environments is likely to contribute to creating trust in electronic business.

An additional area of future attention may address policy frameworks related to the application layer in a transaction. As present-day requirements for transparency are likely to be further raised, it is expected that online applications will increasingly become more demanding in explaining to the end user what they do and actually warranting the performance. To date general conditions and subscriber agreements cover part of this requirement; however, it is further needed to provide a comprehensive description of the technical features and functionality of the online application. In electronic business, consumers and trade partners are likely to benefit from it. Policies for the application layer are likely to become more in demand in electronic government applications, where the requirement for transparency in the transaction is even higher than in electronic business. Finally, specifying policies further to meet the needs of particular groups of organisations is an additional expectation. Again in electronic government it is expected that interoperability will be enhanced through best practices and standards regarding policy in specific vertical areas.

CONCLUSION

While policies emerge as a necessary piece in the puzzle of invoking trust and legal safety in electronic transactions, policy frameworks can still have repercussions that reach well beyond the scope of single transaction elements and procedures in isolated electronic business environments. Formal policy frameworks require additional attention to ensure that apparently loosely linked policy elements do not threaten to overturn the requirements of transaction security and legal safety, which are the original objectives of using policy frameworks. Electronic transaction frameworks for diverse application areas can benefit from the processing of data on the basis of policy-invoked constraints among the parties involved. Large-scale processing that requires policy to convey operational and legal conditions in electronic transactions benefits from a combination of policy instruments, including certificate polices, signature policies, attribute certificate policies, and so forth, to enhance the outlining of the transaction framework and allow the transacting parties to further rely on electronic business for carrying out binding transactions.

KEY TERMS

Certification Authority: An authority such as GlobalSign that issues, suspends, or revokes a digital certificate.

Certification Practice Statement: A statement of the practices of a certificate authority and the conditions of issuance, suspension, revocation, and so forth of a certificate.

Electronic Data Interchange (EDI): The interchange of data message structured under a certain format between business applications.

Incorporation by Reference: To make one document a part of another by identifying the document to be incorporated, with information that allows the recipient to access and obtain the incorporated message in its entirety, and by expressing the intention that it be part of the incorporating message. Such an incorporated message shall have the same effect as if it had been fully stated in the message.

Public Key Infrastructure (PKI): The architecture, organization, techniques, practices, and procedures that collectively support the implementation and operation of a certificate-based public key cryptographic system.

Relying Party: A recipient who acts by relying on a certificate and an electronic signature.

Signature Policy: A set of rules for the creation and validation of an electronic signature, under which the signature can be determined to be valid.

Portable Portals for M-Commerce

Irvine Clarke III
James Madison University, USA

Theresa Flaherty
James Madison University, USA

INTRODUCTION

In the new decade, the call for information technology will be information, anytime, anyplace, and on any device. Accordingly, e-commerce is poised to witness an unprecedented explosion of mobility, creating a new domain of mobile commerce. Mobile commerce, or m-commerce, is the ability to purchase goods anywhere through a wireless Internet-enabled device (e.g., cellular phone, pager, PDA, etc.). Mobile commerce refers to any transaction with monetary value that is conducted via a mobile network. It will allow users to purchase products over the Internet without the use of a PC. Non-existent a year ago, m-commerce is now the buzzword of the marketing industry (King, 2000).

Over the past few years, e-commerce has become increasingly reliant upon portals to attract and retain users. Portals are the preferred starting point for searches that provide the user easily customizable architecture for finding relevant information. Portals provide the valuable gateways for getting users to their desired destinations. Today, about 15% of all Web page view traffic goes through the top nine portals, making them some of the most valuable land on the Web (Monohan, 1999). This heavy traffic flow gives the Web-based portal a unique position in corporate e-commerce strategy—with even greater potential influence for mobile applications. For mobile devices, these portals take on increased significance, as consumers are unwilling to spend long periods "surfing" on these inherently less user-friendly wireless devices. By the year 2006, 25 million people are expected to be dedicated wireless portal users (Carroll, 2000).

As m-commerce success will likely depend upon maintaining consumer utilization of these gateways, the companies that leverage the unique characteristics of wireless devices will gain exploitable advantages in the mobile marketplace. Due to current technological limitations and varying mobile consumer behavior patterns, portals developed for mobile devices must emphasize differing characteristics than conventional Web-based portals. As such, many portals may be unsuited for application in the mobile world.

"Traditional portals are not providing information that is specific enough for the user of a mobile portal. They are not able to incorporate location-specific information nor do they have the data and knowledge of each customer that the mobile operator has." (Durlacher Research, 2000, p. 65)

BACKGROUND

Mobile devices have been the fastest adopted consumer products of all time with, last year, more mobile phones shipped than automobiles and PCs combined (Chen, 2000). By 2003, there will be 1.4 billion mobile phones worldwide, and half will be Internet-enabled (Zabala, 2000). "The wireless world is a parallel universe almost as large as the Net, and the two are beginning a fascinating convergence," said Swapnil Shah, director of Inktomi Europe, a search engine and caching solutions company (Rao, 2000, p. 1). It is predicted that this emergence of mobile commerce will happen even faster than the development of e-commerce—in roughly the time between the invention of the first Web browser and now (Schenker, 2000). "If you look five to 10 years out, almost all of e-commerce will be on wireless devices," says Jeff Bezos, chief executive and founder of Amazon.com (McGinity, 2000, p. 1).

The potential of m-commerce is considerable for those willing to develop mobile-specific business models. However, as m-commerce matures, current mobile operators will rely less upon usage fees and increasingly derive revenues from content and services. Additionally, m-commerce is going to bring about a massive change in the way users consume products and services. As Cindy Dahm, European director for Phone.com, stated:

"It is key that commerce companies recognize m-commerce as a completely unique service. Cell phone users are more impatient than Internet users. The paradigm here is not surfing; all services for the mass market have to be pitched at users in such a seamless way that they need not even be aware that they are accessing the Net." (Rao, 2000, p. 2)

Those best able to provide value-added user experiences, through content aggregation and portal development, will achieve long-term success. Merely extending the current Internet presence will not be enough. "Mobile Internet customers will be more demanding. They will want personalized service to meet their individual wants and needs, and will no longer be satisfied with being a mass market" (KPMG, 2000, p. 2). Providers must take advantage of the characteristics which distinguish m-commerce from e-commerce to develop truly unique and compelling services rather than replicating current e-commerce models.

What is a Portable Portal?

The word portal is derived from the Latin *porta*, or gate, through which something will pass, in an effort to get to another place. In the traditional sense of the word, the portal is not the desired end-state. Rather, a portal is a necessary or convenient place one must go to get to the desired location. For example, the airport is not the desired location for most people, rather a necessary portal through which they must pass to obtain transportation to another location. Similarly, portals assist by directing the transport of the Web user to the ultimate location of their choice. Mobile portals, sometimes referred to as "portable portals," are typically developed to assist wireless users in their interactions with Web-based materials. Today, most mobile portals are being formed by syndicating content providers into a centralized source of personal productivity information. Mobile portals are often modeled by aggregating applications (e-mail, calendar, instant messaging, etc.) and content from various providers in order to become the user's prime supplier for Web-based information. Mobile portals differ from traditional Web-based portals by a greater degree of personalization and localization. Representative objectives for such mobile portals may be to attract the desired viewer, and build valuable customer relationships, through value-added content and community services, to augment the overall wireless Internet experience and build long-term customer loyalty.

"Like portals of the wired world, wireless portals have a degree of control over what users see on the Internet, so the portal provider can charge service providers and advertisers high fees. Given the projected penetration rates of mobile devices and mobile consumers' increased reliance on portal services, many observers expect wireless portals to be as highly valued on the stock market as their established Internet equivalents." (Barnett, Hodges & Wilshire, 2000, p. 166)

Established portal players, such as AOL (www.aol.com/product/anywhere.adp), Yahoo! (mobile.yahoo.com), and MSN (mobile.msn.com) have recognized the potential impact of the mobile Internet and have created mobile portals targeting U.S. subscribers. However, many of the traditional portal players are experiencing difficulties adapting to the mobile world. The mobile portals emerging today are, in many ways, a stripped-down version of traditional Web portals, without an understanding of the special requirements of mobile users. Consequently, these offering are unacceptable to mobile Internet users.

"The mobile portal strategy of the traditional portal players often lacks in-depth understanding of national mobile markets and of the specific local dynamics involved in building businesses in a territory. In addition, the differences between a fixed and more mobile portal model are non-trivial and, as such, lessons learned in the past are not necessarily directly transferable." (Durlacher Research Ltd., 2000, p. 69)

Current portal strategy is based on a traditional paradigm of consumers as passive receivers of communication efforts, with the portal provider holding control of the "when" and "where" of information. With wireless Internet-enabled devices, consumers now have more discretion of "when" and "where" the information that is available, creating a demand for a specialized portal offering.

Unique Advantages of Mobile Portals

The mobility afforded wireless devices will shape mobile portals into a disparate entity from conventional portals. The advantages of mobile devices provide a greater offering of *value-for-time* to users. That is, by accessing the Internet through mobile devices, users will be able to realize additional value allowances for any specified period of time that fixed-line users will not be able to achieve. Information will now truly become available anytime, anyplace, and on any wireless device. Portable portals differ from traditional portals on four dimensions: ubiquity, convenience, localization, and personalization.

(1) **Ubiquity:** Mobile devices offer users the ability to receive information and perform transactions from virtually any location on a real-time basis. Thus, mobile portal users can have a presence everywhere, or in many places simultaneously, with a similar level of access available through fixed-line technology. Communication can take place independent of the user's location. Mobile portals, for example, can leverage this advantage of ubiquity by

providing alert notifications, such as for auctions, betting, and stock price changes, which are specified by the user as an important part of relevant personal content. As such, the real-time, everywhere presence of mobile portals will offer capabilities uniquely beneficial to users. Industries that are time and location sensitive, such as financial services, travel, and retail, are likely to benefit from portals exploiting this value-added feature of m-commerce.

(2) **Convenience:** The agility and accessibility provided from wireless devices will further allow m-commerce to differentiate its abilities from e-commerce. People will no longer be constrained by time or place in accessing e-commerce activities. Rather, m-commerce could be accessed in a manner which may eliminate some of the labor of life's activities and thus become more convenient. For example, consumers waiting in line or stuck in traffic will be able to pursue favorite Internet-based activities or handle daily transactions through m-commerce portals. Consumers may recognize a higher level of convenience which could translate into an improved quality of life.

(3) **Localization:** Knowing the geographical location of an Internet user creates a significant advantage for m-commerce over e-commerce. Location-based marketing, via global positioning technology (GPS), will soon be available in all mobile devices. Through GPS technology, service providers can accurately identify the location of the user so that m-commerce providers will be better able to receive and send information relative to a specific location. Since mobile devices, such as cell phones, are almost always on, vendors will know the location of their customers and can deliver promotions based on the likely consumer demands for that location.

Location-specific information leverages a key advantage a mobile portal has over a traditional Web portal by supplying information relevant to the current geographic position of the user. Portable portal providers will be able to both push and access information relevant to the user's specific location. Portable portals may serve as points of consolidation of consumer information and disseminate the relevant information for a particular location. This can be based on profile data built on the user's past behavior, situation, profile, and location. As such, real-time discounting may become the "killer application" for m-commerce.

(4) **Personalization:** Mobile devices are typically used by a sole individual, making them ideal for individual-based and highly personalized target marketing efforts. Mobile devices offer the opportunity to personalize messages to various segments, based upon time and location, by altering both sight and sound. New developments in information technology and data mining make tailoring messages to individual consumers practical and cost effective. Value-added becomes maximized for those portals that are best able to implement the four distinguishing capabilities of ubiquity, convenience, localization, and personalization. Mobile portals will become differentiated based upon their abilities to integrate and actuate the four advantages which are germane to mobile devices.

CONCLUSION

Mobile portal development is likely to parallel the growth in overall m-commerce. New and even more innovative applications than those discussed here will arise as more people connect to the Web through wireless devices and additional content becomes available. As other functionalities such as file attachments, faster network speeds, Bluetooth, speech recognition, and e-commerce security features are added, more users will be attracted to this intriguing mobile marketplace. M-commerce is still not without its limitations. The problems it must overcome include: uniform standards, ease of operation, security for transactions, minimum screen size, display type and bandwidth, billing services, and the relatively impoverished Web sites. In the short term, portable portals must be mindful to operate within evolving technological constraints, while providing the most amount of flexibility possible. In the end, these problems, much like the initial problems associated with e-commerce, will also be overcome. Long-term mobile portal success is likely to come from consumer-driven, rather than technology-based models.

KEY TERMS

Localization: Through GPS technology, service providers can accurately identify the location of the user so that m-commerce providers will be better able to receive and send information relative to a specific location.

M-Commerce: The ability to purchase goods anywhere through a wireless Internet-enabled device (e.g., cellular phone, pager, PDA, etc.). Mobile commerce refers to any transaction with monetary value that is conducted via a mobile network.

Mobile Networks: A system that allows wireless devices to seamlessly interact with traditional telecommunications and other wireless devices.

Personalization: Developing tailored approaches with relevant material packaged for the particular wireless user.

Portals: A gate through which something will pass, in an effort to get to another place. In the traditional sense of the word, the portal is not the desired end-state. Rather, a portal is a necessary or convenient place one must go to get to the desired location.

Ubiquity: Mobile devices offer users the ability to receive information and perform transactions from virtually any location on a real-time basis.

Wireless Communication: Interaction through a wireless device (e.g., cellular phone, pager, PDA, etc.).

P

Principles of Advanced Database Integrity Checking

Hendrik Decker
Instituto Tecnológico de Informática, Spain

INTRODUCTION

Integrity constraints (hereafter, sometimes simply 'constraints') are formal representations of conditions for the semantic correctness of database records. In science, constraints are usually expressed in declarative knowledge representation languages such as datalog or predicate logic. In commercial databases, they are usually expressed by distinguished SQL statements.

BACKGROUND

Integrity has always been regarded as an important issue for database management, as attested by many early publications (e.g., Fraser, 1969; Wilkes, 1972; Eswaran & Chamberlin, 1975; Hammer & McLeod, 1975; Nicolas, 1978; Hammer & Sarin, 1978; Codd, 1979; Bernstein, Blaustein & Clarke, 1980; Nicolas, 1982; Bernstein & Blaustein, 1982); later ones are too numerous to mention. To express database semantics as invariants, that is, properties persisting across updates, had first been proposed by Minsky (1974). Florentin (1974) suggested to express integrity constraints as predicate logic statements. Stonebraker (1975) proposed to formulate and check integrity constraints declaratively as SQL-like queries.

Referential integrity, a special case of functional dependencies (Armstrong, 1974), has been included in the 1989 SQL ANSI and ISO standards (McJones, 1997). The SQL2 standard (1992) introduced the CHECK option and the ASSERTION construct as the most general means to express arbitrary integrity constraints declaratively in SQL (Date & Darwen, 1997). In the 1990s, uniqueness constraints, foreign keys, and complex queries involving EXISTS and NOT became common features in commercial database products. Thus, arbitrarily general integrity constraints could now be expressed and evaluated in most relational databases.

Integrity constraints may involve nested quantifications over huge extents of several tables. Thus, their evaluation can easily become prohibitively costly. Most SQL databases offer efficient support only for the following three simple kinds of declarative constraints:

- Domain constraints, i.e., restrictions on the permissible range of scalar attribute values of tuples in table columns, including options for default and null values.
- Uniqueness constraints, as enforced by the UNIQUE construct on single columns, and UNIQUE INDEX and PRIMARY KEY on any combination of one or several columns in a table, preventing multiple occurrences of values or combinations thereof.
- Foreign key constraints, for establishing an identity relationship between columns of two tables. For instance, a foreign key on column emp of relation works_in may require that each emp value of works_in must occur in the emp_id column of table employee, where the referenced columns (here, emp_id) must be a primary key.

For more general constraints, SQL database manuals usually ask the designer to renounce declarative constructs and instead resort to procedural triggers and stored procedures. However, declarativity does not need to be sacrificed in order to obtain efficiency. One approach developed to that end, in the framework of predicate logic and datalog, was *soundcheck* (Decker, 1986). In the spirit of the latter, a translation of integrity constraints expressed in predicate logic into SQL is described in Decker (2003).

SIX PHASES OF SIMPLIFIED INTEGRITY CHECKING

Below, the *soundcheck* approach for simplifying the evaluation of integrity constraints is outlined as a succession of six phases. Except Step I, proposed in Decker (1987), this approach originates in Nicolas (1982). All or part of it is used in one way or another in most known methods for integrity checking. It can be easily implemented in SQL (Decker, 2003). In the next section of this article, Steps I-VI are illustrated with an example. The six phases are then discussed in general.

I Generate the difference between the old and the new state
II Skip idle updates
III Focus on relevant integrity constraints
IV Specialize relevant constraints
V Optimize specialized constraints
VI Evaluate optimized constraints

AN EXAMPLE OF SIMPLIFIED INTEGRITY CHECKING

For illustrating Steps I-VI, consider an update of a relational database with tables for workers and managers, defined as follows.

```
CREATE TABLE(worker(CHAR name, CHAR department))
CREATE TABLE(manager (CHAR name)).
```

Now, suppose there is an integrity constraint requiring that no worker is a manager, expressed by the SQL condition:

```
NOT EXISTS (SELECT . FROM worker, manager WHERE
worker.name = manager.name).
```

If the number of workers and managers is large, then checking whether this constraint is violated or not can be very costly. The number of facts to be retrieved and tested is in the order of the cardinality of the cross product of worker and manager, whenever the constraint is checked. Fortunately, however, the frequency and amount of accessing stored facts can be significantly reduced by taking Steps I-VI. Before walking through them, a possible objection at this stage needs to be dealt with.

SQL programmers might feel compelled to point out that the constraint above is probably much easier checked by a trigger such as:

```
CREATE TRIGGER ON worker FOR INSERT :
IF EXISTS
(SELECT * FROM inserted, manager WHERE
inserted.name = manager.name)
ROLLBACK.
```

Its evaluation would only need to access manager and a cached relation inserted containing the row to be inserted to worker, but not the stored part of worker. However, it is easily overlooked that the sample integrity constraint also requires implicitly that somebody who is promoted to a manager must not be a worker, thus necessitating a second trigger for insertions into manager. In general, each occurrence of each atom occurring in a constraint requires a separate trigger, and it is by far not always as obvious as in the simple example above how they should look like. Apart from being error-prone, hand-coded triggers may also bring about unpredictable effects of mutual interactions that are hard to control. Hence, hand-coding triggers, as recommended in many database manuals, hardly seem advisable.

Now, let INSERT INTO worker VALUES ('Fred', 'sales') be an update. Then, running Steps I through VI means the following:

I Generate difference between old and new state

The explicit update INSERT INTO worker VALUES ('Fred', 'sales') may have implicit update consequences on database views, the definition of which involves worker. The set of explicitly and implicitly updated facts constitutes the difference Δ between old and new database state. Each fact in Δ may violate integrity. Thus, Δ must be generated, and each fact in Δ needs to be run through Steps II-VI. For example, suppose a view containing all workers entitled to some benefit, for example, if they work in some distinguished department d, and a constraint C on that view. Then, C needs to be evaluated only if Fred's department is d; otherwise, no additional constraint needs to be checked.

II Skip idle updates

If Fred already has been a worker (e.g., in some other department) before the INSERT statement was launched, then it is not necessary to check again that he must not be a manager, since that constraint has already been satisfied before.

III Focus on relevant integrity constraints

Unless II applies, the constraint that no worker must be manager is clearly relevant for the given update and hence must be checked. Any integrity constraint that is not relevant for the insertion of rows into the worker table needs not be checked. For instance, a constraint requiring that each department must have some least number of workers is not relevant for insertions, but only for deletions in the worker table. Also, constraints that do not involve worker need not be checked.

IV Specialize relevant constraints

For the given INSERT statement, the WHERE clause of the SQL condition:

```
EXISTS (SELECT * FROM worker, manager WHERE
worker.name = manager.name)
```

can be specialized to a much less expensive form:

EXISTS (SELECT * FROM worker, manager WHERE worker.name = 'Fred' AND worker.name = manager.name)

V Optimize specialized constraints

Clearly, the specialized condition in IV can be optimized to

EXISTS (SELECT * FROM manager WHERE name = 'Fred')

VI Evaluate optimized constraints

Evaluation of the query whether Fred is a manager means looking up a single fact in a stored relation. That of course is much less costly than evaluating all integrity constraints in their full generality, as would be necessary without having done I-V.

The example above is very simple. However, by running Steps I-VI, the same proportions of simplification of integrity checking are obtained systematically for arbitrarily complex constraints.

PRINCIPLES OF SIMPLIFIED INTEGRITY CHECKING

Below, the six phases of simplified integrity checking are again walked through, abstracting general principles from the example in the previous section.

Let D be a relational database, where views, if any, are defined by datalog queries possibly involving negation. Further, let IC be a predicate logic sentence representing some integrity constraint in D, and fact be a relational tuple to be either inserted or deleted. Then, doing I through VI means the following:

I Generate the difference between the old and the new state

For each view v in D and each occurrence A of an atom in the definition of v which matches fact (i.e., fact and A have the same relation name and their column values can be unified), the insertion of fact may cause an implicit insertion in v if A is not negated, and an implicit deletion in v if A is negated. Conversely, the deletion of fact may cause an implicit deletion in v if A is not negated, and an implicit insertion in v if A is negated. Recursively, each implicit update may cause further implicit updates, in case of views defined by other views. The original explicit update and all implicitly updated facts constitute the difference Δ. Each fact in Δ has to be generated and run through II-VI.

II Skip idle updates

Usually, identical copies of a tuple in a table or view are considered redundant ("idle") and should be avoided. More precisely, an insertion of a fact is idle if that fact is already present in the table or derivable from a view definition, and a deletion of a fact is idle if a (view-defined or explicit) copy of that fact will persist after the update. For each such idle update, all of III-VI can be skipped.

III Focus on relevant integrity constraints

The general rule for focusing integrity checking on those constraints that are relevant is as follows: IC is relevant for the insertion (resp., deletion) of fact, and thus needs to be checked, if and only if there is an atom A with negative (resp., positive) polarity in IC which unifies with fact.

Polarity is defined as follows: A has positive polarity in A; if A has positive (resp., negative) polarity in some formula B, then A has positive (resp., negative) polarity in the formulas $A \wedge B$, $A \vee B$, $B \rightarrow A$ and also in the universal and the existential closure of B; A has negative (resp., positive) polarity in $\neg A$ and in $A \rightarrow B$.

IV Specialize relevant constraints

The focus obtained in III can be further narrowed by specializing variables to ground values in updated facts. The general rule is as follows: for IC, fact, and A as in III, let ϕ be a most general unifying substitution of fact and A. Then, IC can be specialized to ICθ, where the substitution θ is obtained from ϕ by restricting ϕ to the universally ($\forall$ -) quantified variables in A that are not dominated by an existential quantifier $\exists$ (i.e., no $\exists$ occurs on the left of $\forall$ in IC).

By definition, the quantification of a variable in a formula is obtained by moving either all negations innermost or all quantifiers outermost, such that logical equivalence is preserved (for details, see Decker, 2003; Nicolas, 1982).

V Optimize specialized constraints

The following rewrites should be applied to specialized constraints obtained from IV. If fact is to be inserted (resp., deleted), replace all occurrences of fact by true (resp., false) and recursively apply obvious simplifications: replace $\neg$true by false and $\neg$false by true; replace each of true $\rightarrow$ B, true $\wedge$ B, false $\vee$ B by B; true $\vee$ B and false $\rightarrow$ B by true; false $\wedge$ B by false. For more on such simplifying optimizations, see Demolombe (1989).

VI Evaluate optimized constraints

For evaluating constraints resulting from I-V, built-in database query optimization facilities and access plan improvements should be exploited as far as available. If applicable, also other techniques for evaluating integrity constraints should be used, for example, query containment techniques (Gupta, Sagiv, Ullman & Widom, 1994) and semantic query optimization (Godfrey, Gryz & Zuzarte, 2001).

Neither of the latter two approaches has originally been meant to be applied specifically to simplified constraints as obtained from I-V, but both can be adapted for use in Step VI.

FUTURE TRENDS

In the future, the importance of database integrity is likely to grow further, hand in hand with increasing concerns for the quality, reliability, and dependability of data. Also the declarativity of data integrity is going to become more important, because of the growing complexity of data and applications, the development and maintenance of which would otherwise become too troublesome. The SQL99 standard has tried to do justice to this trend by proposing norms for non-scalar data types, recursive view definitions, and triggers, which however have hardly been taken up uniformly by database vendors (Gorman, 2001).

Commercial databases lag behind the state of the art of integrity checking in academia. Besides a lack of support for the simplification of ASSERTION statements, also the support for declarative constraints on views is scant, if not completely missing in many database products. Technologies still to be transferred from theory to practice are aplenty (see, e.g., Decker, 1998). In practice, integrity support in distributed databases is even worse than for singleton systems (e.g., declarative referential integrity across remote tables is not available), in contrast to a vast literature on this topic (e.g., Ibrahim, 2002; Bright & Chandy, 2003). Also the convergence of distributed databases and agents technology is likely to benefit from advanced approaches of handling integrity constraints efficiently (Sadri & Toni, 2000). Both theory and practice need to advance in terms of integrity support for replicated data. And, beyond distributed databases, there is the problem of the integrity of data on the Web, which certainly is going to receive more attention in the future (for a primer, see Aldana, Yagüe & Gómez, 2002).

CONCLUSION

This article has outlined basic principles for checking semantic integrity constraints that are more advanced than the usual SQL support for constraints related to data types, attribute values, and referential integrity. The principles have been described by examples using SQL syntax, and then more generally in the language of predicate logic.

A systematic translation of constraints expressed in predicate logic into SQL is described in Decker (2003). There, also, a fully automated and provably correct mechanism for translating declarative constraints into efficient triggers is specified. It takes advantage of all simplifications outlined above. Other work related to similar topics is documented in Cochrane, Pirahesh, and Mattos (1996), Ceri, Cochrane, and Widom (2000), and Date (2000).

KEY TERMS

Business Rule: Originally, a statement that defines or constrains the evolution of data pertaining to an enterprise's business. Business rules usually are implemented by integrity constraints or triggers or stored procedures.

Declarative vs. Procedural: Integrity constraints are declarative statements, expressed in languages such as predicate logic, datalog, or SQL. Since their evaluation can be very costly, the potentially troublesome hand-coding of procedural triggers and stored procedures is recommended by most database manuals. The main thrust of this chapter is about reducing the cost of using declarative integrity constraints and avoiding hand-coded implementation.

Integrity: In databases, 'integrity' is largely synonymous to 'semantic consistency', that is, the correctness of stored data with regard to their intended meaning. Integrity, as expressed by integrity constraints, should not be confused with a namesake issue often associated with data security.

Integrity Checking: Systematic tests, ensuring that integrity remains satisfied (see integrity satisfaction). If integrity is violated (see integrity violation), then the update causing inconsistency must be rejected or some other action must be taken to enforce a consistent state, i.e., one that satisfies integrity (see integrity enforcement).

Integrity Constraint: An integrity constraint is a requirement on the consistency of the information stored in a database. Integrity constraints are stated as yes/no conditions in the database schema. They are required to be satisfied in each database state. Thus, integrity constraints are invariants of the database which evolves via updates.

Integrity Enforcement: Actions taken to ensure that integrity remains satisfied across database updates (see integrity satisfaction). Conservative integrity enforcement rejects updates that would violate integrity (see integrity violation). Progressive integrity enforcement attempts to satisfy the update while maintaining integrity by further data modifications, possibly consulting the user.

Integrity Satisfaction: A given database state satisfies integrity if each integrity constraint in the database schema, posed as a query, returns the required yes/no answer. An ostensibly equivalent, but in fact slightly weaker definition says that integrity is satisfied if it is not violated (see integrity violation). The difference between both definitions manifests itself in incomplete databases.

Integrity Violation: In a given database state, integrity is violated if any one of the integrity constraints, posed as a query, returns the opposite of the required yes/no answer.

Predicate Logic: Well-established universal declarative data and knowledge representation language, with capacities of formalizing and automating deductive and other forms of logical reasoning. Its fundamental role for databases and particularly integrity constraints is undisputed and indispensable.

Semantic Integrity: The adjective in 'semantic integrity' is often added to distinguish a set of explicitly defined integrity constraints, either from structural constraints that are implicitly given by the used data model (e.g., data types in relational databases must be scalar) or from integrity as required for the sake of security.

Simplification of Integrity Constraints: Steps taken in order to reduce complexity and costs of integrity checking. Steps I-VI, as described in this article, are prime examples.

SQL: Widely used standard language for the declarative description, querying, and updating of stored data. SQL also allows expression of database schemata including integrity constraints. By an extension with procedural constructs, it also allows the expression and execution of triggers.

Static vs. Dynamic Integrity Constraints: By default, integrity constraints correspond to static properties that are independent of particular database states. As opposed to that, dynamic integrity constraints refer explicitly to several states, mostly consecutive ones, or to their transitions, involving temporal or other procedural integrity constraint constructs. A typical example of a genuine dynamic integrity constraint (otherwise not dealt with in this chapter) is 'salaries must never decrease'.

Trigger: An SQL statement that automatically generates an action (e.g., an update or a reset) upon a specified update request. Triggers are a procedural means to enforce and preserve integrity (see integrity enforcement).

Principles to Guide the Integration and Implementation of Educational Technology

Sara Dexter
University of Virginia, USA

INTRODUCTION

The Educational Technology Integration and Implementation Principles (eTIPs) are six statements that describe the K-12 classroom and school-level conditions under which the use of technology will be most effective. The eTIPs are an example of materials that can aid teachers in designing instruction and participating in creating supportive conditions for technology supported classroom instruction.

BACKGROUND

During the last decade, the call for teachers to be better prepared to teach with technology (CEO Forum, 1999, 2000; Office of Technology Assessment, 1995) has been repeated several times. In response, there are now standards in place to which new teachers are being held that explicitly describe the technology skills all teachers should have to be prepared to teach in a 21st Century school. These include the National Education Technology Standards for Teachers (ISTE, 2000), which were adopted by National Council for Accreditation of Teacher Education (NCATE) as a part of its accreditation requirements, and the Interstate New Teacher Assessment and Support Consortium standards (INTASC, 1992) used by many states as licensing requirements. In general, these standards call for teachers to be able to use technology in the classroom to plan and design learning environments and experiences, and support teaching, learning, and the curriculum. These standards, in turn, imply that teachers must make the consideration of technology use a routine part of their instructional decision making.

Teachers' decision making has been defined as the course of action during which teachers gather, organize, and interpret information, generate alternatives, select a specific course of action, and, after its implementation, consequently evaluate the effectiveness of the decision (Clark & Yinger, 1977; Lipham, 1974). The research literature emphasizes how critical teachers' planning and interactive decisions are in determining what they do, or do not do, in the classroom (e.g., Clark & Yinger, 1977; Jackson, 1968; Peterson & Clark, 1978; Shavelson, 1976). Shavelson and Stern (1981) posit that teachers' decision-making processes are influenced by schemata that are activated from memory.

MAIN THRUST OF CHAPTER

The Educational Technology Integration and Implementation Principles (or eTIPs) are one example of a set of statements that could serve as a schema, or the basis of a schema, for a teacher to organize his or her instructional decision making about the integration and implementation of technology. Principles can assist learners in recognizing and connecting ideas and in seeing how new and old ideas relate (Marzano, 2001), which are key tasks in developing the more elaborate schemas that are characteristic of expert teachers (Carter, 1990; Fogarty, Wang, & Creek, 1983; Kagan, 1992). The six eTIPs summarize what research suggests are the conditions that should be present in order for educational technology integration and implementation to be effective (Dexter, 2002), while offering the advantage of brevity over the 23 NETS-T standards and the five technology-specific statements in the INSTASC standards.

These eTIPs are organized into two dimensions: classroom and school-wide. The classroom principles expand upon the premise that effective technology integration requires the time and attention of teachers in the role of instructional designers, planning the use of the technology so it will support student learning. They assume that educational technology does not possess inherent instructional value but that a teacher must design into the instruction any value technology adds to the teaching and learning processes. Thus, the three classroom eTIPS prompt a teacher-designer to consider what he or she is teaching, what added value the technology might bring to the learning environment, and how technology can help to assess student learning.

Classroom-Level eTIPs

eTIP 1: Learning Outcomes Drive the Selection of Technology.

In order for learning outcomes to drive the selection of technology, teachers must first be clear about their lesson or unit's student-learning outcomes. This is an important first step in determining whether or not the educational technology available can be a support to teaching and learning. It will allow teachers to be more efficient as they search for available, appropriate technologies because they will quickly eliminate those that do not support their learning outcomes. Where technology does seem to support learning outcomes, teachers must also consider the cognitive demands made by the technology and if they are well-suited to the cognitive demands inherent in the learning outcomes. For example, if a learning outcome asks students to analyze or synthesize information, a drill and practice program or reference material on a CD-ROM probably isn't going to match as well as concept mapping or database software.

eTIP 2: Technology Use Provides Added Value to Teaching and Learning.

Using technology to add value—meaning to make possible something that otherwise would be impossible or less viable to do—might mean that it helps to individualize instruction or make it more responsive to a student's questions and interests or that it provides additional resources of information so instruction is more real-world, authentic, and current. Educational technology can also aid teachers in providing "scaffolds" that support learners as they move from what they already know and can do to what they are learning. Educational technology can also help teachers to create social arrangements that support collaborative as well as independent learning by facilitating communication and interaction patterns. Teachers can also use educational technology to support additional opportunities for learners to practice, get feedback, or allow for revision or reflection; thus, it supports knowledge acquisition and practice, so learners become more fluent in their knowledge.

Educational technology can aid students accessing information or representing it in new ways. It can increase access to people, perspectives, or resources and to more current information. Many times, software's interface design allows learner interaction or presents information in a multi-sensory format. Hyperlinks can allow learners to easily connect to related information. Built-in indexes and key word searching support learners by easing their search through a large amount of information to find what is relevant. These features all add value by increasing access to data or the users' control during that access. In terms of processing information, added value might mean that the educational technology supports students learning-by-doing or aids them in constructing mental models, or making meaning, by scaffolding their thinking. For example, a database can allow students to compare, contrast, and categorize information through query features. By asking students to create products with tool software, it requires them to think more deeply about the material in order to represent it with that tool (Jonassen, 2000). Educational technology can also add value to students' ability to show and articulate to others about what they have learned.

eTIP 3: Technology Assists in the Assessment of the Learning Outcomes.

At times, teachers will want to collect and return to students formative data, to let them know about their learning progress. Some software or hardware actually collects formative data during its use, and some technologies also provide help in the analysis of the information. Generally, these are software programs designed to assess student learning, such as tutorial or drill and practice software. Some of these programs, through screens or printouts of information, or other feedback mechanisms, support students' self-assessment of their learning.

Teachers will also want to collect summative information about students' achievement of the learning outcomes. Technology can assist teachers in collecting data that will help them understand how students are meeting or have met the learning outcomes for that lesson or unit. Products students produce through software, whether a database, "mind map," multimedia or word-processed report, or a Web site, demonstrate what they have learned about both the content of their product, the procedural knowledge required to produce it, and their ability to communicate. The capabilities a product might demonstrate include the skills of editing, analysis, group collaboration, or the operation of the software itself.

School-Level eTIPs

Part of what makes teachers' integration activities feasible or not is the level of technology support at a school. The three school-wide principles elaborate upon the premise that the school environment must support teachers in a role of instructional designer by providing adequate technology support. The presence of high-quality technology support programs are correlated to teachers' increased uses of educational technology (Dexter, Anderson & Ronnkvist, 2002). Thinking about the school-level principles while deciding whether or how to integrate technology can help a teacher to take the "technology ecology" of the setting into perspective during instructional design. Together they will help teachers to evaluate the level of access and support available to them in their integration work, which may help to determine whether or not, given their amount of planning time, a particular integration goal is realistic.

eTIP 4: Ready Access to Supported, Managed Hardware/Software Resources is Provided.

Teachers must have convenient and flexible access to and technical support for appropriate educational technology in order for them to utilize it in their classrooms. Perhaps of all the principles, this one is the most self-evident. Without available and working educational technology, it can hardly be utilized in a classroom. But, the two key words in this principle are ready and supported. Ready access means the technology should be close to where teachers need to use it and that it is scheduled flexibly, so that teachers have an opportunity to sign up for it when it is relevant for classroom work. Here, support specifically refers to technical support like troubleshooting help and scheduled maintenance. The idea of ready access should raise for the teacher questions about whether or not the students could be grouped together to work with the educational technology, if it could be a station through which students rotated, or if all students need to have simultaneous access to the educational technology. Ultimately, the access has to be practical. It must be ready enough that working through the logistics of providing students access to the technology does not outweigh the added value it provides.

eTIP 5: Professional Development is Targeted at Successful Technology Integration.

Technology professional development is key to teachers learning to integrate technology effectively into the classroom (CEO Forum, 1999). The learning needs can be thought of as being about (1) learning to operate the software and, (2) learning to use software as an integrated, instructional tool. Too often teachers' learning opportunities are just about the operation of the software. This is necessary, but teachers must also have learning opportunities that address more than these basic skills. Specifically, these learning opportunities should guide teachers in the instructional design I have laid out in the three classroom educational technology integration principles. By having sufficient time to explore educational technology and have their technological imagination sparked by examples of it in use, teachers can identify which materials match their learning outcomes (eTIP #1). Professional development sessions should also provide frameworks or criteria that can aid a teacher in determining whether or not an educational technology resource brings any added value to teaching or learning (eTIP #2). Likewise, through examples and discussion, teachers should have opportunity to consider how educational technology might aid the formative or summative assessment of students' learning (eTIP #3).

eTIP 6: Professional Community Enhances Technology Integration and Implementation.

This principle describes a professional collaborative environment for integrating and implementing technology. In such an environment, technology use would be more effective because the school organization would recognize the contribution individuals make to the collective knowledge of the school (Marks & Louis, 1999). And the entire staff would work toward consensus about the school's performance, in this case with technology, and how they could improve it (Marks & Louis, 1997). A collaborative professional community would serve as the vehicle for school-wide knowledge processing about technology integration and implementation, increasing the likelihood of reflective dialogue, sharing of instructional practices, and generally increasing collaboration on new practices.

FUTURE TRENDS

As educational technology and Internet access become ubiquitous in classrooms and new teachers headed into the classroom arrive from college already skilled in the operation of technology, it is likely that educational technologists will then be able to shift their research efforts to how best to develop teachers' instructional decision making about technology integration and implementation. This suggests that further research is needed about the schema of expert technology integrating teachers, and the key cognitive processes involved in designing and implementing effective technology integrated instruction. Future development efforts are needed in the area of developing instructional supports, such as cases and simulationsthat will aid novice integrators in developing the necessary knowledge and skills.

CONCLUSION

The research literature about teachers' instructional planning suggests that teacher educators working to develop K-12 educators' abilities to incorporate educational technology into the classroom should attend to the development of teachers' schema about technology integration and its implementation. By serving as a schema, or the basis of one, the Educational Technology Integration and Implementation Principles (eTIPs) can help teachers recognize and plan for the effective technology use that is represented in the NETS-T and INTASC standards. The eTIPs point out two key aspects of teachers designing effective integrated instruction: the technology use must match and support teaching and learning, and the larger school environment must provide support for the logistical and learning demands technology integration puts on teachers.

KEY TERMS

Added Value: traditional usage is as an indication that the particular packaging, delivery method, or combination of services in a product brings extra benefits than one would otherwise receive. Applied to educational technology, it communicates that the use of technology brings added value to the teaching or learning processes when it makes possible something that otherwise would be impossible or less viable to do.

Principle: ideas that can assist learners in recognizing and connecting ideas and in seeing how new and old ideas relate.

Professional Community: collaborative activities among a school's faculty members that focus on meaningful, shared issues in a school and also emphasize how each individual staff member can take responsibility for its achievement.

Professional Development: the National Staff Development Council defines this as the term that educators use to describe the continuing education of teachers, administrators, and other school employees.

Schema: mental constructs that aid learners in categorizing problems or situations and selecting appropriate courses of action for their effective resolution.

Technology Implementation: the putting into place at a system level of a school the conditions that support the integration of technology at the classroom level.

Technology Integration: the use of technology in teaching to support learning.

Privacy–Dangers and Protections

William H. Friedman
University of Central Arkansas, USA

INDIVIDUAL AND SOCIAL CONCERNS

It is no wonder that the average citizen is concerned about the difficulty of guarding one's privacy. Now, your own cell phone can reveal your ever-changing whereabouts by means of "location technology" (Lagesse, 2003). Chips that receive coordinates from global positioning satellites now make it possible to locate persons, cars, merchandise, in short, whatever we value. Like most new technology, it is easy to see advantages as well as drawbacks. Some positives of location technology are that ambulances, police and fire services can reach victims more quickly; driving suggestions can be delivered in real time to motorists (thus helping to avoid traffic tie-ups and prevent getting lost); advertisers can inform potential customers of the existence of a nearby hotel, store or restaurant; stores utilizing RFID (see the **KEY TERMS** section for explanations of possibly unfamiliar terms) can trace merchandise movement to reduce waste, replenish inventory, and stem shoplifting. Some negatives are that nefarious agents can also use location technology to track their prey; location-tracking history can be subpoenaed by one's legal adversaries; and it is inevitable that corporations and government will have an interest in conducting such monitoring (Griffin & Whitehead, 2001, 2002).

Privacy is an area that involves governmental, legal, social, managerial, and technical matters. Claims to privacy rights usually involve one or more senses of the notion of privacy. Table 1 gives some idea of the main connotations of "privacy" that are relevant to and will be applied to information technology; hence, they form the basis for the following discussion.

The first definition embodies respect for a computer user's wish to be in an insulated, protected space; no individual or program should interfere with the user's computer activity in a way that unexpectedly and undesirably disturbs that user. This presupposes freedom from concern that someone might hack in to the system and disrupt it, or barge into a chat room. Intrusive pop-up advertisements and junk e-mail can also contravene the first notion of privacy.

The second definition would suggest that any form of even unconcealed monitoring is a breach of privacy. An important exception in many people's minds is that government agencies might need to monitor computer activity when there is reason to suspect criminal or terrorist activity. A very similar exception arises when employers (Haag, Cummings & McCubbrey, 2004) feel that certain employees are abusing computer privileges, not working appropriately, or are otherwise jeopardizing the company's welfare. This can happen when the employee's computer activity leaves the company open to litigation or when the employee discloses company secrets (Brandt, 2001). Each of these exceptional cases, in order to be tolerated in an otherwise free society, presupposes some warranted authority for the monitoring. Less malicious, but perhaps equally bothersome is commercial monitoring to learn our buying habits by observing our Web searches and purchasing proclivities. Cookies to achieve this end are deposited and visible in a "Cookies" folder on our hard drives. Even when only aggregate, not identifiable individual data are harvested, most people would reject such a practice as beginning to slide down a slippery slope of more serious privacy invasion (Hamilton, 2001).

The third sense of privacy appeals to a desire to be free from being the object of concealed surveillance. Governmental and other spies have tried to plant programs or devices in suspect computers to log activities without the users knowing about it and report what they do to a distant receiving station.

The fourth sense expresses our desire not to suffer anyone's forcing his/her way into our space in plain sight in order to seize our computer or copy our files, in complete disregard of our wishes to keep these to ourselves. To have any property or information taken by stealth is offensive, but even more so for information that might presumably be detrimental to our best interests, such as credit card numbers.

The fifth connotation (as used particularly in database contexts) pertains to the natural expectation that our computer files be reserved exclusively for our own dissemination and access. To lose exclusive control over access and dissemination of our data files leaves us open to blackmail, financial fraud (as with discovery of our credit card numbers), malicious mischief, and even identity theft. While crimes may seem to be the modus operandi of ordinary crooks, we must contend with hackers and "script kiddies" who engage in this sort of pursuit for sport and, of course, sometimes also for profit.

The sixth meaning expresses our concern that when we purchase something or register at a Web site, unless we opt in, we do not ordinarily wish to have the information entrusted to the site shared with any other party. An opt-in permission granted to the site should imply that one is later able to cancel the service, or “opt-out”. A great deal of junk e-mail is delivered under the pretext that, at one point, one did opt-in for the program with a related third party, a statement that may or may not be correct.

Very few downloaders of software have the patience to inspect the license agreement that must receive assent before installation can proceed. Nearly everyone accepts it by checking “I agree” without actually scrolling and reading the extended window full of legalese. Unfortunately, the end-user license agreement may not indicate the full extent of what the software does. An honest EULA may state that the program performs anonymous profiling, an assurance that your computer activities are being documented for future use, but not with identifying characteristics of the user per se. This type of software is used to generate a marketing précis of one’s interests and attributes. Thus, if you visit Web sites that feature a certain service or product, you may be directed to other Web sites that feature the same thing. Vendors advertise with spyware companies, because of the selective targeting offered. By catering to consumers’ preferences as exhibited in Web browsing, they presumably also benefit because they are presented only with items that really interest them and are spared much spam. Despite this alleged advantage and with promises of not recording personal data, many consumers disapprove of this practice on general principles and try to delete the uninvited spyware, often a difficult if not impossible task.

There are many techniques to invade our privacy—in both hardware and software. Even the FBI is reputed to use the infamous but mysterious program, “Magic Lantern,” to spy on criminals attempting to hide their activities when using encryption for their e-mail. “When the user types the password, Magic Lantern software would capture it, giving the agency the ability to decrypt users’ communications” (Paulson, 2002).

A wide variety of such snares awaits law-abiding citizens as well, and can be conveniently lumped under the rubric of “spyware”. Table 2 summarizes some of the spyware that can be used to violate privacy.

A person’s first thought upon discovery of a parasite on his/her computer is how to remove it. Although parasites are not easily removed, anti-parasite programs can detect and remove them. In addition, several Web sites have parasite detection scripts that analyze your computer and provide you with removal instructions (for example, visit www.doxdesk.com/parasite). Parasites are often fellow travelers of demos and freeware that are offered on the Web. A surfer must take the trouble to read the small print that appears in the EULA and privacy policy at the bottom of most Web sites. Sometimes one can opt out of selecting any extra utility that asks be installed along with what you originally ordered.

Due care must be given to permission windows asking if you wish to run a certain program, the function of which is not totally clear. ActiveX controls on the Web cannot only install parasites that compromise our privacy but also install viruses. XSS involves everything: all sorts of nefarious activity such as account hijacking, changing of user settings, cookie theft, and fake advertising.

PRE-INTERNET LEGAL PROTECTION

While the U.S. Constitution does not explicitly mention a legal right to privacy, this right is traditionally considered to have been implied by the first, fourth, and fifth amendments to this constitution (Blumenfeld, 1998). The First Amendment does not really grant privacy in any of the senses mentioned earlier; instead, it guarantees free speech (which could pertain to the Internet, but not really to privacy). The fourth amendment prohibits unreasonable searches and seizures (applicable to data and computer equipment, of course). The Fifth Amendment states: “nor shall private property be taken for public use, without just

Table 1. The relevant senses of the concept of privacy

1. Freedom from being subjected to unwanted contact
2. Freedom from overt monitoring
3. Freedom from secret surveillance
4. Freedom from unauthorized intrusion
5. Confidentiality
6. Freedom from disclosure by others of personal data to unauthorized persons

Table 2. Techniques used to violate computer privacy

Cross-site scripting (XSS)

compensation;" but here the concern is with justice, not privacy. The third amendment is quite relevant to privacy, however. It assures that no soldier will be forcibly introduced into a citizen's household, thereby guaranteeing against privacy destroying intrusion by the quartered soldier (Friedman, 2002).

Louis D. Brandeis (1928) became a pioneer in the advocacy of a legal foundation for privacy when he wrote a dissenting opinion for a case about governmental wiretapping to entrap a bootlegger. It is almost prophetic in dealing with as yet unknown technologies:

"The progress of science in furnishing the government with means of espionage is not likely to stop with wire tapping. Ways may some day be developed by which the government, without removing papers from secret drawers, can reproduce them in court…"

The U.S. Privacy Act of 1974 has three important provisions: that there be no secret data banks, that effort must be made to see that the data are reliable, and that the information cannot be used for a purpose different from the original reason for collecting it (Friedman, 2002; Gurak, 2002; Helm, 2000).

POST-INTERNET LEGISLATIVE INITIATIVES TO THE RESCUE

At least a score of bills have been proposed in the U.S. Congress to protect us from Internet privacy abuse—all of the following principal bills and others are described along with their legislative status on this Web site of Thomas (2003):

- TITLE XIII—Children's Online Privacy Protection Act of 1998 (COPPA)
- Online Privacy Protection Act of 2003 (Introduced in the House)
- Consumer Privacy Protection Act of 2003 (Introduced in the House)
- Privacy Act of 2003 (Introduced in Senate)
- Privacy Act of 2003 (Introduced in Senate)
- Identity Theft Protection Act (Introduced in Senate)
- Social Security Number Misuse Prevention Act (Introduced in Senate)

Children under the age of 13 use the Internet for playing games, shopping, schoolwork, or idle surfing. COPPA endeavors to give parents more control by enlisting the aid of the Federal Trade Commission to establish new rules for Web site operators in order to safeguard our children's privacy while they are online. These rules are now part of the 1998 law, known as the Children's Online Privacy Protection Act (COPPA).

A similar act has been proposed to protect adults, namely, the Online Privacy Protection Act of 2003/H.R. 69 H. R. 69, which would require the Federal Trade Commission to prescribe regulations to protect the privacy of personal information collected from and about individuals (who are not covered by the Children's Online Privacy Protection Act of 1998) using the Internet.

An important aim of the Consumer Privacy Protection Act of 2003/H.R. 1636 (introduced in the U.S. House of Representatives) is to provide protection to all consumers by requiring notice of privacy policies and how data gathered from them on the Internet will be used.

Two U.S. Senate bills proposed to protect privacy and confidentiality are the Privacy Act of 2003/S.B. 745, which requires a consumer's prior agreement before personal data can be revealed to a third party, and the Identity Theft Protection Act/S.B. 223, which would require financial institutions to take strong proactive steps to secure the consumer's sensitive data (Cabral, 2001). Another protective bill, the Social Security Number Misuse Prevention Act/S.B. 228, governs the rules for sale and display of one's social security number by others as well as a vendor's requiring it for purchases.

CRITICAL ISSUES PERTAINING TO PRIVACY

Some difficult choices between conflicting values face our technological society (given in Table 3).

FUTURE TRENDS

As governments strive to combat terrorists (Ashcroft, 2004) as well as other suspected criminals by eavesdropping and entering their domiciles unannounced, and as parents and other authorities try to discover sexual activi-

P

Table 3. Conflicting values involving privacy

• Safeguarding one's personal data versus facilitating vendors' catering to our preferences, and as a result lowering costs (Cowley, 2002)
• Keeping one's personal computer activities secret versus the need for national security and fighting crime
• Monitoring employees at work versus infantilizing them psychologically (Friedman, 2002)

ties of children and pornographers, the privacy of even totally innocent parties will be increasingly diminished. Future research might concern the U.S. government's efforts (Center for Democracy and Technology, 2004) to thwart the "SAFE Act, a bipartisan bill that proposes modest fixes to the USA PATRIOT Act to ensure appropriate oversight of the Justice Department" (Center for Democracy and Technology, 2004). The purpose of the Patriot Act as stated in the first paragraph is "to deter and punish terrorist acts in the United States and around the world, to enhance law enforcement investigatory tools, and for other purposes"(USA Patriot Act, 2001).

Furthering this trend, technology is providing low-cost methods of eavesdroping and logging key strokes on a computer, so that idle but unsavorary persons will be able to discover confidental secrets.

CONCLUSION

There is much that an individual or organization can do to protect privacy, in all its connotations. Some of the many proactive and protective countermeasures one can take to thwart abuse are given in Table 4 (all suggestions help with commercial assaults on privacy [which correspond, in Table 1, with all listed senses of privacy]: and the last two might also aid in forestalling unwarranted governmental invasions [usually involving Table 1, senses: 2, 3, and 5]).

Table 4. Suggested ways we can act to protect our privacy

- Deal only with Web sites whose privacy policies are clear and to which you can assent
- Opt out of any suspect product or club registration
- Encrypt sensitive files on one's computer
- Utilize protective software (e.g., firewalls)
- Be careful not to reveal too much, knowingly or unknowingly (e.g., social security numbers or passwords)
- Use credit cards that allow one time use of numbers—each transaction uses a different temporary number linked to the real account number
- Work to secure protective legislation
- Join and cooperate with groups formed to fight privacy invasion

KEY TERMS

ActiveX Control: A Microsoft software module that enables another program to add functionality by calling ready-made components that blend in and appear as normal parts of the program.

Chat Room: Interactive "conversation" involving several people (via typing on a computer terminal or PC) usually centered on a single topic utilizing the Internet. Occasionally members of the chat room break off to form a smaller, more intimate conversation, to the exclusion of all others, thus invoking privacy privileges.

Cookie: Information, usually including a username, Internet address, and the current date and time, placed on the hard drive of a person using the World Wide Web by a Web site that one has visited. This information can be used to identify visitors who have registered or viewed the site, but also to report the visitor's unrelated Web activity, or worse, personal information stored by the user.

Cross-Site Scripting (XSS): An application to trick users into thinking they are dealing with a normal Internet situation, but the real purpose is to gather data from them.

Encryption: A transformation of data from an original readily understandable version (plaintext) to a difficult-to-interpret format (ciphertext) as a way of protecting confidentiality until changed back to the original. Images can also be encrypted to prevent recognition.

EULA: End user license agreement, which spells out the legal rights of both the purchaser and vendor of software.

Exploit: Weakness in a system through which hackers can gain entry into the system.Firewall: Hardware or software to prevent unauthorized users from gaining access to a computer or network.

GIF: Internet graphics image file format.

GPS: Global positioning system. It utilizes a wide-reaching radio broadcasting system, originally produced to aid navigation, consisting of a group of 24 satellites plus terrestrial receiving devices.

Identity Theft: The act of a person who successfully pretends to be another person for the purpose of committing fraud. An identity thief discovers some bit of your personal information and appropriates it for him/herself without your knowledge to acquire a privilege (e.g., driving license), some property, or some service for the victim is billed.

Key Logger, Keystroke Logger: Software that runs imperceptibly during computer use that records each keystroke, either saving the results to a log file or sending the results to a second party.

Magic Lantern: An e-mail containing an attachment that, if opened, would insert a "Trojan horse" that is activated upon launch of the popular encryption program, Pretty Good Privacy. Then it sends all the keystrokes the unwitting user types.

Opt-in: Consciously to accept some situation or condition in a contract. For example, to opt-in to an e-mail subscription means that you want to receive periodic messages, even from third parties (antonym: opt-out).

Parasites: Software that operates in the background and sends details of one's computer activity to an interested party. Such programs are often installed with demos and freeware obtained from the Web.

Pop-Up Advertisements: Windows that suddenly appear while surfing the Web, often involving splashy colors and loud sound effects.

Port Scanning: The practice of sending electronic queries to Internet sites in order to learn what level of security exists. Often the intent is to see if it can be compromised.

RFID: Radio frequency identification. Chips can broadcast information presently 3 to 10 meters away after being scanned by a special device using ordinary radio waves.

Script: A typically small program; also one that might do damage.

Script Kiddies: Derisive term for amateur hackers who illegally invade a system using the path of least resistance.

Spyware: Software that can be rapidly and unobtrusively installed on a computer and that subsequently passes information about one's Internet surfing habits to a designated Web site.

Trojan Horse: A program that appears to be legitimate but is designed to have destructive effects, as to data residing in the computer onto which the program was loaded.

Web Bug: A single pixel, transparent (or sometimes even visible) GIF image that can surreptitiously pass along information about a site user to second party.

Process–Aware Information Systems for Virtual Teamwork

Schahram Dustdar
Vienna University of Technology, Austria

INTRODUCTION

The question of the "right" organizational form and the appropriate information systems support remains of paramount importance and still constitutes a challenge for virtually all organizations, regardless of industrial background. Organizations distribute their required work activities among groups of people (teams), with teams constituting the main building block for implementing the work (tasks). In most cases, team members are organized as "virtual (project) teams." These teams are under heavy pressure to reduce time to market of their products and services and lower their coordination costs. Some characteristics of distributed virtual teams are that team (member) configurations change quite frequently and that team members report to different managers, maybe even in different organizations. From an information systems' point of view, distributed virtual teams often are self-configuring networks of mobile and "fixed" people, devices, as well as applications. A newly emerging requirement is to facilitate not just mobility of content (i.e., to support a multitude of devices and connectivity modes) to team members, but also to provide contextual information on work activities to all distributed virtual team members (Dustdar, 2002a, 2002b, 2002c). By context, we mean traceable and continuous views of associations (relationships) between artifacts (e.g., documents, database records), resources (e.g., people, roles, skills), and business processes. Context is composed of information on the "who, when, how, and why." The remainder of this chapter is organized as follows: The next section provides an overview of related work on classification systems of collaborative systems and provides an overview on evaluation aspects of current collaborative systems for virtual teamwork. Section 3 discusses some issues and problems related to the integration of artifacts, resources, and processes. Section 4 presents one proposed solution. Finally, Section 5 discusses some future trends and concludes the chapter.

FUNCTIONAL CLASSIFICATION OF COLLABORATIVE SYSTEMS

There has been a lot of work on classification models for collaborative systems. However, there is no one-and-agreed-upon taxonomy of analyzing and understanding collaborative systems. Academia and industry suggest various classification schemes. In industry, for example, people frequently use the term *e-mail* and *groupware* interchangeably. More generally, there is the tendency to classify categories of collaborative systems by naming a product (e.g., many use the terms *Lotus Notes* and *groupware* interchangeably). Academic research has suggested many different classification models. For a recent survey of collaborative application taxonomies, see Bafoutsou and Mentzas (2002). DeSanctis and Gallupe (1987), Ellis, Gibbs and Rein (1991), and Johansen (1988) suggest a two dimensional matrix based on time and place, where they differentiate between systems' usage at same place/same time (e.g., electronic meeting rooms), same place/different time (e.g., newsgroups), different place/different time (e.g., workflow, e-mail), different place/same time (e.g., audio/video conferencing, shared editors). This classification model helps one to easily analyze many tools on the market today; however, it fails to provide detailed insights on collaborative work activities themselves, as well as their relationship to business processes. Ellis (2000) provides a functionally oriented taxonomy of collaborative systems that helps one to understand the integration issues of workflow and groupware systems. The classification system of Ellis (2000) provides a framework in which to understand the characteristics of collaborative systems and their technical implementations.

The first category (Keepers) provides those functionalities related to storage and access to shared data (persistency). The metaphor used for systems based on this category is a "shared workspace." A shared workspace is basically a central repository where all team members put (upload) shared artifacts (in most cases, documents) and share those among the team members. Technical characteristics of “keepers” include database features, access control, versioning, and backup/recovery control. Examples of popular systems include *BSCW* (Bentley et al., 1997), IBM/Lotus *TeamRoom* (IBM, 2002), and the peer-to-peer workspace system *Groove* (Groove, 2002). The second category (Communicators) groups all functionality related to explicit communications among team members. This boils down to messaging systems (e-mail). Its fundamental nature is a point-to-point interaction model where team members are identified only by their name (e.g., e-mail address) and not by other means (e.g., skills, roles, or other constructs, as in some advanced workflow systems). The third category (Coordinators) is related to the ordering and synchronization of individual activities that make up a whole process. Examples of Coordinator systems include workflow management systems. Finally, the fourth category (Team-Agents), refers to semi-intelligent software components that perform domain-specific functions and thereby help the group dynamics. An example of this category is a meeting scheduler agent. Most systems in this category are not off-the-shelf standard software. Both evaluation models presented above provide guidance to virtual teams on how to evaluate products based on the frameworks. Current systems for virtual teamwork have their strength in one or two categories of Ellis’ framework. Most systems on the market today provide features for Keepers and Communicators support or are solely Coordinator systems (e.g., Workflow Management Systems) or Team-Agents. To the best of our knowledge, there is no system that integrates at least three of the above categories into one system. In the following section, we evaluate current collaborative systems categories for their usage in virtual teams and summarize their shortcomings with respect to the requirement for virtual teamwork.

Evaluation of Collaborative Systems for Virtual Teamwork

Cooperative tasks in virtual teams are increasing, and, as a consequence, the use of collaborative systems is becoming more pervasive. In recent years, it has increasingly become difficult to categorize systems according to the frameworks discussed previously, due to the increasing fuzziness of systems boundaries and to recent requirements for virtual teamwork. Traditional systems in the area of interest to virtual teamwork are groupware, project management (PM) and workflow management systems (WfMS). These system categories are based on different metaphors. Groupware systems mainly can be categorized along two lines (metaphors)—the *communications* or the *workspace* metaphor.

Communications-oriented groupware supports unstructured work activities using communications as the underlying interaction pattern. One very popular instance of communications-oriented groupware is e-mail. When e-mail is used as the main medium for virtual teams (as in most cases), data and associated information (e.g., attachments) remain on central mail servers and/or personal inboxes without any *context* information in which those e-mail communications were used (i.e., involved business processes, performed activities, created artifacts). Enterprise groupware systems generally focus on enterprise-wide messaging and discussion databases and do not support organizational components and structures, such as people and their associated roles, groups, tasks, and skills. This leads to “organizationally unaware” systems that treat all messages alike (semantically) and without any awareness of underlying business processes that are essential for efficient collaboration in project teams.

Workspace-oriented groupware, on the other hand, allows team members to upload or download artifacts using files and folders to organize their work. Groupware, as previously indicated, usually does not implement an underlying organizational model (i.e., providing information on the structure of a team, such as team members and their roles, skills, tasks, and responsibilities). The lack of explicit organizational structuring is a disadvantage and an advantage at the same time. It is disadvantageous because traditional groupware has no “hooks” for integrating business process information, which is important in order to integrate artifacts, resources, and processes. This will be discussed in more depth in the next section. The advantage of the lack of explicit organizational structure information is that these systems may be used in all organizational settings without much prior configuration efforts, and they lead to increased personal flexibility, as the proliferation of e-mail systems in teamwork demonstrates.

The second category, which we will briefly investigate in this section, is *project management systems*. As we have stated, virtual teamwork is, in most cases, organized as project work. Projects have well defined goals and are defined by their *begin* and *end* dates, as well as by the required resources and their tasks (work breakdown structure). It is interesting to note, however, that PM systems traditionally support the work of the project manager as the main (and sometimes the only) user of the PM system. They do not support dynamic interaction (instantiation) of processes. More recently, project management systems combine with information sharing tools (shared workspaces) to provide a persistent storage for artifacts. The enactment of the task by team members, as defined by the project manager, is not supported by PM systems. In other words, we can conclude that PM systems are not geared towards virtual teamwork, but focused more on the planning aspect. They provide “static” snapshots (usually in the form of GANNT charts) of projects and how they "should" be. There is no support for the work activities performed by the virtual team members.

The purpose of *workflow management systems* is to support the notion of processes within and, in some cases, between organizations (Aalst & Kumar, 2001; Bolcer, 2000; Bussler, 1999). However, WfMS' first requirement is to model a business process (build time) and then to enact this model (run time). This leads to substantial inflexibility for virtual teams (Ellis, 1995). In business, "exceptions are the rule;" therefore, modeling a process (project) is often not possible for creative, innovative virtual teams of knowledge workers such as in product development or consulting teams. A business process can be unstructured (ad hoc), semi-structured, or highly structured (modeled). For example, a business process such as "customer order entry" can be modeled using traditional WfMS. However, highly structured processes only can be enacted (instantiated) as they were designed. If an exception occurs, a workflow administrator needs to remodel the process before the execution can continue. This limits the usability of WfMS in a world where constant adaptation to new situations is necessary and where teams are increasingly mobile and distributed. An example of an *ad hoc* process is discussion of a project's design review using Groupware. A semi-structured process consists of groups of activities that are modelled; however, in contrast to a structured (modelled) process, it may also consist of activities that are not pre-defined. A process is semi-structured when there might be one or more activities between already modeled activities such as *assign process*, which are not known beforehand and therefore cannot be modeled in advance.

It is important to note that requirements for virtual teamwork do not follow the traditional boundaries of systems already presented. We differentiate between synchronous and asynchronous technologies for teamwork support. During our case study requirements analysis, we came to the conclusion that distributed product development in virtual communities requires a blend of synchronous and asynchronous systems support for communications, as well a basic support for asynchronous coordination of team members and their activities. In summary, the requirements for virtual teams cannot be met simply by using a combination of traditional synchronous and asynchronous systems, since the criteria for successful systems in this area differ substantially with traditional "enterprise information systems." We identified and implemented (see Section 4) four fundamental feature sets for our virtual team software—device independence; process-awareness; integration of artifacts, resources, and processes; and organizational awareness. Most systems on the market do not cater to the requirements of virtual teams; namely, *dynamic views of relationships* between artifacts, resources, and process awareness are vital to the work organization of virtual teamwork.

ON THE INTEGRATION OF ARTEFACTS, RESOURCES, AND PROCESSES

Organizations increasingly define the work activities to be fulfilled in virtual teams where team members from within the organization cooperate (i.e., communicate and coordinate work activities) with outside experts, and therefore form virtual teams, which in many cases operate as geographically dispersed teams. In fact, team members work on business processes; however, in many instances, team members view their own work as a project and not necessarily as part of a larger business process fulfilling a business goal in a larger context. The work of virtual team members often results in artifacts (e.g., documents) that need to be shared among virtual team members. The underlying assumption of this chapter is that *process-awareness* is increasingly important to virtual teams. Teamwork is a fundamental property of many business processes. Business processes have well defined inputs and outputs and serve a meaningful purpose, either within or between organizations. Business processes in general and their corresponding workflows, in particular, exist as logical models (e.g., weighted directed graphs). When business process models are executed, they have specific instances. A business process consists of a sequence of work activities. An activity is a distinct process step and may be performed either by a human agent or by a machine (software). A workflow management system enacts the real world business process for each process instance (Craven & Mahling, 1995; Dayal et al., 2001; Schal, 1996). Any activity may consist of one or more tasks. A set of tasks to be worked on by a user (human agent or machine) is called *work list*. The work list itself is managed by the WfMS. The WfMC (WfMC, 1995) calls the individual task on the work list a work item. Software systems for workflow management—Groupware—process modeling (Puustjärvi & Laine, 2001), and project management has been used to automate or to augment business processes in organizations (Casati et al., 2001; Hausleitner & Dustdar, 1999). Workflow management systems have been defined as "technology based systems that define, manage, and execute workflow processes through the execution of software whose order of execution is driven by a computer representation of the workflow process logic" (WfMC, 1995). Workflow systems generally aim at helping organizations' team members to communicate, coordinate, and collaborate effectively, as well as efficiently. Therefore, WfMS possess temporal aspects such as activity sequencing, deadlines, routing conditions, and schedules. WfMS are typically "organizationally aware" because they contain an explicit representation of organizational processes (process model). However, traditional WfMS present a rigid work environment consisting of *roles* and their associated *activities* and *applications*. In this context, they do not provide support for virtual teams such as frequently changing process participants, ad hoc formation of groups collaborating on a business process, and device independent support of group activities. Unfortunately, today's WfMS assume that each *work item* is executed by a *single* worker (Aalst & Kumar, 2001). Most WfMS focus on automating structured (modeled) intra-organizational business processes. Groupware, on the other hand, typically does not contain any knowledge or representation of the *goals* or underlying business *processes* of the group. We argue that, considering the top three problems occurring in virtual teamwork, increasing contextual information in the form of building relationships between artifacts, resources, and business processes solves the fundamental problems and, as an implication, the most dominant problems such as "difficulties in team communications" and "unclear work activities." Our approach for integration of artifacts, resources, and processes comprises a communications and coordination building block where team members exchange "enriched" messages. Workflow research has shown that modeling organizational structures has substantial benefits for business processes. Therefore, we allow modeling of organizational constructs such as groups, roles, skills, and organizational units. Each team member can be associated with those constructs, as shown in Section 4. Furthermore, an integrated database allows for attaching database objects to the communications and coordination activities of virtual team members, enabling integration of resources (organizational constructs) and artifacts. The process modeling component allows the creation of directed graphs consisting of tasks and their relationships with organizational constructs. The next section, therefore, discusses implementation issues on how to make context information (i.e., information about process instances), the team configuration (i.e., participants and their roles), their associated artifacts, and connectivity modes of group members (fixed, mobile, or ad hoc) accessible to all virtual team members.

THE CASE OF AN INTEGRATED INTERACTION MANAGEMENT SYSTEM FOR VIRTUAL TEAMS

In the following section, we will provide an overview of integration issues with which we are concerned, and design an integrated system for virtual teams called *Caramba* (Caramba Labs, 2002). An in-depth presentation of the conceptual foundations, the architecture, or the components is beyond the scope and focus of this chapter and can be found in Dustdar (2002b, 2002c, 2004). The Caramba software architecture is composed of multiple layers—middleware, client suite, and persistence store. Objects and services are accessed through the Transparent Access Layer (TAL) from the CarambaSpace platform (middleware). Depending on access mechanisms and the requested services (e.g., via Java client with RMI protocol or via Web browser with http), Caramba provides a unique way to handle requests using a metamodel framework to describe content and separate presentation, logic, and data. This model permits high flexibility and enables customization and extensions, as well as adopts new devices or technologies. The goal of this layer is to offer transparent access to a CarambaSpace. The TAL utilizes various services to transform, describe, manipulate, and observe objects. All objects managed through a CarambaSpace are described well using a metamodel description framework. Objects can be customized in their structure (e.g., adding columns to tables, adding relations to objects) and in their presentation by adopting their metamodel description. Any changes are dynamically reflected by client components. Based on the metamodel description framework Caramba enables various options to customize data and content and to integrate data from different resources (e.g., corporate databases). This layer also provides facilities for fine-grained object notification services and the implementation of customized services based on object observers. The middleware does not manage states and persistence of objects. Objects are stored, manipulated, and retrieved via the Persistence Layer (PEL). Caramba leverages and adopts standard Java-based technologies (e.g., JDBC, JNDI, HTTP, etc.) to access and integrate data.

An overall conceptual overview of how Caramba implements the requirements and how a work scenario of virtual teamwork may look is depicted in Figure 1. Virtual teams have one or more project managers and several resources (people) with various skill sets and professional backgrounds, as well as possibly different organizational affiliations. The daily teamwork consists of meetings, exchange of documents, and many communications (tasks, e-mails) being sent back and forth. For each project (business process), meetings, documents, and communications occur, and the trail of communications and interactions is depicted as lines between the team members. Without appropriate virtual team software, the relationship between artifacts, resources, and business processes is only available in the "heads" of the team members. For example, each team member has to remember *when* a particular document was sent to *whom* (e.g., a

Figure 1. Conceptual view on virtual team software support

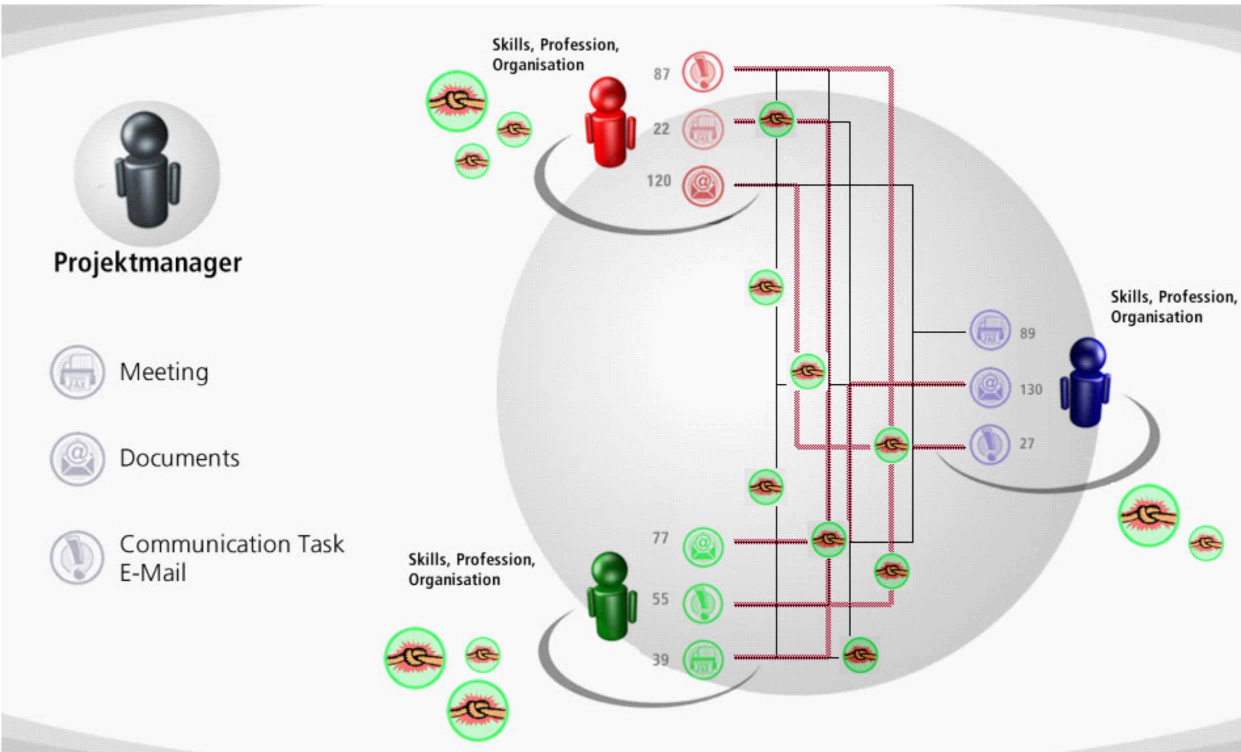

Figure 2. Modelling organizational resources and processes

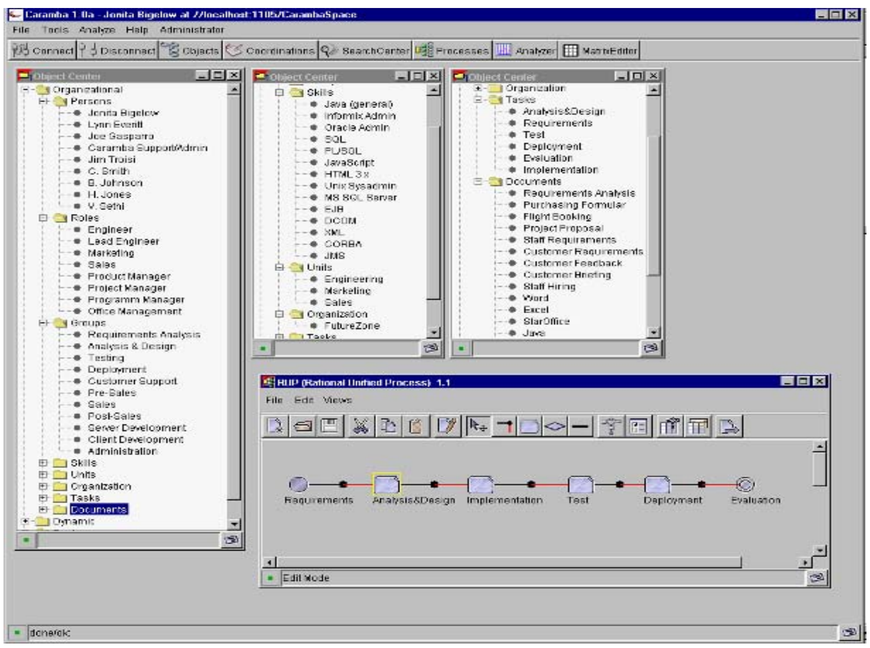

customer) and *why* (i.e., as a part of a particular business process). The goal of virtual team software should be to explicitly provide this relationship information to all team members based on their views and interests.

In order to provide one example of what an implementation looks like, we present the Caramba components. The ObjectCenter component provides mechanisms to link activities with artifacts. Based on a metamodel, Caramba provides a set of organizational objects: Persons, Roles, Groups, Skills, Units, Organization, Tasks, and Documents (i.e., Templates). Utilizing these organizational constructs, an administrator can model any organizational structure, such as hierarchical, flat, or matrix. Each object class consists of attributes describing the object. The object class *Persons* contains attributes about the person, such as name, address, and so forth. The object class *Roles* allows definition of organizational roles such as "Head of IT." The object class *Groups* defines project settings such as "Product Team IT-Solutions." *Skills* enables the definition of required skill sets such as "Certified Java Developer." *Units* describes permanent departments such as "Marketing." The Object Center provides a means (by drag and drop) to link rows of object classes with each other, as depicted in Figure 2. It allows users to view relationships between who (organizational constructs) is performing which activities (Tasks) and using what (Documents). A business process modeller component enables a project manager to model a process template, which may be instantiated later using the built-in Workflow engine. Exceptions to the model are possible, without the need to remodel the process template, by choosing the communications (coordination) partner (from the ObjectCenter). The receiving end can read the appropriate message in his or her inbox.

CONCLUSION

During the last few years, virtually all business processes changed regarding their requirements for flexibility, interconnectivity, and coordination styles. Most business processes are based on teamwork. Most teams are organized as virtual teams, with team members coming from different organizations. In this chapter, we discussed the requirements of modern virtual teamwork and the problems associated with using traditional groupware, project, and workflow management systems for virtual teamwork. A fundamental need for distributed virtual teamwork is to have access to contextual information (i.e., to see a "knowledge trail" of who did what, when, how, and why). We presented the underlying conceptual issues and one implemented information system (Caramba) to support the integration of artifacts, resources, and business processes for virtual teams. Future virtual team systems should provide mechanisms for the integration of organizational models with artifacts and business processes in loosely coupled information systems. In our future work, we plan to design and implement support for definition, configuration, and composition of processes for virtual teams based on Web services. A Web service is an interface that describes a collection of operations that are network accessible through standardized XML messaging using Web servers or Application servers. A Web service is described using a standard, formal XML notion, called its *service description*. It can be published and found by other Web services. To summarize our recommendations and lessons learned, we think that for typical mid-size (e.g., 15-person) virtual teams (geographically dispersed), process-awareness, organizational awareness, and the integration of artifacts, resources, and processes is crucial. In most cases, we found that asynchronous systems support is of paramount importance when there are more team members in a virtual team and when more work occurs across different time zones.

ACKNOWLEDGEMENTS

The author thanks all team members of Caramba Labs Software AG for the fruitful and constructive discussions.

KEY TERMS

Knowledge Trail: Provides information on who did what, when, how, and why.

Process-awareness: (See knowledge trail)

Interaction Management System: An information system providing an environment for communications and coordination of work activities for virtual teams.

Workflow: Comprises cases, resources, and triggers that relate to a particular process.

Process: Indicates what tasks must be performed and in what order to complete a case.

Role: In order to perform tasks, skills are required. A role is a collection of complementary skills.

Task: An atomic process that is not divided further and is a logical unit of work.

Process-Based Data Mining

Karim K. Hirji
AGF Management Ltd, Canada

INTRODUCTION

In contrast to the Industrial Revolution, the Digital Revolution is happening much more quickly. For example, in 1946, the world's first programmable computer, the Electronic Numerical Integrator and Computer (ENIAC), stood 10 feet tall, stretched 150 feet wide, cost millions of dollars, and could execute up to 5,000 operations per second. Twenty-five years later, Intel packed 12 times ENIAC's processing power into a 12–square-millimeter chip. Today's personal computers with Pentium processors perform in excess of 400 million instructions per second. Database systems, a subfield of computer science, has also met with notable accelerated advances. A major strength of database systems is their ability to store volumes of complex, hierarchical, heterogeneous, and time-variant data and to provide rapid access to information while correctly capturing and reflecting database updates.

Together with the advances in database systems, our relationship with data has evolved from the prerelational and relational period to the data-warehouse period. Today, we are in the knowledge-discovery and data-mining (KDDM) period where the emphasis is not so much on identifying ways to store data or on consolidating and aggregating data to provide a single, unified perspective. Rather, the emphasis of KDDM is on sifting through large volumes of historical data for new and valuable information that will lead to competitive advantage. The evolution to KDDM is natural since our capabilities to produce, collect, and store information have grown exponentially. Debit cards, electronic banking, e-commerce transactions, the widespread introduction of bar codes for commercial products, and advances in both mobile technology and remote sensing data-capture devices have all contributed to the mountains of data stored in business, government, and academic databases. Traditional analytical techniques, especially standard query and reporting and online analytical processing, are ineffective in situations involving large amounts of data and where the exact nature of information one wishes to extract is uncertain.

Data mining has thus emerged as a class of analytical techniques that go beyond statistics and that aim at examining large quantities of data; data mining is clearly relevant for the current KDDM period. According to Hirji (2001), data mining is the analysis and nontrivial extraction of data from databases for the purpose of discovering new and valuable information, in the form of patterns and rules, from relationships between data elements. Data mining is receiving widespread attention in the academic and public press literature (Berry & Linoff, 2000; Fayyad, Piatetsky-Shapiro, & Smyth, 1996; Kohavi, Rothleder, & Simoudis, 2002; Newton, Kendziorski, Richmond, & Blattner, 2001; Venter, Adams, & Myers, 2001; Zhang, Wang, Ravindranathan, & Miles, 2002), and case studies and anecdotal evidence to date suggest that organizations are increasingly investigating the potential of data-mining technology to deliver competitive advantage.

As a multidisciplinary field, data mining draws from many diverse areas such as artificial intelligence, database theory, data visualization, marketing, mathematics, operations research, pattern recognition, and statistics. Research into data mining has thus far focused on developing new algorithms and tools (Dehaspe & Toivonen, 1999; Deutsch, 2003; Jiang, Pei, & Zhang, 2003; Lee, Stolfo, & Mok, 2000; Washio & Motoda, 2003) and on identifying future application areas (Alizadeh et al., 2000; Li, Li, Zhu, & Ogihara, 2002; Page & Craven, 2003; Spangler, May, & Vargas, 1999). As a relatively new field of study, it is not surprising that data-mining research is not equally well developed in all areas. To date, no theory-based process model of data mining has emerged. The lack of a formal process model to guide the data-mining effort as well as identification of relevant factors that contribute to effectiveness is becoming more critical as data-mining interest and deployment intensifies. The emphasis of this article is to present a process for executing data-mining projects.

BACKGROUND

The fields of machine learning, pattern recognition, and statistics have formed the basis for much of the developments in data-mining algorithms. The field of statistics is one of the oldest disciplines concerned with automatically finding structure in examples. Discriminant analysis (Fisher, 1936), for example, is the oldest mathematical classification technique used to separate data into classes by generating lines, planes, or hyperplanes. Through the pioneering work on classification and regression trees (CART) by Breiman, Friedman, Olshen, and Stone (1984), the statistical community has made an important contribution in legitimizing the use of decision trees, in data mining, for classification and regression. Pattern-recognition research emphasizes the creation of machines that can perform tasks more accurately, faster, and cheaper than humans (Fukunaga, 1972; Ripley, 1993), and has made an important contribution to data mining by popularizing the use of neural networks. A feed-forward neural network is a network in which the nodes (or processing units) are numbered so that all connections go from a node to one with a higher number. In practice, the nodes are arranged in layers with connections only to higher layers. Back propagation is an implementation for a feed-forward neural network in which error terms, from the output layer, are propagated back to the input layer so that the resulting connection weights at each node adjusted can be adjusted by means of an error-minimization method called gradient descent.

The multitude of data-mining algorithms can be linked to three main data-mining-problem approaches: clustering, association and sequential pattern discovery, and predictive modeling. Clustering (or segmentation) is concerned with partitioning data records into subsets. The *K*-means clustering algorithm is used for demographic clustering because categorical data are predominant. This algorithm, which is efficient for large databases, clusters a data set by determining the cluster to which a record fits best. Once clusters have been found in a data set, they can be used to classify new data. To uncover affinities among transaction records consisting of several variables, association algorithms are used. These algorithms are used to solve problems where it is important to understand the extent to which the presence of some variables implies the existence of other variables and the prevalence of this particular pattern across all data records. Sequential-pattern-discovery algorithms are related to association algorithms except that the related items are spread over time. Finally, the predictive-modeling data-mining-problem approach involves the use of a number of algorithms (e.g., binary decision tree, linear discriminant function analysis, radial basis function, back-propagation neural network, logistic regression, and standard linear regression) to classify data into one of several predefined categorical classes or to use selected fields from historical data to predict target fields.

The initial implementation of data-mining applications has been in the banking, consumer marketing, insurance, and telecommunications industries. Credit scoring, direct-mail target marketing, policy-holder risk assessment, and call graph analysis are but a few of the "killer" applications of data mining in these respective industries. As a result of some of the realized benefits of data mining, new applications are emerging in a number of areas including biomedicine where molecular data are combined with clinical medical data to achieve a deeper understanding of the causes for and treatment of disease, national security where unusual patterns and fraudulent behavior play a role in identifying and tracking activities that undermine security, pharmaceuticals where interest in understanding the 3D substructure of a molecule and how it interacts with the target is a crucial step in the design of new drug molecules, and ecology where large amounts of climate data, terrestrial observations, and ecosystem models offer an unprecedented opportunity for predicting and possibly preventing future ecological problems. Although the frontiers of data-mining applications continue to expand, focus on developing a data-mining process has not met with similar enthusiasm.

DATA-MINING PROCESS OVERVIEW

New product development (NPD) is a well-researched area (e.g., Hauptman & Hirji, 1999) and, thus, it is the foundation for the data-mining process model because NPD projects, by their very nature, are the most complex as they include systems, subsystems, components, and modules, as well as physical product and software aspects. Focusing on the NPD literature and synthesizing the elements of the various process models allows for the development of an information-centric process model for performing data-mining projects. Table 1 provides a baseline of what an inclusive process for performing data-mining projects might look like.

The phases in the baseline data-mining process include Phase 0, Phase 1, Phase 2, and Phase 3. Phase 0 is the *discovery* phase that supports the subsequent three phases. The set of proposed activities in this phase include (a) assessment of the organization's orientation toward data-centricity, (b) assessment of the capability of the organization to apply a portfolio of analytical techniques, and (c) strategy development for the use of analytics throughout the department or organization. Phase 1 is the *entry* phase. The underlying intent of this phase is to define the candidate business problem that is solvable and that can at least partially use existing data resident in the organization's databases. Prospecting and domain analysis, business problem generation and preliminary assessment, and data sensing are the proposed set of activities in this phase. Data sensing in particular is concerned with the representational faithfulness of the data set in question. Phase 2 is the *launch* phase. In this phase the data-mining project becomes a formal project with an associated capital and operational budget. The set of proposed activities in this phase include (a) secure project sponsorship, (b) project planning and project-team resourcing, (c) business problem refinement and validation of business assumptions and constraints, (d) development of the data strategy (i.e., explore the possible need for purchasing data from a third-party provider), and (e) formulation of the data-mining approach. Phase 3, the final phase, is the *execution and infusion* phase. The actual execution of data-mining algorithms takes place here as well as results analysis. The proposed set of activities in this final phase are (a) detailed business-problem definition, (b) data sourcing and enrichment, (c) execution of data-mining algorithms, (d) results interpretation, synthesis, and validation, and (e) information harvesting and business-strategy formulation. This final activity focuses on developing a strategy to tactically leverage the new insight and to communicate this on a department-, division-, or perhaps enterprise-wide basis.

APPLICATION IN BUSINESS

The 1990s are referred to as the "heyday" of the mutual-fund industry in North America. Falling yields from fixed-rate investments, new product creation, and the hope of higher returns drove investors to purchase mutual funds. It is not surprising that mutual-fund companies therefore experienced double-digit growth rates in the range of 25% to 65%. The picture today is vastly different as industry consolidation, a mature business cycle, and flat market growth are causing gross sales to increase at a decreasing rate. Retail investors are now more than ever before scrutinizing management expense ratios (MERs) and fund performance reporting and returns. Competition among the various fund companies is fierce and thus there is a renewed focus on both stealing market share and developing a compelling story about future sales growth rates across multiple product lines. Some of the tactics employed to achieve various business goals are product innovation and quality, superior fund performance, and exceptional sales, marketing, and client service.

The experiences to date of the application of the proposed data-mining process to an analytics project in the mutual-fund industry suggests that the model is playing a role in contributing to a successful outcome. The project is in the early aspects of Phase 3 and therefore because it is ongoing and no actual positive net present value has been realized, conclusions cannot be made at this time. However, some of the key accomplishments that can be attributed to the process model are as follow.

- Project has been formally approved as a result of the capital-budgeting process
- Project team and stakeholders are in place
- Business problem related to effective channel management is understood and defined
- Business entity and data models have been developed
- Strategies to close data gaps and augment data where necessary are in place
- Data-mining approach with an emphasis on clustering exists

Table 1. A summary of a data–mining process

Phase Name	Phase Identifier	Key Activity
Discovery	0	• Assess data centricity • Assess analytics capability • Develop analytics strategy
Entry	1	• Prospecting and domain analysis • Problem generation • Problem assessment • Data sensing
Launch	2	• Project sponsorship • Project planning and core project team • Problem refinement • Problem validation • Data strategy • Data-mining approach
Execution & Infusion	3	• Business-problem definition • Data sourcing and enrichment • Run data-mining algorithms • Results interpretation, synthesis, and validation • Information harvesting • Business-strategy formulation

FUTURE TRENDS

The need for near-real-time information to support business decision making is becoming more and more critical. Data are benign and therefore there is more focus on understanding the "story" behind the data and the relationships among them. From the vantage point of practitioners and managers, there appear to be new patterns emerging specifically in three areas. The software and enterprise-wide-package-implementation industry is experiencing major consolidation, and software companies are realigning their sales efforts to focus on the ever-growing mid-market segment. Once this shakedown is complete, many business intelligence software and solution providers will begin to bundle data-mining solutions with their existing offerings as a response to the already-established demand by customers in this market segment.

The data-mining process today is more akin to craft than interdisciplinary team-based problem solving. Once data mining gains acceptance and has a critical mass in organizations, there will undoubtedly be a shift to using this technology as part of a repertoire of tools to assist planners, product developers, managers, and others to develop strategies and tactical implementation plans for the organization. In this respect, improvement to existing tools in the areas of human interaction and visual presentation of information are expected. Finally, with the realities of virtual teams now solidified, the question of how virtual teams can effectively execute data-mining implementation projects will become relevant.

CONCLUSION

The paramount objective of publicly traded organizations is to focus on creating and maximizing shareholder wealth. However, recently well-publicized corporate shenanigans have shown that single-mindedly pursuing largesse at the expense of corporate social responsibility is not only fundamentally wrong, but also something that cannot be sustained indefinitely. Managers, C-suite executives, and corporate directors are now once again facing increasing scrutiny about revenue, profit, and earnings quality; adoption of accounting rules; and timely disclosures regarding the going concern of business entities. As managers craft, implement, and execute various growth, talent management, cost reduction, and competitive differentiation strategies, information technology will without a doubt continue to play an important role in enabling, supporting, leading, and transforming business, government, and not-for-profit organizations. Data mining as a technology is not an end, but rather a means to an end. Through the use of a disciplined and structured process, data-mining benefits can be obtained by the operationalization of data-mining results, via a business strategy, to achieve specific business-unit and enterprise-wide objectives.

KEY TERMS

Classification Trees: Type of decision tree that is used to predict categorical variables, whereas regression trees are decision trees used to predict continuous variables.

Cluster: Subset of data records; the goal of clustering is to partition a database into clusters of similar records such that records that share a number of properties are considered to be homogeneous.

Data Mart: Scaled-down version of an enterprise-wide data warehouse that is created for the purpose of supporting the analytical requirements of a specific business segment or department.

Data Mining: Analysis and nontrivial extraction of data from databases for the purpose of discovering new and valuable information, in the form of patterns and rules, from relationships between data elements.

Data Warehouse: A platform consisting of a repository of selected information drawn from remote databases or other information sources, which forms the infrastructural basis for supporting business decision making.

Information: Interpreted symbols and symbol structures that reduce both uncertainty and equivocality over a defined period of time.

Knowledge: Information combined with experience, context, interpretation, and reflection.

Operational Data Store: An integrated repository of transaction-processing systems that uses data-warehouse concepts to provide "clean" data in support of day-to-day operations of a business.

Programmed Instruction, Programmed Branching, and Learning Outcomes

Robert S. Owen
Texas A&M University-Texarkana, USA

Bosede Aworuwa
Texas A&M University-Texarkana, USA

INTRODUCTION

This chapter discusses the principles of two qualitatively different and somewhat competing instructional designs from the 1950s and '60s, *linear programmed instruction* and *programmed branching*. Our hope is that an understanding of these ideas could have a positive influence on current and future instructional designers who might adapt these techniques to new technologies and want to use these techniques effectively. Although these older ideas do still see occasional study and debate (e.g., Dihoff, Brosvic & Epstein, 2003, 2004), many current instructional designers are probably unaware of the learning principles associated with these (cf., Fernald & Jordan, 1991; Kritch & Bostow, 1998).

BACKGROUND

An important difference between these instructional designs is associated with the use of feedback to the learner. Although we could provide a student with a score after completing an online multiple-choice quiz, applications that provide more *immediate feedback* about correctness upon completion of each individual question might be better. Alternatively, we could provide *adaptive feedback* in which the application provides elaboration based upon qualities of a particular answer choice.

Below is a discussion of two qualitatively different instructional designs, one providing immediate feedback regarding the correctness of a student's answer, the other providing adaptive feedback based on the qualities of the student's answer. Suitability of one design or the other is a function of the type of learner and of the learning outcomes that are desired.

MAIN THRUST OF THE ARTICLE

Although the idea of non-human feedback would seem to imply a mechanical or electronic device, other methods could be used. Epstein and his colleagues, for example, have used a multiple-choice form with an opaque, waxy coating that covers the answer spaces in a series of studies (e.g., Epstein, Brosvic, Costner, Dihoff & Lazarus, 2003); when the learner scratches the opaque coating to select an answer choice, the presence of a star (or not) immediately reveals the correctness of an answer. Examples of the designs discussed below are based on paper books, but they are easily adaptable to technologies that use hyperlinks, drop-down menus, form buttons, and such.

Linear Programmed Instruction

The programmed psychology textbook of Holland and Skinner (1961) asked the student a question on one page (the quote below starts on page 2) and then asked the student to turn the page to find the answer and a new question:

"A doctor taps your knee (patellar tendon)
with a rubber hammer to test your __________."

The student thinks (or writes) the answer and turns the page to find the correct answer ("reflexes") and is then asked another question.

Questions or statements are arranged in sequentially ordered *frames* such as the single frame above. A frame is completed when the student provides a response to a stimulus and receives feedback. Skinner contended that this method caused learning through *operant conditioning*, provided through positive *reinforcement* for stimuli that are designed to elicit a correct answer (c.f., Cook, 1961; Skinner, 1954, 1958).

Skinner (and others who use his methods) referred to his method as *programmed instruction*, which incorporates at least the following principles (cf., Fernald & Jordan, 1991; Hedlund, 1967; Holland & Skinner, 1958, 1961; Whitlock, 1967):

- Clear learning objectives.
- Small steps; frames of information repeat the cycle of stimulus-response-reinforcement.
- Logical ordered sequence of frames.
- Active responding by a student who works at his/her own pace.
- Immediate feedback to the response in each frame with positive reinforcement for correct answers.

A technique in programmed instruction is to help the student a great deal at first, and then gradually reduce the cues in latter frames; this is called *fading* (Fernald & Jordan, 1991; Reiff, 1980). If correct responding suggests that a student is learning at a quick rate, *gating* can be used to skip over frames that repeat prior information (Vargus & Vargus, 1991). The programmer is expected to use information about student performance to make revisions; if the student is not succeeding, then it is due to a fault of the program, not to an inability of the student (Holland & Skinner, 1961; Vargus & Vargus, 1991).

Programmed Branching

Crowder (e.g., 1959, 1963) and others (e.g., Pressey, 1963) were critical of Skinner's approach, arguing that students not only learn from knowing a correct answer, but also learn by making mistakes. Crowder distinguished between his *automatic tutoring device* and the Skinner-type *teaching machine*, proposing that the automatic tutoring device is more flexible in allowing the student to receive an explanation when an error is made. Crowder (1959, pp. 110-111) provides an example of how this approach could be used in a programmed textbook:

> "In the multiplication of 3 x 4 = 12, the number 12 is called the *product* and the numbers 3 and 4 are called the
>
> Page 15 quotients.
> Page 29 factors.
> Page 43 powers."

In this *programmed branching* method of Crowder, the student is taken to one of several possible discussions depending on the qualities of the answer.

While Skinner's design would be expected to work only when stimuli elicit correct answers, Crowder's design allows for mistakes and must be designed to anticipate particular mistakes. Crowder believed that this method caused learning through *cognitive reasoning*. Whatever answer is chosen by the student, the programmed textbook (or machine) makes a *branch* to a discussion associated with issues relevant to the answer that was chosen. This is followed by a return to the same question if the student had made an incorrect choice, or a jump to new a *frame* containing the next question if the student had made a correct choice.

Learning Outcomes

Many issues have been raised about programmed instruction methods. Reiff (1980) discusses several criticisms:

- It does not take into consideration the sequence of development and readiness to learn (e.g., children of different ages or children vs. adults).
- It develops rote learning skills rather than critical thinking skills.
- Students can in some implementations cheat.
- The encouragement to respond quickly could develop bad reading habits.

Crowder's *programmed branching* design, which has received far less attention and study than Skinner's ideas, would seem to answer at least some of these criticisms. Crowder's design provides an explanation to both correct and incorrect answers, so the learner is not rewarded for cheating or working too quickly. Since the explanation is tied to the learner's thinking at the time a choice was made, Crowder's design would appear to be better to develop critical thinking skills, but might not be so good at developing rote learning skills. Crowder's design would appear to be better suited to students who have a greater readiness to learn, while perhaps not so well suited to a student who is at an earlier stage of learning a subject.

The above discussion suggests that each of these designs is useful, but that each is useful in different kinds of situations and that the *learning outcomes* of each approach might be different. Skinner's teaching machine, for example, might be more useful in situations where students are learning lists and definitions. The automatic tutoring device, on the other hand, might be more useful when the student is already at a higher level of understanding, whereby s/he can now use reasoning to derive an answer, or in situations where the student understands that there are degrees of right and wrong without concrete answers. The Skinner-type teaching machine might be better suited to "lower-order" levels of learning, while the Crowder-type automatic tutoring device might be better suited to "higher-order" levels of learning.

Although many ideas have been proposed with regard to a hierarchical perspective on "lower" and "higher" levels of learning, the most well-known, "Bloom's Taxonomy" (A Committee of College and University Examiners, 1956), originated in about the same timeframe as the ideas of Skinner and Crowder. "Bloom's Taxonomy" proposes that the objectives of learning lie on a hierarchical continuum: (1) knowledge of terminology and facts, (2) comprehension of translation and paraphrasing, (3) application, (4) analysis, (5) synthesis, and (6) evaluation.

"Bloom's Taxonomy" is actually only Part I of a two-part work. The first part above is known as the *cognitive domain*. Part II (Krathwohl, Bloom & Masia, 1964) focuses on the *affective domain*: (1) willingness to receive ideas, (2) commitment to a subject or idea, (3) feeling that an idea has worth, (4) seeing interrelationships among multiple ideas, and (5) the integration of ideas as one's own.

FUTURE TRENDS

Fernald and Jordan (1991) discuss several reasons as to why programmed instruction might have fallen out of use in more recent decades:

- It was seen to dehumanize the teaching process.
- Educators feared that it might be too effective and threaten their jobs.
- The importance of the learning principles weren't understood.
- Applications were often not effectively designed.

Technology, economics, and attitudes have since changed. As economics and student demand push us to use distance education methods, the first two arguments would seem to become more diminished in the future.

It is hoped that this chapter assists in diminishing the latter two arguments by introducing instructional designers to the principles discussed in this chapter and by encouraging instructional designers to create more effective designs with regard to appropriateness for a particular student audience, and with regard to the type and level of learning outcomes that are desired. By better understanding the past, we can better affect the future.

Curiously, there has been less attention devoted to Crowder's ideas of adaptive feedback than to Skinner's ideas of immediate feedback and reinforcement. We continue to see occasional research devoted to related issues, such as issues of immediate vs. delayed feedback (e.g., Dihoff et al., 2003, 2004; Kelly & Crosbie, 1997) or of allowing students to keep selecting answers from a multiple-choice set until the correct answer is finally discovered (Epstein et al., 2003). However, we still can only speculate with regard to conditions under which a Skinner-style of instructional design would be better and when a Crowder-style of design would be better. It is hoped that this chapter generates greater awareness of and use of these designs in new technologies, but also that greater interest in these ideas will stimulate more research into the learning mechanisms associated with them.

CONCLUSION

New technologies such as Web browsers now make it relatively easy for educators with the most modest of skills to present instructional frames in a linear sequential ordering or as branches that are dependent on the student's selection of answers from a list. In adapting some of these older ideas to newer technologies, we hope that instructional designers will be better equipped to select appropriate methods by considering:

- the student's level of readiness for learning,
- the basis for learning when different instructional designs are used, and
- the qualitatively different kinds of learning outcomes that are possible with different instructional designs.

KEY TERMS

Adaptive Feedback: Immediate feedback in the form of an explanation or discussion that is tailored to the qualities of the student's answer.

Automatic Tutoring Device: A device that uses programmed branching and adaptive feedback. Learning results from cognitive reasoning.

Cognitive Reasoning: Learning through the process of thinking about an issue; the student learns new ideas and relationships by relating an issue to previously learned material.

Frame: A small piece of information or a statement to which the student is exposed, such as a page with a single question. In linear programmed instruction, a frame includes a stimulus, a response, and reinforcement (positive feedback).

Hierarchy of Learning: The concept that learning can be sequentially ordered along a continuum from lower order to higher order. "Bloom's Taxonomy" is one of many that have been proposed.

Linear Programmed Instruction: A design whereby a series of frames are presented to the student in a specific sequential order. The student actively responds to stimuli in each frame and receives immediate feedback to that response. Learning results through operant conditioning.

Operant Conditioning: Learning through immediate positive feedback (reinforcement) regarding the correctness of an answer; the student learns to respond in a particular way to a particular question or issue (stimulus). **Fading** can be used by gradually reducing stimulus cues in subsequent frames when material is repeated.

Programmed Branching: A method whereby the student is taken to one of several possible explanations or discussions depending on the qualities of an answer that is given to a question. **Gating** is a simple skip of frames which repeat prior information when a student's answers suggest that the material has been adequately learned.

Teaching Machine: A device that uses linear programmed instruction, whereby frames present a question followed by feedback of the correct answer. Learning results from reinforcement of the student's correct answer.

Program Execution and Visualization on the Web

Cristóbal Pareja-Flores
Universidad Complutense de Madrid, Spain

J. Ángel Velázquez-Iturbide
Universidad Rey Juan Carlos, Spain

INTRODUCTION

Programming is a central activity in the computing profession. It is facilitated by different tools (editors, compilers, debuggers, etc), which are often integrated into programming environments. Programming also plays a central role in computer science education. For this purpose, a number of complementary tools were developed during the last decade: algorithm animators, program visualizers, problem generators, assignment graders, and so forth.

After the Web explosion, teachers of programming rapidly turned their attention to the Web. Although the Web has speed and power limitations, it also has several advantages that make it invaluable for educational purposes. Mainly, it provides universal accessibility and platform independence, and solves the distribution problem by always making available the last version of any tool.

This article describes Web-based tools for program execution and visualization (Pareja-Flores & Velázquez-Iturbide, 2002) in two sections. Each section gives a brief overview of their evolution, describes educational uses, and, in the case of visualization, includes some definitions and reports of lessons learned. Finally, we outline our view of future trends in the use of the Web for programming education and our personal conclusions.

BACKGROUND

The simplest use of the Web for programming education is as a public repository of high quality problems. Many collections have no structure or, at best, are lineally or hierarchically structured. We note several initiatives hosted by the ACM: the *Lab Repository* (Knox, 2002), *Computer Science Education Links* (McCauley, 2001), and the *ACM International Collegiate Programming Contest* (Skiena & Revilla, 2003). Other useful resources are also collected on Web sites, such as slides and audio lectures (Skiena & Revilla, 2003), algorithm animations (Brummond, 2001; Crescenzi et al., 2003), or programming tools (English, 2001). More advanced repositories provide a management system that, using (semi)structured mark-up languages, allows retrieving, maintaining and publishing. Good representatives are eXercita (Gregorio-Rodríguez et al., 2001, 2002) and SAIL (Kovourov, Tamassia, Bridgeman & Goodrich, 2000).

A more complex initiative consists in porting programming tools to be executed on the Web. We focus on two kinds of tools. The first kind is aimed at supporting program execution. Programming is a task that involves several activities: editing, compiling and testing, at least. These activities require running a number of applications: an editor, a compiler and the program itself. In addition to their conventional use in standalone computers, they can be used on the Web in a number of ways, increasing flexibility from an educational point of view.

A second kind of tools supports software visualization. This field studies the visual representation of software entities (Stasko, Domingue, Brown, & Price, 1998). Visualization requires an effort to abstract the target entity to visualize and to make a good graphical design that may yield many different representations: text vs. graphics, level of abstraction, static vs. dynamic visualizations, one or multiple views, behavior vs. performance, errors, and so forth. Algorithm animation is a subfield of software visualization aimed at the dynamic visualization a piece of software illustrating the main ideas or steps (i.e., its algorithmic behavior), but without a close relationship to the source code. The graphical nature of software visualization in general and algorithm animation in particular makes them very conducive to the hypermedia features of the Web.

Web-Based Program Execution

The simplest use of the Web for programming execution is as a medium to submit programs. A more advanced capability is the support of Web-based program edition, compilation and execution. This can be implemented in different ways, depending on how the client/server load is balanced. For instance, the system by Elenbogen, Maxim and McDonald (2000) includes a set of interactive Web exercises on C++ delivered by Java applets. A different option consists in using the Web as the medium to transfer programs and data to the server, which is then responsible for compiling and executing programs. In this approach, programs may be edited by the client and then remotely compiled and executed on a server (Hiltz & Kögeler, 1997). The server may also work as a black-box tester based on input-output pairs (Arnow & Barshay, 1999; Skiena & Revilla, 2003).

There are few systems with full programming capabilities on the server side, including debugging. Ibrahim (1994) developed a system that allowed the programmer to use the Web as a front-end to edit a program, send it to the Web server, and debug it by performing tracing actions on the program running at the server. Finally, other systems give support to the graphical visualization of execution (Domingue & Mulholland, 1997) or allow the user to experiment by controlling which parts must be executed and how (Berghammer & Milanese, 2001).

Algorithm Animation

Algorithm animation is a research field which is now 20 years old and still evolving. There is a consensus with respect to the videotape Sorting Out Sorting presented in 1981 by Baecker (1998) a landmark on animation, which included animations of nine sorting algorithms. Afterwards, some works established the main techniques for specifying and implementing algorithm animation: BALSA (Brown, 1988), Tango (Stasko, 1990), and Pavane (Roman, Cox, Wilcox & Plun, 1992). Systematic categorizations of software visualizations have been proposed since then (Price, Baecker & Small, 1998).

In the mid-nineties, many of the existing systems were ported to the Web, and many additional systems were specifically designed for the Web. A representative work from these years is that of Naps (1996), in which he carried out a study of the technical alternatives that could be used to make animations produced by previous systems available on the Web. Other systems are JCAT (Brown & Raisamo, 1997), Mocha (Baker, Cruz, Liotta & Tamassia, 1995), and JHAVÉ (Naps, Eagan & Norton, 2000). A second group from these years is formed by the systems that were not specifically designed for the Web, but based on stand-alone multimedia and hypermedia. Although they could not be used directly on the Web, they and Web-based systems had similar hypermedia features. A good example is the HalVis system (Hansen, Schrimpsher & Narayanan, 1999).

Another category of systems automatically produce program animations, enhanced with graphical representations. These can be considered as extensions of programming environments with advanced animation capabilities which are usable on the Web. Three examples are ISVL for Prolog (Domingue & Mulholland, 1997), KIEL for ML (Berghammer & Milanese, 2001), Jeliot for Java programming (Haajanen et al. 1997) and WinHIPE for functional programming (Naharro-Berrocal, Pareja-Flores, Velázquez-Iturbide & Martínez-Santamarta, 2001).

EDUCATIONAL USES OF WEB-BASED PROGRAM EXECUTION AND VISUALIZATION

Program Execution

Currently, the most common use of the Web for programming courses is as a communication medium, facilitating submission and administration of assignments and grades (Burd, 2000). As we have described previously, it may also be used as a medium to retrieve exercises and to send, run and even debug programs at the server.

Web-based program execution is also being used in more specific ways within courses. First, if the Web interface of the programming tool is carefully designed, only one aspect can be considered at a time (the condition of a conditional statement, the body of a loop, etc.), allowing novice students to concentrate on program fragments that illustrate certain syntactic or semantic elements. This feature is especially important at the beginning, when novices ignore program structure and other details. Second, program execution on the Web can be used as a testing tool. For instance, the teacher can use the system for student inquiry by proposing that the student predict the behavior expected for a given input, or vice versa, by guessing the input that yields a desired output (Elenbogen et al., 2000). Finally, by using the Web to drive visualizations and animations (as explained in the next section), information can be given graphically to the programmer about errors, about the progress of the computation, and so on.

Algorithm Animation

From the outset, the main use of algorithm animation was educational, rather that industrial (for instance, as a debugging tool). Algorithm animation systems have been used in several ways: as a complement to lectures on algorithms, for self-study, or within laboratories. A more demanding use of animation systems consists in requiring students to build their own animations.

The best documented experience ran for about 20 years at the Computer Science Department of Brown University (Bazik, Tamassia, Reiss & van Dam, 1998). All of the experiences reported in the available literature agree that students are highly motivated by algorithm animations. After various experiments and studies, the community has come to the conclusion that animations are effective only if students are actively engaged (Naps et al., 2003).

Lessons Learned from Using Animation Systems

It is difficult to provide canned recipes for the design of visualizations and animations. Gloor (1998) and Khuri (2001) summarize some general recommendations for their design. These are also commonly accepted suggestions for educational use:

- Make the meaning of the different graphical representations explicit, explained either by embedding them in the system or reinforced by allocating time to the subject during the course.
- Adapt to the knowledge level of the user, either novice or expert.
- Complement animations with explanations.
- Be interactive, allowing flexible control of animations (including movement in a backwards direction), customization, input data, or unfolding unexpected short questions.
- Provide multiple views, which must be consistently coordinated.
- Include performance information, for example, data collected during the execution of an algorithm, or animating several algorithms simultaneously.
- Include execution history.

FUTURE TRENDS

Program execution for programming courses is still an application field of the Web in which program educators have had little experience. From an educational point of view, inflexibility and delays are the most serious drawback of using the Web for program execution. Wider use of the Web will require careful implementation of comprehensive programming systems. The implementation of these systems is even more demanding than traditional ones, because a Web-based architecture and a different user interface must be designed. It will be some years before a satisfactory level of maturity is achieved by these kinds of Web applications.

In contrast, software visualization and animation achieved technical maturity in the early nineties. In the years thereafter, most efforts have focused on their educational adequacy. In this respect, some maturity is being achieved, but additional efforts are still necessary. We believe that we will see more efforts aimed at designing and using some of the elements constituting effective animations, and at facilitating their easy construction and customization by the user.

Finally, there are currently several research efforts aimed at designing and developing dynamic electronic books, with dynamic contents and virtual laboratories. We believe that these virtual laboratories for programming will incorporate interfacing with programming tools such as program compiling and execution, and will include automatic visualization and animation.

CONCLUSION

We have provided a panoramic view of the educational use of program execution and visualization on the Web. We have offered an overview of the main technical achievements and the educational uses of them. In the case of algorithm animations, we have also explained some of the lessons that have been learned. In the near future, we expect that there will be increased interest in Web-based tools to support these activities.

KEY TERMS

Algorithm Animation: Visualization of a piece of software illustrating the main ideas or steps (i.e., its algorithmic behavior), but without a close relationship to the source code.

Information Visualization: Visualization of phenomena by means of appropriate representations. It is a field different from scientific visualization since information visualization emphasizes delivering visualizations that improve comprehension, whereas scientific visualization emphasizes delivering realistic visualizations.

Multiple Views: Visualization technique consisting in showing several aspects or views of a program, where any view typically shows few aspects and must be comprehensible by itself. Typical views are code vs. data, several levels of abstraction, logic vs. performance, history, and several simultaneous algorithms.

Pretty-Printing: Rudimentary form of program visualization whose goal is to make source code easier to read by means of spacing, indentation and layout. Pretty-printers are programs that systematically indent the source code of a source program according to its syntactic structure and given aesthetic rules. Sophisticated pretty-printers can also highlight different parts of a program and even generate a “program publication”.

Program Execution: To make a computer to follow the instructions stated in the program. It is also known as running a program.

Program Testing: To execute a program in order to check whether it is correct with respect to its specification. Testing requires a previous planning to design input data that cover all or almost all of the cases.

Program Tracing: To follow the execution of a program under control of the programmer. It is usually carried out with incorrect programs in order to debug and fix them. Typically, there are different operations that allow the programmer to control the pace of program execution and to watch the state of different structures.

Program Visualization: Visualization of a piece of software so that the representation has a close relationship to the source code.

Visualization: To make something visible by means of some representation. A visualization consists of two elements: a mental process and a graphical language. Note that “to visualize” is different from “to see”.

Web Repository: A Web site that contains a wide collection of items. It can be unstructured, semi-structured or structured.

Project Management Best Practices to Increase Success

Jeffrey L. Brewer
Purdue University, USA

INTRODUCTION

Utilizing good project management practices has become one of the key differentiators in delivering successful information technology projects. Kerzner (2001) defines project management as "the planning, organizing, directing, and controlling of company resources for a relatively short-term objective that has been established to complete specific goals and objectives" (p. 4). The field of project management has seen explosive growth in the amount of individuals holding a job title such as project manager, in the amount of research being conducted, and in the amount of books and articles being published. This paper explores the reasons for this growth, the reasons why project management has become so important to the on-going success of IT projects and thus the success of organizations and what future directions the field of project management will travel.

BACKGROUND

In 1995, a study entitled "CHAOS" was conducted by the Standish Group. The study surveyed 365 information technology (IT) executive managers in the United States who managed more than 8,000 IT application projects. The sample contained small, medium, and large companies across several industry segments including banking, securities, manufacturing, retail, wholesale, health care, insurance, and local, state, and federal organizations. The Standish Group also conducted focus group sessions and numerous personal interviews to provide a qualitative background for the survey results. The results of the study showed, as the title of the study indicates, that IT projects in the United States were in total disarray (see *Table 1*). "A huge portion of the more than $250 billion spent annually on IT application development is wasted because companies fail to utilize effective project management practices." Average cost overruns were 185%, average time overruns were 222%, only 16.2% of projects were counted as successful and the projects were only delivering 61% of the desired features. Successful projects were defined as meeting all project objectives on time and on budget. The study concluded that project management was one of the top catalysts to ameliorate these statistics.

Wilder & Davis (1998) agreed with the CHAOS study stating that poor project management is a major contributing factor leading to failed IT projects.

The Standish Group repeated the study in 2001 entitled "Extreme Chaos" and observed some noteworthy improvements (see *Table 1*). Successful projects had increased from 16.2% to 28%, and average time overruns had diminished from 222% to 63%; likewise average cost overruns went from 185% to 45% and delivery of required features rose from 61% of the total to 67%. The study listed the following items as contributors to the improvements in IT project results:

1. Improved project management
2. Better development tools
3. Reduction in hardware and software costs
4. Better management processes.

One of the major reasons for the improvements, mentioned in the CHAOS study, was attributed to better project management practices and better-trained project managers. When you look at how these distressing statistics were improved and read about some of the tremendous project disasters (Bailey, 1996; Gibbs, 1994; Lucas, 1995), they demonstrate how important project management has become. The importance of project management to today's organization continues to increase. Schwalbe

Table 1. Standish Group Study Results

	1995	2001
Successful IT Projects	16.2%	28%
Percent of projects cancelled	31%	23%
Average time overruns	222%	63%
Average Cost overruns	185%	45%
Delivery of required features	61%	67%

(2004) reports that the U.S. spends $2.3 trillion on projects every year, an amount equal to one-quarter of the nation's gross domestic product. All nations combined spend nearly $10 trillion of its $40.7 trillion gross product on projects of all kinds. More than half a million new IT application projects were started in 2001, up from 300,000 in 2000 (The Standish Group, 2001).

We can see from these statistics that project management is and will continue to be important to the success of today's organization. The next section outlines three key "best practices" that need to be adopted by organizations to allow project management to reach a higher level of success.

BEST PRACTICES

This section of the article lists and describes three project management best practices: a project management office, establishing a project management methodology, and finding or making good project managers. The top three best practices were chosen based on the literature review, personal interviews, and the author's 20 plus years of IT project management experience. The literature review consisted of journal articles, books, and case studies (Cai et al., 2004; Crawford, 2002; Johnson et al., 2001; Kerzner, 2003; McConnell, 1998; Murch, 2001; Perks, 2003; TechRepublic, 2001; The Standish Group, 2001; Visitacion, 2003).

Three large organizations with established project management practices were used to conduct the personal interviews. The interviews were done in face-to-face sessions held at the respective organization's facility. Two to three project managers with an average of 15 years of project management experience each were interviewed at each organization. The interviews were designed to serve two purposes: one, to substantiate the information that was gathered during the literature review and, secondly, to generate new ideas. The three organizations, two large pharmaceutical companies and a large cardiovascular medical product company asked that their names not be mentioned.

Establish a Project Management Office (PMO)

There are several variations that exist on what a PMO is; depending on what role a PMO plays in an organization and what level it operates at. A PMO is the "administrative mechanism by which a focal point is provided for organizational project management activities" (Rad, 2001). In some corporations, a PMO functions as a support organization that caters to multiple projects with administrative, time tracking, reporting, and scheduling services, while in some others it is merely responsible for business and technical management of a specific contract or program only. Depending on the maturity and capability of a PMO, it can serve different functions. Crawford (2002) discusses how PMOs can operate at three different levels. Level 1, or the individual project level, helps add value to individual projects by defining basic processes that can then be adopted by other projects. At Level 2, the PMO helps to diffuse the processes and uniform methodology to other projects and divisions. Level 3, the corporate level, has PMOs managing the entire collection of the organization's projects and reviewing their goals, history, and progress.

PMOs can help improve project success rates and establish standard project management practices throughout the organization (Kerzner, 2003). However, there is no uniform approach for success of a PMO. Each PMO has to conform to the specific company's culture. Robert Handler, vice-president of Meta Group's enterprise planning and architecture strategy service, feels that a PMO has to be "instituted in a way that doesn't fly in the face of the culture" (Santosus, 2003). If done correctly, a PMO can offer more accurate schedule estimates, improve stakeholder satisfaction levels and facilitate higher employee productivity rates. Even though many organizations have been moving from a functional organizational structure to a matrix or projectized structure in recent times, the PMO might represent a revolutionary change. Crawford (2002) states that, "reorganizing a company's work around projects is the equivalent of moving from a feudal system to participatory democracy."

The efficacy of a PMO has been questioned by several organizational decision-makers. As with any new technology or concept, there are proponents and detractors. There are those who dismiss the concept of a PMO as a fad and regard it with a high level of distrust. Tom Pohlman, an analyst at Forrester Research Group and author of the report *How Companies Govern Their IT Spending* feels that too many PMOs function as "process cops and report compilers for executive teams and often lose sight of what they are supposed to be doing — making sure projects are running effectively" (Hoffman, 2003). "People think about implementing a project office and they usually think bureaucracy paperwork and increased costs" (Bernstein, 2000).

The current concept of a PMO, which now has the responsibility for maintaining all project knowledge (Kerzner, 2003), evolved as recently as 2001 and hence it is still in its fetal stage. A study conducted by the Forrester group, based on telephone interviews with 704 North American IT decision-makers between late April and June of 2003 reported that 67% of the respondents said that their organizations have one or more PMOs, up from 53% the previous year. Gartner group has predicted that, "through 2004 companies that fail to establish a project office will experience twice as many major project delays, overruns, and cancellations as will companies with a project office in place."

Kerzner (2003) lists the following benefits of using a PMO:

- Standardization of operations
- Company rather than silo decision-making;
- Better capacity planning (i.e., resource allocations)
- Quicker access to higher quality information
- Elimination or reduction of company silos
- More efficient and effective operations
- Less need for restructuring
- Fewer meetings that rob executives of valuable time
- More realistic prioritization of work
- Development of future general managers

Adopt a Project Management Methodology

Achieving project management maturity and increased project success generally comes from having defined repeatable processes that are used on every project. These repetitive processes are referred to as the project management methodology (Kerzner, 2003). In a recent PM Network article, Jeff Sterba, Chairman, President and CEO, PNM Resources Inc., stated that they implemented project management methodologies in 2001 to manage enterprise project efforts. The tools and processes they developed allowed them to meet their goals on time by eliminating do-over work and controlling last-minute changes. "Now, we have trained more than 1,400 employees in project management skills, and these cross-functional team members help ensure success in all of our project management initiatives, saving us valuable resources and improving our productivity" (p. 31). In this same article; Tony Salvaggio, President, Computer Aid Inc., is quoted as saying "I saw that we could have a dramatic competitive advantage if we implemented advanced project management for all our activities…It keeps us from making monstrous mistakes and also keeps us from making the same mistakes repeatedly" (p. 32).

Www.dictionary.com defines a methodology as: a body of practices, procedures, and rules used by those who work in a discipline or engage in an inquiry; a set of working methods. Murch (2001) defines four key components:

- Guidelines – defined flexible steps necessary for successful application development
- Techniques – detailed process descriptions that support the activities throughout the product development lifecycle
- Tools – project management tools used in support of the methodology
- Templates – Reusable documents and checklists

The need for adopting a project management methodology is clearly established, what remains is which one and how.

To lower cost, reduce resource requirements for support, minimize paperwork, and eliminate duplicate effort an organization should maintain and support a single methodology across the organization (Kerzner, 2003). Many methodologies exist either commercially or as a by-product of hiring a consulting company that has its own. Murch (2001, p. 143) offers several examples: Process Engineer from Platinum, Inc., SUMMIT from Price Waterhouse Coopers, METHOD/1 from Andersen Consulting, and Architect from JMC, Inc. Many organizations have chosen to develop their own methodology starting with a defined, complete body of knowledge and adapting this to their organization.

All three of the organizations interviewed for this article had their own project management methodology, which was based on some established principles and methods. The path they each used to evolve from a standard body of knowledge to a tailored methodology was very similar:

1. Current assessment of projects, organizational culture and identification of control metrics
2. Obtain senior management commitment and executive champion
3. Training for the entire organization
4. Don't start from scratch, base it on some proven tools and techniques
5. Start with a light or less complex methodology and grow it as you learn
6. Integrate the project management methodology with other management processes.
7. Review lessons learned and adapt.

The Project Management Institute (PMI) describes their body of knowledge in a document called A Guide to the Project Management Body of Knowledge (PMBOK). The PMBOK defines 5 process groups (initiating, planning, executing, controlling, and closing), which overlap over time during the project, and nine knowledge areas (management of integration, scope, time cost, quality, human resources, procurement, risk, and communications). In the U.K. there is PRINCE2, a process-based approach for project management providing a customizable and scaleable method for the management of all types of projects. PRINCE2 stands for (PRojects IN Controlled Environments) and consists of seven major processes: starting up a project, initiating a project, managing stage boundaries, controlling a stage, managing product delivery, planning, and closing a project (Prince2, 2004). IEEE/EIA 12207 is another body of knowledge, which describes the major component processes of a complete software life cycle and the high-level relations that govern their interactions. This standard covers the life cycle of software from conceptualization of ideas through retirement. IEEE/EIA 12207 describes 17 processes that define the software development life cycle starting at initial concept, through requirements analysis, design, coding, testing, installation, operation, maintenance, and retirement (Gray, 2000).

Finding or Making Good Project Managers

As organizations are becoming more "project" based (Crawford, 2002), the current number of IT project management positions is creating demand for experienced competent project managers. It is important for these organizations to place individuals in a project manager role that have the skills to be successful. As demonstrated earlier in this article from the CHAOS studies done by The Standish Group, project management and better trained project managers are essential to help increase the success rates of IT projects. A project manager must have skills in addition to the basics of project management to succeed. According to David Foote, managing partner at Foote Partners LLC in New Canaan, Connecticut, "It requires all these soft skills that have to do with getting things that you want (and) adjudicating issues between people, managers, egos and agendas. It's how to get a job done without annoying people" (Melymuka, 2000). These soft skills can include basic leadership and team building abilities that are needed for the team to complete the designated project

Finding the right people to fill the roll of project manager has become a major problem for most organizations. Many of these "soft skills" are thought to be innate and may not be teachable. Organizations, in trying to find potential project managers from inside, have turned to personality tests, such as the Myers-Briggs Type Indicator or The Keirsey Temperament Sorter. "The MBTI descriptions of personality did what no other personality instrument has done before, be able to give most people some insight into themselves and others" (Viawest, 2003). Using these evaluations, organizations can examine a person based on the skills required to be a successful project manager and decide whether to put them in that role, whether they will need further training to be successful in a project manager role, or whether they would be best placed in a different position.

FUTURE TRENDS

Many key trends have emerged since the turn of the twenty-first century and will continue to guide project management in the near future. Listed below are several key trends that organizational leaders must pay close attention to.

- Strategic outsourcing – many firms are finding a positive ROI when looking outside of the United States to service many parts of their development efforts. These relationships will create a need for new project management skills in the areas of managing geographically remote teams and diverse culture issues.
- Product and service life-cycles becoming shorter – building solutions faster with higher quality for lower cost will lead to more complex projects to manage.
- Ever increasing rate of technology discovery – technology continues to mature at faster and faster rates adding more technology related risk to IT projects.
- The increasing role of the Internet – The Internet has softened the borders of our organizations, creating new and diverse projects and project teams, creating the need for project managers to master new tools and technique.
- Sophistication of end users – Users of today's technology are getting more sophisticated in their use of technology and more demanding forcing project leaders to be more technology knowledgeable.
- Increasing use of maturity models – Organizations are beginning to use maturity models to assess themselves on improvements in their project management practices. Models such as Capability Maturity Model Integrated (CMMI) from SEI or the new Organizational Project Management Maturity Model (OPM3) from PMI. Project leaders will be held accountable for more than just the successful completion of a single project - are they moving the organization up the maturity scale? (More information about these maturity models can be found at the relevant Internet sites: www.sei.com and www.pmi.com).

CONCLUSION

This article has established that better project management practices are essential to all organizations that wish to increase the success rate of current and future projects.

The number of IT projects is only increasing and requiring more and better-trained project managers. The success rate of IT projects has improved, although much more is needed. Establishing a PMO, although not a silver-bullet, holds great promise in improving repeatable successes. The tools and techniques needed to perform good project management practices have existed for some time; the issue has been and continues to be getting organizations to recognize the benefits to building and using a single sound methodology and training their people to become better project leaders.

KEY TERMS

Capability Maturity Model Integrated (CMMI): A five-level framework laying out a generic path to process improvement for software development in organizations.

Project: A temporary sequence of related activities that produces a unique product or service.

Project Management: The application of knowledge, skills, tools and techniques to project activities in order to meet or exceed stakeholder needs and expectations of a project.

Project Management Institute: International professional society promoting good project management practices.

Project Management Methodology: A defined repeatable process to aid in the successful completion of projects.

Project Management Maturity Model: A framework for helping organizations improve their practices and processes.

Project Management Office: A project office is a corporate management organization that evaluates measures and essentially enforces the performance and interaction of the implementation of IT project processes across a company's business units (Computerworld, 2003).

Project Management for IT Projects

Len Asprey
Practical Information Management Solutions Pty Ltd, Australia

INTRODUCTION

The provision of information systems, technology, and communications is a fundamental requisite to support competitive strategies and improve service levels in enterprises. Increasingly, with e-commerce developments using the Internet and World Wide Web (WWW), combined with increased compliance and regulatory requirements, medium to large businesses and governments are relying on IT to support operations and administration. Small to medium businesses also make use of Web, e-mail, and office productivity packages to gain commercial advantage.

Organizations establish projects to deliver business solutions using IT systems. Each project is unique and may be characterized by specific objectives, defined start and finish dates, a unique set of activities, resources (funds, people, and equipment), a discrete organization structure, and a requirement for management (Willson-Murray, 1997). Projects need to be managed, because set objectives have to be achieved within constraints such as scope, time, and budget.

Project management (PM) is not a discipline confined to the IT environment. PM is universal across industry sectors, both commercial and government sectors, and professions. The Project Management Institute (PMI), which had 70,000 members worldwide in 2001, included 15,000 members that had joined the Information Systems Specific Interest Group (Schwalbe, 2002).

International Standard (IEEE Std. 1490–1998) publishes a subset of the Project Management Institute's *A Guide to the Project Management Body of Knowledge*, embodying "generally accepted" knowledge and practices. The term "generally accepted" means that the content of the Standard applies to most projects, and that there is pervasive agreement about their suitability and value. However, it does not mean that the content applies consistently to all IT projects without taking into account appropriateness.

BACKGROUND

The framework of PM incorporates concepts of a project life cycle, thus demonstrating the nature of projects; essentially, projects are temporary endeavors with a defined start and end. Each project life cycle consists of phases. Each phase is a manageable portion of work, and the phases collectively make up the project life cycle. PM processes are applied to define, manage, and complete a project or phase of a project.

A Guide to the Project Management Body of Knowledge (Project Management Institute, 2002), commonly referred to as *PMBOK*, distinguishes five interrelated processes, as follows:

- *Initiating*: covers activities for initiating and authorizing a project and formulating a project charter
- *Planning*: involves defining objectives and selecting the best project approach
- *Executing*: relates to the coordination of people and resources to execute the plan
- *Controlling*: deals with monitoring, measuring progress, and managing variances to a plan
- *Closing*: deals with acceptance and closure of the project

However, there are alternative approaches, including the structured *PRINCE2* PM method. *PRINCE2* is a nonproprietary methodology developed by the U.K. Government (Office of Government Commerce, 2004). It features a startup component prior to project initiation and processes for directing a project, controlling a stage (or phase), managing stage boundaries, as well as closing a project. There are other approaches, such as four interrelated processes, being definition, planning, execution, and close-out (Verzuh, 1999).

It is important to understand the relationship between product life cycle methodologies and PM processes when initiating and managing an IT project. Both are interrelated, but the differentiation between the two is not always clear and may depend on the methodology adopted for the project.

Product life cycle methodologies provide guidelines for planning and implementing "products" such as IT systems. There is a diversity of life cycle methodologies in the commercial or public domains that apply to IT projects. Each methodology may offer unique features, but each usually consists of a series of phases, such as requirements, design, construction, and operation (Verzuh, 1999). They may present a product-centric life cycle approach with a more extensive series of phases (Willson-Murray, 1997).

PM processes may be applied to the project life cycle and the various phases within that cycle. Processes also intersect during a project or phase of a project. It is not unusual for product life cycles and PM processes to be combined for an IT project. Some PM methodologies integrate product-centric life cycles and processes, recognizing that IT projects deliver products, not activities (Bentley, 2000).

For example, a product life cycle might be applied to the deployment of a new IT system to cover the project from initiation to closure. The life cycle usually consists of a number of phases, one of which might be "procurement." PM processes might be applied to that specific phase to manage the procurement of hardware, software, communications, and professional services.

PM methodologies provide a generic interpretation of IT product life cycles and integrated PM processes. Specific methodologies may focus on the application of PM to types of IT products, covering a range of complex software implementation projects.

One example includes a project approach to supply chain management solutions (Ayers, 2003). Another example addresses the delivery of customer relationship management systems, to reduce the high failure rate in those types of projects (Gentle, 2002). Similar work has included the application of PM to integrated document and Web content management systems (Asprey & Middleton, 2003).

APPLICATION

PM processes are complemented in *A Guide to the Project Management Body of Knowledge* by nine knowledge application areas, covering the management of project integration, scope, time, cost, quality, human resources, communications, risk, and procurement (Project Management Institute, 2002).

Integration Management

Integration management relates to the coordination of elements such as developing and executing the project plan and integration of change control.

Plan development begins at initiation, once the aims of the project are mandated, initial constraints and assumptions are identified, and an approach is adopted. Planning draws upon other organizational strategies, plans, and knowledge resources.

Project managers utilize a work breakdown structure (WBS) technique to capture specific tasks in a logical assembly of related activities. The WBS is an input to a Gantt chart, and is often created in a Gantt chart tool, generally embodied within PM software. A Gantt chart is used to generate a project schedule, incorporating activities (or tasks), durations, start and finish dates, allocated resources, and linkages between activities.

The project plan is the key planning document for a project. Its structure varies depending on the PM methodology, but common elements are observable. A plan typically incorporates the project mandate (or charter), documents the project strategy or approach, and includes definition of scope inclusions and exclusions, and lists key stakeholders. It includes the description of the critical success criteria and performance measures. It defines the project organization, resourcing, budget and cost estimates, and key activity/deliverable and milestone dates. The plan also includes communication strategies and reporting structures, a risk/mitigation strategy, and is usually annexed with the relevant Gantt schedule.

When approved, the project plan is termed a "baseline" plan, being the original "approved" plan. Project execution is the process of putting the project plan into effect. The project manager is required to direct technical resources and coordinate organizational interfaces. The baseline project plan is monitored by the project manager, who takes corrective actions where activities or events impact the plan. Performance against the plan is evaluated by submission of status reports and planned meetings with a project sponsor or project board, who have governorship of the project.

Where variations to the scope of a project are required during the life cycle, these changes are subject to formal change control. Change control is a key component of integration management. It includes the management and processes for changes to project scope across all elements of PM. Integration management embraces the requirement to take into account the impacts of the change on elements such as schedule, costs, resources, risk, and quality management.

Change control usually involves submission of a change request form, which is logged in a change control register. The change request is assessed in terms of its impact on scope, costs, project timelines, and deliverables, and an evaluation of benefits and risk. The change request is then submitted for approval by the project board or other governing authority, and if approved, is then incorporated within the project scope.

Scope Management

Key to successful project delivery is the definition and management of scope, which defines the work to be performed by the project, and that work which is specifically excluded. Scope is typically defined during project initialization, encapsulated in a *project charter* or *project* *initiation document*, depending on the project methodology. The scope statement should include a detailed list of work that is within scope, and a definitive list of work that is not within scope. Where work activities are not determined as scope inclusions or exclusions, these need to be documented and resolved.

Complexities can arise with scope management, because scope may not be clearly understood by either customer or solution provider during the initiation of a project, or it may not be defined in sufficient detail to avoid ambiguities. The classic approach to scope management frequently involves a struggle between project manager and customer, particularly when requirements become clearer during the development of specifications.

An iterative approach to software development may be useful, and rapid application development (RAD) is one example of an iterative approach to requirements development, which helps to accelerate delivery of IT systems (Gantthead.com, 2004). However, RAD may not always be applicable, depending on a range of project characteristics, including scope, size, geographical dispersion, and other factors. RAD appears to be most useful where projects have a limited, well-defined scope, and a measurable outcome (Shelford & Remillard, 2003).

Time Management

Time management deals with processes aimed at the timely completion of projects. During the creation of a project plan, the specific activities that need to be performed are defined in the WBS, and these are related in a logical sequence. Resources are assigned to the activities and the level of effort required to perform each activity is determined.

Estimates for the duration of each activity are based on a number of factors. These include the nature of the activity and the capabilities of available resources. They also include the knowledge of the project manager or technical resources, and the application of quantitative measurements, where applicable. Consideration of duration needs to take into account the difference between "elapsed time" and "level of effort." For example, the elapsed time for end-user training might be two days, but the level of effort of a training manager during that activity might only be 0.5 days, as the resource activity might represent, for example, a coordination effort.

The durations assigned for activities are monitored during the execution of the project. If assigned activities take longer than planned, then those aspects need to be managed. Generally, contingencies are built into a project schedule to make provision for minor slippages in durations, but if a major slippage occurs, then change control processes may be invoked. If new activities emerge that were not anticipated during scope definition, change control may also be required.

Cost Management

Cost management provides practices for completion of projects within budget and embraces processes such as resource planning, estimating costs, preparing budgets, and controlling costs. Costs need to be determined during project planning and incorporated into a resource plan.

Project costing needs to include costs that will be directly incurred by executing the project (i.e., direct costs), for example, costs such as labor, materials, supplies and equipment, direct facility purchases, training, travel, and miscellaneous. When costing, provision must also be made for indirect costs, such as fringe benefits, facilities (e.g., rent, utility costs, and maintenance), and general and administrative support (Heerkens, 2002).

A common feature of IT projects is that they may be underfunded from the outset of the project. When cost overruns occur during project execution, it may indicate that inadequate cost analysis occurred during planning. Consequently, careful attention must be given to cost estimates when forecasting budget, as these can be subject to levels of inaccuracy.

Much depends on the domain experience of the project manager and technical resources. However, estimating difficulties can also have as their root cause business pressures to fit a project to an approved budget. Estimates may also be understated to provide an initial enticement for project approval. Scope creep can also impact costs, when project requirements are changed without change control (Frame, 2003).

Actual costs are captured during the project against an assigned project code that identifies the project as a cost center. These costs are typically managed using organizational financial management systems. These systems produce reports for analysis by the project manager and enable cost variances to be reported to the project sponsor or project board.

Quality Management

The international quality management standard (International Organization for Standardization, 2004) provides the framework for quality management requirements. Subsequent supporting standards have been developed, e.g., *HB 90.9-2000: Software Development—Guide to ISO 9001:2000*, which provides guidelines for software development (Standards Australia, 2004).

These types of standards are supported by nonproprietary approaches to quality management, such as total quality management and continuous improvement.

The essential elements for delivering IT systems and supporting effective PM are quality planning, quality control, and quality assurance. Quality planning involves identifying the quality standards and principles that are relevant to an IT project, and the development of a quality management plan for the project.

Quality control relates to the management of project deliverables, testing processes, and management of issues, risks, and change control, using monitoring on a regular basis. Quality assurance relates to verifying that the quality control processes are effective, eliminating unsatisfactory performance and instituting corrective actions.

Human Resource Management

The project plan identifies the resource types that are required to be assigned to project activities. It needs to be closely analyzed to determine project dependencies and establish whether there are any resource conflicts that would require schedule revision.

Once the project plan is thus optimized, available resources may be allocated to defined roles, and resource gaps can be identified for subsequent acquisition activities. Additional resources for the roles required may already exist within an organization, or they may have to be in-sourced under a contract arrangement or outsourced to a service provider.

A challenge facing IT project managers is that resources for the particular activities required may be scarce. Skilled resources may not be widely available for a new product or new version of a product, or resources that are skilled and experienced in the product might be in high demand, and unavailable. Planning for resources needs to occur early, and resource acquisition activities, where required, should commence soon thereafter.

Matrix management may be a complication, because resources assigned to a project may report to a line manager outside the project. This situation can give rise to resource management issues, not the least of which is conflicting priorities and directions, with consequential risk. The foundation for matrix management is a clear mandate communicated at project initiation, assisted by resolute project leadership and regular interaction between project and line managers.

It is a project manager's responsibility to provide leadership and direction, delegate actions and act as mentor, develop individual and team competencies, deal with conflict, drive mentor team building, and conduct performance appraisals. These responsibilities may be exacerbated when project members are not colocated.

Advances in technology and communications have also heralded the development of the "virtual team," The benefit of a virtual team is that it can be established quickly and can draw on experiences of resources that are not otherwise available in one location (Rad & Levin, 2003). Challenges can arise due to cultural and language diversity, and different time zones, such that the project manager needs to develop strategies to manage these aspects.

Communications Management

Communications management deals with timely and effective communications. The communication strategy should be developed and incorporated within the project plan. The strategy identifies the key stakeholders and their specific communication needs, such as the type of information they need and when and how it will be provided.

Information must be made available to stakeholders when required, and it must be relevant to the context represented by the stakeholder. For example, an executive manager is unlikely to have a requirement to review a detailed Gantt chart, and may simply require a high-level overview of key activities and milestones, and thus be informed of the manner in which the project is to be executed.

Project reporting also needs to be established such that the project board, project sponsor, project manager, and key stakeholders are aware of the reporting requirements, such as status reports, performance reporting, and budget forecasts.

At the conclusion of the project, there are closure activities for finalizing project information requirements and disseminating appropriate information to relevant stakeholders.

Risk Management

There are two fundamental techniques that support the endeavors of a project manager. These techniques are issue and risk management, each supported by relatively simple tools, i.e., an issues register and risk register.

An issue may be considered as any event or series of related events that have become an active problem that threatens the integrity of a project or related project (Young, 2003). An issue impacts upon a project's ability to satisfy objectives, time frames, or budgets. It needs to be dealt with as a matter of priority, due to the impacts on the project. The issue is documented in the issues register, and processes are invoked for assessing the issue, identifying the impact, and performing the action required, by whom and when, to resolve it.

A risk is a situation that may emerge and that may impact the project. The process of managing risk should begin with a review of the initial project assumptions (Kendrick, 2003). It involves identifying a risk, developing ways to reduce it, and determining how it is to be managed (Healy, 1997).

Each risk needs to be identified and evaluated in terms of its likelihood and potential impact on the project. The risk is documented in the risk register, together with mitigation actions, and a resource is assigned to the actions, with specific dates for resolution.

Procurement Management

Procurement management deals with the acquisition of products and services from parties external to the organization. The procurement process involves identifying what products and services need to be procured, when, and why. Consideration needs to be given to options such as build, lease, or buy, depending on the requirements of the project.

Solicitation of the product or service involves preparation of a detailed scope of work, encompassing requirements specifications, terms and conditions, and contractual conditions. The organization may use a request for information (RFI) to obtain an initial set of offers from suppliers, and then a request for proposal (RFP) to obtain firm proposals, potentially from a restricted set of suppliers. Alternatively, the organization may choose to use an RFP based on open or restricted procurement conditions.

The selection of a supplier involves evaluating proposals, assessing commercial compliance, product, or service capabilities, assessing delivery and support capabilities, and evaluating the risks associated with supplier performance and financial viability as a provider. The primary deliverable from the selection process is the award of contract.

Contract administration involves managing the relationship with the supplier, including contract change control, reporting, and payments. These activities might be supported by contract administration software and financial management systems for invoice processing and payments. Procurement management concludes with the completion of the contract, with formal acceptance and closure.

IMPORTANCE

The PM profession has emerged to meet a need within businesses and governments to deliver projects to scope, on time, and within budget. The requirement for PM has gained importance in the IT community because of the growing complexities in the development and integration of diverse business applications into unified enterprise applications architecture, and integration of the supporting hardware and communications infrastructure. The assignment of a project manager is aimed at assuring that one individual has the authority and responsibility for directing the project, to develop and execute the project

Table 1. A summary of critical issues for PM

Unclear project mandate/charter Project sponsor's inability to articulate aim and strategy of project may impact success	**Cost overruns** Inadequate cost estimating, scope creep, and time delays may impact the project budget
Inadequate planning Poor project planning may impair outcomes, with impacts on scope, time, and budget	**Poor quality** Deliverables may meet time frames but lack quality, creating a poor impression, and may require rework
Scope out of control Inadequate baseline definition of scope may impact project due to vagaries associated with scope definition; scope creep may impact budget, deliverables, and outcomes	**Lack of skilled/experienced resources** Competition for resources may present difficulties in securing skilled/experienced resources; resources may leave a project at a critical time
Time delays Inadequate management of time, i.e., resources focused on nonproject activities, may impact project schedule	**Lack of communication** Failure to communicate with all stakeholders may create tension and may impact the timely review/sign-off of deliverables
Issues/risks mismanaged Issues and risks that are not identified, qualified, quantified, and managed, may have a low, medium, or major impact on the project	**Procurement mismanaged** Inadequate specifications and procurement processes may impact project deliverables; inappropriate/inadequate technology may be selected

plan, monitor performance against the plan, and undertake corrective actions.

CRITICAL ISSUES

Some of the key issues facing project managers are presented in Table 1.

CONCLUSION

PM is vital to the successful implementation of IT projects, irrespective of whether the requirement is a multimillion dollar investment in software, infrastructure, and services for a global deployment, or the acquisition of a first computer, peripherals, software applications, and connectivity to meet the needs of a small business owner.

Knowledge of PM theory does not guarantee a successful project. The project manager has to apply PM principles using innate skills, acquired competencies, and learned experiences, typically relevant to the specific business or technology domain of the project. Professional certification is available to project managers through educational and industry groups, such as the Project Management Professional (PMP) certification offered by PMI.

KEY TERMS

Gantt Chart: The Gantt chart displays schedule information in a graphical form. It may display tasks, duration, start/finish dates for activities and milestones, dependencies, and allocated resources.

PM: Project management.

PMBOK: *A Guide to the Project Management Body of Knowledge,* which is the term used to describe the collective knowledge within the project management profession. It is a book published by the Project Management Institute.

PMI: Project Management Institute: details for which can be obtained on the Internet at http://www.pmi.org

Rapid Application Development (RAD): A methodology that consists of techniques to accelerate application development. It features prototyping aimed at achieving demonstrable results quickly; iteration, an approach that commits to incremental development of the prototype; and a time-box concept that focuses on delivery, not scope.

Request for Information (RFI): An invitation sent to suppliers that seeks information about products or services and requests initial pricing estimates.

Request for Proposal (RFP): A request sent to suppliers that seeks proposals for products or services and requests detailed pricing information.

Work Breakdown Structure (WBS): A logical assembly of related activities that describes the totality of the work to be performed. Each activity may contain multiple subactivities or groups of subactivities in a descending order of detail.

Project Management and Graduate Education

Daniel Brandon
Christian Brothers University, USA

INTRODUCTION

Project Management is "the application of knowledge, skills, tools, and techniques to the project activities in order to meet or exceed stakeholder needs and expectations from a project" (Duncan, 1996). A project is defined as "a temporary endeavor undertaken to create a unique product or service" (Duncan, 1996). This article provides an overview of the coverage of the project management discipline in academic graduate education.

BACKGROUND

A number of professional organizations have developed around the world to address and foster this specific discipline. Most notable is the Project Management Institute (PMI, www.pmi.org) with about 100,000 members worldwide. Other major international organizations are the Association for Project Management (APM) and the International Project Management Association (IPMA) (Morris, 2001). These organizations have recognized there is a distinct skill set necessary for successful project managers, and the organizations are devoted to assisting their members develop, improve, and keep current these skills (Boyatzis, 1982; Caupin, Knopfel & Morris, 1998).

Several universities have also recognized the fact that project management involves distinct skills, and that the traditional degree programs and courses in both business schools and other schools do not adequately cover and/or integrate these skills. The *Chronicle of Higher Education* recently reported that seven Philadelphia-area corporations established ties with four universities in that region to improve the business skills of computer science and IT students; most of these key skills involved the project management skill sets, which are specifically identified later in this document (*Chronicles of Higher Education*, 2001).

Perhaps self-evident from the previous paragraph is the fact that the knowledge and training needed by project managers covers both traditional business disciplines and disciplines involved with building or making things. Often the skills involved with building or making things would be found in an engineering curriculum, and also in information technology or computer science curriculums.

Since the skill sets needed by project managers are extensive, and since these skills involve both business and engineering disciplines, and also since most candidate students are degreed working adults, most schools have developed their project management curriculums as graduate school programs. A number of universities also have a single "project management" course offered as a graduate or undergraduate course.

TYPES OF GRADUATE DEGREE PROGRAMS

An analysis of universities currently offering graduate project management programs indicates several types of programs being offered:

1. A master's level general degree program (such as an MBA) with a specialization in Project Management;
2. A full masters level (generally MS) program in project management; and
3. A "certification program" of several project management courses.

Some universities offer more than one of these program types. Also in some universities the program is offered in the School of Business (or Management) and in some schools the program is offered in the School of Engineering. In most universities, many of the courses appeared to be shared with other graduate degree programs; in other words, not all of the courses in the program are focused on project management.

PMI (and the other international project management organizations) have a certification program, and for PMI the designation is "Project Management Professional" (PMP). To obtain PMP certification, an individual must have 4,500 hours of documented project management experience over a period of six years, have a BS level college degree, and pass a rigorous 4-hour examination. The first PMP exam was given in 1984 to about 30 people, and today there are over 30,000 PMPs worldwide (Foti, 2001). Once the PMP status is obtained, an individual must earn 60 PDUs (Professional Development Units) every three years. Some universities offer a PMP Exam

Preparation course or cover exam prep material in one of their project management courses. However, most graduate programs do not cover exam prep; in fact, the graduate programs studied herein are more geared to providing the PDU credits for PMPs.

Figure 1 summarizes the program types for most of the U.S. universities offering project management programs "certified" by PMI. The list of such schools is on the PMI website (www.pmi.org). Out of the 19 schools listed, 11 offer a certificate program, six offer an MBA/MS specialization, and eight off a full Master's is project management. In 14 of the 19 schools, the program is entirely in the Business (or Management) school.

PROJECT MANAGEMENT KNOWLEDGE ORGANIZATION

PMI has developed an index of project management skills and knowledge called the "Project Management Body of Knowledge" (PMBOK). The PMBOK has been developed through several iterations over many years; the first version was developed in 1976 (Cook, 2004). The latest version (PMBOK, 2000) has been released (for certification testing beginning 1/2002) (PMI, 2000). It defines nine "knowledge area" which are organized into 37 "processes". The processes are grouped into five "process groups". This is illustrated in Figure 2 (for PMBOK, 1996) (Duncan, 1996).

Since so many resources have been put into the development and refinement of the PMBOK and it has been so well received by the project management community, it seemed prudent to us to organize our graduate program courses around the processes defined within PMBOK. The issue then became how do we "slice and dice" the processes as shown in Figure 2 into distinct (but integrated) courses. The PMBOK document itself organizes its write-up by knowledge area. However, most classic overall project management books and textbooks are organized by process groups (Badiru, 1989; Cleland & King, 1988; Hajek, 1984; Kerzner, 1980; Meredith & Mantel, 1989; Royce, 1988; Verzuh, 1999). There are however a number of books concerning particular parts of project management, and these cover particular knowledge areas, but they are not specifically written as "textbooks" (Fisher & Fisher, 2000; Fleming & Koppelman, 2000; Pinto & Trailer, 1999; Schuyer, 2001; Verma & Thamhain, 1996).

Looking at the universities currently offering degree programs to see how their curricula were organized, we defined three general types of organization:

1. "Step" – Courses are organized in the traditional manner from less depth to more depth over most of the knowledge areas. For example, the first course might be "Introduction to Project Management"; the next might be "Intermediate Project Management"; and the next would be "Advanced Project Management";
2. "KA" – Follows the PMBOK knowledge areas (Scope, Time, Cost, …); and
3. "PG" – Follows the PMBOK process groups (Initiation, Planning, …).

Figure 2. PMI process groups and knowledge areas

	Initiation	Planning	Executing	Controlling	Closing
Integration		Project Plan Development	Project Plan Execution	Overall Change Control	
Scope	Initiation	Scope Planning Scope Definition	Scope Verification	Scope Change Control	Scope Verification
Time		Activity Definition Activity Sequencing Activity Duration Estimation Schedule Development		Schedule Control	
Cost		Resource Planning Cost Estimating Cost Budgetting		Cost Control	
Quality		Quality Planning	Quality Assurance	Quality Control	
Human Resources		Organizational Planning	Staff Acquisition	Team Development	
Communications		Communications Planning	Information Distribution	Performance Reporting	Administrative Closure
Risk	Risk Identification	Risk Identification Risk Quantification Risk Response Development		Risk Response Control	
Procurement		Procurement Planning Soliciation Planning	Solicitation Source Selection Contract Administration	Contract Administration	Contract Closeout

Most programs do not fit entirely into one of these molds, but they were categorized according to the best fit. Overall, out of the 19 schools, 10 use primarily the Step method, six use primarily the KA method, and two use the PG area.

For schools offering certification, five use the Step method, six use the KA method, and none use the PG method. For schools offering the MBA/MS specialization, none use the KA method, one uses the PG method, and the rest use the Step method. For schools offering the full MS in Project Management, two use KA's, one uses PG's, and the rest (five) use the Step method.

The issue of course material organization is a difficult one for a university. As discussed earlier, universities offering these programs are taking different approaches in this area. We feel the "Step" approach is only useful for programs that have two or three project specific courses. The "KA" approach requires much more "course preparation" time, textbooks are limited, and instructors need depth in these skills. One possible curriculum design would be to use a combination of "PG" and "KA". For "PG", separation into two process "super-groups" may be appropriate: project planning and project control; both covering scope, time, and cost. Separate "KA" courses would likely involve: procurement, risk, quality, and human resources/communications.

PROJECT MANAGEMENT CONTENT IN PROGRAMS

As can be seen from Figure 1, not all of the courses in a project management program are project management specific courses. For most schools, the certification offering is made up of mostly project management specific courses (the #PM in Figure 1 is the number of project management specific courses). For the project management specialization, most schools use three to six project management specific courses. For the full MS Project Management degree, the number of project management specific courses is about one-third to one-half of the courses. These non-specific courses in the full MS degree program vary widely from school to school especially if the degree is in the Engineering school instead of the Business school. Some of these non-project management specific courses are typically: general management, organizational behavior, leadership, managerial accounting, information technology, finance, human resources, quantitative methods, quality assurance, procurement and contracting, and risk management.

DELIVERY

Some universities are offering some, all, or portions of their courses in the form of "distance learning". So the issue becomes: "where on the spectrum from 'bricks to clicks' should a program position itself." There are many pros and cons on both sides of this issue, and most of those pros and cons depend on exactly how a course is made available "online" and the university's overall vision, mission, and tradition. This issue encompasses most degree programs (not just project management), so we are not going to further debate it here, except to indicate it is highly dependent on a particular school's mission, tradition, and demographics. As discussed in the following section, the potential students for such a graduate program are working adults, so attention has to be given to the best delivery for that market. Many schools are holding classes on weekends or evenings to accommodate the adult audiences for these types of programs (*San Diego Business Journal*, 2001).

PROGRAM STAKEHOLDERS AND THEIR NEEDS

We have discussed and surveyed the needs of the stakeholders of a graduate program in our region. The external stakeholders we identified were those companies and those individuals who would benefit from such a program. The companies would benefit by the introduction or reinforcement of the specific project management methodologies into their organizations; this has both an educational and training perspective.

Our individual stakeholders are primarily degreed working professionals. This is similar to the market served by the other universities we investigated, since those other universities like ourselves are located in large metropolitan areas. These individuals benefit from a "continuing education" perspective that makes them individually more valuable. Those individuals having earned PMI PMP Certification would have another way to earn PDU credits (a credit course at a university earns 15 PDUs per semester credit hour). Currency of methods and tools is also quite important to both corporations and individuals.

FUTURE TRENDS

For future university programs in project management, four dimensions can be defined. The PMI PMBOK focuses on the dimension of breadth of the knowledge areas (and the 37 processes) but intentionally does not go into much depth. Going into depth gets into method and tool specifics. Thus, a future trend in university programs would be to address not only the breadth but also the depth of these key processes.

The next dimension identified is industry particulars. While there is much commonality to project management in all industries, there is also much that is specific to each area. For example, task estimation for an IT project is much different than task estimation in a construction project. So this should be considered as another added dimension to new programs, certainly not for all industries but for the major ones in a school's geographic region.

The next dimension we identified was that of time or "currency". This not only includes the use of current tools, but the practice of project management in the current business and technical environment. Issues such as "virtual teams", international coverage, and Web-based systems would be included in this dimension.

CONCLUSIONS

Herein, we have examined content, approach, and logistics issues in graduate education for project management. The university programs surveyed were all relatively new programs, so there is little or no data available for a statistical or comparative historical analysis at this time. In the future, one may be able to survey graduates from the different types of programs to determine the pros and cons of each type of program organization and the "best practices" for project management education.

KEY TERMS

APA: Association for Project Management.

IPMA: International Project Management Association.

Knowledge Area (KA): Project Management Knowledge Area; For PMI there are nine knowledge areas: Integration, Scope, Time, Cost, Quality, Human Resources, Communications, Risk, and Procurement.

Process Group (PG): A grouping of project management processes; for PMI, there are five process groups: Initiation, Planning, Executing, Controlling, Closing.

Professional Development Unit (PDU): A unit of continuing education for certified project managers.

Project Management: The application of knowledge, skills, tools, and techniques to project activities in order to meet or exceed stakeholder needs and expectations of that project.

Project Management Body of Knowledge (PMBOK): A consolidation and organization of information about project management including “best practices”.

Project Management Institute (PMI): The largest of the professional organizations which foster the discipline of project management.

Project Management Professional (PMP): The highest level of professional certification of project managers by PMI.

Project Management Models in IT

Marly Monteiro de Carvalho
University of São Paulo, Brazil

Fernando José Barbin Laurindo
University of São Paulo, Brazil

Marcelo Schneck de Paula Pessôa
University of São Paulo, Brazil

INTRODUCTION

The implementation of formal efficiency procedures is quite new in IT projects. There are different approaches regarding the best practices in the IT project management (Carvalho, Laurindo & Pessôa, 2003; Laurindo, Carvalho & Shimizu, 2003).

Humphrey (1989) identifies maturity levels in the IT project development process, based on the managerial behavior found in companies. The fundamental concepts of the process maturity derive from the belief that the development management process is evolutionary. Paulk, Weber, and Curtis (1995) identify the distinguishing characteristics between immature and mature organizations, as showed in Table 1.

CAPABILITY MATURITY MODEL (CMM)

The CMM (Humphrey, 1989; Paulk et al., 1995; Pessôa & Spinola, 1997) was developed by SEI—the Software Engineering Institute of Carnegie Mellon University—and presents five maturity levels, each corresponding to a set of structural requirements for key process areas (Figure 1).

Although each project is unique, it could be organized in a process to be applied in other projects. IT project managers used to apply a "methodology," that is, they established the steps to be followed in order to develop a system. Another singular characteristic is the dynamic technologies breakthrough that demands continuous improvements in the development methods and management of changing process, as described in CMM model, at Level 5, the highest level of maturity.

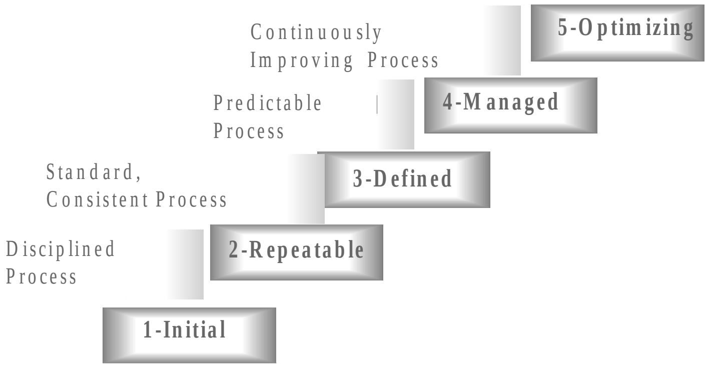
The CMM second level has a consistent project management structure, and the goal of this level is to deliver projects on time. To perform this, the model has several points that must be achieved, like effort and size estimation, strong process control (such as periodic meetings between technical people and managers), and several measures to show project status more clearly.

CMM is not an adequate reference for the assessment of internal methodologies, since it was not conceived to perform this kind of analysis. ISO 15504 (1998) proposed the standard project SPICE as a more appropriate model to evaluate maturity level of specific processes. While CMM level of maturity specifies a set of processes that have to be performed, ISO 15504 establishes maturity levels for each individual process: Level 0—Incomplete; Level 1—

Table 1. Immature organization x mature organization (Paulk et al., 1995)

IMMATURE ORGANIZATION	MATURE ORGANIZATION
• *Ad hoc*; improvised process by practitioners and managers • Not rigorously followed and not controlled • Highly dependent on personal knowledge • Little understanding of progress and quality • Compromising product functionality and quality to meet schedule • High risk when new technology is applied • High maintenance costs and unpredictable quality	• Coherent with action plans; the work is effectively achieved • Processes are documented and continuously improved • Perceptible top and middle management commitment • Well controlled assessment of the process • Product and process measures are used • Disciplined use of technology

Figure 1. Maturity levels (Paulk et al., 1995)



Performed; Level 2—Managed; Level 3—Established; Level 4—Predictable; Level 5—Optimizing. This is a different approach of CMM, since an organization does not perform a maturity level, but has a maturity profile: a maturity level is measured for each specific process. This new approach is very useful to the organization perspective because one can easily measure strong and weak points of their process, and plan improvement activities. Furthermore, from the companies' point of view, it is easier to understand staged levels, as the performed processes are already predefined.

The SPICE approach defined in standard ISO 15504 (1998) had firstly influenced *CMM for Systems Engineering*, published in 1995, and more recently influenced CMM I (CMM-I1; CMM-I2), just published in 2002. CMM-I, the integration model, was enhanced in two dimensions: *scope dimension* and *evaluation dimension*.

In the scope dimension, this new model incorporated other published models and covered all project activities, not only software, as the original software CMM did, but also other engineering fields. In the evaluation dimension, CMM-Il incorporated both approaches: the traditional (called staged CMM) and the maturity profile (called continuous CMM). Figure 2 shows the continuous CMM-I representation to be compatible with ISO/IEC 15504 standard.

CMM-I (and software CMM) considers that maturity level is an organizational characteristic and is independent of the professionals involved. Nowadays, there is a strong tendency towards the adoption of CMM-I models, which were sponsored by the Department of Defense (DoD); meanwhile ISO standards are less used.

PROJECT MANAGEMENT MODELS

Project management plays an important role in the competitive scenario and in the '90s achieved the status of methodology. The model proposed by the Project Management Institute—PMI (2000), called PMBoK, provides

Figure 2. Continuous maturity process representation in CMM-I (CMM-I1, 2002)

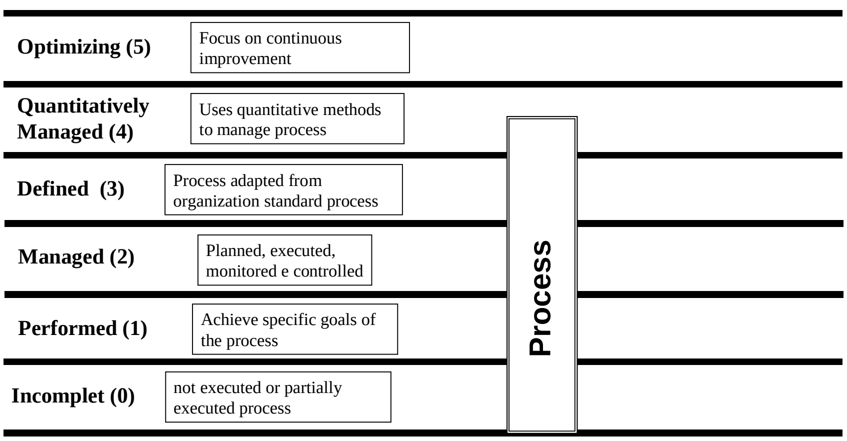


Figure 3. Project management maturity model (Adapted from Kerzner, 2001)

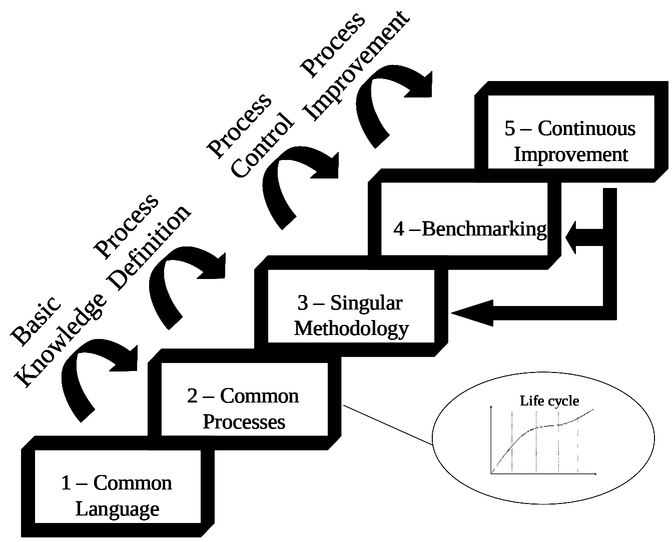


a framework to manage project efficiency, balancing scope expectations and the available resources in nine key areas (Rabechini & Carvalho, 1999).

Nevertheless, the PMBoK framework cannot provide a standard benchmark for project management capability as CMM to software engineering capabilities. In order to extend the Capability Maturity Model to project management, Kerzner (2000, 2001) proposes a Project Management Maturity Model (PMMM).

The PMMM differs in many aspects from the CMM, but this framework also introduces benchmarking instruments for measuring an organization's progress along the maturity model, detailing five levels of development for achieving maturity, as shown in Figure 3 (Carvalho et al., 2003).

It is important to highlight the differences in terminology between the CMM and PMMM (compare Figures 2 and 3) which could lead to misunderstanding when both models are being implemented in the IT domain of the same organization.

PMMM addresses the key knowledge areas across the project management process, in compliance with PMBoK, and integrates them with the Project Management Office (PMO) in the strategic level.

Kerzner (2000) identifies a life cycle in PMMM Level 2, Common Processes, which could be broken into five phases, as shown in Figure 4. It is important to note that some simultaneity among the phases can occur.

The embryonic phase means that the organization starts to recognize the benefits of project management (PM), usually by lower and middle levels of management. The two next phases are achieved when the PM concepts are accepted, and have visible support and commitment by executive and line management.

Kerzner (2001) emphasizes the growth phase as the most critical, because it is the beginning of the creation of the PM process and warns that different methodologies for each project should be avoided.

The last life cycle phase—maturity—is difficult to achieve due to several factors such as organizational resistance to project cost control and horizontal accounting.

The main characteristics of these life cycle phases emphasized by Kerzner (2001) are described in Table 2.

QUALITY SYSTEMS

It is important to note that the adoption of systems models, such as ISO 9000, focuses on the creation and maintenance of a quality system, applied to any process. The ISO 9001:2000 new version, published in the year 2000, was fully restructured to have a more clear process-focused approach. Other ISO standards offer an overview of these standards to the software field and contribute to deploying this approach to specific processes such as software products (ISO 9126-NBR 13596), quality requirements for software packages (ISO 12119), and the software life cycle process (ISO 12207).

ISO 9000-3 (2001) is a guide to help with ISO 9001 interpretation for the software field (Pessôa & Spinola,

Table 2. Life cycle phases' characteristics (Kerzner, 2001)

Phase	Characteristics
embryonic	• recognizing the need for PM • recognizing PM's potential benefits • applications of PM to the business • recognizing the changes necessary to implement PM
executive management acceptance	• visible executive support • executive understanding of PM • project sponsorship • willingness to change the way the company does business
line management acceptance	• visible line management support • line management commitment to PM • line management education • release of functional employees for PM training programs
growth	• development of company PM life cycles • development of a PM methodology • a commitment to effective planning • minimization of scope • selection of PM software to support methodology
maturity	• development of a management cost/schedule control system • integration of schedule and cost control • development of an educational curriculum to support PM

1997). The previous versions of this guide were developed by the ISO/TC/SC2 committee, the quality branch of ISO. Nowadays this ISO 9000-3 guide is being revised by ISO/IEC JTC1/SC7, the information technology branch. The ISO 9001:2000 new structure made this task easier than previous versions, and it is incorporating a map of the relationship between IT standards (ISO/IEC JTC1/SC7) and its respective quality systems described in ISO 9001 to this standard. For example, ISO 9001 specifies that the organizations have to identify their processes, and ISO 12207 proposes a set of processes involving software development, supply, acquisition, and maintenance. In addition to ISO 12207, other standards are referenced, such as ISO 9126 for software products, ISO 12119 for quality requirements for software packages, and ISO 15504 for software evaluation. This was considered an improvement of the standards structure that matches quality system standards with technical and specific standards.

ISO 9001:2000 standards have the purpose of certifying organizations whose quality systems comply with the standards, and provides a structure to manage quality independently of the organizational activity. This is not enough for specific fields of application, and for this reason there are complementary sets of standards in some areas, like QS-9000 for the automobile industry and TL-9000 for the telecommunications industry.

The standards from ISO/IEC JTC1/SC7 have the purpose of complementing the quality system for the IT-specific area, not focusing on applications as with the automobile or telecommunications industry, but considering the specifics of software and systems development.

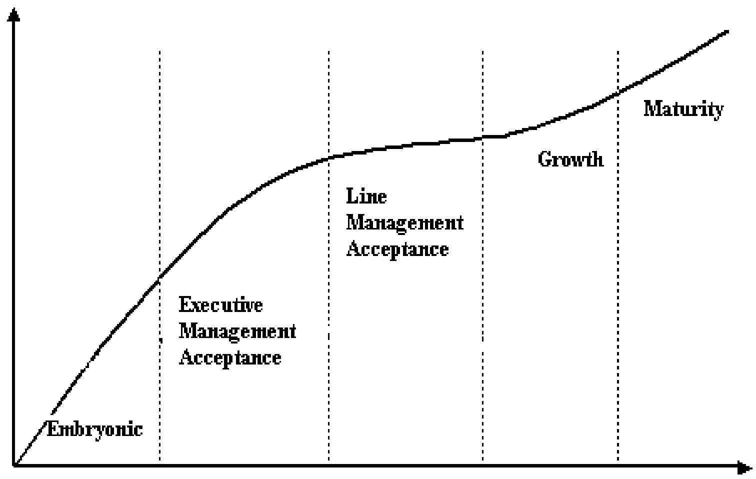
In general, ISO 9000 can be a good starting point for implementing a quality system. This system allows organizations to disseminate quality culture and create the initial structure to implement more specific quality systems.

In general, the quality system (ISO 9000), processes (CMM), and project (PMI) models have the possibility of mutual and complementary synergy, maintaining consistency with their fundamental points. On the other hand, there are important differences among these models, especially concerning the degree of abstraction. (Pessôa, Spinola & Volpe, 1997b; Tingey, 1997).

CONCLUSION

In spite of different approaches regarding the best practices in the IT project management, there is a general consensus about the importance of the following widely used efficiency models: the CMM (Humphrey, 1989; Paulk *et al.*, 1995), the Project Management Maturity Model—PMMM (Kerzner, 2000, 2001); the Project Management Body of Knowledge—PMBoK (PMI, 2000), and quality systems for software—ISO 9000-3 (2001) and ISO 12207 (1995). All of these are empirical and were developed based on best practices used in real projects. Although

Figure 4. Life cycle phases (Kerzner, 2000)



they have different approaches in their conception, they are rather more complementary than conflictive. These models consider that maturity level is an organizational characteristic and it is independent of the professionals involved.

KEY TERMS

Capability Maturity Model (CMM): A framework to achieve maturity in project activities in the software field which presents five maturity levels, each corresponding to a set of structural requirements for key process areas.

CMM I (CMM-I1; CMM-I2): A model, which has enhanced in two dimensions: *scope dimension* and *evaluation dimension*. The CMM-Il incorporated both approaches: the traditional (called *staged CMM*) and the maturity profile (called *continuous CMM*).

ISO 9000-3: A guide to help ISO 9001 interpretation for the software field, i.e., the development, supply, acquisition, and maintenance of software.

ISO 15504: An international standard that proposes the standard project SPICE, which establishes maturity levels for each individual process: Level 0—Incomplete; Level 1—Performed; Level 2—Managed; Level 3—Established; Level 4—Predictable; Level 5—Optimizing.

Life Cycle: Common processes identified in PMMM Level 2 which could be broken into five phases: embryonic, executive management acceptance, line management acceptance, growth, and maturity.

Project Management Body of Knowledge (PMBoK): Provides a framework to manage project efficiency, balancing scope expectations and the available resources. This model proposes the following nine key areas: (i) integration, (ii) scope, (iii) time, (iv) cost, (v) quality, (vi) human resource, (vii) communication, (viii) risk, (ix) procurement.

Project Management Maturity Model (PMMM): A framework that introduces benchmarking instruments for measuring an organization's progress along the maturity model, detailing five levels of development for achieving maturity: Level 1—Common Language; Level 2—Common Processes; Level 3—Singular Methodology; Level 4—Benchmarking; Level 5—Continuous Improvement, as shown in Figure 3.

P

Promotion of E-Government in Japan and Its Operation

Ikuo Kitagaki
Hiroshima University, Japan

INTRODUCTION

In Japan, e-government has been considered since 2001 as one of the strategies of so called "e-Japan" (Ohyama, 2003). It had been decided that e-government shall be constructed within the fiscal year 2003. Preparation in terms of the legal system and technological developments made steady progress towards that goal. The construction of e-government should alleviate residents' burdens in terms of bureaucracy, enhance service quality rationalization, lean and transparent administrative agencies, countermeasures for natural calamities, more participation in policy making and administration by residents and so forth. Various tasks have been carried out at many places. For example, in autumn of 2002 a "basic residential register network" was established. Its initiation enjoyed broadly smooth operation. Residents had received administrative services only within certain jurisdiction limits until then. Now they are free to enjoy access to any administrative services from anywhere in Japan thanks to this e-system. Some local authorities introduced electronic tenders to enhance transparency of administration. Some local authorities adopted an electronic voting system in part of their areas. This paper explains the details of how the construction of the e-government came about and the status of its operation.

In constructing an e-government, basic researches in respect of relevant individual electronic chores are necessary. In reality, however, planning and drawing up an idea will often be brought about, depending on certain actual domestic social circumstances of the legal systems or certain consensus within and between relevant representative bodies of the government. Because of such circumstances, we have decided to list up general magazines easily available which report often on these themes, and the most up-to-date URLs of relevant organizations of the Japanese government (see Appendix).

BACKGROUND

Information processing on the part of the public administration has progressed in line with each development of computers (Makiuchi, 2003). It followed the progress of information processing in the private sector. The first steps included, as early as the 70s, information processing for specified jobs such as accounting and salary payments. It also controlled systems of government offices on the basis of one PC per person, as personal computers spread around 1990, internet technologies were introduced, and so forth. In particular, the Patent Office in Japan adopted an online system for patent application to speed up the processing of patent applications and it did substantially increase.

Nevertheless, given the progress and more use of the information processing for administration, the mentality that it only simply meant computers would replace mechanical style jobs lived a long time. In addition, it exerted a negative influence in that the conventionally vertical administration confined the progress of the information processing for administration to specific ministries and offices. And it made services difficult to access from the standpoint of the people.

The Mori Cabinet came into power in 2000. He decided to shift the nation to the use of state-of-the-art information under his "e-Japan strategies". He would emphasize the importance of information processing in Japanese society in order to get out of the economic slump. Objectives were placed in five fields; broadband infrastructure, education, public/administration services, e-commerce, and security. Among the items, administration services are selected so that e-government will be realized within the fiscal year 2003. Preparation in terms of legal systems and technological developments have made progress in that respect. Legal systems were reviewed. Now, there are the Online Transmission Regulations, Revised Basic Residential Register Law, Public Individual Certification Law etc. On the technological front, there were also some new introductions of electronic systems for administrative procedures, for example all-purpose reception system for applications, the introduction of a one-stop system for import/export harbor and taxation procedures as well as the electronic tender system. Electronic systems for revenue bookings allows payments per Internet and an online transfer system. The purposes of the introduction of information processing for administrative chore and business operations are; simplification of work for human resources, salaries, etc. and connection of the National Networks with LGWAN (Local Government Wide Area Network) owned by communalities.

Electronic procedures will be put into practice in various fields as described above. From their own perspectives, users consider more or less that the essential part of e-government is mainly the given opportunity of the electronic application and its ease.

E-government is one of the e-Japan Strategies in the Five Year Plan which started in 2000. Preparatory activities on legal systems and system construction are to be completed by March 2004. On the other hand, as regards set-up of broadband infrastructure, the objective was set that 30 million households would use it by the end of the fiscal year 2005. In reality, 50 million households (the actual number of subscribers is about 5.70 million) were able to use it as early as June 2002 due to the rapid progress of information telecommunication technologies. Partly as a result of these unexpected circumstances, e-Japan Strategies could enjoy another review only after one and half year of their inception.

E-Japan strategies seem to have advanced rapidly. An international comparison survey by a consultancy company called Accenture shows, however, that Japanese e-government ranked 17th.According to this study, the top three positions are Canada, Singapore and the USA. The same survey classifies and names these three nations as the "pioneering leaders". Australia, which clad the 4th, to the 13th positioning it calls the nations as "visionary challengers". It calls the 14th positioning to Japan, which is the 17th, as "emerging performers" and the 18th onwards as "platform builders". Whether or not they succeed in construction of e-government can be a good clue, a basis requirement for international competition for any country.

SYSTEM DEVELOPMENT CASES

Here are some cases of e-governments established on national scheme or at local authorities.

Basic Residential Register Network System

Resident registration cards, tax payment certificates etc. are normally applied for at the desk of an agency. The regional jurisdiction of a resident is responsible and issues them. E-government will enable any application at home or application and issuance from an office outside the resident district. Confirmation of the subject person beyond an administrative boundary and the necessary information exchange between administrative bodies in this respect becomes easier with the use of Basic Residential Register Network. The Basic Residential Register Law regulates undertakings for this system, how its operation should look and its practical use. Information contained in this system be the four items: name, birth date, gender, and address. It also contains resident card code numbers and information of any changes to them. The resident card code allows easy access to these four data items. It consists of eleven digits, selected at random, and will be issued only in Japan without duplication for any other person. This code can be changed at the request of the subject person. The system constellation is 3-fold in vertical; the levels consist of national, prefecture and municipalities. Depending on the distance between the "clients" making use of the common contents from each other, the option would be made which of the 3 levels of networks should be used. If two towns sit in the same prefecture, the communication server of one of the two towns and the dedicated line in connection with this server on the level of the prefecture would be used in order to communicate with the other town magistrate. If the communication should go to the level of prefecture-prefecture, the network of this constellation level would be working plus the national network involved. Communication servers have firewalls both inside and outside to prevent illegal access (Inoue, 2003; Yoshida, Mizokami & Watanabe, 2003)

ElectronicTender

Here is a case of Yokosuka City in Kanagawa Prefecture (Hirokawa, 2003). Up until the 1997, order placement of civil works in the city took place mainly by public tender in which 7-10 specified and pre-selected bidders could join the tender. However, it became known that there had been some collusions on the bidding. It was considered that reform is necessary. The tender system was changed in the fiscal year 1998 to a conditionally open tender where any business entity could participate, if inspection standards prescribed were satisfied. In the fiscal year 1999 information on order placements started to be shown on the agency's homepage.It became possible for companies wishing to participate to confirm general picture of an order. Where is the site? What is the nature of this work? Firstly, a company wishing to bid will transmit a tender application form to the contracting section by facsimile. If confirmed that this company is qualified to participate, it will purchase design documents from a designated printing company, and draw up an estimate. Then it sends the tender documents poste restante at the Yokosuka Post Office by registered mail with a delivery certificate by the deadline. On the date appointed, the contract section of the magistrate will open all the tender documents collected at that time and chose the successful bidder with representatives of the participating companies witnessing. All the tender results will be publicized on the homepage after that. The effect is that the number of tender companies increased by 2.5 times on average before and after the reform. At the same time the annual average success ratio (the ratio of a successful bid to the expected price) declined from 95.7% before the reform to 85.7%.

In the fiscal year 2001, the series of procedures above were to be carried out by the Internet. The purpose is to further widen the door to bidding companies and save on administrative work of the contract section. Companies put in a tender bid on the tender document transmission screen first and then transmit it by the Internet. The tender documents will at once be transmitted to the server of the authentication bureau, where the guarantee of originality and perception time stamps are added. Then it will be transmitted to the contract section. In other words, the function conventionally carried out at a post office has been transferred to an authentication bureau. The average success bid ratio for this fiscal year fell as low as 84.8%.

Noteworthy is the fact that the reform of the tender system was brought about only with the strong will on the part of the personnel, with the mayor on the top, down to all those who worked on the reform who did not give up facing various forms of resistance.

Electronic Voting

For electronic voting there are two options, voting made from a household PC and another made by ballot. Both are under examination now. The former is carried out where an electronic voting paper is obtained by a household from a voting server. Here, voting contents are filled in and transmitted to a sum-up server. However, a security problem has been pointed out in cases of electronic voting by household. Some people held the view that it should be limited to persons with physical disability. On the other hand, electronic voting at a ballot is carried out in that on voting contents decisions will be made via touch panels. Also, an electronic pen can be used at the voting terminal. This has been put into practice in Niimi City, Okayama Prefecture and part of the Hiroshima City. Various technologies for voting have been proposed, but none of them has been developed enough in any of the business in e-government. The reason appears to be that the frequency of an election itself is low; at most, it is once in a year. Therefore, cost efficiency of system development is not clear as a result. Furthermore, security must be perfect etc. A voting logic where contents and choice of an individual voter will not be known, not only to others but also to the system itself, is under study. The system must cope with bribery and corruption and misuse of strong power, and there remain difficult issues to be solved (Kitagaki, 2003; Shiraishi et al., 2003).

Various Resident Services

In Yokosuka City (Hirokawa, 2003) Geographical Information Service (GIS) was introduced to enhance and reach greater efficiency of administrative services in order to facilitate residents' participation in the regional community activities. Common use on the level of the municipal office was possible by integrating information owned by each division and bureau in the municipal office at one place, except for that information which would violate the protection of personal data. In the fiscal year 2002, Yokosuka City arranged so that citizens could obtain maps using Web-GIS from home. That was a result of an alliance with a map company in the private sector. On the Web site, information on medical institutions, bargain sales at shopping centers, sightseeing information, etc. became available. Many organizations and individuals such as the Chamber of Commerce and Industry, medical associations, SOHO workers etc. are engaged in preparation of these data and operation in cooperation.

In Kochi Prefecture (Ishikawa, 2003), the information super-highway has been in operation since the fiscal year 1997. Further improvement has been sought to accompany the preparation of the administrative networks and the changes in the information environment. In the fiscal year 2001, telecommunication services in the private sector started to be carried out as well, under a new basic conception. The main circuit of the information highway was changed from the previous 50Mbps to 2.4Gbps. Preservation control and stable operation throughout the year were guaranteed. In addition, main circuits were open to ISP (Internet service providers) and businesses in the private sector providing CATV services. They became compatible with IPv6, etc.

Sapporo City in Hokkaido showed its basic policy in the fiscal year 2002 amid the progress of various businesses with information technology in mind. It is considered a "city for cooperation between administration, citizens and enterprises". It should be an ideal state of city management, the city listens carefully to residents' voices. It started to operate a call center business to reflect this in administration. This center deals with various kinds of inquiries from citizens. The city has made experiments with citizens monitoring. Trial operation has further expanded since the fiscal year 2003. In addition, the city attempted to distribute IC cards. For example, it has prepared the environment to be able to use them for all the municipally operated subways.

Further, payment of administrative services with IC credit cards (Endo, 2003), provision of various electronic municipality software developed with the residents' standpoints (Shimada, 2003), as well as technological issues of its operation (Maeda, Okawa & Miyamoto, 2003), are under examination.

DISCUSSION AND FUTURE TRENDS

Smooth application of e-government in the near future depends on the following factors. First, is the convenience of the portal site, especially seen from the user's point of view. How quickly users can come across with the desired information at the portal site of e-government, is important. The electronic portals of the USA show construction standards for the portal of e-governments of each federal organization, state, etc. By doing so, each portal is linked organically to the whole. Compared to the case in the USA, some people point-out, the portal of the Japanese e-government does not give any thoughtful consideration to the integration of the whole. In fact, inconvenience may arise in that the same information must be input every time an electronic application is made to different representative bodies of the government without linkages to other representative bodies of the government.

The second factor is related to the present work contents and review of procedures. Basically, the information processing carried out by each representative body of individual governments has put in old procedures based on financial and accounting laws from the Meiji Era and shift them into electronic databases. Therefore, E-government now needs to reform the whole processing of work data as well as distribution structure, and change them to an effective and integrative work processing system.

The third is related to a greater efficiency of works and systems. In the future, review of excesses and deficiencies of procedures will be necessary. Experts will be required to add a new function conforming to the existing e-government. Experts sought must be fully familiar with both work contents and information technologies, and at the same time be able overview the whole landscape.

The fourth is related to the transfer of these works to the private sector. Outsourcing in the private sector will be necessary in order to raise the efficiency and rate of utilization of the introduced systems, and to reduce costs. At the same time, selection of outsourcing companies and contract contents are important in order for information of administration and individuals not to be leaked.

Lastly, all of the cases mentioned here are on-going projects, thus the relevant evaluation activity has not been yet done. In the near future, verification process ought to be planned.

KEY TERMS

Basic Residential Register Network: A network to confirm the being of a person, a subject. Its use is common throughout Japan and jointly operated by local authorities.

E-Government: The government and local authorities which construct an electronic processing system for administrative procedures with full command of information telecommunication technologies. It provides various kinds of services for residents in line with these.

E-Japan Strategies: The national strategies decided in the first conference of the Strategic Headquarters for the Promotion of an Advanced Information and Telecommunications Network Society (the IT Strategic Headquarters) held on the 22nd January 2001. It was laid on the IT basic strategies decided at the Joint Conference of the IT Strategic Conference and the Strategic Headquarters for Information Telecommunications (IT) Technologies (27th November 2000).

Electronic Tender System: A system to carry out a series of works from notification of order placement information on the homepage etc., application for tender participation, sending a tender document, opening tender documents to the public announcement of the result.

Electronic Voting System: A system to vote electronically, using an information terminal of a personal computer etc. Various technologies have been created to prevent illegal actions such as alteration of voting contents or the use of abstainers' votes.

Online Communication Regulation Law: A law to enhance application in the administration, which is decided by laws exceeding 50,000, and cover all these laws for conducting application electronically. It is considered that this communication regulation law has completed the basic legal frameworks necessary for the e-government such as electronic signature law.

Public Individual Certification Law: A law to prepare a system to provide individual certification and authorization services in order to process on-line the public application and notification on-line.

Public Sector Case Study on the Benefits of IS/IT

Chad Lin
Edith Cowan University, Australia

Graham Pervan
Curtin University of Technology, Australia

INTRODUCTION

While organisations continue to invest heavily in IS/IT, research studies and practitioner surveys report contradictory findings on the effect of the expenditures on organisational productivity (Grover et al., 1998). Therefore, it is not surprising to see that the term "productivity paradox" is gaining increasing notoriety as several studies point toward fairly static productivity and rising IS/IT expenditure. Despite large investments in IS/IT over many years, it has been difficult to determine where the IS/IT benefits have actually occurred, if indeed there have been any (Willcocks & Lester, 1997). The main objective of this article is to generate a deeper understanding of issues surrounding the current practices and norms in managing IS/IT benefits and investments evaluation.

RESEARCH APPROACH

A case study was conducted to investigate the practices of IS/IT investment evaluation and benefits realisation in large Australian organisations. Semi-structured interviews were used to gain a deeper understanding of issues.

CASE DESCRIPTION

Seven interviews were conducted with participants from a Western Australian state government department and two major outsourcing contractors. The questions asked related to the formal benefits realisation methodology used, major outsourcing contracts, contractual relationship between department and contractors, and IS/IT investment evaluation methodology or technique deployed. Other data collected included contract documents, planning documents and minutes of relevant meetings. Around 80 pages of transcripts were coded and analysed. The analysis was conducted in a cyclical manner and followed guidelines for interpretive research set out by Klein and Myers (1999).

CASE STUDY RESULTS

A number of issues arose from the analysis of this text data and the key issues are presented next.

Issue 1: Lack of formal IS/IT investment evaluation methodology

Most of the participants claimed that some sort of formal methodology or process was put in place for evaluating these contracts. However, closer examination revealed that what was described did not constitute a formal IS/IT investment evaluation methodology. Participants wrongly considered various contract control mechanisms as a formal IS/IT investment evaluation methodology.

Issue 2: A formal IS/IT benefits realisation methodology was used

Every participant was aware that a formal IS/IT benefits realisation methodology was being used for outsourcing contracts and projects. A benefits realisation approach was used as an end-to-end process to assist in: (1) providing a rigorous process to select the right projects; (2) placing responsibility and accountability at the appropriate level; (3) driving process re-engineering through changes in the organisation; (4) ensuring benefits are realised; and (5) ensuring agreed re-investment of time savings applied as expected.

Issue 3: Lack of understanding of IS/IT investment evaluation methodology

The confusion indicated in Issue 1 about what constitutes a formal IS/IT investment evaluation methodology demonstrated a lack of understanding of such methodologies. This may be due to the fact that the department was unable to introduce a formal IS/IT investment evaluation methodology because it was required to follow the state government's outsourcing guidelines (MOPC, 2000; SSC, 1999b).

Issue 4: Existence of an informal IS/IT investment evaluation process

Despite the fact that no formal IS/IT investment evaluation methodology or process was used, contract control and evaluation mechanisms specified within the SLAs or government guidelines do represent an informal IS/IT investment evaluation process. Although these informal mechanisms may not totally replace a formal methodology (e.g., Kaplan and Norton's (1992) Balanced Scorecard), they were able to assist in evaluating the performance of the outsourcing contracts. These mechanisms were largely based on the standard state government contract process and purchasing guidelines (SSC, 1999a, 1999b).

Issue 5: Good understanding of benefits realisation practices

A benefits realisation methodology, called benefits realisation approach, was introduced before outsourcing IS/IT functions because there was a concern that IS/IT investments did not deliver value (which would jeopardize future government funding). To ensure that the IS/IT investments deliver the promised value and benefits as well as bring the focus back to the department's main business, a large internal change program was required.

Issue 6: Focus on quantitative IS/IT investment evaluation measures

Without employing more qualitative measures (e.g., relationship, culture and leadership) and a formal IS/IT investment evaluation methodology or process, the use of quantitative or accounting-based measures alone did not assist in full evaluation and monitoring of the performance.

Issue 7: Different motivations for outsourcing

Several reasons were put forward as the main motivation for IS/IT outsourcing. Only two of the four contractor representatives cited access to the required technical expertise as one of the department's reasons to outsource and two either did not know or did not respond to the question. However, all of the department's participants mentioned access to required technical expertise as a major reason to outsource some IS/IT functions. Therefore, the department's motivation for outsourcing was somewhat different from the contractors.

Issue 8: Success of the contracts perceived differently by stakeholders

Customer satisfaction, achieving the contractor's projected revenue, bringing value/benefits to the organisation, and meeting the SLA provisions were mentioned. Other criteria mentioned included technical competence to deliver what is required, risk factors, contractors' experience in a relevant area, and business continuity of the contractors. Both representatives from the first contractor mentioned achieving the projected revenue for themselves and satisfying customers as their only criteria for determining the success of their outsourcing contracts with the department. This may indicate that the first contractor's aim is to maximise the profit while maintaining a certain level of customer satisfaction. However, participants from the department seemed to have used different criteria for determining the success of the outsourcing contracts. Bringing value/benefits to the organisation, meeting the SLA provisions, and pricing/cost were mentioned by three out of four participants.

Issue 9: Better control over the IS/IT skill shortage within the department

Access to the required technical expertise was the most often cited reason for outsourcing. The department did not have the required IS/IT expertise to implement a major internal change program and outsource some of its IS/IT functions. In order to obtain the required technical expertise and skills from outside, the department had to transfer some of its IS/IT staff to the first contractor. According to most of the participants, those who went across to the first contractor were quite happy about the whole process. However, the department did not lose the capacity to manage and assess its own IS/IT needs after relinquishing the control of some of its IS/IT functions and staff, as has happened in many outsourcing organisations previously (Currie & Willcocks, 1998).

Issue 10: Embedded contract mentality

Staff of the department seemed to have a "contract mentality," as the operation of the contracts was based on the specifications set out in the SLAs within the outsourcing contracts. Several participants clearly indicated that there was a pre-agreed set of evaluation and control mechanisms in the SLAs within the outsourcing contracts such as metrics, monthly reports, reviews, and regular meetings. Moreover, half thought these contract control mechanisms were all part of the IS/IT investment evaluation methodology.

Issue 11: Lack of user involvement/participation in contract development

There appeared to be an organisational memory gap where units within the department possessed knowledge of different parts of the IS/IT systems development cycle. However, the knowledge did not seem to be shared by all units because different units participated in different stages. The department's whole outsourcing process may have been more successful if the participants were involved in both original tendering and outsourcing contracts negotiation as well as benefits realisation process.

Issue 12: Conflict between motivations and success criteria for outsourcing

It seemed that the participants had different expectations regarding the outsourcing as a whole and the outsourcing contracts. Alternatively, they may have felt that the outsourcing contracts had already brought in the required technical expertise and should not be used as a criterion for determining contract success

Issue 13: General lack of commitment by contractors

It was easy to see that department and contractors had different agendas in mind, despite the fact that the contract was a partnership-type arrangement. The first contractor's criteria for determining success of outsourcing contracts seemed to be maximisation of profit/revenue while keeping the customers satisfied. The contractors' lack of commitment could also be demonstrated by the fact that they either did not know why the department outsourced, or could not agree on a single reason for outsourcing. However, the department agreed that access to required technical expertise was a reason for outsourcing.

Issue 14: Restrictive government outsourcing contract guidelines

All state departments have to follow the contract tendering and outsourcing guidelines set out by the State Supply Commission (SSC, 1999a, 1999b). This was one reason why the department failed to adopt a formal IS/IT investment evaluation methodology. The state government guidelines specify numerous principles, steps, and procedures for state departments to follow when dealing with external contractors. However, they do not determine what formal IS/IT investment evaluation methodology a department should use.

Issue 15: Benefits realisation methodology provides rigorous processes

As mentioned in Issue 1, the benefits realisation approach provided the department with rigorous processes for achieving benefits delivery. These processes did not exist prior to its introduction. Instead, some crude methods had been used in an attempt to realise benefits within the organisation. These methods included budget cuts, projects statements presentations, and activity surveys. The introduction of the benefits realisation approach provided the department with rigorous processes.

Issue 16: Ability to manage the outsourcing contracts without external influence and assistance

To acquire technical expertise and skills, the department had to outsource some of its IS/IT functions and transferred some of its IS/IT staff to the first contractor. However, unlike other outsourcing organisations, the department appeared able to manage its outsourcing contracts internally without external influence or assistance. This may be because the department had transferred as few IS/IT staff to the first contractor as possible and, simultaneously, benefited from the second contractor's IS/IT technical expertise obtained under the contract.

CONCLUSION

This case study was conducted in a large government department with a mix of insourced and outsourced IS/IT activities. While the department appears to operate without any major problem, the mostly negative issues shown previously indicate weaknesses in the way it deals with the level of formality and integration in applying the methodologies. The problems mentioned in Issues 6 -14 were mostly caused by the lack of attention to IS/IT investment evaluation (Issues 1, 3, and 4). For example, if formal IS/IT investment evaluation was adopted by the department, more qualitative measures may been used to evaluate the outsourcing contracts (Issue 6).

So why didn't the department formally evaluate its IS/IT investments? One possible explanation was that the restrictive nature of the state government's outsourcing contract guidelines (Issue 14) made it difficult to implement a formal IS/IT investment evaluation methodology. Another explanation was that none of the IS/IT staff was familiar with the formal IS/IT investment evaluation process and hence possessed an "embedded contract mentality" (Issue 10) by simply following conditions set out within the SLAs. Seddon et al. (2001) suggest that under some circumstances, cost of formal IS/IT evaluations may seem likely to exceed benefits. However, several positive issues (Issues 9, 15, and 16) from this case study indicate that the use of a benefits realisation methodology enabled greater control and better management of outsourcing contracts.

Despite large investments in IS/IT over many years, it has been difficult for organisations to determine where benefits have occurred, if indeed there have been any. IS/IT investment evaluation practice remains a hotly debated topic in the IS literature. Little published work has been conducted in Australia and there is still a lot to be learned in the area of processes and practices of IS/IT investment evaluation and benefits management. We hope that more studies of the practice of IS/IT investment evaluation will benefit other researchers in this field and the business community as a whole. Through the research program introduced in this article it is hoped that better approaches may be developed for Australian organisations.

KEY TERMS

Benefits Management: A managed and controlled process of checking, implementing and adjusting expected results and continuously adjusting the path leading from investments to expected business benefits.

Benefits Realisation: See Benefits Management.

IS/IT Benefits Realisation Methodologies: Approaches that are used to ensure that benefits expected in the IS/IT investments by organisations are realised or delivered.

IS/IT Investment Evaluation: This is the weighing up process to rationally assess the value of any acquisition of software or hardware that is expected to improve business value of an organisation's information systems.

IS/IT Investment Evaluation Methodologies: Approaches that are used to evaluate organisations' IS/IT investments.

IS/IT Outsourcing: The process of transferring IS/IT assets, staff, and management responsibility for delivery of services from internal IS/IT functions to external contractors.

Productivity Paradox: Despite large investments in IS/IT over many years, there have been conflicting reports as to whether or not the IS/IT benefits have actually occurred.

Public-Key Cryptography

Eberhard Stickel
Hochschule der Sparkassen - Finanzgruppe
University of Applied Sciences, Bonn GmbH, Germany

INTRODUCTION

Secure transmission of private information is a crucial issue in today's highly computerized world. Cryptographic algorithms are used to provide privacy of message transmission and to certify authenticity of sender and/or receiver of a message and message integrity as well as undeniability of transmitted messages (Menezes et al., 1996).

The message that is sent by the sender is called the plaintext, the secured message is called the ciphertext. To get the ciphertext, the plaintext is encoded by the sender. The receiver reconstructs the plaintext from the ciphertext by decoding. For encoding and decoding so-called keys are used (Koblitz, 1994, p. 55).

In the simplest setting, sender and receiver have agreed on a common private key, which is kept secret. This is called symmetric key cryptography. The secret private key is utilized for encoding and decoding messages sent between the two parties. For encoding the plaintext is XOR-ed with the secret key. The decoding is done in the same way using the ciphertext and the secret key on the receiver's side (Menezes et al., 1996, p. 15).

To be specific, if for example the plaintext message is given by the bit string 10011101 and the secret key is 11011100, the ciphertext is then given by 01000001. By using XOR-operations with ciphertext and key once more the plaintext is returned. Note that the XOR operation between two bit is defined as follows: $0 + 0 = 1 + 1 = 0$, $1 + 0 = 0 + 1 = 1$.

If key length and length of plaintext do not coincide, the plaintext may be blocked. This leads to the concept of block ciphers (Menezes et al., 1996, p. 223).

Symmetric key techniques generally can be implemented very efficiently. The corresponding algorithms are very fast. The problem, however, lies in the fact that two parties must have agreed on a common key before they can start to communicate and exchange messages. This would be highly impractical, for example, for transactions in electronic commerce (Menezes et al., 1996, p. 31).

BACKGROUND

A major breakthrough was the publication of the Diffie-Hellman key exchange scheme (Diffie & Hellman, 1976). The technique developed by Diffie & Hellman allows one to agree on a secret key through an insecure channel,for example, the Internet. The authors rely on a problem that is hard to solve, at least using today's knowledge and computing power: Let p be a large prime or the power of a large prime. Let g be a number with $1 < g < p$. g and p are publicly known. Given $g^a \bmod p$ and $g^b \bmod p$, compute $g^{ab} \bmod p$. This is the so-called Discrete Logarithm problem. Here mod refers to division with remainder. $a \bmod b$ is the remainder, if a is divided by b. Details may be found in Menezes et al. (1996, p. 515). The security of the method relies on the fact that it is impossible to solve the sketched problem in feasible time if the prime p is large enough. No efficient algorithms for solving the Discrete Logarithm problem are yet known.

Suppose that Alice and Bob want to agree on a secret key over an insecure channel. The Diffie-Hellman method runs as follows:

- Alice has published p, g and $g^a \bmod p$ as her public key. a is kept secret as private key.
- Bob chooses b which is kept secret, forms $g^b \bmod p$ and $(g^a)^b \bmod p$ and submits the latter number to Alice.
- Alice computes $(g^{ab})^{1/a} = g^b \bmod p$. This is the secret key exchanged.

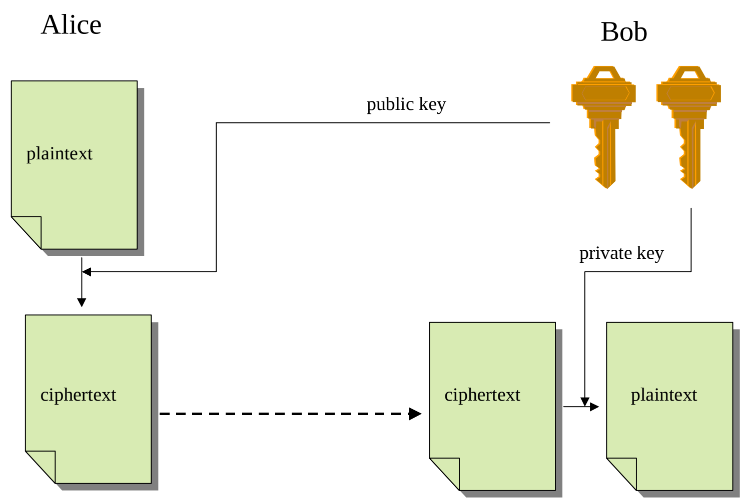
Note that various components of the algorithm are now publicly known. It is therefore called a public-key algorithm.

Various public-key algorithms are discussed in the literature and employed in practical applications. Probably the most famous algorithm is the RSA-algorithm, denoted by RSA after its founders Rivest, Shamir, & Adleman (Rivest et al., 1978). *Figure 1* shows the details.

RSA relies on the problem of factoring large numbers, for example, the product of two 1024-bit prime numbers. No algorithm exists so far that allows one to solve such a problem in feasible execution time. The basic idea of RSA is the following:

- Suppose Alice wants to transmit a secret message to Bob. Alice gets Bob's public key,for example, by accessing his Internet site.
- Alice encrypts the plaintext using the public key of Bob. Then she transmits the ciphertext to Bob.

Figure 1. Public-key cryptography



- Bob uses his secret private key to decrypt the ciphertext and recover the plaintext.

Generally public-key algorithms require a pair of keys. The public key is published, while the private key is kept secret. The public key is used for enciphering a message, while the private key is used to decipher the ciphertext.

Applying public-key methods for transmitting secret data is not efficient. The underlying algorithms are much slower and more complex than symmetric key methods (Menezes et al., 1996, p. 31). Typically a public-key algorithm is used to agree on a symmetric session key. During the session, data are protected by encrypting plaintext with the symmetric key obtained. This approach combines the advantages of symmetric and public-key technology.

Note, that there is still a problem that needs to be solved. It is necessary to assure the authenticity of the public key of a person, for example, of Bob's in the explanation of the RSA-algorithm. Otherwise, it is possible that a potential third party adversary pretends to be Bob (bogus identity). He would provide his public key to Alice, Alice would encrypt the plaintext using this key and the adversary would be able to read the secret message that was addressed to Bob. To solve this problem, trust-centers that certify the authenticity of public keys have been implemented (Menezes et al., 1996, pp. 491, 547, 581).

DIGITAL SIGNATURES

Public-key algorithms as discussed in the last section allow one to encipher secret messages. Thus, they provide privacy of information transmission. Especially in electronic commerce it is necessary to assure authenticity of messages as well as of communication partners. This is done by means of digital signatures (*Figure 2*).

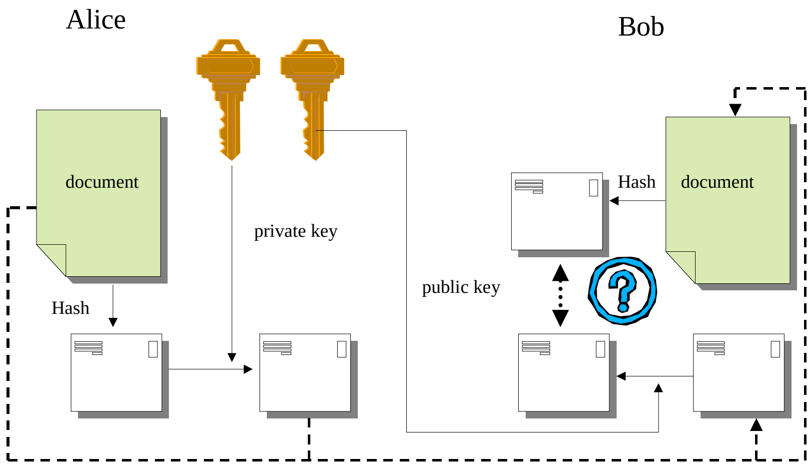
Fortunately, most of the well-known public-key techniques need only slight modifications in order to be used as digital signatures. The basic idea is as follows (Zhang & Wang, 2003, p. 24):

- Suppose Alice wants to sign a message *m* and forward it to Bob. First, Alice computes a so-called digital fingerprint *d* of the message *m*. This fingerprint usually consists of a bit string of a certain length that corresponds to the message *m*. Alice signs *d* with her private key. This means that Alice encrypts *d* using her secret private key.
- Bob fetches the public key of Alice and decrypts the signature. He thus holds *d* as well as the message *m*. A digital fingerprint *d'* is computed from the transmitted message. If $d = d'$, he accepts message and signature, otherwise the transaction is rejected.

Digital fingerprints are computed using so-called hash functions. A hash function compresses a message to a bit string of specified length. Hash functions should be collision resistant and not invertible. Collision resistance implies that two different (meaningful) messages should have different fingerprints (hash values). Lack of invertibility assures that it is infeasible to construct a meaningful message given a specified digital fingerprint. For details refer to Goldreich (2001, p.136).

Note, that in the process of signing the roles of private and public key are simply interchanged.

Figure 2. Digital signatures



If the two digital fingerprints computed do not coincide, the message has been corrupted or the sender did not provide a valid signature. In either case it is correct to reject the transaction.

Various signature schemes are discussed in the literature. Popular candidates are DSA (Digital Signature Algorithm), which is based on RSA (Menezes et al., 1996, p. 452) or ElGamal signatures (Menezes et al., 1996, p. 454).

Again, it is important to certify the correctness of the public key of the signer. As already indicated in the previous section this is generally done by trusted third parties. Such trust centers provide certificates signed by their digital signatures. Their signatures are certified in turn by trusted parties on a higher hierarchic level and so on (Li & Wang, 2003, p. 39).

Of course, it is possible to combine secure message transmission with digital signatures. In this case, sender and receiver need to possess a pair of private and public keys. The sender encrypts the message using the public key of the receiver. He also signs a fingerprint of the message using his private key. The receiver decrypts the message using his private key. He also decrypts the digital fingerprint using the public key of the sender. He then computes a digital fingerprint of the decrypted message and compares it to the decrypted fingerprint received. In case of equality the transaction is accepted, otherwise it is rejected.

FUTURE TRENDS

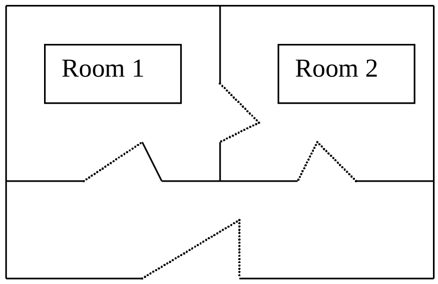
In many applications it is necessary to identify potential users to providers of resources (typically hosts or servers). If the identification is successful, access is granted. Passwords still are widely used for identification purposes. The use of passwords, however, has severe drawbacks (Menezes, 1996, p. 388). The password is usually transmitted. This allows password sniffing by potential adversaries. There is also potential hazard that users act carelessly with their passwords. One example is the use of meaningful, easy to guess passwords. The password is usually stored in a file located on the server. This password file may be attacked and corrupted. Various possibilities exist to improve on these potential weaknesses. In any case, however, meaningful data for identification purposes have to be transmitted. This is why passwords are considered as weak authentication techniques (Menezes et al., 1996, p. 388).

Challenge and response techniques provide a higher level of security. Server and client generally share a common secret key. The server randomly generates a bit string and sends it to the client (challenge). The client encrypts the bitstring using the shared secret key and resends the ciphertext to the server (response). The server checks by decrypting if the correct key was used (Menezes, 1996, p. 397).

Challenge and response identification does not require transmission of secret information (passwords). It still requires storage of a secret common key on the server, however. The corruption of the corresponding file is a potential hazard.

To summarize, it is desirable that secret information is neither transmitted nor stored on the server side. Zero-knowledge authentication schemes have been developed for this purpose (Goldreich, 1999, p. 12; Menezes et al., 1996, p. 405). A completely non-mathematical treatment of this rather quantitative subject can be found in Quisquater et al. (1990).

Figure 3. Illustration of zero-knowledge protocols



Zero-knowledge protocols allow one to prove to a third party that someone knows a secret without revealing this secret. The illustration in *Figure 3* will be used to motivate the key ideas behind this approach.

Figure 3 shows a house with an entrance hall and two rooms that may be accessed via the entrance hall. There is a door between the two rooms, which is generally locked. Only Alice has the secret key to open the door between these two rooms.

Suppose now that Alice wants to convince Bob that she has the key (i.e., that she knows a secret) without showing the key to Bob or letting Bob go into the two rooms (i.e., without revealing her secret).

At the beginning, Alice and Bob stand in front of the closed door of the entrance hall. Alice proceeds inside and closes the door. She then randomly goes into the left or the right room. Let us assume that in the first round she chooses the left room. Bob enters the hall and randomly chooses a bit b. If $b = 1$ he orders Alice to step out of the right door, otherwise he orders Alice to step out of the left door. In case $b = 0$, Alice may easily step out of the door without using her secret key. In case $b = 1$, she has to use the secret key enabling her to step out of the right door.

If Bob's choice is purely random, Alice has a chance of exactly 50% of stepping out of the correct door without having to reveal her secret. Thus, she may cheat with a probability of 50%. Conversely, Bob knows with a probability of 50% that Alice indeed possesses the secret key.

In order to reduce the probability of cheating this experiment has to be repeated for a suitable number of times. After 10 successful trials for example the probability of cheating is less than 0,1% (exactly $2^{-10} = 1/1024$). Thus, it is possible to reach arbitrary high levels of security that Alice knows the secret. Absolute security, however, can never be gained. This is why the approach sketched is called a probabilistic approach.

The idea sketched in *Figure 3* may be formalized in order to get an executable protocol. Usually the Fiat-Shamir protocol is applied (Fiat & Shamir, 1987). The security of this protocol relies on the difficulty of extracting discrete square roots. Let n be a composite number (e.g., the product of two distinct large prime numbers). The problem of computing x if $x^2 \bmod n$ is known is a computationally hard problem (comparable to the Discrete Logarithm problem and the problem of factoring large integers). The secret used in this protocol is the knowledge of a square root of a known integer $y \bmod n$. When executing the protocol a third party should be convinced that such a square root is known without revealing the square root.

CONCLUSION

Public-key cryptography is widely used in today's computerized world. Public-key algorithms allow to secure the privacy of communication and to assure the integrity of exchanged messages and the identity of the sender of a message (digital signatures). They may also be used for solving the identification problem between clients and servers offering valuable resources. Public-key algorithms rely on the existence of computationally hard problems such as the Discrete Logarithm problem. If the underlying problem size (key size) is large enough, it is infeasible to break these algorithms using today's knowledge and computing power. However, knowledge and computing power are permanently improving so that consequently the key size needs to be increased continuously. Public-key techniques are also applied in the area of electronic payment systems (Kou, 2003).

An excellent more detailed summary of current techniques and research in this area may be found in Delfs & Knebl (2002) or Biham (2003).

KEY TERMS

Symmetric-Key Cryptography: Sender and receiver agree on a common secret key. This key is used to exchange encrypted messages.

Public-Key Cryptography: Public-key cryptography allows the exchange of encrypted messages without prior key agreement. The receiver of an encrypted message has a secret private key and a published public key. The public key is used by anyone who wishes to send a message to the receiver. Only by means of the private key of the receiver, can the original message be retrieved by decoding.

Trust Center: It is important to assure the identity of the owner of a public key. Otherwise potential adversaries may pretend to have another identity by using their own public keys in confidential transactions. Trust centers certify the identity of owners of public keys.

Digital Signatures: Digital signatures may be used to electronically sign documents. The signature can be checked by anyone and if properly used assures integrity of the signed message, as well as the identity of the signer.

Digital Fingerprints: Larger documents are not signed in its entirety. Generally a digital fingerprint of the larger document is computed and signed. For this purpose hash functions are used. They should be collision resistant and not invertible. Then two different meaningful messages have different fingerprints and it is not possible to construct a meaningful message, given a fingerprint.

Challenge and Response: This is a cryptographic technique used to identify a client to a server. Server and client share a common secret key. The server sends bit strings (challenges) to the client who encrypts these strings and resends them to the server (response). The server may then check the correctness by applying the secret key and comparing the result to the original bit string.

Zero-Knowledge Protocol: This is another cryptographic technique to provide identification to a third party. For this purpose and in contrast to other techniques no secret information is transmitted between the communicating partners. Nor is any secret information stored on the third parties server. Zero-Knowledge protocols try to prove that the client knows a secret without revealing this secret to a third party.

Computationally Hard Problems: A mathematical problem is considered computationally hard if a slight increase in problem size dramatically increases the time for solving the problem. Typically, runtime is an exponential function of problem size for computationally hard problems. A lot of cryptographic applications are based on computationally hard problems like the Discrete Logarithm problem, the Discrete Square Root problem and the problem of factoring large integers.

Q

QoS-Oriented MAC Protocols for Future Mobile Applications

Alexander Markhasin
Siberian Telecommunications University, Russia

Stephan Olariu
Old Dominion University, USA

Petia Todorova
Fraunhofer FOKUS, Germany

INTRODUCTION

Common intended access to a physically unshareable resource requires arbitration. Since in wireless communications the transmission medium cannot be shared without loss of information, *medium access control* (MAC) plays the role of an arbiter stipulating, for each of the intended users, the conditions and parameters of exclusive access rights. The major challenge in designing a good MAC protocol is to provide each user with the negotiated quality-of-service (QoS) parameters while, at the same time, utilizing the network resources as efficiently as possible. Thus, an ideal MAC protocol must strike a balance between the conflicting goals of QoS provisioning, efficiency, simplicity, and service controllability. The MAC protocol improvements ensure a dominant effect on the development of the QoS and other future breakthrough wireless technologies.

BACKGROUND

Future generation of global wireless and satellite multimedia communications for mobile multi-service applications requires dynamic (soft) control and stringent QoS guarantees. The MAC technology employed depends on the bandwidth allocation strategy, the scheduler algorithms used, and on the MAC protocol itself. As showed in Markhasin, Olariu, and Todorova (2004), QoS-oriented MAC technology, along with the all-IP/ATM architecture, is expected to provide cost-efficient broadband multi-service to mobile and geographically distributed users anytime and anywhere.

Assume that at some time t the system contains N_t mobile users belonging to k data priority service classes, with input multimedia traffic intensities G_{ikt}, output traffic intensities S_{ikt}, and total input intensity $G_t = \sum_{i,k} G_{ikt} \le C_{MAC}$, where C_{MAC} is the MAC protocol efficiency, and $C_{MAC} = \max_{\{G_t,t\}} \sum_{i,k} S_{ikt}(G_{ikt})$. A *QoS-oriented MAC* protocol must guarantee for each point in time t belonging to some interval $[t_1, t_2)$ the following required values:

a) QoS characteristics: average delay, loss probability, throughput;
b) traffic parameters: peak and average rates; and
c) bandwidth: the amount of bandwidth necessary to support the negotiated QoS.

Perhaps the most natural and straightforward arbitration strategies used in MAC is token based. Specifically, an artifact known as the *token* regulates access to the transmission medium. The arbiter allocates the token to users according to a scheduling strategy. The user that possesses the token has access to the resource; once the token is relinquished, the access right to the resource is lost. Many multimedia applications require effective control of the *token requests generation rate* variation, including token bank fair queuing (TBFQ) proposed in Wong, Zhu, and Leung (2003), recurrent M-sequences RS-token broadcast reservation (TBR-RS) proposed by Markhasin (1996), and also scheduler algorithm *priority parameters* regulation, local queue *buffer size*, and *ARQ quantity* of automatic request for repeat adjusting, as also shown in Markhasin (1996).

One can define static (*hard) QoS provisioning* as a session with static control parameters satisfying predetermined traffic profiles $G_{ikt} = const(t)$. Bandwidth resource $Y_{it} = const(t)$, ...$t \in [t_1, t_2)$ and other control parameters are regulated at long-term intervals only. Therefore hard QoS out-of-profile traffic is not guaranteed, so that performance degradation is possible (Wong et al., 2003).

Similarly, one can define *soft QoS provisioning* as a session with dynamic controlled/adapted QoS characteristics according to traffic profiles variation $G_{ikt} = \mathrm{var}(t)$. Bandwidth resource $Y_{it} = \mathrm{var}(t)$, $\ldots t \in [t_1, t_2)$ and other control parameters are regulated at short-term intervals (Markhasin, 1988).

According to Fattah and Leung (2002) and Wong et al. (2003), existing scheduler algorithms can be classified as *work-conserving* with non-priority service disciplines and *non-work-conserving* using priority service disciplines.

In order to develop QoS-oriented MAC protocols for all-IP/ATM mobile applications, Markhasin (2001) shows that one has to overcome three main impediments:

- the time barrier: concerning the degradation of long-delay MAC efficiency when the round-trip time is significantly increased;
- the dynamical barrier: concerning the instability of the dynamic on-the-fly control of QoS provisioning; and
- the economic barrier: concerning the unacceptably large cost of the wireless broadband ATM networks with centralized architecture.

A SURVEY OF MAC PROTOCOLS

The main goal of this section is to provide an overview of various proposed MAC protocols and to compare them in terms of their ability to provide mobile users with QoS guarantees. Historically, *ALOHA* was the first MAC protocol offered for packet radio networks proposed (Abramson, 1970). It is classical *free (random) access* protocol. Unfortunately, the maximum throughput of this protocol is only 1/2e. Some two years later, the well-known *slotted ALOHA*, which doubles the efficiency of ALOHA, was offered (Roberts, 1972). The next fundamental contribution was the development of several *carrier-sense* protocols, known generically as CSMA (Kleinrock & Tobagi, 1975). Some multi-access methods, later referred to as slotted and non-slotted ALOHA and CSMA, were proposed and analyzed (Markhasin, 1969). There also the *slotting effect* about protocol efficiency increasing was opened. Rubin (1979), Tobagi (1980) and others show that the majority of other classical *free*, *controlled*, and *hybrid* access methods were also proposed in the 1970s-1980s.

The first generation of MAC protocols was not QoS-aware. Some adjusting mechanisms were used for adapting the time intervals division mainly to burst data traffic. Differentiation and service quality control problems were raised in the 1980s for integrated packet radio and satellite networks (Rubin, 1979; Li, 1984; Markhasin, 1985). The development of asynchronous transfer mode (ATM), along with multimedia information technologies and *m-applications*, triggered an interest in guaranteed QoS control. Wong et al. (2003) noted that much research has been focused on hard QoS provisioning of integrated services. For *short-delay wireless media*, *hard QoS-aware* demand assignment protocols SFRs type, including DQRUMA (Karol, Liu & Eng, 1995) and others (for an overview, see Gumalla & Limb, 2000). The TBQF scheduling scheme for wireless packet-switched networks, which provides *soft QoS* guarantees for heterogeneous traffic, was also proposed (Wong et al., 2003).

The soft QoS-oriented multifunctional medium access control (MFMAC) technology for *long-delay satellite mediums* was proposed by Markhasin (2001), who also introduced MFMAC technology based on soft QoS-aware RS-token broadcast reservation (TBR-RS) MAC protocol (Markhasin, 1996). This protocol uses the recur-

Table 1

a) MAC classification matrix with protocol examples

Access regulation mechanism \ Time process access to medium		Stochastic access process: Continuous process	Stochastic access process: Discrete process – Definite frame	Stochastic access process: Discrete process – Adaptive frame	Deterministic (Fixed) access process
Controlled access	Centralized controlled access	Non-slotted Polling	DAMA, FPODA, ARDA, SFR	Slotted Polling	S-TDMA, PAMA

2b) Long-delay efficiency (*Time barrier* overcoming)

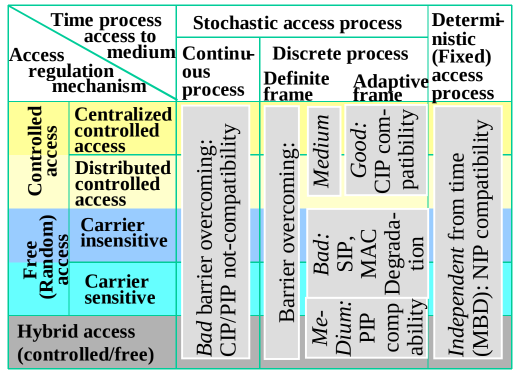

Table 3

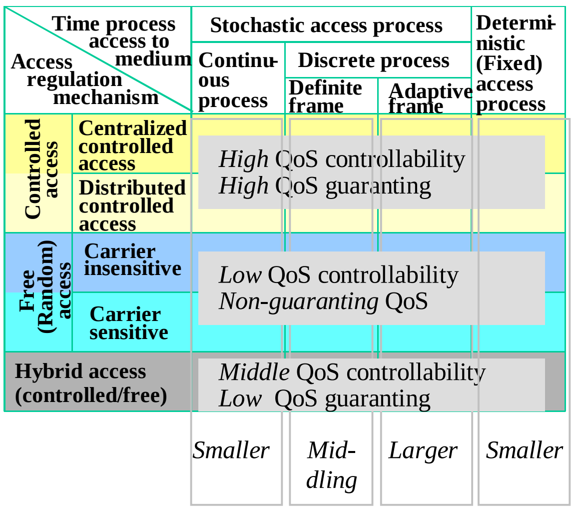
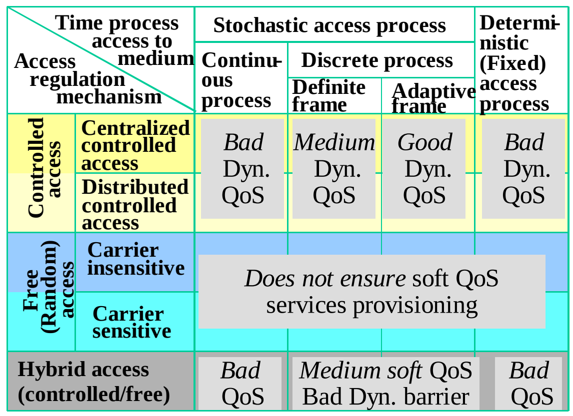
3a) Static QoS Control



3b) Soft QoS Control (dynamical barrier overcoming)



rent M-sequences (RS) MAC-addressing opportunities to organize highly effective multiple access to long-delay space mediums. Based on TBR-RS MAC protocol, the multifunctional broadband ATM Spacemedium Hyperbus Architecture for satellite multimedia system was developed and presented (Brand et al., 2001). A satellite communication *scheduler problem* consisting of reservation and allocation of network resources to individual connections before data transmission, based on the information available, was clearly stated and investigated (Todorova & Markhasin, 2003). A novel paradigm for future m-commerce applications was proposed and implemented based on a completely distributed all-IP/ATM architecture for global satellite multimedia communications and soft QoS-oriented MAC technology (Markhasin, Olariu & Todorova, 2004).

For comparison of QoS-oriented MAC protocols, matrix systematization is well suited (Markhasin, 1984). Matrix systematization is based on two fundamental characteristics of MAC protocols: the matrix rows represent the *media access regulation mechanisms*, and the matrix columns represent the *media access time processes* (Table 1).

Table 1b shows an example of MAC protocols short-delay (medium bit delay MBD ≤ 10 bit) efficiencies. One can see that the matrix *ij*-th elements of MAC protocol characteristics are correlated via matrix *i*-th strings and *j*-th columns, respectively. As shown by Markhasin (1984), the highest short-delay efficiency ensures the adaptive protocols with controlled access mechanisms, adaptive time process, and smallest MAC expenses (see Table 1b).

Table 2 illustrates a comparison of MAC protocols in terms of short-delay and long-delay (MBD much larger than 10 bits) efficiency and real maximum throughput criterions. The MAC protocols with *adaptive frame* time processes (third column) ensure a highest short-delay efficiency and real maximum throughput. The same column protocols with controlled access and parallel-conveyer MAC instruction processing ensure the best time barrier overcoming abilities (Markhasin, 1996).

Table 3 compares MAC protocols in terms of soft QoS-provisioning capabilities. The following criteria were assumed: a) for static (hard) control—as its characteristics of the *controllability*, *differentiation*, and *guarantee* by the QoS and traffic parameters control, and bandwidth resources assignment; b) for dynamic (soft) control—as, added to criteria defined above, the *dynamical efficiency* and *stability* by the dynamical QoS and traffic parameters control, and bandwidth resources assignment.

The best soft QoS capabilities ensure MAC protocols with *adaptive frame* time access, *controlled (reservation)* access mechanisms, and *parallel-conveyer processing* of MAC instructions. One of them is the MAC protocol TBR-RS, which provides stable and automatic "on-the-fly" adaptation of the M-periodical hyperframe to traffic intensity (Markhasin, 1988, 1996). At the same time, this protocol allows one to realize universal RS-token MAC tools *"all-by-one"* for soft (up to real-time) control of QoS, traffic parameters, and bandwidth resources.

FUTURE TRENDS

Now that mobile networks are being called upon to support real-time interactive multimedia traffic, such as video tele-conferencing, these networks must be able to provide their users with quality-of-service (QoS) guarantees. Although the QoS provisioning problem arises in wireline networks as well, mobility of hosts and scarcity of bandwidth makes QoS provisioning a challenging task in wireless networks. It has been noticed that multimedia applications can tolerate and gracefully adapt to transient fluctuations in the QoS that they receive from the network. The management of such adaptive multimedia applications is becoming a new research area in wireless networks. As it turns out, the additional flexibility afforded by the ability of multimedia applications to tolerate and to adapt to transient changes in the QoS parameters can be exploited by protocol designers to significantly improve the overall performance of wireless systems. A major role in the task of QoS provisioning for multimedia application will be played by the MAC technology.

CONCLUSION

This article introduces an advanced QoS-aware MAC technology and a fully distributed architecture for future global wireless multi-service platforms 3G+/4G, which can support an integrated set of mobile multimedia applications, such as m-commerce, m-enterprise, m-business, m-positioning, e-government, e-work, e-education, e-health, e-culture, and so forth. This QoS-oriented MAC technology provides advanced broadband communication multi-services for a large population of geographically dispersed users, in support of anytime-anywhere communications.

KEY TERMS

Collision: A usually destructive event resulting from the simultaneous access to the same bandwidth resource by multiple users.

Multiple-Access (MA): Procedures regulating the simultaneous use of a common transmission medium by multiple users.

Controlled MA: A class of coordinated centralized or distributed collision-free *multiple- access* protocols.

Free (random) MA: A class of non-coordinated distributed *multiple-access* protocols where *collisions* may occur.

Hybrid MA: A class of *multiple-access* consisting of a combination of *controlled multiple-access* and *free multiple-access*.

Medium Access Control (MAC): According to the OSI terminology, an interface between the physical layer and LLC sub-layers.

Medium Access Control (MAC) Protocol: A set of rules, algorithms, and interfaces that define and control access to a common *medium*.

Quality of Service (QoS): A collection of performance parameters for network service including bandwidth, average delay, jitter, packet loss probability, among many others.

Qualitative Methods in IS Research

Eileen M. Trauth
The Pennsylvania State University, USA

INTRODUCTION

As information technologies have evolved, so too has our understanding of the information systems that employ them. A significant part of this evolving understanding is the role of the human contexts within which information systems are situated. This, in turn, has led to the need for appropriate methods of studying information systems in their context of use. Just as decisions about information systems need to be considered within their contexts of use, so also do choices about the appropriate research methodologies to employ for studying them. Increasingly, qualitative methods are chosen as an appropriate method for studying contextual aspects of information systems development, use and impact.

Qualitative research refers to research methods that engage in the interpretation of words and images rather than the calculation of numbers. These methods include: ethnography, case study, action research, interviews, and text analysis (i.e., conversation analysis, discourse analysis, and hermeneutics). Qualitative research can be theory-driven in much the same way as quantitative analysis. However, it can also employ grounded theory techniques in order to develop theory (Glaser & Strauss, 1967).

Following some early uses of qualitative methods in the 1980s (e.g., Benbasat et al., 1987; Kaplan & Duchon, 1988; Lee, 1989; Mumford et al., 1985), there has been a significant growth in the use of qualitative methods for information systems research since the 1990s (e.g., *Journal of Information Technology*, 1998; Lee et al., 1997; *MIS Quarterly*, 1999, 2000; Nissen et al., 1991; Trauth, 2001).

Accompanying the increased use of qualitative methods for IS research has been a discussion of various methodological issues. Among the key aspects of this dialogue are discussions about the suitability of qualitative methods for various types of research and issues arising from a particular type of qualitative methods: interpretive methods. This article presents a reflection on some these discussions in the form of a consideration of five factors that can influence the choice of qualitative (particularly interpretive) methods for information systems research.

FACTORS INFLUENCING THE DECISION

The Research Problem

The research problem, *what* one wants to learn, should determine *how* one goes about learning it. Heaton (1998) chose observation, interview and document analysis to examine the social construction of computer-supported cooperative work in two different cultures in order to learn how the meaning of "culture" was reflected in the design of systems. Trauth (2000) used ethnographic methods to explore the influence of socio-cultural factors on the development of a nation's information economy. Bentley et al.'s (1992) ethnographic study of the work practices of air traffic controllers informed their design of an interface to an air traffic control database. Walsham and Sahay (1999) conducted extensive interviews to gain an in-depth understanding of the implementation of geographical information systems for administrative applications in India. Phillips (1998) employed public discourse analysis to reveal the way in which concerns about anonymity, surveillance, and privacy are integrated into public understanding of a consumer payment system.

The Epistemological Lens

Orlikowski and Baroudi (1991) considered the influence of the epistemological lens – positivist, interpretive or critical – on the conduct of IS research. While there is some positivist, qualitative IS research (e.g., Lee 1989), most qualitative IS research is either interpretive or critical because of the assumption that "our knowledge of reality is a social construction by human actors" that precludes obtaining objective, value-free data (Walsham, 1995, p. 376). The interpretive epistemology has also spawned IS research employing hermeneutic methods (e.g., Boland, 1985, 1991, and Trauth & Jessup, 2000). Ngwenyama and Lee (1997) used the critical lens to examine information richness theory.

The Uncertainty Surrounding the Phenomenon

According to Galliers and Land (1987), the added complexity from including relations with people and organizations in a view of information systems introduces greater imprecision and the potential for multiple interpretations of the same phenomenon. Hence, alternatives to quantitative measurement are needed. Others argue that the less that is known about a phenomenon the more difficult it is to measure it. Benbasat et al. (1987) explained that the case study approach is appropriate for IS research areas in which few previous studies have been carried out. Paré and Elam (1997) built theories of IT implementation using case study methods. Orlikowski's (1993) rationale for choosing qualitative methods and grounded theory to study the adoption of CASE tools rested on the absence of systematic examination of the organizational changes accompanying the introduction of CASE.

The Researcher's Skills

The absence of formal study of qualitative methods may serve as a barrier to choosing these methods. Orlikowski (1991) suggested that institutional conditions have inhibited the teaching of qualitative methods because of the functionalist/positivist perspective of American business schools where IS is typically taught. These institutional conditions, within which doctoral studies are conducted and dissertations are written, have inhibited the use of alternative research paradigms and methodologies with long-term implications for the choice of methods used in IS research. Schultze's (2001) reflection on her decision to choose interpretive methods for her dissertation illustrates the importance of institutional influence. Exposure to advisors with expertise in interpretive methods gave her methodological opportunities not available to other students.

The Academic Politics

The choice of research methods is influenced by the country in which one works, whether one has completed the PhD, whether one has a tenured position, one's academic rank, and the particular inclinations of the university at which one works. The norms and values of the field are reinforced during one's education and beyond. What is taught in research methods seminars sets the standard for "acceptable" research. Advice to junior faculty, peer review of journal articles and the tenure review process all reinforce those norms and values. Fitzgerald and Howcroft (1998) described the polarization of positions into "hard" and "soft" perspectives. Klein and Myers (1999) contributed to closing this methodological divide by developing a set of principles for conducting and evaluating interpretive field studies.

FUTURE TRENDS

As our understanding of the context of information systems grows, our desire to understand and explain contextual factors will motivate researchers to explore new ways to employ qualitative methods. Therefore, we can expect greater use of the critical epistemological lens in the use of qualitative methods in IS research. We can also expect to see the increased use of *virtual* qualitative research methods. That is, the traditional face-to-face methods of data generation used in qualitative research will find increasing analogues in the virtual world. We can expect to see, for example, "virtual ethnographies," "virtual participant observation" and "online interviews".

CONCLUSION

The primary advantage of using qualitative, particularly interpretive, methods is the flexibility it affords the researcher during data generation and analysis. The main disadvantage of qualitative, particularly interpretive, methods is overcoming concerns about validity and generalization of findings. The concepts of both statistical validity and statistical generalization need to be redefined for qualitative research. The *MIS Quarterly* "Special Issue on Intensive Research" has addressed the validity issue by publishing exemplar research papers that provide evaluative criteria for other researchers to use in establishing validity. The generalizability issue is being addressed in thoughtful pieces such as the recent article by Lee and Baskerville (2003).

Despite these issues, the acceptance of qualitative methods for IS research is evidence of a growing consensus that these methods make a valuable contribution to the study of information systems in context. In making the decision to use qualitative methods a number of factors must be taking into consideration. These factors relate to the characteristics of the research problem, the researcher and the research environment.

KEY TERMS

Case Study: An examination of a phenomenon in its natural setting using fixed boundaries such as time.

Critical Research: Critique of the status quo through the exposure of what are believed to be deep-seated, structural contradictions within social systems.

Ethnography: Research characterized by an extended period in the field and which involves the researcher being immersed in the community being studied.

Grounded Theory: A method used to systematically derive theories of human behavior from empirical data.

Interpretive Research: Exploring the deeper structure of a phenomenon within its cultural context by examining the subjective meanings that people create.

Positivist Research: Research premised on the existence of a priori fixed relationships among phenomena.

Qualitative Methods: Methods for data collection and analysis that focus on understanding of text and observation rather than numeric calculation.

Quality Assurance Issues for Online Universities

Floriana Grasso
Liverpool University, UK

Paul Leng
Liverpool University, UK

INTRODUCTION

Online delivery of degree-level programmes is an attractive option, especially for working professionals and others who are unable to contemplate full-time residential university attendance. If such programmes are to be accepted, however, it is essential that they attain the same standards and quality as conventionally delivered degrees. The key challenge is to find ways to ensure that the qualities that make university education attractive are preserved in the context of a new and quite different model of delivery.

Many systems have been developed to support online learning (see, e.g., Anderson & Kanuka, 1997; Davies, 1998; Persico & Manca, 2000; Suthers & Jones, 1997; Yaskin & Everhart, 2002). These systems may or may not mimic conventional lecture-room teaching, but will necessarily involve major differences in the ways in which teaching and student support are organised. Furthermore, the Internet lends itself naturally to an internationalisation of education delivery, but this also poses challenges for universities that have developed their structures within the framework of national education systems. To address these issues, it may be desirable for the university to work in partnership with other agencies, for example to provide local support services for students. This too, however, may introduce new problems of quality control and management. We will discuss here what structures are required to ensure the quality of the education provided and the standards of the degrees offered in this context.

BACKGROUND

The emergence of the Internet as a way of delivering higher education has led to examinations of its implications for education policy in many national and international contexts. A set of benchmarks for quality of online distance education was developed by the (U.S.-based) Institute for Higher Education Policy (2000). This identified a total of 24 benchmarks, in seven categories. In the UK, the Quality Assurance Agency for Higher Education has issued guidelines on the Quality Assurance of Distance Learning (QAA, 2000a), with a similar scope to those of the IHEP. A comparison of the main headings of the two frameworks is illustrated in Table 1. Also relevant, when the delivery model involves partnership with external agencies, is the QAA Code of Practice in relation to Collaborative Provision (QAA, 2000b). Similar issues are examined in an Australian context by Oliver (2001), and from Hong Kong by Yeung (2002). Yorke (1999) discusses quality assurance issues in relation to globalised education, touching especially on collaborative provision. Other perspectives are offered by Pond (2002), Little and Banega (1999), and Davies et al. (2001).

Much of the work in this field reflects "an implicit anxiety that the 'values' of traditional teaching may some-

</table>

how be eroded" (Curran, 2001). There is consequently, in most prescriptions, a strong emphasis on replicating in an online context the characteristics of quality that we might expect to (but do not always) find in conventional teaching. Thus, one of the precepts of (QAA, 2000a) calls for "…..managing the delivery of each distance learning programme of study in a manner that safeguards the academic standards of the award"; and one of the benchmarks of the IHEP specifies that "Feedback in student assignments is provided in a timely manner". Unexceptionable as they are, these requirements are not peculiar to online distance learning. The key issue is not, therefore, one of defining quality assurance criteria, but rather that of providing structures to ensure their implementation.

QUALITY ASSURANCE FOR ONLINE DEGREES

Pedagogic Issues

Before examining quality assurance as such, we will first consider questions relating directly to the pedagogic approach used in online learning. In this respect, the premise that quality in online learning involves only a replication of on-campus characteristics is, we believe, limiting. We start, instead, from the standpoint that lecture-based teaching, whatever its merits, is not necessarily an ideal which online teaching must emulate. Students all too frequently attend lectures in an entirely passive mode, expecting to listen and receive the information they require while making no positive contribution themselves. Interaction between lecturer and students, and within groups of students is low, especially in the large classes that are typical of modern universities.

Conversely, online teaching makes it possible to recreate, through the medium of moderated online discussion, an atmosphere that is closer to that of a small-group on-campus seminar, and, paradoxically, can be far more involving and interactive than is typically the case in on-campus teaching. Two broad principles inform the approach: *constructivism* (Wilson, 1996), and *collaborative enquiry*. Collaborative enquiry via Internet-mediated communication provides a framework for this mode of learning (Stacey, 1998). The aim is to use the medium to foster the creation of a *learning community* (Hiltz & Wellman, 1997) that will enable dialogue between participants, sharing of information, and collaborative project work.

Moderated discussion (Collins & Berge, 1997) is a key feature of the teaching paradigm here, and serves a number of purposes that are relevant to the question of quality. Most obviously, it provides the means by which students may share information and experience, comment on the course materials and assignments, raise questions, and bring to the class knowledge and expertise that is outside the experience of the course teacher. To a significant extent, the students thus participate actively in the teaching process, augmenting the overall learning experience. Less obviously, there are other issues of quality in which classroom discussion can have a role; we will discuss these next.

Quality Assurance Issues

Key issues of quality assurance in an online degree programme include:

- Academic control
- Academic standards
- Staff appointment and training
- Monitoring of programme delivery
- Assessment procedures
- Student identity and plagiarism
- Student progression and support

Our review of these issues, next, draws on our experience with the online degree programmes at the University of Liverpool (Gruengard, Kalman & Leng, 2000).

Academic Control

The primary requirement of the frameworks defined by the QAA and other bodies is that all academic aspects of an online degree programme should remain the responsibility of the parent university, which should have structures and procedures that are effective in discharging this responsibility. The issue here is that the academic standards and quality of the programme may be threatened by differences between the parties involved in its delivery, especially when there is only an indirect relationship between the university and some of the people involved (for example, regional partner organisations, or locally-based tutors).

In principle, these problems can be resolved by placing online degree programmes firmly within the framework defined by the university for approving and managing its courses. To oversee this, we have at Liverpool established a dedicated organisational unit within the university, the e-Learning Unit.

Academic Standards

A corollary this is that, wherever possible, the quality management of an online programme should follow procedures that are comparable to those established for other degrees of the university, especially in respect to those procedures that define and maintain the academic standards of the degree. These will include course and module approval and review procedures, assessment criteria, and so forth. In most cases, it should be possible to exactly replicate the procedures that apply on campus.

Staff Appointment and Training

In the Liverpool University online programmes, teaching is principally carried out by part-time *instructors* who are based throughout the world. All appointments, however are subject to University approval using the same procedures and criteria that apply for the approval of non-established staff to teach on internal programmes. All instructors are required to first undertake an (online) training programme, over a period of 6 weeks, in which they are instructed on the use of the software platform and the methodology and pedagogic approach used in the programme. Further to this, in the first module they teach, the instructor is overseen by an academic *mentor* whose role is to advise and guide the novice.

Monitoring of Programme Delivery

A key aspect of quality assurance, especially when instructors as well as students are not campus-based, is the monitoring of module delivery. Interestingly, it is easier to do this effectively than is the case for on-campus teaching. In the Liverpool University model, *all* significant communications between staff and students are made electronically, as postings in or through a "virtual classroom". Thus, all are subject to scrutiny by "lurking" in the classroom while the module is being delivered, and/or by examining the recorded history of the class subsequently. In this way the academic staff of the e-Learning Unit monitor the delivery of each module to ensure that the appropriate standards and quality criteria are met. The module monitor is required to complete a report that also incorporates a review of feedback from students and the comments of the instructor. These reports are reviewed routinely by a Board of Studies.

Assessment Procedures

Assessment in this model is readily subject to moderation by the module monitor, who has access to all the relevant information contained in the record of the virtual classroom. Review of assessment outcomes is an explicit part of the end-of-module procedures, and these are finally subject to confirmation by the Board of Examiners, which in the UK framework includes an external examiner from another university. The external examiner also has full access to the virtual classroom and so, in practice, has the opportunity for a more detailed examination of assessment processes and standards than is usually possible in on-ground teaching.

Strict management of the assessment process is in our experience essential when instructors are drawn from a wide variety of cultures. In this case consistency of assessment can only be achieved by defining very clear grading descriptors and criteria, and by insisting that the interpretation of these is moderated firmly within the university's assessment model.

Student Identity and Plagiarism

One of the questions that most exercises organisations considering online learning is that of how to confirm the identity of participants, together with the related question of protecting against plagiarism. In this respect a key role is played by discussion in the virtual classroom. Participation in discussion provides a means of monitoring the effective involvement of each student, and assists in preventing impersonation and plagiarism. Research has shown (Klemm & Snell, 1996; Lai, 1997) that involvement in online discussion is rarely wholly effective unless moderated by external facilitators, and we believe that it is important that it be made a requirement, equivalent to the attendance requirements of on-campus degrees.

The fact that all communications take place online, and are recorded and preserved indefinitely, provides further protection against plagiarism. It is easy to apply programs that perform comparisons of work submitted in the virtual classroom, or use services that perform checks against plagiarism throughout the Web.

Student Progression and Support

The requirement to participate in online discussion also provides a means of monitoring student progress. If a student is failing to keep up with the requirements of the programme, this rapidly becomes apparent as his/her contributions to the discussion falter. At this point the instructor can intervene to investigate and take action if required.

FUTURE TRENDS

A key precept for quality assurance of online degree programmes is that, wherever possible, procedures and structures that are thought to be necessary on campus should have an online equivalent. As the previous discussion reveals, creating equivalent processes is usually

Table 2. Comparison of on-campus and online characteristics

	On Campus	**Online**
Teaching/learning mode	Predominantly lecture-based	Predominantly seminar-based
Interpersonal interactions	Low: via classroom discussions/questions	High: via moderated e-mail dialogue
Verification of student identity	Personal appearance	Textual/linguistic characteristics
Student support	Face-to-face meetings with tutors	E-mail interactions with tutors
Review of standards of attainment	Scrutiny of examination scripts	Inspection of work in online classrooms
Mentoring/monitoring of staff performance	Inspection of selected lectures/classes	"Lurking" in ongoing online classes

possible, but some significant differences emerge, highlighted in Table 2. The comparison of conventional lecture-based teaching with our model of online learning is not, we believe, to the disadvantage of the latter.

Although online degree programmes will not replace campus-based education, we believe there will be a strong future trend towards programmes that will meet particular areas of demand, especially the needs of working adults. Examples of successful online higher education programmes are, so far, relatively few, especially in Europe. We believe firmly that the successful programmes of the future will be those that focus on pedagogy, and give precedence to academic standards and quality assurance, rather than those that emphasise technological aspects or focus on low-cost delivery.

CONCLUSION

Quality in online degree programmes is often perceived to imply a replication of on-campus characteristics. We believe, conversely, that in some respects online delivery provides an opportunity to enhance the quality of learning opportunities for students. Especially this is so when the learning paradigm encourages a high degree of discussion and interaction between staff and students in the virtual classroom.

In other respects, it is indeed necessary to maintain comparability with on-campus degrees, especially in relation to academic standards. Here, however, the key issues do not relate to the definition of standards and quality criteria, but to the creation of mechanisms to uphold them. We believe it is necessary to establish well-defined and rigorous monitoring procedures for this purpose. Again, a learning environment that emphasises classroom discussion is a help in many aspects of quality management.

KEY TERMS

Constructivism: A form of learning in which students construct their own unique understanding of a subject through a process that includes social interaction, so that the learner can explain understandings, receive feedback from teachers and other students, clarify meanings, and reach a group consensus.

Globalised Education: Educational programmes in which both students and educators may be globally distributed.

Higher Education Programme: The processes, learning materials, and associated procedures and facilities that lead to the completion of a degree or related qualification.

Moderated Discussion: Discussion that is supervised, partly directed, and evaluated by a programme tutor.

Moderation of Assessment: External oversight of an assessment process to ensure that appropriate standards are maintained.

Online Learning: A programme of education that is carried out wholly or primarily through the medium of the Internet.

Quality of Education: Refers to the effectiveness of the programme in promoting student learning and achievement, in relation to its expected outcomes and standards.

Standards (of Education): Refer to the level of attainment achieved by students, in relation to the qualification awarded.

Virtual Classroom: An internet-mediated forum for distribution of learning materials, classroom discussion, and collaborative working.

Q

Quality of UML

John Krogstie
NTNU and SINTEF, Norway

INTRODUCTION

According to Booch, Rumbaugh, and Jacobson (1999), developing a model for an industrial strength software system before its construction is regarded increasingly as a necessary activity in information systems development. The use of object-oriented modeling in analysis and design started to become popular in the late eighties, producing a large number of different languages and approaches. Lately, UML (2004) has taken a leading position in this area.

In this article, we give an overview assessment of UML using a generic evaluation framework. We will first present the evaluation framework. We will then evaluate the language quality of UML before pointing to the future direction and potential of UML.

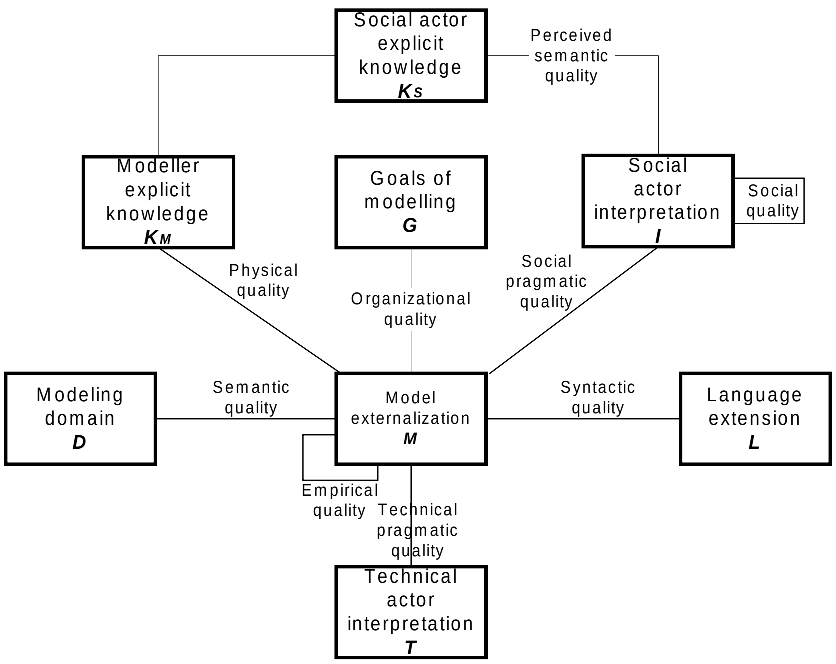
BACKGROUND

Krogstie, Sindre and Lindland (1995) and Krogstie and Sølvberg (2003) have developed a framework for quality of models and modeling languages.

The main concepts of the framework and their relationships are shown in Figure 1 and are explained in the following. Quality has been defined referring to the correspondence between statements belonging to the following sets:

- G, the goals of the modeling task.
- L, the language extension, that is, the set of all statements that are possible to make according to the graphemes, vocabulary, and syntax of the modeling languages used.
- D, the domain, that is, the set of all statements that can be stated about the situation at hand.
- M, the externalized model itself.
- K_s, the relevant explicit knowledge of those being involved in modeling. A subset of these is actively involved in modeling, and their knowledge is indicated by K_M.
- I, the social actor interpretation, that is, the set of all statements that the audience thinks that an externalized model consists of.
- T, the technical actor interpretation, that is, the statements in the model as "interpreted" by modeling tools.

Figure 1. Framework for discussing the quality of models



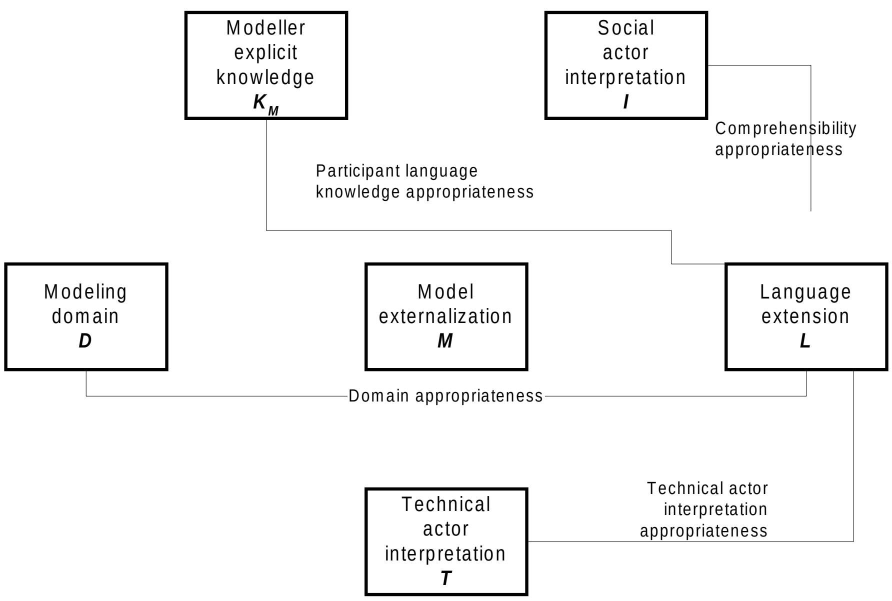
The main quality types are indicated by solid lines between the sets, and are described briefly in the following:

- Physical quality: The basic quality goals on the physical level are externalization, that the knowledge K of the domain D has been externalized, and internalizeability, that the externalized model M is available.
- Empirical quality deals with predictable error frequencies when a model is read or written by different users, coding (e.g., shapes of boxes) and HCI-ergonomics for documentation and modeling-tools. For instance, graph layout to avoid crossing lines in a model is a mean to address the empirical quality of a model.
- Syntactic quality is the correspondence between the model M and the language extension L.
- Semantic quality is the correspondence between the model M and the domain D. This includes validity and completeness.
- Perceived semantic quality is the similar correspondence between the audience interpretation I of a model M and his or hers current knowledge K of the domain D.
- Pragmatic quality is the correspondence between the model M and the audience's interpretation of it (I). We differentiate between social pragmatic quality (to what extent people understand the models) and technical pragmatic quality (to what extent tools can be made that interpret the models).
- The goal defined for social quality is agreement among audience members' interpretations I.
- The organizational quality of the model relates to that all statements in the model contribute to fulfilling the goals of modeling (organizational goal validity), and that all the goals of modeling are addressed through the model (organizational goal completeness).

Language quality relates the modeling languages used to the other sets. Four quality areas for language quality are identified, with aspects related both to the meta-model and the notation as illustrated in Figure 2.

1. Domain appropriateness. This relates to the language and the domain. Ideally, the conceptual basis must be powerful enough to express anything in the domain, not having what (Wand & Weber, 1993) terms construct deficit. On the other hand, you should not be able to express things that are not in the domain, that is, what is termed construct excess (Wand & Weber, 1993). Domain appropriateness is primarily a mean to achieve physical quality, and through this, to achieve semantic quality.
2. Participant language knowledge appropriateness relates the participant knowledge to the language. Participant language knowledge appropriateness is primarily a mean to achieve physical and pragmatic quality.
3. Participant comprehensibility appropriateness relates the language to the social actor interpretation. The goal is that the participants in the modeling effort using the language understand all of the possible statements of the language. Comprehensi-

Figure 2. Language quality in the quality framework



bility appropriateness is primarily a mean to achieve empirical and pragmatic quality.

4. Technical actor interpretation appropriateness relates the language to the technical audience interpretations. For tools interpretation, it is especially important that the language lend itself to automatic reasoning. This requires formality (i.e., both formal syntax and semantics being operational and/or logical), but formality is not necessarily enough, since the reasoning must also be efficient to be of practical use. This is covered by what we term analyzability (to exploit any mathematical semantics) and executability (to exploit any operational semantics). Different aspects of technical actor interpretation appropriateness are a mean to achieve syntactic, semantic and pragmatic quality (through formal syntax, mathematical semantics, and operational semantics).

OVERVIEW OF EVALUATION

The evaluation is structured according to the four areas of language quality presented previously. Before presenting the evaluation, we will position UML in relation to the sets of the quality framework.

Domain: According to OMG (2004), UML is a language for specifying, visualizing, constructing, and documenting the artifacts of software systems, as well as for business modeling and other non-software systems. In other words, UML is meant to be used in analysis of business and information, requirement specification and design. UML is meant to support the modeling of (object-oriented) transaction systems, real-time and safety critical systems. As illustrated in Favre (2003), UML is used and adapted for a number of different specific areas.

Language: We Have Based the Evaluation on UML (version 2.0).

The sets "Knowledge", "Model", and "Interpretation" must be judged from case to case in the practical application of a modeling language and tools. Also, when it comes to weighting the different criteria against each other, this must be done in the light of the specific modeling task, such as has been done, for example, by Arnesen and Krogstie (2002).

Due to the limitation on the length of an article of this kind and the breadth of the evaluation, we will only have room for presenting some of the major results. See Krogstie (2003) for a more detailed description of using the framework for evaluating UML.

Domain Appropriateness

Looking briefly on the coverage of the seven main modeling-perspectives in information systems modeling (Krogstie & Sølvberg, 2003), we find:

- UML has a very good support for modeling according to an object-oriented perspective, especially for design.
- The structural perspective is also well-supported, although not as well as in languages made specifically for this purpose.
- The behavioral perspective is supported using statecharts.
- The functional (process) perspective is supported on a high level through use case modeling, a language that has been highly criticized for not being well-defined (Hitz & Kappel, 1998). Whereas use cases are meant for requirements modeling, activity diagrams can be used for simple procedural descriptions by showing control flow and the production of data or objects in a process flow. This is useful for design. Many have also attempted using activity diagrams for business models. Improvements of activity diagrams is introduced in UML 2.0 in this regard. The lack of traditional dataflow in activity diagrams has been noted as a problem.
- The actor-role perspective is partly covered using the collaboration diagrams. Using roles in sequence diagrams or "swimlanes" in activity diagrams, we also get a role-oriented view, but there is no intuitive way to represent organizational and group-structures and relationships in UML.
- There are some general problems with constraints expressed in an OO modeling framework (Høydalsvik & Sindre, 1993). Temporal and deontic constraints are hard to express. The same problem applies to non-functional requirements. There is no support for modeling of goal-hierarchies (Mylopoulos, Chung, & Tu, 1999).
- The language-action perspective, which is most useful for the analysis of businesses, is not supported.

A meta-model of UML is defined (using UML), and there exist extension mechanisms to make the language more applicable in specific domains.

Most of UML is first useful during design. These parts of the language should not be used in analysis and requirements specification, even in areas where the transition from analysis to design is "seamless". (There is much evidence that, especially for business systems, this transition is far from seamless even when using object-oriented modeling in all domains (Davis, 1995; Høydalsvik & Sindre, 1993).) Proper guidelines for avoiding this are not consistently provided, and there is no support for avoiding using analysis and design concepts in the same model.

There are also mismatches between underlying basis and external representation. In sequence diagrams, for instance, a number of concepts are semantically vacant (Morris & Spanoudakis, 2001). Some of the problems are addressed in UML 2.0. We also find examples of concrete constructs in the meta-model, with no representation in the notation (e.g., namespace and model).

Participant Language Knowledge Appropriateness

It can be argued that for those being familiar with the main OO-modeling concepts and main OO modeling-languages, the core of UML should not represent a too steep learning curve. Almost all CS and IS-degrees now include courses where UML is lectured and used. On the other hand, we have noted the complexity of the language previously described. The large number of constructs in UML is partly due to its diverse diagramming techniques (Siau & Cao, 2001). Constructs in use case diagrams are very different from constructs in class diagrams. Class diagrams are also very different from activity diagrams or statecharts. This diversity causes problems. First, there are more constructs to learn. Second, the knowledge and experience gained in using one diagramming technique cannot be transferred to another diagramming technique in UML.

Participant Comprehensibility Appropriateness

Some main observations on this area are:

UML is argued to be overly complex, with 233 different concepts (in UML 1.4) (Castellani, 1999). In Siau and Cao (2001), a detailed comparison is presented. Although UML has more diagramming techniques when compared to object-oriented methods such as OMT, OOAD and Shlaer/Mellor, each of the diagramming techniques in isolation is no more complex than techniques found in these methods. On the overall method level on the other hand, UML stands out noticeably, being most complex according to most of the metrics.

With so many concepts, it is not surprising that some redundancy and overlap is witnessed.

Examples of lacking symbol differentiation is found, for example,.that both classes and objects are shown using rectangles. On the other hand, since the text-style of the object gives an indication of this, this is a minor problem.

UML contains many possibilities of adding (often small) adornments to the models, which often are difficult to see and comprehend.

A uniform use of symbols is not adhered to. An example is that different symbols are used for a role if it is external to the system (pin-man) or internal (rectangle).

Technical Actor Interpretation Appropriateness

The UML-syntax is rigorously defined, and the language is described through a meta-model made in the structural model of UML with accompanying natural language descriptions of the semantics. Using UML to model UML means that some of the definitions are circular, and this leaves UML (formally speaking) undefined. This would be unproblematic if most practitioners already understood the meaning of the concepts (classes, inheritance, and associations) that are involved. In UML 2.0, a formal (operational) action language has been included to support a wider repertoire of modeling techniques.

FUTURE TRENDS

Modeling as a general technique within information systems development has received increasing interest over the last years, and will continue to be of high importance, for example, in connection to the OMG MDA approach and business process support. Due to its strong support, UML is probably the best general modeling language to adopt as a basis for object-oriented development if one is not already using another language with good tool support that one is satisfied with. Most of the accidental problems such as inconsistencies in the language-descriptions found in earlier version of UML seem to be addressed in UML 2.0, but there are still concerns, and UML 3.0 is already planned, but it is difficult to judge what this will look like.

CONCLUSION

UML has been developed and refined over a number of years, but there are still some major weaknesses with the approach. Even if it has not been possible to agree on a standard process, outline process guidelines need to be included – even if the best that can be done is to describe a number of alternatives. Particularly problematic is the logical/physical confusion in the UML-definition. As discussed by Davis (1995), there are fundamental differences between the models related to analysis, design, and requirement specification. What our investigation has also illustrated is that although there is a perceived need to extend the expressiveness and formality of the language, the language has several weaknesses regarding comprehensibility appropriateness, and is already viewed as difficult to comprehend, with a steep learning curve. The distinction between infrastructure and superstructure provided for UML 2.0 tries to address this, but it is too early to judge to what extent this is successful. Looking at the accepted 800-page proposal for UML 2.0 does not give us much hope that UML will be particularly much easier to learn and use, especially because of the strong need for backward consistency.

KEY TERMS

Analysis Model: A model developed to learn all aspects of a problem domain to determine the best way to solve a specific set of user needs.

Design Model: A model developed to represent the optimal technical solution of a specified user need (as represented in a requirements model).

Model: An abstraction represented in a modeling language.

Modeling Language: A language (i.e., a set of symbols, and rules for how to combine these symbols) to represent knowledge relevant in information systems development.

Requirements Model: A model to represent the external requirement to a system without taking into account how the system looks inside.

Unified Modeling Language (UML): A general-purpose visual modeling language that is used to specify, visualize, construct and document the artifacts of a software system.

Visual Modeling Language: A diagrammatic modeling language.

Querying Multidimensional Data

Leonardo Tininini
Istituto di Analisi dei Sistemi e Informatica "Antonio Ruberti", Rome, Italy

INTRODUCTION

A powerful, easy-to-use querying environment is without doubt one of the most important components in a multidimensional database. Its effectiveness is influenced by many aspects, both logical (data model, integration, policy of view materialization, etc.) and physical (multidimensional or relational storage, indexes, etc.). Multidimensional querying is often based on the core concepts of multidimensional data modeling, namely the metaphor of the data cube and the concepts of facts, measures and dimensions (Agrawal, Gupta, & Sarawagi, 1997; Gyssens & Lakshmanan, 1997). In contrast to conventional transactional environments, multidimensional querying is often an exploratory process, performed by navigating along dimensions and measures, increasing/decreasing the level of detail and focusing on specific subparts of the cube that appear "promising" for the required information.

BACKGROUND

Multidimensional data are obtained by applying aggregations and statistical functions to elementary data, or more precisely to data groups, each containing a subset of the data and homogeneous with respect to a given set of attributes. For example, the data "Average duration of calls in 2003 by region and call plan" is obtained from the so-called fact table, which is usually the product of complex activities of source integration (Lenzerini, 2002) on the raw data corresponding to each phone call in that year. Several groups are defined, each consisting of calls made in the same region and with the same call plan, and finally applying the average aggregation function on the duration attribute of the data in each group. The pair of values (region, call plan) is used to identify each group and is associated with the corresponding average duration value. In multidimensional databases, the attributes used to group data define the dimensions, whereas the aggregate values define the measures of data.

The term multidimensional data comes from the well known metaphor of the data cube (Gray, Bosworth, Layman, & Pirahesh, 1996). For each of the n attributes, which are used to identify a single measure, a dimension of an n-dimensional space is considered. The possible values of the identifying attributes are mapped to points on the dimension's axis, and each point of this n-dimensional space is thus mapped to a single combination of the identifying attribute values and hence to a single aggregate value. The collection of all these points, along with all possible projections in lower dimensional spaces, constitutes the so-called data cube. In most cases, dimensions are structured in hierarchies, representing several granularity levels of the corresponding measures (Jagadish, Lakshmanan, & Srivastava, 1999). Hence, a time dimension can be organized into days, months and years; a territorial dimension into towns, regions and countries; a product dimension into brands, families and types. When querying multidimensional data, the user specifies the measures of interest and the level of detail of the information required by indicating the desired hierarchy level for each dimension. In a multidimensional environment, querying is often an exploratory process, where the user "moves" along the dimension hierarchies by increasing or reducing the granularity of displayed data. The operation of drill-down corresponds to an increase in detail, for example, by requesting the number of calls by region and month, starting from data on the number of calls by region or by region and year. Conversely, roll-up allows the user to view data at a coarser level of granularity (Cabibbo & Torlone, 1997).

OLTP VS. OLAP QUERIES

Multidimensional querying systems are commonly known as On-Line Analytical Processing (OLAP) systems (Li & Wang, 1996), in contrast to conventional On-Line Transactional Processing (OLTP) systems. The two types have several contrasting features, although sharing the same requirements on fast "on-line" response times.

- *Number of records involved.* One of the key differences between OLTP and multidimensional queries is the number of records required to calculate the answer. OLTP queries typically involve a rather limited number of records, accessed through primary key or other specific indexes, which need to be processed for short, isolated transactions or to be issued on a user interface. In contrast, multidimensional queries usually require the classification and aggregation of a huge amount of data (Gupta, Harinarayan, & Quass, 1995).

- *Indexing techniques.* Transaction processing is mainly based on the access of a few records through primary key or other indexes on highly selective attribute combinations. Efficient access is easily achieved by well-known and established indexes, particularly B+-tree indexes. In contrast, multidimensional queries require a more articulated approach, as different techniques are required, and each index performs well only for some categories of queries (Chan & Ioannidis, 1998; Jürgens & Lenz, 1999).
- *Current state vs. historical DB's.* OLTP operations require up-to-date data. Simultaneous information access/update is a critical issue, and the database usually represents only the current state of the system. In OLAP systems, the data does not need to be the most recent available and should, in fact, be time-stamped, thus enabling the user to perform historical analyses with trend forecasts. However, the presence of this temporal dimension may cause problems in query formulation and processing, as schemes may evolve over time and conventional query languages are not adequate to cope with them (Vaisman & Mendelzon, 2001).
- *Target users.* Typical OLTP system users are clerks, and the types of query are rather limited and predictable. In contrast, multidimensional databases are usually the core of decision support systems, targeted at management level. Query types are only partly predictable and often require highly expressive (and complex) query language. However, the user usually has little experience even in "easy" query languages like basic SQL: the typical interaction paradigm is a spreadsheet-like environment based on iconic interfaces and the graphical metaphor of the multidimensional cube (Cabibbo & Torlone, 1998).
- *Dimensions and measures.* Early statistical database research has already shown (Shoshani & Wong, 1985) that the standard relational model and operators (commonly used to represent and query transactional databases) are inadequate for effective representation and querying of multidimensional data. This led to the distinction between category attributes (the dimensions) and summary attributes (the measures). The distinction between dimensions and measures is also at the basis of most models for OLAP systems. However, as noted by several authors, this distinction has some drawbacks, mainly because some operations easily expressible in relational algebra become cumbersome in multidimensional models. Some authors have proposed multidimensional models with a symmetrical treatment of measures and dimensions to cope with this problem (Agrawal, Gupta, & Sarawagi, 1997; Cabibbo & Torlone, 1997; Gyssens & Lakshmanan, 1997).

EXPRESSING MULTIDIMENSIONAL QUERIES

As noted earlier, the metaphor of the data cube and the concepts of facts, measures and dimensions are fundamental to both multidimensional data modeling and querying. In particular, techniques proposed in the literature and/or implemented in commercial systems to retrieve such data are based on the idea of determining the cube of interest and then navigating along the dimensions, increasing or decreasing the level of detail through roll-up and drill-down or selecting specific subparts of the cube through the operation of slice and dice.

The query languages for multidimensional data support both these standard operations and additional ones for performance of more sophisticated calculations. A first broad distinction can be made among:

- Languages based on an algebra (usually an extension of the relational algebra), where queries are expressed by using operators representing facts, measures and dimensions. Examples of these languages are the grouping algebra proposed by Li and Wang (1996) and the algebra for "symmetrical" cubes (Agrawal, Gupta, & Sarawagi, 1997).
- Languages based on a calculus (usually an extension of the relational calculus), where queries are expressed in a more declarative way. An example is MD-CAL, a multidimensional calculus for fact tables (Cabibbo & Torlone, 1997).
- Visual languages, usually relying on an underlying algebra, and based on a more interactive and iconic querying paradigm: This is the approach of most commercial OLAP products. A visual query language for statistical aggregate data was proposed by Rafanelli, Bezenchek, and Tininini (1996) and for the MD model by Cabibbo and Torlone (1998).

Multidimensional query languages can also be classified by the type of model used to represent the data:

- Query languages based on a relational representation of multidimensional data, hence based on extensions of the relational algebra and calculus.

ROLAP (Relational OLAP) systems are based on such languages. Examples are that described by Gyssens and Lakshmanan (1997), and SQL(H) (Jagadish, Lakshmanan, & Srivastava, 1999), an extension of SQL to embed hierarchies in the relational model.
- Query languages based on specifically designed multidimensional models, usually based on an abstraction of cubes or fact tables, to which the algebra operators are applied. Many commercial, so-called MOLAP (Multidimensional OLAP) systems are based on these languages.

Some further issues must be considered to express multidimensional queries in a statistical environment, mainly because: (i) it is crucial to preserve privacy in statistical databases and excessively detailed aggregate data can disclose confidential information about individual persons; and (ii) much of the data in statistical databases originates from sample surveys, and corresponding aggregate data are not significant at the finest levels of detail.

As a consequence, an interface enabling free navigation of dimension hierarchies would often lead the user to express a query referring to non-permissible data. Specific techniques are therefore required to establish a trade-off between the characteristic freedom of multidimensional navigation and the constraints of significance and disclosure prevention imposed by statistical databases.

EVALUATING MULTIDIMENSIONAL QUERIES

Query evaluation is the process of translating the query expressed in the chosen language into an (efficient) evaluation plan which retrieves the necessary information and calculates the required results. Note that the adoption of a particular query language may have a significant impact not only on how easily the desired query can be expressed, but also on how efficiently it can be evaluated.

A fundamental requirement of OLAP systems is the ability to perform multidimensional analyses in on-line response times. As multidimensional queries usually involve a huge amount of data to be aggregated, the only way to achieve this is by pre-computing some queries, storing the answers permanently in the database and reusing them (almost exclusively) in the query evaluation process. These pre-calculated queries are commonly referred to as materialized views. From an abstract point of view, the determination of the evaluation plan can be seen as the process of transforming the source query into an equivalent target query, referring (possibly exclusively) to the materialized views. This is known in literature as the (aggregate) query rewriting problem. Aggregate query rewriting techniques are usually based on:

- A collection of rewriting (transformation) rules usually applicable to queries of specific forms. The rules are iteratively applied to the original query to decompose it into more elementary sub-queries, until all (or most of) the sub-queries obtained are available as materialized views. This is the approach in, for instance, Gupta, Harinarayan, and Quass (1995).
- The detection of homomorphisms from the views to the query (as for non-aggregate queries). This enables the query optimizer to distinguish queries usable for rewriting from the useless ones. Usable queries are then combined, usually in conjunctive (AND) form. Rewriting techniques of this type are presented in Srivastava, Dar, Jagadish, and Levy (1996) and Grumbach, Rafanelli, and Tininini (1999).
- Query equivalence criteria, as in Cohen, Nutt, and Serebrenik (1999). The original query, the usable views and the rewritten query are all expressed through an extension of Datalog with aggregate functions (again COUNT, SUM, MIN and MAX) as the query language. Several candidate rewritten queries are considered, and the views in each body are unfolded (i.e., replaced by their body in the view definition). Finally, the unfolded candidate is compared with the original query to verify equivalence through use of known equivalence criteria for aggregate queries.

All rewriting algorithms proposed in the literature are based on the attempt to obtain a rewritten query with a particular form by using (possibly only) the available views. An interesting question is: “Can I rewrite more by considering rewritten queries of more complex form?” and the even more ambitious one “Given a collection of materialized views, is the information they provide sufficient to rewrite a query?” In Grumbach and Tininini (2000), the problem is investigated in a general framework based on the concept of query subsumption.

An interesting issue related to multidimensional query evaluation is the efficient computation of the materialized aggregate views. As for OLTP queries, the use of indexes can have dramatic consequences on the overall process efficiency. However, unlike OLTP queries where B+-tree based indexes (Comer, 1979) achieve excellent performances in almost all practical situations, there is no “universally good” index for OLAP queries, but rather a variety of techniques, each of which may perform well for specific data types and query forms but be inappropriate for others (Chan & Ioannidis, 1998; Jürgens & Lenz, 1999).

FUTURE TRENDS AND CONCLUSIONS

In this article, we have discussed the main issues related to the querying of multidimensional data. Querying is strictly connected to the way data is modeled, and particularly to the concepts of data cube, fact table, measure and dimension. Multidimensional queries have several features which distinguish them from conventional queries on transactional systems. Aggregation functions and dimension hierarchies play a major role in this distinction. Although there is a general consensus on the key concepts, a common unified framework for multidimensional data querying is still lacking, particularly a standardized query language independent from the specific storage technique (e.g., MOLAP and ROLAP).

We have presented the main characteristics of multidimensional query languages proposed in the literature and the main issues related to the evaluation of such queries, in particular the query rewriting problem, that is, how an original query can be transformed into an equivalent one expressed in terms of some materialized views and consequently more efficiently computable. A substantial effort is still needed in this field, and important contributions may stem from results in other research areas like logic programming and automated reasoning.

KEY TERMS

Data Cube: A collection of aggregate values classified according to several properties of interest (dimensions). Combinations of dimension values are used to identify the single aggregate values in the cube.

Dimension: A property of the data used to classify it and to navigate on the corresponding data cube. In multidimensional databases, dimensions are often organized into several hierarchical levels, for example, a time dimension can be organized into days, months and years.

Drill-down (/roll-up): Typical OLAP operation, by which aggregate data are visualized at a finer (/coarser) level of detail along one or more analysis dimensions.

Fact: A single elementary datum in an OLAP system, the properties of which correspond to dimensions and measures.

Fact Table: A table of (integrated) elementary data that are grouped and aggregated in the process of multidimensional querying.

Measure: A numeric value obtained by applying an aggregate function (like count, sum, min, max or average) to groups of data in a fact table.

Materialized View: A particular form of query whose answer is stored in the database to speed up the evaluation of further queries.

Query Rewriting: Process by which a source query is transformed into an equivalent one referring (almost exclusively) to a collection of materialized views. In multidimensional databases, query rewriting is fundamental to obtain acceptable (online) response times.

Slice and Dice: Typical OLAP operation by which specific subparts (“slices”) of the data cube are selected and arranged for visualization.

Real Options Analysis in Strategic Information Technology Adoption

Xiaotong Li
University of Alabama in Huntsville, USA

INTRODUCTION

Many information resource managers have learned to be proactive in today's highly competitive business environment. However, limited financial resources and many uncertainties require them to maximize their shareholders' equity while controlling the risks incurred at an acceptable level. As the unprecedented development in information technology continuously produces great opportunities that are usually associated with significant uncertainties, technology adoption and planning become more and more crucial to companies in the information era. In this study, we attempt to evaluate IT investment opportunities from a new perspective, namely, the real options theory. Its advantage over other capital budgeting methods like static discounted cash flow analysis has been widely recognized in analyzing the strategic investment decision under uncertainties (Amram & Kulatilaka, 1999; Luehrman, 1998a, 1998b). Smith and McCardle (1998, 1999) further show that option pricing approach can be integrated into standard decision analysis framework to get the best of the both worlds. In fact, some previous IS researches have recognized the fact that many IT investment projects in the uncertain world possess some option-like characteristics (Clemsons, 1991; Dos Santos, 1991; Kumar, 1996). Recently, Benaroth and Kauffman (1999) and Taudes, Feurstein and Mild (2000) have applied the real options theory to real-world business cases and evaluated this approach's merits as a tool for IT investment planning.

As all real options models inevitably depend on some specific assumptions, their appropriateness should be scrutinized under different scenarios. This study aims to provide a framework that will help IS researchers to better understand the real options models and to apply them more rigorously in IT investment evaluation. As the technology changes, the basic economic principles underlying the real options theory do not change. We do need to integrate the IT dimension into the real options based investment decision-making process. Using electronic brokerage's investment decision in wireless technology as a real-world example, we show the importance of adopting appropriate real options models in IT investment planning. By specifically focusing on the uncertainties caused by IT innovation and competition, our study also gives some intriguing results about the dynamics between IT adoption and the technology standard setting process.

REAL OPTIONS THEORY

It is generally believed that the real options approach will play a more important role in the highly uncertain and technology driven digital economy. Before reviewing the real options literature body that is growing very rapidly, we use an example to give readers an intuitive illustration of the values of real options and their significance in financial capital budgeting.

Pioneer Venture: The Value of a Growth Option

In this example, the management of a large pharmaceutical company wants to decide whether to acquire a young biomedical lab. If they decide to acquire it, they should provide $100,000 funding to cover the initial costs for the pioneer venture. Five years after the initial funding, the management will decide whether to stop the pioneer venture or to expand it significantly according to the market situation at that time. If they choose to expand it, additional $1,000,000 is needed. The cost of capital is assumed to be 15%. Five years after acquisition of the lab, the management will face two scenarios. The good scenario will occur with 60% likelihood, while the bad one will have 40% likelihood of happening. All expected future cash flows during the next 10 years are given in Table 1. Using standard capital budgeting method, we can find that the NPV for the pioneer venture is -$15,215. For the period of large-scale production, the NPV is -$71,873. As the NPVs for both periods are negative, it seems that the management should give up the acquisition. However, the acquisition will be a good investment if we consider the growth option associated with it. By acquiring the lab, the company also buys a growth option that enables it to

Table 1. Projected cash flows in the example of pioneer venture project

Year	Pioneer Stage	Larger Scale Stage	Total Cash Flows	Discount Rate
0	-$100,000		-$100,000	15%
1	$10,000		$10,000	
2	$10,000		$10,000	
3	$50,000		$50,000	
4	$50,000		$50,000	
5	$20,000	-$1,000,000	-$980,000	
6		$100,000	$100,000	
7		$100,000	$100,000	
8		$500,000	$500,000	
9		$500,000	$500,000	
10		$200,000	$200,000	
	Large Scale Stage	Good Scenario	Bad Scenario	Prob (good)
5	-$1,000,000	-$1,000,000	-$1,000,000	0.6
6	$100,000	$130,000	$55,000	
7	$100,000	$130,000	$55,000	
8	$500,000	$650,000	$275,000	
9	$500,000	$650,000	$275,000	
10	$200,000	$260,000	$110,000	
	NPV Pioneer Stage	-$15,215.42		
	NPV Large Scale Stage	-$71,872.54		
	NPV with Growth Option	$13,749.98		
	Value of the Option	$28,965.40		

expand the lab when the conditions are favorable 5 years later. In this case, the good scenario will occur with 60% likelihood. After simple calculation, it is easy to find that the growth option has a value of $28,965. Combining its value with the negative NPV during the pioneer venture period, the adjusted NPV of the acquisition is $13,750, which means this investment is strategically plausible.

Many researchers recognized the potential of this options pricing theory in capital budgeting because traditional DCF (discounted cash flows) technique has its inherent limitation in valuing investments with strategic options and many uncertainties. Table 2 gives a comparison between an American call option on a stock and a real option on an investment project. Despite the close analogy, some people may still question the applicability of option pricing theory on real options that are usually not traded in a market. However, Cox, Ingersoll and Ross (1985) and McDonald and Siegel (1984) suggest that a contingent claim on a non-traded asset can be priced by subtracting a dividend like risk premium from its growth rate.

Recent development in real option theory focuses on the valuation of more complicated real options like shared options, compounded options and strategic growth options. Dixit and Pindyck (1994) examine the dynamic equilibrium in a competitive industry. Their model suggests that a firm's option to wait is valuable when uncertainty is firm-specific. For industry-wide uncertainty, there is no value to wait because of the asymmetric effects of uncertainty.

FOUR CATEGORIES OF IT INVESTMENT OPPORTUNITIES

As shown in Figure 1, we have four types of IT investment opportunities based on the two criteria: (i). Shared opportunities with high IT switching costs; (ii). Shared opportunities with low IT switching costs; (iii). Proprietary opportunities with low IT switching costs; (iv). Proprietary opportunities with high IT switching costs. It is worth noting that each category has distinctive requirements on the application of real options models. We use the continuous-time model developed in McDonald and Siegel (1986) as a benchmark to show why we differentiate IT investment opportunities based on the two criteria. It basically suggests that the option to defer uncertain investment is very valuable and should be taken into account when a company makes investment decisions. A

Table 2. Comparison between an American call option and a real option on a project

AMERICAN CALL OPTION ON STOCK	REAL OPTION ON A PROJECT
Current Stock Price	Present Value of Expected Cash Flows
Option Exercise Price	Investment Cost of a Project
Right to Exercise the Option Earlier	Right to Invest in the Project at any time before the Opportunity Disappears
Stock Price Uncertainty	Project Value Uncertainties
Option Price	Value of Managerial Flexibility Associated with the Project
Expiration Time	Time Window of the Investment Opportunity
Traded in Financial Market	Usually not Traded
Easy to Find a Replicating Portfolio	Hard to Find a Replicating Portfolio

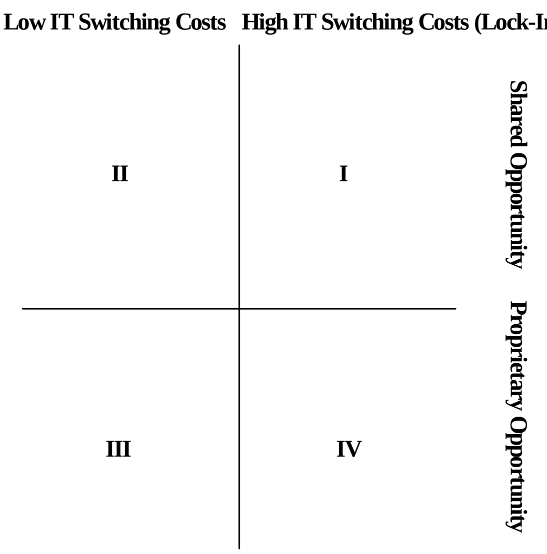
major assumption of this model is that there is no competitive erosion; in other words, the investment project is a proprietary opportunity. Without this assumption, the value of the project should not follow the symmetric geometric Brownian motion described in their model. The reason is simple: the existence of potential competition makes the distribution of future project value asymmetric, with high project value less likely to occur. It is worth noting that the well-known Black-Scholes option pricing formula is also based on the assumption that the underlying asset price follows the geometric Brownian motion. In the real business world, most investment opportunities are shared or at least partially shared. Especially in the IT business sector where intensive competition is pervasive, those real options models assuming symmetric uncertainty in investment opportunity value are generally inappropriate. Intuitively, competition pressure will decrease the value of the option to defer an investment. There are usually two approaches to deal with this issue. One approach is to model the competitive entries as exogenous shocks. For examples, Dixit and Pindyck (1994) and Trigeorgis (1991) use a Poisson Jump process to describe the competitive arrivals. Their studies show that the effect of the competitive erosion can be expressed as the following equation

Strategic NPV= NPV+ (Value of Option to Wait - Competitive Loss).

In other words, strong competition will restrict managerial flexibility if the investment opportunity is shared. We need to evaluate the investment opportunity in the context of the real options theory by considering the growth option and the waiting option simultaneously. Alternatively, we can incorporate the preemptive effect into the standard real options models. For example, Li (2001) proposes a real options model with strategic consideration based on the model in McDonald and Siegel (1986).

The other criterion we used to categorize different IT investment opportunities is the IT switching cost. We all know that future uncertainty makes the options embedded in an investment opportunity valuable. Theoretically, there is no need to single out technology uncertainty from

Figure 1. Four categories of IT investment opportunities



all other uncertainties in the real options model. All these uncertainties have the same effect: they make the future payoff of an investment project less predictable. However, we will concentrate on the technology uncertainty in this study because it plays a pivotal role in affecting IT investment payoff. Perhaps the most important question that management faces before committing an IT investment is whether the technology adopted is the right choice. More specifically, will the adopted technology be the best solution to maximize the expected investment payoff? Clearly there is not a simple answer to this question because there are so many uncertainties involved. Some very promising or popular IT solutions may become obsolete in a few years. In some other cases, some neglected IT solutions may evolve to be the standard solution. Nevertheless, most technology uncertainties can be resolved as the process of technology competition goes forward. A typical process of technology competition includes:

- Problem identification: An important problem is identified and new technology is sought to solve it.
- Technology solutions proposition: Several technology developers/vendors propose different solutions to solve the problem.
- Solution testing and comparison: Different technology solutions are competing in the market and their effectiveness is tested and compared.
- Technology standardization: The best solution will flourish over time. Based on it, the technology to solve the problem will be standardized.

For many IT investment projects, decision makers face an uncertain technology environment where several IT solutions are competing in the market. Obviously, the future successes of these projects will to some extent depend on whether the IT solutions adopted will win the technology competition. Consequently, decision makers do have an incentive to use the deferring option to let more technology uncertainties be resolved. Under this scenario, many option-to-wait models can be easily extended to find the optimal investment strategy. However, to apply these real options models we must presume that there are significant technology switching costs once an IT solution is adopted. Otherwise, the uncertainties in technology competition will not make the option to wait valuable because the decision makers can easily switch to other IT solutions after they implement the investment project. As pointed out by Shapiro and Varian (1998), the IT switching costs are very significant in many cases. They use the term "technology lock-in" to describe the situation where management has little flexibility to switch to other technology solutions once they have adopted one IT solution.

Now it should be clear why we use IT switching cost as the second criterion to classify different IT investment opportunities. When the IT switching cost is significant (technology lock-in), the option to wait is valuable. Therefore, real options analysis should concentrate on the managerial flexibility in deferring an IT investment to let more technology uncertainties be resolved. When the switching cost is low, high IT uncertainties cannot be used to justify the wait-and-see policy. On the contrary, we should use real options analysis to quantify the value of the option to switch that usually makes an investment opportunity more appealing to the management.

To summarize our discussion, let us look at the four categories of IT investment opportunities based on the two criteria.

- Category I: Shared investment opportunity with high IT switching cost. For this type of IT investment opportunity, we must consider both the strategic benefit of early preemptive investment and the valuable option to wait. Potential competitive pressure forces investors to be proactive. However, preemptive investment will incur the loss of the valuable option to wait. So for this type of IT investment opportunity, the key in the real options analysis is to consider the strategic growth option and the option to wait at the same time. By balancing the two contradictory effects, we can find the optimal investment point at which the expected investment payoff will be maximized.
- Category II: Shared investment opportunity with low IT switching cost. For this type of IT investment opportunity, early preemptive investment is usually the best strategy. As we discussed before, it is beneficial to invest early to preempt potential competitors. Moreover, IT uncertainties will not make the wait-and-see strategy more appealing because the IT switching cost is low. Therefore, real options models should be used to quantify the values of the growth option and the switching option embedded in the IT investment opportunity.
- Category III: Proprietary investment opportunity with low IT switching cost. It is worth noting that the option to wait is a very valuable component of a proprietary investment opportunity. However, technology uncertainty will not contribute a lot to the value of the option to wait because the IT switching cost is low for investment opportunities in this category. So in the real options analysis we should pay attention to other business uncertainties that may increase the value of the option to wait.
- Category IV: Proprietary investment opportunity with high IT switching cost. Wait-and-see is the dominant strategy for this type of IT investment

opportunity. So real options analysis should concentrate on the option to defer an investment. With the presence of technology lock-in, decision makers should be more patient before they commit a proprietary investment.

In the real business world, an IT investment opportunity may dynamically evolve from one category to other ones. So decision makers should be very cautious when they conduct real options analysis. In the next section, we use a real-world case to show the importance of adopting appropriate real options models as the IT investment opportunity evolves.

CONCLUSION

Although some recent studies recognized the potential of real options theory in evaluating strategic IT investment opportunities, we believe that the applicability of various real options models should be scrutinized under different scenarios. Standard real options models assuming symmetric uncertainty in future investment payoffs cannot be directly applied to the shared opportunities because of the competitive erosion. With the presence of potential competitive entry, real options analysis should balance the strategic benefit of preemptive investment and the value of the option to wait. IT switching cost is another important factor we must consider when we conduct real option analysis. As high IT switching cost or technology lock-in is very common in the digital economy, decision-makers should pay more attention to the technology uncertainties before committing early investment to preempt their competitors.

KEY TERMS

Black-Scholes Option Pricing Model: A model that is used to calculate the value of an option by taking into account the stock price, strike price and expiration date, the risk-free return, and the standard deviation of the stock's return.

Deferred Option: Option to defer a project or an investment gives a firm an opportunity to make an investment at a later point in time.

Managerial Investment Flexibility: Flexibility in the timing and the scale of an investment provided by a real investment option.

Net Present Value (NPV): The present value of an investment's future net cash flows minus the initial investment.

Option: The right, but not the obligation, to buy or sell an asset by a pre-specified price on before a specified date.

Real Options Theory: Financial valuation tool that helps in calculating the value of managerial flexibility under uncertainties.

Switching Costs: Switching costs refer to the hidden costs consumers face when switching from one product or technology to another in the marketplace.

Reasoning About User Preferences

Tamara Babaian
Bentley College, USA

INTRODUCTION

Personalization has been identified as a key task to the success of many modern systems. As Riecken (2000, p. 28) writes in the editorial of the special issue of the *Communications of the ACM* devoted to this subject, "personalization means something different to everyone." Personalization can take various forms; however, it can be broadly described as the set of mechanisms by which an application is tailored to a particular end user and his or her goal.

Modern systems typically have a large set of features designed to carry out a multitude of tasks, or operate using an enormous wealth of information available on the Internet. The effectiveness with which a system is able to help its user achieve the desired effect, as well as the user's satisfaction from interacting with the system, depend critically, among other factors, on the user's ability to identify and use relevant, customizable options. Configuring the system for optimal performance requires that the user specifies his or her individual preferences related to many different tasks. However, the user's ability to provide this kind of personal information is often greatly impaired by the following drawbacks in the way personalization is implemented.

- Customization is carried out as a separate process that is taken out of context of the task in which such personal information is used, thus obscuring from the user the purpose and advantages of supplying such information.
- The amount of potentially useful personal information is sometimes overwhelming, thus the systems are installed with a set of settings that are considered typical. Further customization has to be initiated by the user. However, inexperienced users rarely take advantage of customization even if they are aware of potential benefits due to the lack of information on available options. As a result, experience demonstrates (Manber, Patel, & Robison, 2000) that many users shy away from customization when they can benefit from it a great deal.

The items above characterize the shortcomings of a typical process of configuring customizable features. On the other hand, there are problems that the developers of software face in *designing* for personalization. As Pednault (2000) points out, the underlying representation of "the human-side and the technology-side" is the key. However, representations currently in use, at times, lack flexibility to be easily adjustable and reusable. This is largely a consequence of the absence of a rigorous model of what constitutes personalization. The lack of such model results in ad hoc representations used by most systems.

The approach to personalization that we present here is inspired by the view of interfaces as the means of collaboration between a human user and a computer system, articulated by Shieber (1996), in which the collaborative model of human-computer interaction is contrasted to the view of a system as a mere set of tools available to the user. As a theoretical framework, collaboration theory and its existing philosophical and formal mathematical accounts (Bratman, 1992; Cohen & Levesque, 1991; Grosz & Kraus, 1996) can inform both design and usability analysis of systems, and highlight problems that need to be addressed to make interfaces better collaborative partners. Examples of interfaces that have been created following this view have already been built and are described in Babaian, Grosz, & Shieber (2002), Ortiz and Grosz (in press), Rich, Sidner, and Lesh (2001), and Ryall, Marks, and Shieber (1997).

Theories of collaboration postulate:

1. commitment of the parties to a shared goal, and
2. sharing of knowledge and communication in an effort to establish agreement and mutual knowledge of the recipe for completing the task

as the key features of a collaborative activity. Stemming directly from this view, in our approach the collaborator system has the ability to elicit personal information at the time when the user is most motivated to provide it, that is, when the system is processing a task for which such information is critical. The novelty of our approach and its implementation also lies in defining the task of collecting personal information declaratively via informational goals and preconditions on the actions that the system takes in response to a user's request. This is enabled by

(a) the use of a knowledge base that stores all gathered preference information, and

(b) an automated reasoning and planning system that can reason autonomously about knowledge, lack of knowledge, and actions that the system may take to acquire the necessary but missing information.

The system can perform information gathering autonomously (by inspecting available personal information, such as, for example, a person's Internet bookmarks) as well as by direct user querying. This approach to personalization ensures gradual adaptation of the system to the user's preferences. At the same time, the declarative definition of personal information and its relationship to system actions make it easy to fine-tune personalization options, resulting in a more easily adjustable and extendable design.

BACKGROUND

The problem of end-user tailoring, also known as customization of software, is not new (see, for example, Morch, 1997). Recent explosion of the Internet and its ubiquity in our everyday life have created new challenges and opportunities for the advancement of research on this subject, in particular, in the area of customizing information-access interfaces. Numerous works have addressed the issue of information overload and the resulting need for effective information retrieval and presentation of the results that is tailored to the needs of each individual visitor. A thorough review of these works is beyond the scope of this chapter; however, we briefly describe the leading approaches and provide the reader with a set of further references. Availability of logs of Web site usage has provided an excellent opportunity and an exciting domain for technologies such as machine learning and data mining (for a review see Anderson, 2002; Pierrakos, Paliouras, Papatheodorou, & Spyropoulos, 2003). In the artificial-intelligence community, two approaches to automated personalization on the Web have been explored and used most successfully: adaptive Web sites and collaborative filtering. Adaptive Web sites and Web site agents (e.g., Pazzani & Billsus, 1999; Perkowitz & Etzioni, 2000) attempt to dynamically tailor the layout and the contents of a Web site or suggest a navigation path for each individual user by observing the user's initial interaction with the Web site and matching it to the previously observed behaviors of others. Likewise, collaborative filtering (Amazon.com is probably the most familiar example) is a technique that creates recommendations that are based on the choices of previous users with similar interests or requests.

Recently, many traditional concepts and techniques of artificial intelligence have been applied in the area of intelligent user interfaces, in particular, to interface personalization (we refer the reader to the *Proceedings of the International Conference on Intelligent User Interfaces*). An article by Weld et al. (2003) surveys a set of research projects aimed at developing representations and methods for user-directed customization and automatic system adaptation of various kinds of application interfaces.

Many applications of machine-learning and data-mining technologies to Web-based computing have been enabled by the availability of logs recording various details of the interaction of millions of users with the Web sites. At the same time, non-Web-based systems (e.g., common desktop editors, spreadsheets, etc.) have also benefited from the emerging culture of personalization and now commonly incorporate a few personalizable features. Nevertheless, the advancement of research in personalization of common desktop applications has been lagging behind, partly due to the absence of detailed data on their actual usage. The method of software customization presented in this article is applicable to a broad set of software tools and not limited to just Web-based systems.

FUTURE TRENDS

Goal-Directed Personalization in Writer's Aid

Writer's Aid (Babaian et al., 2002) is a system that works simultaneously with an author writing a document, helping him or her with identifying and inserting citation keys, and autonomously finding and caching papers and associated bibliographic information from various online sources.

At its core, Writer's Aid contains

(a) a knowledge base that contains a system's knowledge about the state of the world, and
(b) an automated planning system.

The planner is given a description of the actions that Writer's Aid can execute and works to automatically combine these actions into a plan that will achieve a specified goal. Each action is described via preconditions that must be true prior to executing the action, and effects that the action brings about. Plan generation is accomplished by representing both goals and actions using a logic-based language and using a specialized reasoning engine that can infer what is true after performing a sequence of actions. For an example, consider the following action of searching a user's personal directories for bibliographic collections.

Action 1: FindLocalBibliographies

Preconditions: none
Effects: knowing locations of all bibliographic collections of a user

Personalization in Writer's Aid consists of the initial tune-up of the system to the user's parameters, and the dynamic personalization that occurs while Writer's Aid works on accomplishing a user goal.

Initial Tune-up

Initial tune-up occurs at the time of the installation. The goal of the initial tune-up is to identify and enter certain user-specific parameters, such as, for example, the user's own locally stored bibliographic collections, his or her preferred online bibliographies, and so forth. To direct the system to collect data about the location of local bibliographies, it is sufficient to post the following goal on the list of goals to be accomplished during the tune-up.

Personalization Goal 1 = knowing the locations of all of the user's bibliographic collections

In response, Writer's Aid will generate a plan (in this case consisting of a single Action 1) described above, which accomplishes Personalization Goal 1, and thus provides Writer's Aid with access to the user's personal bibliographies.

This approach to the initial customization, directed by a set of declarative goals that the planner automatically finds a way to achieve, greatly simplifies the personalization process. Personalization goals are now separated from the rest of the system code, and the overall personalization design is much more flexible then the typical hard-coded procedure.

Dynamic Personalization

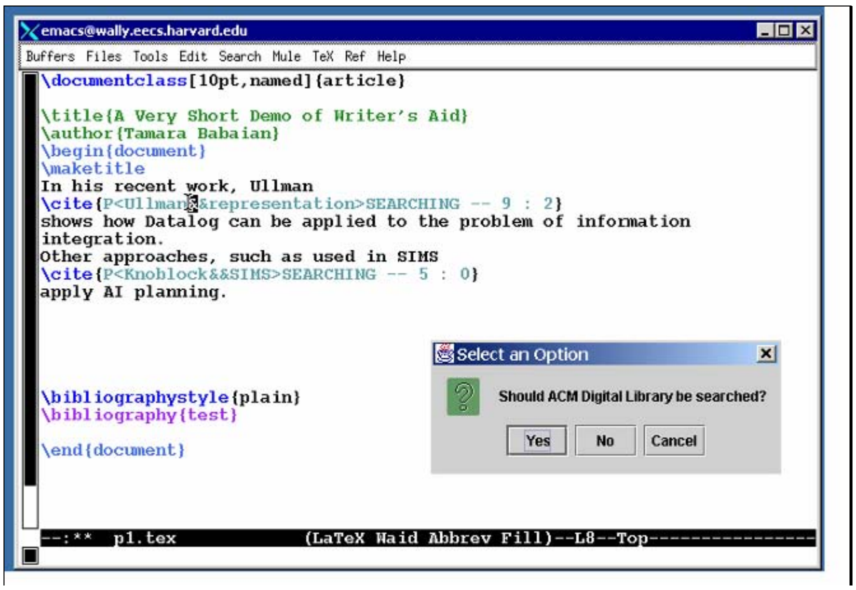
Imagine the following scenario. Writer's Aid is working to locate a viewable version of a paper that the user has requested. The plan for locating the paper includes an action of querying a known paper collection, namely, the ACM digital library. In order to avoid wasting time on searching collections of papers on subjects unrelated to the user's research field, this action contains a precondition that the paper collection be one of the user's *preferred* collections.

Action 2: QuerySourceForPaper (source, paper)

Precondition: source must be user's preferred source
Effects: knowing whether source contains viewable version of paper.

Writer's Aid does not know if ACM digital library is the user's preferred bibliography, so it cannot establish the precondition unless it executes an action (namely,

Figure 1. In the editor window, the user has entered two citation requests (identified by the blue /cite labels). While working on a request for papers related to keywords "Ullman" and "representation," Writer's Aid is asking the user whether ACM Digital Library is one of his or her preferred sources.



Action 3 described in Figure 1) of asking the user himself or herself to obtain the necessary information.

Action 3: AskUserAboutSource (source)

Precondition: user permits system to post questions
Effects: knowing whether source is a user-preferred source

The user's response determines whether the ACM digital library will be queried; it is also recorded in the Writer's Aid knowledge base for future use.

Dynamic personalization occurs gradually, always within a context of a particular task, thus eliciting the user's input at the time it is used and providing the user with the understanding of how the personal information is being used by the system.

DISCUSSION

We have presented a novel approach to personalization, which involves mixed-initiative interactions between the user and the computer system. This approach uses an explicit representation of the knowledge about the domain and the user, and relies on automated reasoning and planning techniques for

(a) identifying the necessary yet unknown personal-preference information, and
(b) constructing and executing a plan to obtain such information from various sources, including the user.

Note that the classical planning framework, in which the planning agent is assumed to have a *complete* specification of the world state, cannot be used in the system interface for the task of representing and acquiring relevant domain and user-preference information because, initially, the system has only incomplete knowledge about the user. Thus, the formalism used for the knowledge base and the planning system should satisfy the following needs.

1. It should be able to effectively represent and reason with only a *partial*-state specification. Indeed, an interface that adapts to a particular environment and user should be able to start with little or no knowledge of the domain and the user, dynamically identify the need for such knowledge, and collect it using information-gathering actions.
2. The planner should perform such information gathering in a nonredundant way and be able to draw all relevant and valid conclusions from the information it has collected, especially when the user is one of the sources of information. If the system ever repeated a question for which it had already obtained the user's answer, the user would likely be annoyed and stay away from taking time to provide any additional personalization information.

The planners that do not rely on the assumption of complete information (also known as a closed-world assumption, or CWA) are said to operate in an open world. Clearly, a planner that is used for collecting customization information instead of relying on the predefined default must be an open-world planner since it must assume that the information is initially unknown and plan to collect it.

The planning formalism used in Writer's Aid, PSIPLAN (Babaian, 2000; Babaian & Schmolze, 2000), satisfies these requirements: It effectively represents and reasons about the known and the unknown given a partial specification of the world. Furthermore, it includes an algorithm for planning in an open world that operates to ensure nonredundancy of information gathering.

Personalization via knowledge preconditions remedies commonly occurring problems with customization, outlined in the introduction, by adopting a mixed-initiative approach to customization. However, special attention should be given to aspects of mixed-initiative interfaces to assure the system acts in a manner that does not greatly disrupt the user's ongoing activity. On the other hand, the user must have access to the same customization data as the system and be able and aware of the way of modifying those settings at any time.

Deployment and experimental evaluation will doubtlessly identify ways of further improvement of dynamic personalization. A set of principles of mixed-initiative user interfaces introduced by Horvitz (1999), and the recent study of instant-messaging interruption on the user's performance in ongoing computing activity (Cutrell, Czerwinski, & Horvitz, 2001) can provide a starting point for further investigations.

CONCLUSION

We presented a method of software customization that is based on an explicit declarative representation of (a) user preferences and (b) knowledge preconditions of system actions. Automated reasoning about actions and change is used to relate particular user preferences to system actions. The advantages of using this framework include the ability of the system to recognize the lack or availability of user-preference information that is relevant to an action immediately prior to the system performing the action via a precondition satisfaction check. Furthermore, by employing automated planning, the system is capable of creating and executing a plan aimed at collecting the missing preference information.

Representing a personalization task via a set of information goals addresses the problems with the way personalization is approached in most modern systems, outlined in the beginning of this paper, in the following ways.

- It leads to preference elicitation that occurs within the context of the particular task that requires personal information, thus informing the user of his or her choices, motivating the response, and ensuring its accuracy.
- Personalization occurs gradually at the times when the personal information is critical to the satisfaction of a user's goal and is initiated by the computer system, thus relieving the user from the potentially time-consuming task of specifying all preferences at once.
- Personalization defined declaratively via information goals separates customization of the interface from the overall system architecture, making the interface more easily adjustable and extendable.

KEY TERMS

Automated Planning: An area of artificial intelligence concerned with solving the problem of finding a sequence of actions that transforms a specified initial state into a specified goal state.

Closed-World Assumption (CWA): An assumption made in classical planning that all facts that are not implied by the knowledge base are *false*. CWA rests on the assumption of *completeness* of knowledge.

Collaborative Interface: Interface in which the interaction between the user and the system is guided by the principles of collaborative behavior.

Dynamic Personalization: End-user tailoring that occurs during the regular use of the system within a context of a user task as opposed to a specific context-free activity directed at the selection of customization options.

Knowledge-Based Personalization: Personalization that is based on (a) explicit representation of knowledge about the user and the domain of operation and (b) automatic inference from that knowledge.

Open-World Assumptioin (OWA): An assumption made while reasoning with *incomplete* knowledge: all facts that are not implied by the knowledge base are assumed to be *unknown*.

Personalization: A set of mechanisms built into a system in order to tailor it to a particular user and his or her goal .

Recursive Nature of the Market for Enterprise Applications

Fergal Carton
University College Cork, Cork, Ireland

Frédéric Adam
University College Cork, Cork, Ireland

INTRODUCTION

The paper explores the recursive elements of the market for enterprise systems by examining the evolution of the sales discourse from vendors of enterprise applications. Enterprise systems are continually sold and implemented, on the basis that greater integration of the modules supporting business functions is a good thing. In this paper we question this assumption, principally based on the redundancy of much of the information that is produced.

Following the development of computer applications from early Material Resources Planning (MRP) days through to today's latest offerings in the form of Enterprise Resource Planning II (ERP II), we try to understand the circumstances which have generated the requirement (needs discourse). In parallel, it is posited that the sales discourse is characterised by a continual extension and re-packaging of existing solutions, responding to the business users' evolving requirements with ever greater integration between the operational modules. This tendency to over-integrate exacerbates the problem of information overload that is experienced by managers trying to monitor the organisation's performance, efficiency and effectiveness.

MRP was once implemented to gain better visibility and control of inventory, because it was understood that this was the most costly element of the cost of goods sold. Reducing inventory levels is a well understood management goal in most manufacturing organisations. On the other hand, the abundance of information that has accompanied the gradual computerisation of business functions doesn't seem to elicit a similarly "economical" attitude towards information. Instead of encouraging information excess, we argue in favour of a "Just-in-Time" approach to information provision, where appropriate information is delivered where and when it is needed, rather than exhaustive information being available to all. Going as far back as the fundamental design issues of enterprise applications, we question whether business value can be gained from continually integrating business functions into a single data structure.

BACKGROUND

The focus of industry in the years following the Industrial Revolution was on providing as much output as possible, as opposed to controlling inventory (Mokyr, 2001). With this change came the increasing need for systems to support the increasingly complex nature of mass production facilities and activities (O'Gorman, 2004).

Research had shown, however, that the main problem of managers was not a lack of relevant information, rather an overabundance of irrelevant information (Ackoff, 1967). In that era, the constraining factor on the level of computerisation was cost. The gradual commoditisation of technology has meant that storage hardware is (relatively) cheap, therefore there is no culture of economy with its use (or abuse).

This "changing cost balance" has been attributed to the original growth in the uptake of computer applications to support MRP (Miller & Sprague, 1975). Although the MRP logic was already available and widely applied, the use of systems had been hitherto prohibitively expensive for most businesses. Computation costs were falling as inventory costs were rising. The rapid update capability of computers, coupled with the MRP logic and appropriate data, made it possible for managers to cope intelligently with the thousands of changes that inevitably occur between the planning and execution of primary tasks.

The natural propensity of computer manufacturers is to sell new systems that use lots of computer time (Miller & Sprague, 1975). The same increase in price performance ratio prompted the adoption Enterprise Resource Planning (ERP) systems in the 1990's, integrated systems capable of uniting and correlating the basic units of the business transaction (from sales order to finished goods, from demand forecast to master production schedule).

In order to achieve this integration, ERP systems rely on large central relational databases. The amount of storage and memory required to manipulate and operate these databases grew in tandem with the improvement in cost/performance of the hardware. Furthermore, software houses gradually moved away from the client/server model to the "thin client", capable of running on any PC with a browser. For the first time it was feasible for an organisation to operate its entire transaction processing infrastructure from a remote centralised server, using the internet to deliver functionality to the desktop.

Sammon et al. (2003) describes these 2 components of ERP systems as the solution to "operational" integration problems and "informational" requirements of managers. These are the same concepts expressed by Zuboff (1988) in describing the use of technology not only to automate manual tasks, but also to "informate" management tasks, such that "events, objects and processes become visible, knowable and shareable in a new way".

ERP systems are therefore expected to deliver the following benefits: (1) reduce costs by improving efficiencies through computerization; and (2) enhance decision-making by providing accurate and timely enterprise-wide information (Poston and Grabski, 2001).

Whether these centralized information systems really are capable of delivering both types of benefit has been a topic of debate for some time. "The notion that a company can and ought to have an expert (or a group of experts) create for it a single, completely integrated super-system – an MIS – to help it govern every aspect of its activity is absurd", according to Dearden (1972).

The Trend Towards Greater Integration

In a traditional manufacturing organisation, materials accounted for 75-80% of the total cost of provision of the cost or service (O'Gorman, 2004). The attitude of planners in the 70's was therefore to develop methods that minimised inventory excess (in materials, WIP or finished goods).

Conversely, the focus of today's ERP vendors as they strive for ever greater integration has been to provide as much information as possible (analogous to a "build to stock" model in manufacturing terms) rather than trying to control it.

ERP systems, with their focus on the integration of processes and their dependence on the integrity of data at the point of entry, can be compared to virtual assembly lines, where each stage in the business process is optimised for the throughput of high volumes of transactions.

A major downside to this level of integration of business processes is that informational "stock-outs" can occur (one small piece of relatively unimportant information missing can block a business critical transaction). A classic example would be an exchange rate missing blocking an invoice from printing.

One of the benefits of employing what ERP vendors call "best practice" is that all transactions must fit in the same system model, regardless of the relative importance of the transactions. Thisignores the 80:20 rule as elaborated by Orlicky (1975), in what is probably the definitive book on MRP, according to Browne, Harhen & Shivnan (1996). If 20% of the components account for 80% of the cost, why apply the same rigour to recording transactional movements of inventory across 100% of components?

Sammon & Adam (2004) describe how businesses can succumb to the "ERP steamroller" of integration in the area of procurement. The integration of procurement into one single instance ERP system implies a rationalisation of local suppliers and purchasing patterns and the elimination of redundant suppliers. This can result in the organisation losing its ability to vary the source of supply. It can also have the effect of "steamrolling" local differences in the supply base, for example, locally sourced components not having exactly the same specification as counterparts in other countries. As with all elements of master data (suppliers, parts, customers etc.), integrated systems covering global operations are intolerant of local nuances in data structure.

One downside to the large scale integration of business processes as exemplified in ERP systems is the onus it puts on data capture: the more integrated the system, the more data is required at the point of entry in order that flags and triggers encountered during subsequent steps in the process are populated. Broadly speaking, ERP systems push the onus of data quality back to the point of entry, decentralising responsibility for data quality back to the rightful owners of that data.

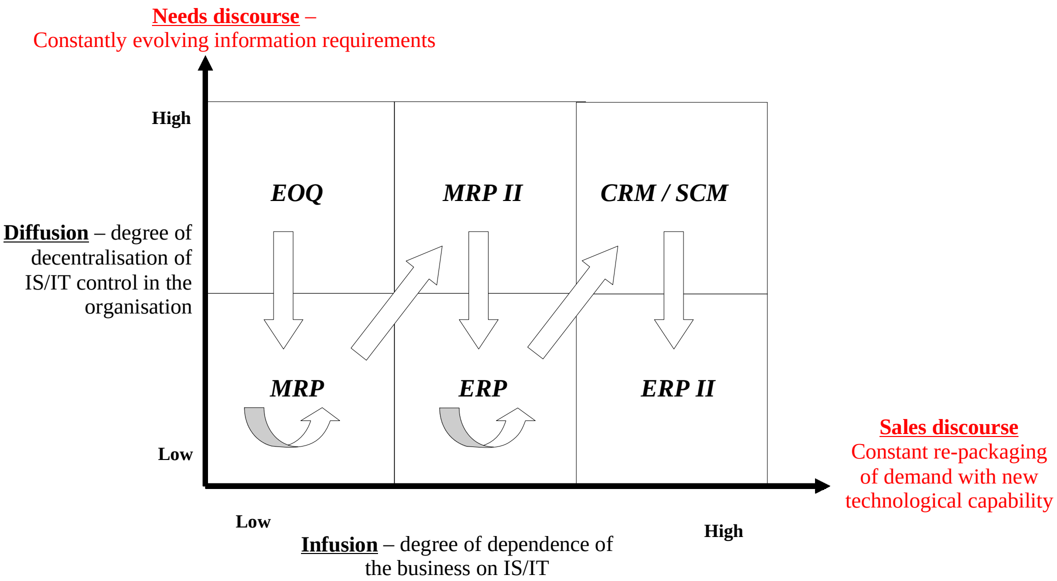
The Cyclical Nature of the ERP Market

The table in Figure 1, adapted from the IT planning matrix developed by Sullivan (1985), depicts the different stages in the evolution of planning requirements and corresponding management approaches. This evolution is plotted against the 2 main forces of change in IT: dependence of the business on IT (Infusion), and the degree of decentralisation of IT planning and control (Diffusion).

In simple manufacturing processes with few dependencies, material acquisition could be based on a principle of Economic Order Quantity (EOQ), whereby re-ordering of stock items was triggered automatically based on a minimum stock level. MRP originated in the early 60's as a computerised approach for the planning of materials acquisition and production for more complex manufacturing processes where interdependencies between components existed. Orlicky (1975) realised that a computer enabled the detailed application of the technique, making it effective in managing manufacturing inventories.

Based around the Bill of Materials (BOM), early applications exploded a production plan for a top level parent item into a plan of production and purchasing for compo-

Figure 1: The evolution of planning requirements and corresponding management approaches.



nent items. These systems were implemented on large mainframe computers run in centralised material departments for large companies.

A strong influence in the promotion of MRP was the campaign of communication launched by the 11,000 member American Production & Inventory Control Society in the early 70's. The computer industry soon followed with a range of applications. Almost all the major computer manufacturers had developed and were pushing software applications to support MRP, and virtually every major industrial consulting firm was advising on their implementation (Miller & Sprague, 1975).

Starting, therefore, under the "traditional" influence of IT, the use of these applications became more widespread, leading to the extension of the software to support various related operational functions. In particular, the combination of the planning and execution modules, with the potential for feedback from the execution cycle to the planning cycle, was termed closed-loop MRP.

So closed-loop MRP, together with some financial modules, developed into an integrated approach to the management of manufacturing resources. This approach became known as Manufacturing Resource Planning or MRP II. From the 1980's onwards, MRP II applications became available at lower cost on minicomputers and then microcomputers.

The attraction of the move to MRP II in the 80's lays not only in its role as decision making support, linking as it did, the planning and execution modules of manufacturing; but more importantly, in its integrative role within the manufacturing organisation (Browne, Harhen, Shivnan, 1996). Similarly, the attraction of moving to ERP in the 90's lay not only in its integrative role within the organisation, but also in its integrative role within the corporation, forcing geographically disparate entities to toe a common line with respect to operational procedures.

FUTURE TRENDS

The growth in popularity of ERP systems can be linked to an increasing business trend towards globalization, mergers and acquisitions. To be successful, a global company must be able to control and coordinate their various remote operating units. Accurate, real-time information provided by an ERP system has the ability to integrate the more remote subsidiaries into corporate practice because an ERP system allows the sharing of information in standard format across departments, currencies, languages and national borders. Thus, ERP systems can be used to provide a "common language" between units (Bingi *et al.*).

On the other hand, many post-ERP companies are realising that despite the huge implementation expense of the project, the business is no better off in terms of having access to summarised information which might assist managers in making decisions. CIO's might well demand, after the extravagant sales discourse and staggering budgets commanded by ERP vendors, what is the cost of having stockpiles of detailed transactional information?

As we look to the future, computation costs are still falling, while pressure on cost reduction has been growing since the worldwide economic recession in the new millennium. Vendors, desperate to make up for the dearth in large IT investments, attributed to Y2K fears, never saw the purse strings loosened as IT budgets were reduced in line with all corporate spending cuts. What is the solution? The natural propensity of computer manufacturers is to tout new systems that use lots of computer time (Miller & Sprague, 1975).

Cue the emergence of the Enterprise Resource Planning II market, billed by some vendors as the means to realising the benefit originally planned for ERP, and by others as the continuation of the "integration" of business processes. This continuing integration is focused on the area of Product Lifecycle Management, whereby engineers and product designers are "integrated" into the sales process at one end of the cycle, to allow better translation of customer requirements, and to manufacturing at the other end of the cycle, to facilitate the development of efficient production processes.

CONCLUSIONS

In a survey of 20 US companies, Lederer and Mendelow (1987) found that top managers did not view information as a business resource to be managed for long-term benefit. They only appreciated its criticality when they could not get what they needed.

Business resources (for example, assets, inventory, employees) are managed carefully because managers understand that making efficient use of these resources is key to the survival of the business. Investment in these areas is always evaluated carefully with respect to what contribution they will bring to the business.

It has been notoriously difficult in the past to cost-justify investments in information systems, and therefore vendors have opportunistically hitched their offerings to requirements that have an in-built business case (reducing inventory costs, for example).

A fundamental question worthy of further research is: to what extent do vendors instigate new demand for products simply by integrating application modules that share a common underlying data structure?

In their discussion of management fads and fashions in the ERP community, Sammon and Adam (2004) suggest that there is a mutually beneficial undercurrent to the constant re-packaging of the expert discourse: for every fad there will be a corresponding "panacea". In dealing with the complex problems facing organisations today, the language promoted by vendors in the ERP community tends to help formulate old problems in new ways, such that clients can elaborate the needs discourse in a way that is new, stimulating and irrefutable.

However, with each further step into the spiders web of integration, and letting what "can" be done take precedence over what "needs" to be done, the organisation is perhaps forgetting that: a) this apparent progress rarely gives tangible benefits, and b) flexibility is often more important than integration.

KEY TERMS

Bill of Materials (BOM): A Bill of Materials is a hierarchical product structure, showing the sub-components and interdependencies of any given finished good. Akin to a recipe, it is the underlying link between end product demand and material requirements. It also facilitates production costing, as each component in the hierarchy can be costed.

Closed loop MRP: The combination of MRP functionality with planning and production execution modules, with the potential for feedback from the execution cycle to the planning cycle, is termed "closed loop MRP".

Economic Order Quantity (EOQ): An approach to defining the lot size for purchasing raw materials, the EOQ is a mathematical expression of the trade-off between ordering costs (for purchased items) or set-up costs (for manufactured items) and the cost of storing material as inventory. If set-up or ordering costs are high, it may make sense to deal in larger batches, with the inherent knock-on effect of increasing inventory costs.

Enterprise Resource Planning (ERP): ERP systems are integrated applications that satisfy the transaction processing requirements for a wide range of business activities, including purchasing, production planning, warehouse management, inventory control, sales order processing, distribution, finance and human resources.

Enterprise Resource Planning II (ERP II): Enterprise Resource Planning II (ERP II) is a term that has been coined to denote the applications aimed at satisfying organisations who have already implemented ERP. This appears to include the realisation of efficiency gains originally planned for ERP, the implementation of ERP solutions to more vertical market segments and the further integration of key business processes (for example, to include PLM)

Manufacturing Resource Planning (MRP II): MRP II is closed loop MRP, enhanced with some financial modules for production costing and creditor management, usually running on a single integrated technical platform. MRP II was the immediate pre-cursor of Enterprise Resource Planning systems.

Material Requirements Planning (MRP): MRP, originating in the early 60's, was a computerised approach to the planning of materials acquisition and production for more complex manufacturing processes where interdependencies between components exist. The application of computers to MRP was a significant initial step in the evolution of ERP systems.

Product Lifecycle Management (PLM): Product Lifecycle Management is an approach whereby engineers and product designers are "integrated" into the sales process at one end of the cycle, to allow better translation of customer requirements, and to manufacturing at the other end of the cycle, to facilitate the development of efficient production processes. The "lifecycle" is derived from the notion of managing product design from inception through to execution and eventually retirement.

Relating Cognitive Problem–Solving Style to User Resistance

Michael J. Mullany
Northland Polytechnic, New Zealand

INTRODUCTION

This chapter explores cognitive problem-solving style and its impact on user resistance, based on the premise that the greater the *cognitive difference* (*cognitive gap*) between users and developers, the greater the user resistance is likely to be. Mullany (1989, 2003) conducted an empirical study demonstrating this. This study contradicts the findings of Huber (1983) and supports Carey (1991) in her conclusion that cognitive style theory, as applied to IS, should not be abandoned. Mullany's findings, in fact, are the opposite. Kirton (1999, 2004) supported Mullany's results. In particular, Mullany made use of Kirton's (2004) adaption–innovation theory. The emergent instrument, called the Kirton adaption–innovation inventory (KAI; Kirton, 1999, 2004), was used by Mullany as his measure of cognitive style.

Mullany's study also investigated the relationship between user resistance and user ages and lengths of service in the organisation. It failed to show any relationship between these factors and user resistance. This countermands the findings of Bruwer (1984) and dismisses any intimation that older or longer-serving employees are necessarily more resistant to change as myths.

BACKGROUND

Ever since the early 1980s, experts have identified user resistance to new systems as an expensive time overhead (see studies by Hirschheim & Newman, 1988, and Markus, 1983). Some authors suggest the greater importance of age and length of service. Bruwer (1984), for instance, claimed to have demonstrated that the older or longer-serving an employee, the more resistant he or she is likely to be to a new computer system. Clarification of issues surrounding user resistance has also highlighted *cognitive style theory* as potentially important, but to date, its impacts have only been sparsely researched in relation to user resistance, many of the prior studies being open to question. This research, on the other hand, proposes that a system will fail when the developer and user differ significantly in their problem-solving approaches. To reduce user resistance, it thus makes sense to recommend system designs that suit the user's approach to problem solving.

This issue appears only to have been studied empirically by Mullany (1989, 2003). He formulated the research question, "Is there a relationship between user resistance to a given information system and the difference in cognitive style between the user and the developer?" With the aid of his own instrument for measuring user resistance and the Kirton adaption–innovation instrument (Kirton, 1999) to measure the cognitive styles of users and associated system developers, he found a highly significant relationship between developer–user cognitive style differences and the level of user resistance to systems.

Why no other studies along similar lines have been reported in credible current research is difficult to explain. One possibility is that the literature contains speculative studies, such as that by Huber (1983), that discredit cognitive-style theory as a tool in understanding system success. Other studies, such as that by Carey (1991), while encouraging the continued use of cognitive-style theory in studying system phenomena, do not demonstrate its predictive success in information systems (IS). The remainder of this chapter thus examines the meaning and measure of cognitive style, the measure of user resistance, the specific findings of Mullany (1989, 2003), and outlooks for the future in this area of research.

THE MEANING AND MEASURE OF COGNITIVE PROBLEM-SOLVING STYLE

Liu and Ginther (1999) defined *cognitive style* as, "An individual's consistent and characteristic predispositions of perceiving, remembering, organizing, processing, thinking and problem-solving." Schroder, Driver, and Streufert (1967), in a discussion of human information processing, suggested that organisms "either inherit or develop characteristic modes of thinking, adapting or responding and go on to focus upon adaptation in terms of information processing." In short, an individual exhibits characteristic ways of processing information (and, hence, solving problems), known as his or her "cognitive style." Table 1 gives an historic summary of key experts over the years

Table 1. Cognitive-style constructs: Key studies.

Reference	Cognitive-Style Construct	Instrument
Kelly (1955)	Cognitive complexity or simplicity	**RepGrid** (Repertory grid)
Jung (1960)	Jungian typology	**MBTI** (Myers–Briggs type indicator)
Witkin et al. (1967)	Field dependence or independence	**EFT** (Embedded figures test)
Hudson (1966)	Converger or diverger	None
Schroder et al. (1967)	Cognitive complexity	**DDSE** (Driver's decision-style exercise)
Ornstein (1973)	Hemispherical lateralisation	Brain scan
Kirton (1976)	Adaptor–innovator continuum	**KAI** (Kirton adaption–innovation inventory)
Taggart (1988)	Whole-brain human information processing	**HIP** (Human information-processing instrument)

who have endeavoured to name and measure the construct of cognitive style. Of these, the MBTI (Myers–Briggs type indicator) is the most used in current, credible research literature, followed by the KAI (Kirton, 1976, 1984). As previously stated, the only evident effort made to relate cognitive style to user resistance was carried out by Mullany (1989) using the KAI. The reason for his preferred use of the KAI stemmed from its ability to provide a near-continuous, bipolar scale, convenient for finding correlations and associations. The MBTI, by contrast, yields only certain cognitive classifications, where no mutual order is evident. The correlation with other factors would then have been more difficult to show statistically.

Turning to the theory behind the KAI, Kirton (1999) identified two extremes of cognitive style; namely, the *adaptor* and the *innovator*. The adaptor tends to follow traditional methods of problem solving, while the innovator seeks new, often unexpected, and frequently less-accepted methods. The adaptor tends to "do well" within a given paradigm, where the innovator tends to "do differently," thus transcending accepted paradigms. The adapter is prepared to be wedded to systems, solving problems "in the right way," but is often seen as "stuck in a groove." The innovator has little regard for traditions, is often seen as creating dissonance, and elicits comments such as, "He wants to do it his own way, not the 'right' way." All humans, Kirton proposed, can be located on a continuum between the extremes of these two cognitive styles.

Both cognitive extremes can be highly creative, can resist change, and can act as agents for change. Adaptors support changes to the conservative, back to the "good old ways," and resist changes to novel methodologies. Innovators support changes toward unprecedented systems and technologies and resist changes to the traditional.

Kirton's instrument, the KAI, has been widely demonstrated to be a successful measure of his construct of cognitive problem-solving style. The instrument takes the form of a questionnaire, on which the respondent has to rate himself or herself against 33 character traits. KAI scores can range from 32 to 160, with a mean of 96 and a standard deviation of about 16. A person scoring above the mean of 96 is considered to be an innovator; conversely, a person scoring below 96 is rated as an adaptor. However, in the range of 80 to 112 (that is, within one standard deviation of the mean), a third cognitive style can be identified—the mid-scorer. Such persons tend to have human rather than technical problem-solving preferences and can relate better to the extreme scorers than either can to the other.

A DESCRIPTION AND MEASURE OF USER RESISTANCE

Mullany (1989) measured user resistance at personal interviews with the key user of each system selected for investigation. The user was asked to list the problems that he or she recalled had occurred during the system's development and implementation. They were asked, in effect, to make complaints, in confidence, against the system and its manner of implementation. Then they were requested to rate the severity of each complaint on a seven-point scale (with seven representing the most severe weighting). The sum of severities of all the complaints measured the respondent's *resistance score* or *R-score*. Obvious criticisms of the R-score method are as follows:

1. It may be highly influenced by the cognitive style of the interviewer.
2. At an interview, the user might forget certain crucial problems that had been experienced.

Mullany refuted (1) on the grounds that the same person (himself) did all the interviewing in his study. He assumed (2) to be of limited impact, because the object of the R-score method is to observe the user in the process of complaining. Consequently, the resistant user is capable of exaggerating or even inventing complaints, making the issue of those forgetten less relevant. However, he conceded the limitation that there are covert forms of resistance, such as absenteeism and withdrawal, that are not necessarily related to overt complaints.

To investigate a relationship between cognitive-style differences and user resistance, Mullany (1989) set out to collect data from a suitable sample of computer system developers and users. Bivariate data were to be collected, namely, the analyst–user KAI difference and the R-score for each user. The association between these was then to be measured. For his association measure, he used both the Kendall-*t* and the more traditional Spearman-*r*, which are equally reliable for significance testing (Liebetrau & Kendall, 1970). According to Kendall (1970; who invented the Kendall-*t* measure of association) and as confirmed by Liebetrau (1983), sample sizes of 10 to 20 are sufficient for such tests. The author thus selected a much larger sample size of 34 systems in 10 South African organizations. However, the following further criticisms were identified and addressed:

1. The sample size is small compared with some other studies in IS.
2. A user who champions a system may point out deficiencies in the hopes of improving that system.

Referring to the first of these criticisms, one should be alerted to the fact that sample representivity is more important than size in obtaining reliable results. In fact, the larger the sample, the less the researcher is likely to be able to guarantee a lack of significant bias. For example, suppose that with the aid of a suitable instrument, one sets out to measure the diligence of some human population. If a large sample size is sought through a postal, Web-based, or e-mail survey (the only practicable methods for really large samples), only the most diligent respondents are likely to respond, giving a bias to the more diligent and, thus, casting serious doubt on the results. To reduce this effect, Mullany (1989) collected all the data at personal interviews with the analysts and users. Furthermore, organisations he approached were requested to provide a fair spread of systems in use. He thus used legitimate power lent to him by the organisations to interview those as he required.

The second criticism was addressed by obtaining approval to keep all employees' responses confidential and to make this clear at each interview. This meant that a user would be unlikely to complain to Mullany in the hopes of achieving some system improvement, as he or she knew that no information would be relayed to the rest of the organisation. Every effort was made to preserve standard interviewing conditions: these being freedom from pressure or interruption and complete assurance of confidentiality. In short, interviewing conditions similar to those of face-to-face counselling were achieved. Furthermore this technique of measuring user resistance has been confirmed by respected researchers. First, both Markus (1983) and Hersheim et al. (1988) identified complaint as an overt symptom of, if not even a form of, resistance. Kirton (2004), in a discussion of Mullany's study, confirmed the technique as valid.

THE RELATIONSHIP BETWEEN USER RESISTANCE AND THE DIFFERENCES IN COGNITIVE STYLES BETWEEN THE USER AND THE DEVELOPER

The key developer and key user of each were interviewed. In each case, measures were obtained for the developer KAI score, user KAI score, and user R-score. At the same time, demographic data were collected; most particularly, the ages and lengths of service of the respondents, in order to test the findings of Bruwer (1984). A relationship as an association was found for the user R-scores versus the absolute differences between developer and user KAI scores. The association (with $p < 0.005$) proved to be strong, suggesting that user resistance can be minimized by matching a user with a developer of similar cognitive style. However, no significant associations were found between the ages and lengths of service of users and their R-scores, in contradiction of Bruwer's (1984) results. Rosen and Jerdee's (1976) study, which sought a similar result for occupational groups in general, agrees with Mullany's findings in this respect.

An interpretation of the R-score was demonstrated based on a near-perfect direct proportion that proved to exist between the weighted and nonweighted numbers of the users' complaints. In this relationship, the constant of proportionality was found to be 3.913 (that is, nearly 4). The R-score can thus be described as approximately four times the number of complaints a user will make retrospectively, in private, concerning a system and its manner of implementation.

FUTURE TRENDS

This study reignites the issue of cognitive style as an important issue in IS and completely countermands the conclusions of Huber (1983). It substantially strengthens the case made by Carey (1991) that cognitive-style issues in IS research should not be abandoned. Further, it suggests that user resistance and the related constructs of user dissatisfaction and system success can be predicted from cognitive-style measures (that is, KAI scores) prior to system development.

Areas for further research centre upon the main limitation of this study. For instance, there is little known regarding how the developer-user cognitive gap influences the system development life cycle (SDLC) over a significant passage of time, and neither this study nor any other found in the literature has achieved this. In fact, the literature is devoid of any attempts to conduct such research. A longitudinal study where SDLC curves are compared with the developer-user cognitive gap would be of immense importance and interest. New rules for system development based on cognitive-style testing would be expected to emerge.

CONCLUSION

It is clear that cognitive problem-solving style, as defined by Kirton and measured using the KAI, impacts user resistance. The greater the cognitive gap between users and developers, the greater the user resistance is likely to be. This contradicts the findings of Huber (1983) and supports Carey (1991) in her conclusion that cognitive-style theory, as applied to IS, should not be abandoned. Mullany's findings, in fact, are the opposite.

The failure to show any relationship between users' ages and lengths of service, and their resistance ratings, countermand the findings of Bruwer (1984) and suggest that organisations should be alerted to the danger of discriminating against older or longer-serving users or dispensing with their services on such grounds.

As mentioned above, areas for further research centre upon the main limitation of this study. A longitudinal study where SDLC curves are compared with the developer–user cognitive gap would be of great importance and interest.

KEY TERMS

Adaptor: An adaptor tends to follow traditional methods of problem solving, tending to "do well." He or she is often seen as "stuck in a groove" (Kirton, 1999).

Association: A relationship between two statistical variables. Unlike a *correlation*, an association does not yield a quantitative result but is contingent upon the ranking of the bivariate data values only.

Cognitive Gap: The difference in cognitive problem-solving style between two people, especially two people who are obliged to interact as members of a group or team.

Cognitive Problem-Solving Style: The position an individual occupies between two extremes of cognitive problem-solving style personality; namely, *the adaptor* and *the innovator*.

Cognitive Style: An individual exhibits characteristic ways of processing information and, hence, solving problems, known as his or her "cognitive style."

Innovator: The innovator seeks new, often unexpected, and frequently less acceptable methods. He or she has little regard for traditions, is often seen as creating dissonance, and elicits comments such as, "He wants to do it his own way, not the 'right' way" (Kirton, 1999).

KAI (Kirton Adaption-Innovation Inventory): An instrument that measures cognitive problem-solving style. It takes the form of a questionnaire, on which the respondent is asked to rate himself or herself against 32 character traits.

R-Score (Resistance Score): A method of measuring user resistance where, at personal interviews with the key user of a given system, the user is asked to list system problems and then to rate the severity of each on a seven-point scale. The sum of severities of all the complaints measures his or her *R-score* (Mullany, 1989).

User Resistance: Any user behaviour, action, or lack of action that inhibits the development, installation, or use of an information system.

Relationship Cardinality Constraints in Relational Database Design

Dolores Cuadra

Universidad Carlos III de Madrid, Spain

INTRODUCTION

Database modelling is a complex task that involves conceiving, understanding, structuring and describing real universes of discourse (UD) through the definition of schemata using abstraction processes and data models. Traditionally, three phases are identified in database design: conceptual, logical and physical design. The conceptual modelling phase represents the most abstract level since it is independent of any database management system (DBMS) and, consequently, it is very close to the user and allows him/her to collect almost completely the semantics of the real world to be modelled.

A conceptual schema, independent of the data formalism used, plays two main roles in the conceptual design phase: a *semantic* role, in which user requirements are gathered together and entities and relationships in a UD are documented, and a *representational* role that provides a framework that allows a mapping to the logical design of database development. Three topics are involved in the database conceptual modelling process: data modelling formalism, methodological approach, and CASE tool support. One of the most extended data modelling formalisms, extended entity relationship (EER) model, has proved to be a precise and comprehensive tool for representing data requirements in information systems development, mainly due to an adequate degree of abstraction of constructs that it includes. Although the original ER model was proposed by Chen (1976), many extensions and variations as well as different diagrammatic styles have been defined (Hull & King, 1987; McAllister, 1998; Peckhan & Maryanski, 1988).

In database conceptual analysis, one of the most difficult concepts to be modelled is the relationship concept, especially higher order relationships, as well as its associated cardinalities. Some textbooks (Boman et al., 1997; Ullman & Widom, 2001) assume that any conceptual design can be addressed by considering only binary relationships since its aim is to create a computer-oriented model. We understand the advantages of this approach although we believe that it may produce certain loss of semantics (some biases are introduced in user requirements), and it forces to represent information in rather artificial and sometimes unnatural ways.

Concerning the logical design, the transformation process of conceptual schemata into relational schemata should be performed trying to preserve the semantics included in the conceptual schema completely; the final objective is to keep such semantics in the database itself and not in those applications that access to the database. Nevertheless, sometimes a certain loss of semantics is produced, for instance, *foreign key* and *not null* options in the relational model are not sufficient to control relationship cardinality constraints.

CONCEPTUAL MODEL REVISED

Central concepts of the ER conceptual model are entities and relationships; these constructs were introduced by Chen (1976) and have been incorporated in other conceptual models although with different names: *class, type*, and so forth, for entities and *associations* for relationships. Nevertheless, those concepts do not have a precise semantics, and, consequently, it is necessary to fix their meaning.

Although the entity concept is widely used and accepted, there is no agreement on one definition; for instance, Thalheim (2000) collects 12 different entity denotations. Although experts are not able to give a unique definition, the underlying concept is coincidental in all of them and its usage as design element does not suppose great disadvantages. An entity definition is not given here, just to highlight, according to Thalheim (2000), an entity is a *representation* abstraction with modeling purposes. Date (2004) adds that the represented concept is a distinguishable object, but we do not consider this feature as essential because it depends on the designer's point of view.

The relationship concept is more confused; it is defined as an *association* among entities. This definition offers many interpretations; for instance, in several design methods there are some differences depending on the number of relations can participate in other relationships as in HERM (Thalheim, 2000) by means of association entities as in UML, OMG (2000), or by grouping as clusters a set of entities and relationships (Teorey, 1999). These differences occur because a relationship combines *association* features with *representation* features, and therefore, it might be considered a relationship (if association aspects are highlighted) or an entity (if representation aspects are emphasized).

Cardinality constraint is one of the most important restrictions that can be established in a relationship, and in general, in a conceptual schema. Its functionality is to limit the number of entity occurrences associated in a relationship. Even though it is a simple concept, the definition of this constraint admits several variants.

Two main approaches are discussed: the Chen's constraint that is an extension of the mapping constraint (a special case of cardinality constraint that considers only the maximum cardinality and that for binary relationships can be 1:1, 1:N or N:M) (Chen, 1976); the Chen's constraint has been adopted or extended in different data models and methodologies. On the other side, the MERISE approach (Tardieu, Rochfeld, & Coletti, 1983) incorporates the participation semantics. These two approaches meet each other when cardinality constraints for binary relationships are defined (excepting the natural differences in graphical notations). Both of them represent the same semantics in binary relationships although the way of expressing it is different. Table 1 summarises the semantics associated to cardinality constraint for the occurrences of *A* in the binary relationships *R*.

In n-ary relationships, the two approaches Chen and Merise, previously commented, do not represent the same semantics. Table 2 summarises the semantics associated to cardinality constraint for *A* in the n-ary relationship *R* depending of the approach.

TRANSFORMATION OF CONCEPTUAL SCHEMATA INTO RELATIONAL SCHEMATA

The main difficulty when transforming a conceptual schema into a relational schema is information preservation. Generally, to achieve a complete mapping between both models and keeping their inherent and semantic restrictions from conceptual model to relational model is quite complicated. Usually, restrictions that cannot be applied in the relational model must be reflected in the application in some different way, that is, outside the DBMS. In this way, there are several extensions to the relational model proposed by Codd (1970), Codd, (1979), Date, (2004) and Teorey (1999) that provide a more semantic model.

The principal transformation rules are described in most database textbooks (Date, 2004; Elmasri & Navathe, 2003; Ramakrishnan & Gehrke, 2002), but these rules do not reflect the cardinality constraints transformation. In general, these rules can be classified for binary relationships transformation depending on the relations number that generated (Table 3). Option 1 makes a relation for each constructor, therefore the R relationship is transformed in a relation. Option 2 uses *key propagation* that is applied to a relationship which mapping constraint is 1:N or 1:1. Last, Option 3 only considers just one relation, to store the information of A, B and R constructors. This option

Table 1. Cardinality constraint in binary relationship summary

	A — R — B	
Cardinality constraint for **A**	Minimum	Maximum
0	**Optional**: there are occurrences of entity A that not participates in the relationship R	Inapplicable
1	**Mandatory**: all occurrences of entity A participates in the relationship R	**Uniqueness**: there is at most one occurrence of the entity B related to an occurrence of the entity A
k>1	**K-Mandatory**: each occurrence of the A participates at least K times in the relationship	**K-Limit**: There are at most K occurrences of the B related to each occurrence of the A
N	Inapplicable	Without limit of maximum participation

Table 2. Cardinality constraint in n-ary relationship summary

	Chen Approach		Merise Approach	
Cardinality constraint for **A**	Minimum	Maximum	Minimum	Maximum
0	Presence of unknown information	Inapplicable	Optional participation of the A ocurrences	Inapplicable
1	No constraint	For each (n-1) record there is one unique ocurrence related with one ocurrence of the entity A in the R	Mandatory participation of the A	For each A ocurrence there are at most one ocurrences related in the R
k>1	For each (n-1) record there are at least more than one ocurrences of the entity A related in the R	For each (n-1) record there is at most K ocurrences related with one ocurrence of the entity A in the R	For each A ocurrence there are at least more than K ocurrences related in the R	For each A ocurrence there are at most K ocurrences related in the R
N	Inapplicable	Without limit of maximum participation	Inapplicable	Without limit of maximum participation

is more restrictive than the others and only can be applied in a relationship which mapping constraint is 1:1.

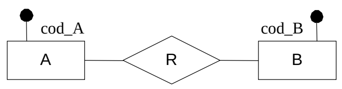
Table 4 explains when the different options explained in the Table 3 can be used depending on cardinality constraints (max. and min.) associated with the entities A and B and summarizes main transformation rules, indicated by options and relational constraints that must be included to add semantics. Relational constraints considered are: primary key (PK), unique key (UK), foreign key and the reference to relation X (FK_X), and optional attributes (N).

As we can see in Table 4, in most cases the minimum cardinality, the three first rows in the table, is not considered so its associated semantics is lost at the transformation.

When we transform n-ary relationships, we must take into account:

- the cardinality constraint approach used in the conceptual model;
- whether a relationship should be decomposed in minor grade relationships; and
- if the study cardinality constraint validation is needed.

Table 3. Binary relationship transformation options



Option 1	**Option 2**	**Option 3**
A (cod_A,...)	A (cod_A,...,cod_B)	R (cod_A, cod_B,...)
B (cod_B,...)	B (cod_B,...)	
R (cod_A, cod_B,..)		

The relationship decomposition and cardinality constraint validation study is a complex task that needs the interaction with domain experts to be solved. Therefore, transformations rules, on the whole, presented easy rules.

An example of different transformation rules with the Merise and Chen approaches for a ternary relationship is presented in Table 5. As it is shown in the table, rules only depend on mapping constraint.

In addition, the principal transformation rules for a ternary relationship, adopted for most design methodologies, appear independent of minimum cardinality constraints. This situation appears also in higher relationships.

Therefore, we can summarize that the cardinality constraint is one of the most important restrictions that can be established in a relationship, and in general, the semantics associated is loss in the transformation process to relational model.

CRITICAL ISSUES OF CARDINALITY CONSTRAINTS

After reviewing all conceptual constructs, it is needed to achieve a conceptual model as a tool that is able to reflect the situations that frequently appear in data modelling scenarios where it is required. The redefinition of the conceptual model, taking into account previous aspects as well as the development of a wider notation, are tasks to be dealt with.

The detection and specification of abstractions in an UD that lead to a correct and complete schema are critical problems that combine psychological and methodological aspects. There are many other aspects associated with the specification of constraints. Their identification and validation require more formal treatments. Identification can be faced up to with a lexical analysis of a problem

Table 4. Transformation rules summarised

A and B cardinalities	Option	Constraint
(0/1,n) (0/1,n)	1	UK on R: (cod_A, cod_B) FK_A on R: cod_A FK_B on R: cod_B
(0,1) (0/1,n)	1	PK on R: cod_A NN on R: cod_B FK_A on R: cod_A FK_B on R: cod_B
	2	FK_B on A: cod_B N on A: cod_B
(1,1) (0/1,n)	2	FK_B on A: cod_B NN on A: cod_B
	1	PK on R: cod_A NN on R: cod_B FK_A on R: cod_A FK_B on R: cod_B
(0,1) (0,1)	1	CC on R: cod_A o cod_B NN on R: cod_A, cod_B FK_A on R: cod_A FK_B on R: cod_B
	2	FK_B on A: cod_B NN on A: cod_B o FK_A on B: cod_A NN on B: cod_A

A and B cardinalities	Option	Constraint
(0,1) (1,1)	2	FK_A en B: cod_A NN on B: cod_A
	1	UK on R: cod_A, cod_B NN on R: cod_A, cod_B FK_A on R: cod_A FK_B on R: cod_B
(1,1) (1,1)	2	FK_B on A: cod_B NN on A: cod_B **or** FK_A on B: cod_A NN on A: cod_B
	1	CC on R: cod_A, cod_B NN on R: cod_A, cod_B FK_A on R: cod_A FK_B on R: cod_B
	3	PK on R: cod_A NN on R: cod_B

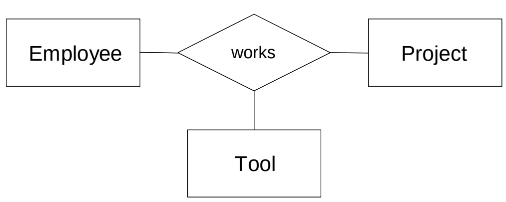
UK : Unique Key
PK: Primary Key
FK_A: Foreign Key reference to A
N: Column Null
NN: Column Not Null

description. Syntactic and semantic validation of relationships is a critical aspect of internal coherence with the UD. To obtain these properties, it is very important to:

- clarify the relationship definition;
- define formally relationship cardinality constraints and consider the two main approaches unification to higher order relationships;
- classify several approaches and provide conceptual model mappings; and
- provide a set of rules to validate relationships.

On the other hand, another problem is how to preserve the cardinality constraint semantics in n-ary relationships for their implementation in a DBMS. There are some approaches, for example, in Balaban and Shoval (2002), an extension of the extended entity relationship (EER) model is made by including methods to control the semantics associated with Chen's cardinalities. This approach adds a dynamic component to the model, but any database management system supports it. Camps (2002) makes a complete analysis of the transformation of maximum cardinality constraints into the relational model, considering

Table 5. Transformation rules to apply an example



Employee (cod_e,...)
Project (cod_p,...)
Tool (cod_t,...)
works (cod_e, cod_p, cod_t,...)

Chen Approach

Rule 1: **N:M:P**
Candidate keys = {(cod_emp, cod_proy, cod_tec)}
Rule 2: **1:N:M**
Candidate keys = {(cod_proy, cod_tec)}
Rule 3: **1:1:N**
Candidate keys = {(cod_proy, cod_tec), (cod_emp, cod_tec)}
Rule 4: **1:1:1**
Candidate keys = {(cod_proy, cod_tec), (cod_emp, cod_proy), (cod_emp, cod_tec)}

Merise Approach

Rule 1: **N:M:P**
Candidate keys = {(cod_emp, cod_proy, cod_tec)}
Rule 2: **1:N:M**
Candidate keys = {(cod_emp)}
Rule 3: **1:1:N**
Candidate keys = {(cod_emp), (cod_proy)}
Rule 4: **1:1:1**
Candidate keys = {(cod_emp), (cod_proy), (cod_tec)}

Chen and Merise cardinalities for ternary relationships. They use equivalencies between cardinality constraints and functional dependencies, but this work does not concern to the transformation of minimum cardinalities problem. Finally, Cuadra et al. (2002) present the transformation of EER schemata into relational schemata using an extended relational model with active capabilities giving solutions to this problem.

CONCLUSIONS

Conceptual models are well-known tools to achieve a good design of information systems. Nevertheless, the understanding and use of all constructs and constraints which are presented in these models are not an easy task, and sometimes it causes loss of motivation. Disagreements between main conceptual models, such as the confusion in the use of some of their constructs and some open problems in these models, are shown.

Another important topic treated in this chapter is the conceptual schema transformation into logical schema. Some solutions are presented in order to clarify the relationship construct and to extend the cardinality constraint concept, as well as several approaches to preserve the cardinality constraint semantics in n-ary relationships.

KEY TERMS

Cardinality Constraints: One constraint established in a relationship. It limits the number of entity occurrences that are associated in a relationship.

Chen Approach: One way to calculate cardinality constraints. It limits the participation of a combination of the other entity(ies) with an entity in the relationship.

Conceptual Models: Tools to achieve a good design of information systems. These tools are used to express information system requirements specification, and their principal characteristic is easy and intuitive use.

Entity: The basic element in a conceptual model that represents an abstraction with modelling purposes.

Logical Models: In a design methodology, tools to transform conceptual schemata into a schemata near to implementation. A well known principal model is the relational model.

Merise Approach: Another way to calculate cardinality constraints. It limits the participation of an entity in the relationship.

Relationship or Association: The basic element in one conceptual model. It is defined as an association among entities.

Semantics: Property that collect UD specifications and that should be preserved in the transformation schemata for all methodology phases.

Reuse of Formal Specifications

Laura Felice

Universidad Nacional de San Luis, Argentina

INTRODUCTION

During the Rigorous Approach to Industrial Software Engineering (RAISE) specification development process, a variety of components and infrastructures are built. All of these components are not independent, but related to one another, especially when we specify different systems into the same infrastructure. The RAISE method (Bjorner, 2000) is based on the idea that software development is a stepwise, evolutionary process of applying semantics-preserving transitions. Thus, the reuse process is crucial in all of the stages of the development, but there is no explicit reference to the specification reusability in this development process.

Software components are typically very rich in information, making the task of characterizing them and capturing their relevant properties difficult. However, this is not the only reason that makes software reuse difficult. Krueger (1992) provides a brief general survey and very clear view of different approaches for software reuse.

Information retrieval methods based on analyses of natural-language documentation have been proposed to construct software libraries (Helm & Maarek, 1991; Maarek, Berry & Kaiser, 1991). Software components represented by natural language can make the retrieval process a task with ambiguity, incompleteness and inconsistency. Using a rigorous method to the retrieval of a component can minimize all of these problems.

Based on these observations, we introduce a Reusable Component (RC) model for the definition of the reusable component structure into RAISE. Related to this method, it is important to emphasize the work of Beltaifa and Moore (2001). They propose an infrastructure to support reuse improving the efficiency of reusing software components.

RC model integrates RAISE Specification Language (RSL) specifications (George et al., 1992) and object-oriented code. RC model describes object-oriented classes at different levels of abstraction:

- Specialization: hierarchies of RSL implicit specifications related by formal specialization relationship.
- Realization: hierarchies of RSL complete algebraic specifications related by realization relationship.
- Code: hierarchies of imperative RSL schemes related by implementation relationship and linked to object-oriented code.

Also, a rigorous process for reusability of RC components is defined. Its manipulation, by means of specification building operators (Rename, Extend, Combine and Hide), is the basis for the reusability.

Our approach allows that the properties of components formally specified can be characterized by giving a functional (RSL specification) description. Therefore, they may be useful to someone searching for a particular component.

Different possible classes of existing RC components may be retrieved using a formal reasoning technique: an exact match to the query specification, a component more general than the query, or a component more specific than the query.

BACKGROUND

Different approaches to specify reusable components functionalities have been proposed. The way in which the components can be used with others can play a critical role in the reuse implementation.

Related with the RAISE method, we emphasize the work of Beltaifa. They propose an infrastructure to support reuse which improve both the ease and efficiency of reusing software components. The main difference with our work is the integrated process defined for all stages of the development method.

As a typical related work, we can mention Hennicker and Wirsing (1992) who present a model for reusable component definition. A reusable component is defined as an unordered tree of specifications where any two consecutive nodes are related by the implementation relation and the leaves are different implementations of the root. The work of Chen and Cheng (1997) is another approach that provides a formalism to register components properties to reuse them based on the architecture and integration of the system. They are related to LOTOS tools to facilitate the retrieval of the reusable component.

On the other hand, the work of Zaremski and Wing (1997) is related to the specification matching. It is very important to emphasize this proposal has been referenced by a lot of authors.

There are two main activities in the RAISE method: writing an initial specification, and developing it towards something that can be implemented in a programming language (George, 2002). Writing the initial specification is the most critical task in software development. If it is wrong, that is, if it fails to meet the requirements, the following work will be largely wasted. It is well known that mistakes made in the life-cycle are considerably more expensive to fix than those made later.

What kinds of errors are made at the beginning? The main problem is that we may not understand the requirements. The requirements are written in a natural language, and, as a result, likely to be ambiguous. The aim of the initial specification is to capture the requirements in a formal and precise way.

MAIN THRUST OF RAISE AND REUSE

The aim of the project RAISE was to develop a language, techniques and tools that would enable industrial usage of "formal methods" in the construction of software systems. The results of this project include the RSL language, which allows us to write formal specifications; a method to carry out developments based on such specifications, and a set of tools to assist in edition, checking, transforming and reasoning about specifications.

RSL is a "wide spectrum" language that can be applied at different levels of abstraction as well as stages of development. It includes several definition styles such as model-based or property-based, applicative or imperative, sequential or concurrent.

A development in RAISE begins with an abstract specification and gradually evolves to concrete implementations. The first specification is usually an abstract applicative one, for example, functional or algebraic. A first algebraic specification should have:

- A hierarchy of modules whose root is the system module;
- A module containing types and attributes for the non-dynamic identified entities; and
- The signatures of the necessary functions associated with types. These functions should be categorized as generators (if the associated type or a type dependent on it appears in their result types) and as observers. Besides, preconditions should be formulated for partial functions. These preconditions are expressed by means of functions called "guards".

The specification may contain invariants expressed as functions.

RC Model Description

RC describes object classes at three different conceptual levels: specialization, realization and code. These names refer to the relations used to integrate specifications in the three levels. A more detailed description can be found in Felice, Leonardi, Favre, and Mauco (2001).

RC Components

The specialization level describes a hierarchy of incomplete RSL specifications as an acyclic graph. The nodes are related by the specialization relationship. In this context, it must be verified that if P(x) is a property provable about objects x of type T, then P(y) must be verified for every object y of type S, where S is a specialization of T.

Specialization level reconciles the need for precision and completeness in abstract specifications with the desire to avoid over-specification.

Every leaf in the specialization level is associated with a sub-component at the realization level. A realization sub-component is a tree of complete specifications in RSL:

- The root is the most abstract definition.
- The internal nodes correspond to different realizations of the root.
- Leaves correspond to sub-components at the implementation level.

If E1 and E2 are specifications E1 can be realized by E2 if E1 and E2 have the same signature and every model of E2 is a model of E1 (Hennicker & Wirsing, 1992).

Adaptation of reusable components, which consumes a large portion of software cost, is penalized by overdependency of components on the physical structure of data.

The realization level allows us to distinguish decisions linked with the choice of data structure. In RAISE, there are four main specification style options. They are applicative sequential, imperative sequential, applicative concurrent and imperative concurrent (George, Haxthausen, Hughes, Milne, Prehn, & Pedersen, 1995). Associated with them, there are two styles: abstract and concrete. Imperative and concrete styles use variables, assignments, loops, channels (in concurrent specifications), and so forth, that are related to design decisions about data structures. Every specification at the realization level is linked to sub-components at the code level.

The code level groups a set of schemes in RSL associated with code. The RAISE method provides translation processes, which start with a final RSL specification and produce a program in some executable language, for example, C++ using the translation tool component of the RAISE toolset (George, 2001).

RC Relationships

It is worth considering that the three relations (Specialization, Realization and Code) form the "RAISE implementation relation" (George et al., 1992). Any formal system that aims to provide a means of specification and development must provide a notion of implementation. That is, if specification E1 is related to specification E2 in the model, we need to know if E1 and E2 are in the "RAISE implementation relation". The following properties must be satisfied:

"Properties preservation: All properties that can be proved about E1 can also be proved for E2 (but not vice versa in general).
Substitutivity: An instance of E1 in a specification can be replaced by an instance E2, and the resulting new specification should implement the earlier specification".

RAISE DEVELOPMENT PLAN APPLYING A REUSE MODEL

Engineers usually proceed from applicative to imperative specifications. The proposal is to introduce the RC model for the definition of the reusable component structure into RAISE method. Where does one introduce this model? RAISE developers start with the module scheme specification, define an abstract applicative module, and develop a sequence of concrete applicative modules and the corresponding set of imperative modules from the final applicative modules. Figure 1 summarizes the overview of the method.

During the first stages of development, when the interaction with the stakeholders is crucial, the use of client-oriented requirements engineering techniques seem to be necessary in order to enhance the communication between the stakeholders and the software engineers. It has been proposed that a systematic reuse approach integrates natural language requirement specifications with formal specifications in RSL. Some heuristics are described to develop a formal specification in RSL starting from models which belong to the requirements baseline (Mauco & George, 2000).

The goal is that engineers can make reuse in all development stages. Therefore, by introducing the RC model in all the development steps, it will be possible to make use of abstraction, selection, specialization, and integration of software artifacts in the RAISE method.

THE REUSE PROCESS

Formal specifications are used to model the problem requirements and the function of the library components. The specifications are written in RSL language. The classification scheme consists of a collection of formal definitions representing possible component features in the domain. The formalization of the scheme permits automated classification of the specifications. The retrieval mechanism is based on syntactic comparison of features sets. The components returned by the retrieval mechanism are passed on to a more detailed evaluation that uses specification matching to determine reusability.

The work of Penix (1998) is an important approximation, because he proposes automated component retrieval and adaptation using a heuristic based on specification semantics to indicate component reusability.

Figure 1. Overview of the RAISE method

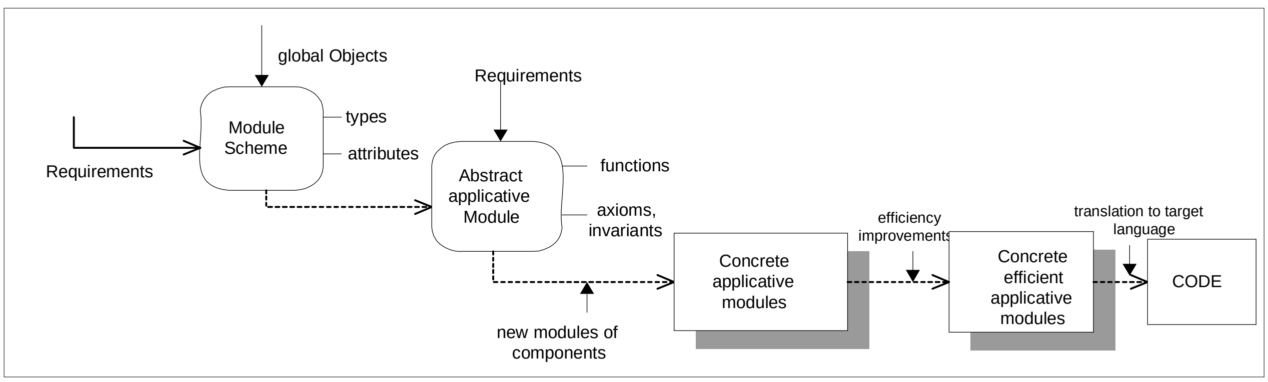

Figure 2. The method

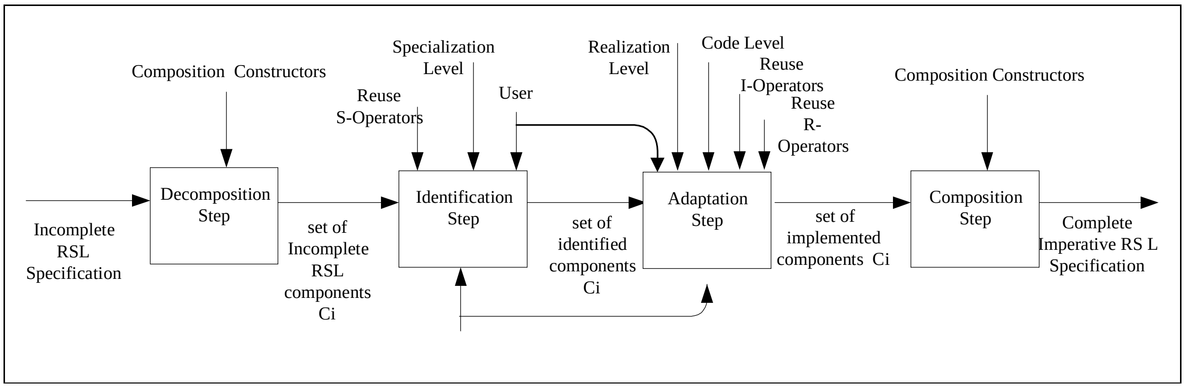

The results of specification matching determine the relationship that exists between the retrieved components and the requirements specification. The adaptation phase allows in determining whether a mechanism exists to adapt or combine the retrieved components to solve the problem.

The main idea is to transform the incomplete RSL specification into complete imperative specification by reusing existing components. The method has the following steps: decomposition, identification, adaptation and composition depicted in Figure 2.

- Decomposition step: the decomposition of a goal specification Eg into sub-specifications E1, E2, ... En is formalized.
- Identification step: for each specification Ei a component Ci (in the specialization level) and a sequence s1,s2,...,sn of RSL specifications must be identified, verifying the implementation relation. A node in Ci must be selected as a candidate to be transformed. The identification of a component is correct if it can be modified by rename, hide and extend operators to match the query Ei.
- Adaptation step: not only a leaf in the sub-component associated in the realization level but also a sequence of operators used in the previous steps are applied. Then, a scheme in the code level is selected and the same operators in the selected leaf are applied.
- Composition step: the sub-specifications Ei and their implementations are composed. Next, the Identification step is introduced.

RC Identification

The component classification is described by a set of features. Each feature represents a property or an attribute of the component. They can be refined to give them a more precise meaning. The objective is to support effective retrieval of component. So, in order to be useful in practice, the component specifications should be independent of the kind of component, allowing the storage of different kinds of them, for example, requirements definitions, designs, documentation, and so forth. A very important approach that provides a formalism to register components properties is the work of Chen and Cheng (1997). It is based on the architecture and integration of the system facilitating the retrieval of a reusable component.

Being a RSL specification is a collection of modules, and a module basically a named collection of declarations as either a scheme or an object -objects and schemes defined using class expressions-, we propose a classification based on a feature-oriented model. Each feature describes a property of the component, and is characterized by:

(a) *kind of component*: describing the function of different kinds of components like: requirements specifications, designs specifications, systems specifications, documentation, and so forth;
(b) *operations* performed;
(c) *component structure*: modules involved (schemes and objects):
(c.1) *granularity of each module*: list of objects related with the class;
(d) *relationships* to another component ('implements' relations and composition of components); and
(e) *component specification style* (applicative sequential, imperative sequential, imperative sequential, applicative concurrent or imperative concurrent and abstract and concrete styles).

By localizing the possible components, the goal is to compare a component with the query. This process has two essential steps: signature matching and semantic matching. The signature matching enables a syntactic comparison of a query specification with specifications

Signature–Matching:

Query-Signature X RC-Library X Match-Predicate $\rightarrow$Set-of RC-Components

Signature-Matching(Q,C,P) = { c $\in$ C/ P(Q,C)}

existing in RC reusable components. The semantic matching compares the specifications dynamic behavior. The bases of the signature matching come from Zaremski and Wing (1997), even though they were adapted to the identification of RC components.

The signature of a specification consists of a set of sorts and a set of operations, each operation being equipped with a particular functionality.

Let L=<SL, FL> be the signature of a library specification and Q=<SQ,FQ> the signature of a query specification where SL and SQ are sets of sorts and FL and FQ are sets of operation symbols, the signature matching is defined in the figure above.

This means that given a query specification Q, a RC library C and a predicate P, it gives back the RC components that satisfy P. The signature matching is based on operations matching. Different kinds of operation matching can be applied. They are the exact, generalized and specialized matching of operations. This matching requires a specifications signature matching (sorts and operations) and the axioms proofs between pairs of operations.

Searching for a Reusable Candidate

The RC library is a fundamental piece to the engineering because it contains existing components that will be reused later in the large systems constructions. The appropriate use of it requires:

- the organization of the library, in order to facilitate the search of the components and to improve the efficiency retrieval, and
- the comparison between the description of the library component with the description of the new description.

The identification consists: first, in a syntactic comparison between a library component in RSL language and the user query one, and then, in a semantic comparison of the library component behavior with the query specification behavior both expressed by axioms. The former description corresponds to the syntactic matching, and the latter corresponds to the semantic matching. A very important factor to consider is the granularity levels of components. They are the list of objects that belong to a RSL module. The component can modify its size, from construct operations of the language to modules for big software systems. To describe and to reuse components they must be encapsulated.

FUTURE TRENDS

Our goal is to solve a problem which is a weakness of the RAISE formal method. Therefore, the proposal of our future work is to apply not only the software components reuse but also a domain specifications reuse, that is, in the confines of the domain engineering.

CONCLUSION

An overview of the strategy to classify and select a RAISE reusable component is presented. The RC model serves for the description of reusable components and a transformational process with reuse from RSL specifications to code is presented. This model aims to solve a problem that is a weakness of RAISE formal method.

KEY TERMS

Algebraic Specification: A technique whereby an object is specified in terms of the relationships between the operations that act on that object. A specification is presented in four parts:

1. Introduction part, where the sort of the entity being specified is introduced and the name of any other specifications that are required are set out;
2. Informal description of the sort and its operations;
3. Signature, where the names of the operations on that object and the sorts of their parameters are defined; and
4. Axioms, where the relationships between the sort operations are defined.

Reusable Component: The aim of reusable components is to provide services to other components and to require services from others. There are three concepts associated with them: their interfaces, their architectures and their realizations.

Reuse Process: A method having the following steps: the decomposition of the goal specification, the identification for each specifications, the adaptation step using the appropriate operators and the composition of the sub-specifications.

Rigorous Process: A mathematically-based technique for describing and reasoning about system properties. It provides frameworks within which people specify, develop, and verify systems in a systematic manner.

Semantic Matching: Semantic matching compares the specifications dynamic behavior.

Signature Matching: Signature matching enables a syntactic comparison of a query specification with specifications existing in a model.

Specification Matching: The process to determine if two software components are related. It allows us to distinguish when two component specifications match, we know that certain guarantees about the behavior of the system will hold if we substitute one component for the other.

Risk Management in the Digital Economy

Bob Ritchie
University of Central Lancashire, UK

Clare Brindley
Manchester Metropolitan University, UK

INTRODUCTION

Digital Economy and Risk: A Two-Edged Sword

The digital economy has been generated by radical changes to every aspect of business and commerce in the last two decades. These changes are far more significant than the developments in Information and Communication Technologies (ICTs) that have largely facilitated the digital economy itself. Every business sector has witnessed changes in the competitive structure of the marketplace, consumer preferences, buying habits, marketing and promotional strategies, production operations, internal administration systems, supply chain arrangements, and the opening up of the global economy. Managers would concede that the uncertainties and risks in running their businesses, as a result of such changes, are not only much greater than previously but increasing. However, the digital economy is a two-edged sword in the sense that the ICTs generating the additional uncertainties and risks also provide the means to enable decision makers to manage them more effectively. The key to survival in the digital economy rests with the abilities of the managers to utilize ICTs effectively to manage uncertainties and risks.

ICTs have largely been seen as helping to enhance database access, analytical powers, and the communications capacity of managers. The justification for these efforts has been based on the premise that more and better quality information will result in reduced uncertainty and improved risk perceptions in decision situations. In short, the outcome would be reflected in "better quality" decisions in terms of risk assessment and resolution.

BACKGROUND

The Digital Economy

The term "digital economy" reflected in the title of this paper may be viewed from a variety of perspectives:

1. Technology developments, especially those relating to the digital communication of data and information, are usually considered the primary driver in the creation of the digital economy. Increases in speed, improvements in capacity, accuracy, reliability, general quality, and ease of use are all features that have enabled the widespread adoption and development of digital technologies. The developments in audiovisual communication technologies and wireless technologies are opening up further opportunities for the transmission and exchange of business intelligence.
2. Socio-economic changes have been equally influential in the rapid adoption of the new technologies. Individuals of all ages, educational and social backgrounds are prepared to regularly use mobile communications, access the Internet and engage in interactive video communications, often with friends and family in different parts of the globe. The impact that these changes in individual and group social behaviors have had on the rate of adoption of new technologies should be fully appreciated. The reasons underlying such changes are multifaceted and complex and beyond the scope of our present discussion, although they have broadly been influenced by individual social and economic needs.
3. Micro-economic factors at the level of the individual organization have been responsible for "pulling" and "pushing" organizations and their management towards increased attention and adoption of the digital economy. Significant "pull" factors include demands from end users of the product or service (e.g., requests for more detailed information on the product/service prior to and subsequent to the purchase, in terms of performance, maintenance, modifications, upgrades). The "push" factors are typically associated with the business organization seeking to maintain its competitive position by offering services equivalent to those of its main competitors, especially if these may be viewed as providing a distinctive competitive advantage (e.g., providing detailed product information via the Web and enabling customers to order directly). Some of

Table 1: Key topic areas presented in this article.

Key topic areas relating to digital economy and risk presented in this article include:
• primary elements of the digital economy
• overview of risk and risk management
• risk and uncertainty
• individual/organizational response to resolving risk
• role of information search and corporate intelligence
• contribution of the digital economy to risk resolution
• individual characteristics and risk perceptiveness
• management of risks
• risk perception
• information processing and risk resolution
• risk management within the digital economy

the issues involved will be discussed further in later sections of the paper.

4. Macro-economic factors are particularly significant in enabling the development of the digital economy, although they are often less evident when exploring individual product/market developments. Changes in legislation affecting consumer rights, guarantees of financial transactions, security of information held on computer systems, and commercial contracts negotiated via the Internet are all examples of the changes in the macro-economic environment needed to facilitate and support the development of the digital economy. Without such changes, individual organizations and customers might consider the risks of such commercial transactions to be too high. In essence, the responsiveness of governments and other similar institutions have lagged behind many of the demands placed on them by the rate of change in the digital economy.

It may be argued that defining the term "the digital economy" remains problematic due to the number of perspectives from which this term may be viewed and due to the number and interactive nature of the variables involved.

OVERVIEW OF RISK AND RISK MANAGEMENT

The key dimensions of risk and its management are represented in Table 2.

Risk and Uncertainty

This seemingly simple term "risk" has proved somewhat problematic in arriving at an agreed definition. Most academic fields and researchers (e.g., Dowling & Staelin, 1994; Knight, 1921) provide variations on the theme, though most would agree that risk relates to two dimensions: the *Likelihood* of a particular event occurring (i.e., probability), and the *Consequences* should this event occur.

In the case of the consequences, it has been common to assume that these are generally undesirable, e.g., financial loss or even loss of life. Sitkin and Pablo (1992, p.9) define risk as "the extent to which there is uncertainty about whether potentially significant and/or disappointing outcomes of decisions will be realised." Similarly, MacCrimmon and Wehrung (1986) identified three components of risk: the magnitude of loss, the chance of loss, and the potential exposure to loss. However, it is important to recognize that there would be no point in taking risks unless there were some benefits to compensate for the possible negative outcomes (Blume, 1971). An associated feature is that of differing risk perceptions. Different individuals, groups of individuals, and organisations may view or perceive the risks (i.e., the likelihood of occurrence, nature and scale of negative consequences, and the potential rewards) differently (e.g., Forlani & Mullins, 2000; March & Shapira, 1987).

The term "uncertainty" typically reflects the ambiguity surrounding the decision situation in terms of the precise nature of the situation, its causes, possible solutions, and the reaction of others to possible actions taken. Rowe (1977) has defined uncertainty as the absence of information concerning the decision situation and the need to exercise judgment in determining or evaluating the situation.

Table 2. Key dimensions of risk and its management

• risk and uncertainty
• risk solution
• role of information search and corporate intelligence
• contribution of the digital economy
• individual characteristics
• management of risk
• risk perception

Risk Resolution

A natural reaction by decision makers facing uncertainty and risk is to seek to resolve the uncertainty and risk inherent in the decision situation. There are several actions that may be taken:

- seek to understand the parameters of the "problem" or situation;
- assess the predictability of the parameters;
- consider the possibility of eliminating or ameliorating the risks; and
- assess the attitudes of the decision takers towards the risks.

These elements represent the process that individuals and organizations develop to manage the risk, to position the organization, and to develop appropriate strategies to manage the impact of such events (Bettis, 1982). The increasing complexity and multitude of relationships consequent to the digital economy pose new challenges for the management of risk at the organizational level.

Role of Information Search and Corporate Intelligence

The decision maker confronted with a risky decision situation naturally follows a process of gathering more information, processing this in different ways, and evaluating this in relation to the risks faced. This information is then used—maybe consciously or unconsciously—by the decision maker to assess to what extent the risk has been removed, reduced, or resolved. If the decision maker is not satisfied that s(he) has achieved sufficient resolution of the risks involved, then further information searches, analysis, and processing will occur. However, this intelligence-gathering process need not necessarily result in improved understanding and risk resolution. Uncovering more information may reveal more influencing variables causing perceptions of greater uncertainty, both as a consequence of uncovering new influencing variables and an increasing sense of complexity. Ritchie and Marshall (1993) argued that the quality and sufficiency of the information available will influence the perception of risk by those involved in the decision-making process. Ritchie and Brindley (1999) argued that risk perception is both the consequence of information search and analysis as well as its determinant.

Contribution of the Digital Economy

Information can be considered as a risk-reduction or risk-insulating tool, on the basis that more and better information would result in improved decision making and more effective risk management. The rapid pace of ICT developments (Kalokota & Robinson, 2000; Rycroft & Kash, 1999) and the emerging digital economy (Brindley & Ritchie, 2001) demonstrate that both individuals and organizations have easier access to more information that is more immediate and arguably more relevant. The decision makers can therefore access through their own desktops, internal data, external market reports, competitor information, etc. Swash (1998) recognized that it is essential to overcome the problem of information overload by ensuring the Internet is used frequently, thus improving the users' surfing proficiency and their knowledge of "useful" sites. Zsidisin and Smith (2004), in examining the impact of the Internet on supply chain decisions, suggested that it is natural that information exchange improves. Improvements in the voluntary exchange of information may produce better knowledge of the situations surrounding the dynamics of a business or commercial relationship. This provides greater potential for detecting, averting, and managing risks.

Individual Characteristics and Risk

It is generally accepted that there are differences in individual risk perception, information-processing styles, and decision-making attributes (e.g., Chung, 1998). There is perhaps less agreement on the nature and consequences of such individual differences. For example, differences in gender have been posited as the reason for women being more meticulous in information search, responsive to decision cues, and being more risk averse than men (e.g., Chung, 1998). Others have failed to establish significant differences (e.g., Masters & Meier, 1988), suggesting that other contextual variables (e.g., social, educational, and experiential background) may be more relevant to any differences in behavior. For example, the decision to start a business may generate differences in risk-taking behavior that is not gender-, culture- or age-related (Busenitz, 1999; Shapira, 1995). A number of authors (see Forlani & Mullins, 2000; Ghosh & Ray, 1997; Kahneman & Lovallo, 1993) have suggested that the provision of structured decision approaches and information search frameworks can provide the appropriate mechanism to overcome any biases and improve the quality of decisions.

Management of Risk

The strands of risk together with business intelligence in the digital economy may be captured in the three dimensions of individual/group/organizational behavior when confronted with risk in given decision situations:

- Willingness to seek further resolution of the decision situation faced, both in terms of the context and the decision-specific variables.
- Desire to identify and measure the risks in some way, either objectively or subjectively.
- Information search and processing to support the decision.

These three dimensions are closely inter-related and are employed to modify the risk perceptions of the decision makers. In addition to these decision-making activities is the range of activities associated with risk management. Some risk management activities may be undertaken prior to the decision itself (e.g., insuring against certain risks) or after the decision (e.g., effective management of relationships with customers to reduce the likely incidence of disputes). While activities of this type may be employed fairly readily with local markets, many managers may find it more difficult to avoid the risks resulting from increased global competition in their home or local markets, consequential of the digital economy.

Risk Perception

Throughout the decision process, an individual is seeking information to remove the uncertainties and to resolve the risks involved in the decision.The factors that contribute to the perceptions of uncertainty and risk experienced by the individual may be represented in table 3.

The integration and interaction of many of these components increases the complexity of understanding both risk perception and decision behavior. For example, although funding may be available to undertake intensive research, the pressures of time to respond to a given situation may preclude such activities even though they may be considered desirable.

Information Processing and Risk Resolution

The information-processing behavior of the individual may be presented in terms of the process described in Diagram 1. The decision maker seeking to resolve the risks perceived will search for appropriate information, process, analyze, evaluate, and synthesise this with other information relating to the situation. The contribution of the digital economy is evident not only in providing the initial intelligence but in assisting the decision maker in the processing and manipulation of the data prior to the decision-making stage. It is suggested that the decision maker either consciously or sub-consciously assesses whether the risks have been sufficiently resolved or not. In many respects, this may be posing the question concerning one's own degree of confidence in proceeding with the decision, though it may also be influenced by the factors identified.

An assessment that the risks had not been adequately resolved would normally result in further information search, analysis, synthesis, etc., repeating this cycle until the individual believed the risks had been sufficiently resolved to proceed. It is unlikely that the decision maker would achieve the situation where s(he) was fully confident concerning risk resolution. The probable outcome, even after seeking further risk resolution, is that of having to make the decision even though the risks are not fully resolved, as a consequence of pressure of time, lack of resources to pursue further information, or the feeling that further search is unlikely to prove cost-effective. This is probably a very common outcome reflected in the statements of many decision makers that "there are many other angles that we ought to explore but we no longer have the time to do so."

In situations where the decision maker considers that the risks have been adequately resolved, one might conclude that the normal procedure would be to proceed with the decision. Another possible outcome could be suggested where the decision maker decides to delay the decision. This may be simply a reluctance to commit oneself even if one is fairly clear and confident of the decision to be made. Alternatively, it may reflect a more deliberate tactic of delay to await changes in the decision situation, to assess the likely responses of other participants in the competitive situation, or perhaps in the hope that someone else may take the responsibility. The making of the decision is no longer viewed as the concluding stage in the process. Attention is increasingly being directed to the post-decision activities that seek to ensure

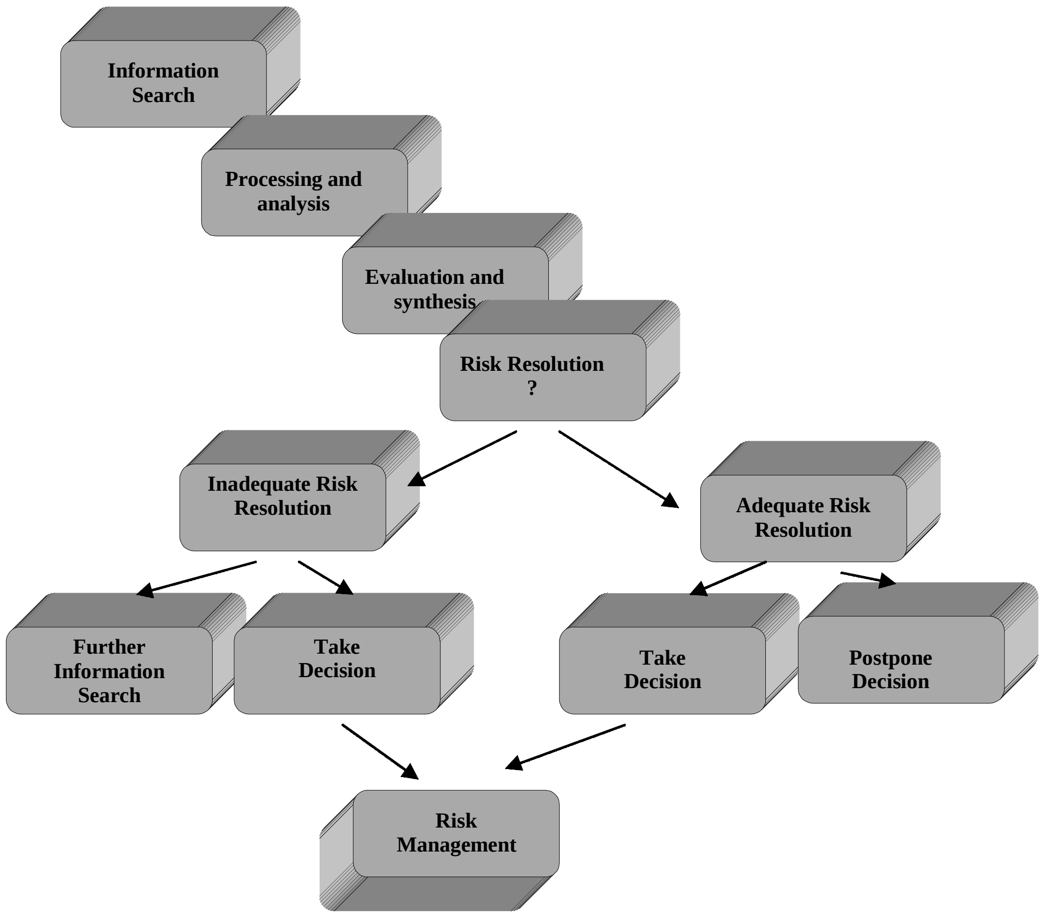
Table 3. Main groups of factors influencing individual risk perceptions

• direct implications in terms of costs and benefits and the scale of these
• other decision outcomes, known with less certainty (e..g. reactions of peers and colleagues)
• time available in which to take the decision, typically constrained
• funding available to undertake the research, analysis and evaluation processes involved
• achievement of personal goals that decision maker(s) seeks to satisfy
• data quality which may significantly influence the nature of the risks perceived

Source: Brindley and Ritchie (2001)

R

Diagram 1: Information processing and risk resolution. Adapted from Ritchie and Marshall (1993).



that the opportunity is taken to avoid potential risks anticipated in the decision processing to avoid risks seen as less likely to impact on the situation, and to minimize the likelihood and consequences of those risks seen as more likely to occur. A generic term for these activities is *Risk Management*. Examples of Risk Management activities are presented in Table 4.

FUTURE TRENDS

Risk Management within the Digital Economy

The digital economy will impact on organizations irrespective of their size, geographic location, or sector. While such developments will engender greater uncertainty and risks, they will also facilitate solutions and opportunities for organizations to resolve and manage the new risks. Specific challenges for the organizations in the digital economy are:

1. Fundamental changes in the marketplace as a consequence of providing more direct communications with the consumer, greater heterogeneity in the market in terms of consumer needs and behavior, and a movement in the balance of power towards the consumer as opposed to the manufacturer or service provider.
2. Individuals and organizations are unlikely to behave in a rational and structured manner to resolve risks. The previous emphasis on predictable patterns of information search, corporate business intelligence, and evaluation of information is likely to be replaced by less predictable demands as the nature of the problems encountered are less predictable. This will have significant implications for the development and design of business intelligence systems.
3. Predictions that the digital economy—by providing improved access to information and processing capabilities—will lead to improved decisions is unlikely to be sustainable.

Table 4. Risk Management Activities

• insuring against the financial consequences of particular outcomes
• developing formal contractual arrangements with trading partners to limit scope for non-prediction behaviour
• training and staff development
• communication of intentions within the appropriate internal and external networks to ensure involvement and commitment (e.g. relationship marketing)
• detailed planning, monitoring and control at all stages
• building close relationships with key partners to generate a sense of common purpose and trust (e.g. partnering)
• developing more effective Risk Management strategies through more effective communications at all levels both within the organisation and with external partners

4. The modus operandi of competitive and business relationships within the digital economy will evolve as the nature and extent of risks faced change, both in terms of novel risk situations encountered and the rate at which these occur.
5. The development and training of the individual in terms of the appropriate knowledge, skills, and behavior patterns provides an important requirement to utilize the information available effectively.
6. The nature of what constitutes "effective" risk management may well change in the digital economy (Ritchie & Brindley, 1999).

CONCLUSIONS

The digital Economy has produced a fundamental change in the nature of the risks faced and increased the likelihood that the marketplace will remain turbulent, unstable, and risk prone. Managers now need to have the capability—through improved knowledge, skills, and understanding—to identify, analyze, and manage these competitive developments and the associated risks. Associated with the improved capability to manage the risks is the ability to implement a wider range of risk management strategies to ameliorate the consequences of the incidence of risks and their consequences. The digital economy and the associated ICTs improve the opportunities to ensure effective risk management.

KEY TERMS

Decision support: the tools, techniques, and information resources that can provide support to the decision maker in improving the efficiency and effectiveness of his/her decisions. Many of these decision support tools may employ ICTs and be part of the Management Information System itself.

Digital economy: accepts as its foundation, the ICT developments and represents the impact that these have had on the conduct of business and commercial activities. Changes in markets and supply chains as well as increasing global competition all represent what is encapsulated within the term the digital economy.

Information and Communication Technologies (ICTs): a generic term used to encapsulate the diverse range of technological developments (e.g., computer storage and retrieval, computing capacity, wired communications, wireless communications, portable technologies) that have enhanced the internal and external activities of organizations. Especially important is the manner in which these strands of technological development have been integrated to provide greater synergy.

Management Information: a term that covers a wide variety of sources and types of information that may prove valuable to the decision making, management, and control of an organization. This term would include quantitative and qualitative information types, internal and externally sourced information, as well as classifying the information in terms of its quality (e.g., accuracy, detail, relevance, timeliness).

Risk: in a limited manner, the decision situation in which the full range of possible outcomes are known with certainty and the probability of their occurrence can be assessed accurately, usually by some objective means (e.g., rolling the dice is a classic risk decisions situation). More usually, the probabilities must be assessed subjectively, often based on previous experiences or intuition, and the outcomes themselves may not be fully identifiable. The term "risk" is used commonly to generally define decision situations that are really a combination of classical risk and uncertainty, i.e., the more normal decision situation in organizations.

Risk Management: the range of activities that may be taken to avoid the occurrence of an undesirable event or to modify, minimize, or eliminate the consequences should the event occur (e.g., an insurance policy against particular risks would not prevent the occurrence, but would compensate for the financial and other consequences of the outcome).

Risk Perception: the term used to express how a situation is viewed or seen by the decision maker(s). Individual characteristics, experiences, and beliefs may influence the way in which we might view a given situation as being either more or less risky. Usually this is measured on a subjective and relative scale (i.e., Situation A is perceived as riskier than B) rather than on an objectively measurable scale.

Uncertainty: the situation where less than perfect knowledge exists about a particular problem or decision requirement. There exists a wide variation in terms of degrees of uncertainty from extreme uncertainty (i.e., very limited knowledge of outcomes or likelihood of their occurrence) to near certainty (i.e., almost complete knowledge of the outcomes and the likelihood of occurrence). Generally, an uncertain decision situation refers to one containing ambiguity about part or all of the decisions parameters.

Rotating Banner Advertisements on the World Wide Web

Subhasish Dasgupta
The George Washington University, USA

Rajesh Chandrashekaran
Fairleigh Dickinson University, USA

INTRODUCTION

Advertising spending on the Internet has soared. Indeed, by some accounts, Internet advertising is projected to reach $23.5 billion by 2005 (eMarketer, 2002). Although there are several ways of advertising on the Internet, for example, buttons, banners, paid links, superstitials, and so forth, banner advertising is the most common form of advertising on the Internet (Meland, 2000). Advertising using banners (usually placed near the top of a page) is currently the most popular form of online advertising. Banners may be static (stationary) or dynamic (rotating). In the case of static banners, all visitors to a particular site are exposed to the same banner. In contrast, dynamic banners describe cases where ad servers to a particular site deliver different banners to different clients/visitors. This approach presents the possibility of time/space sharing among different advertisers.

This article discusses one particular type of dynamic/ rotating banner advertising. Specifically, we present a model to deliver and track the effectiveness of dynamic rotating banner advertisements. The advertising is dynamic in that different banners may be delivered to different users, and it is rotating in that each user (depending on the length of time spent at that site/page) will be exposed to multiple advertisements. These banners may be from a single advertiser (different executions of an ad) or from different advertisers. The latter allows for better space/time sharing and cost effectiveness.

Rotating ads provide the ability to deliver multiple ads to users by associating many ads with a single Web page. Most Web sites have popular pages that users visit often. Rotating banners allow companies to deliver more than one advertisement for these pages, thereby increasing their yield from the page.

Measuring click-through, that is, clicking on an ad banner, has been and remains important in assessing the effectiveness of online advertisements. Research has shown that there are many factors that influence peoples' click- through behaviors (Cho, 2003a). For example, many banner-related factors, for example, the size of the banner, location of the banner, and dynamic animation (Razzouk & Seitz, 2003) and other individual factors, for example, person's involvement with the product/service being advertised (Cho, 2003b; Yoon, 2003) determine the effectiveness of banner ads on the Internet. For example, Cho (2003b) confirmed that while people whose involvement is low are generally less likely to seek additional information, they are also more likely to be influenced by ad-related factors.

However, of late, click-through rates have been declining (Dreze & Hussherr, 2003). This disturbing trend has caused advertisers to think about ways in which click-through rates may be improved. Recent findings suggest that advertisers may be able to reverse the trend by using rotating and dynamic banner advertisements. For example, Chatterjee, Hoffman and Novak (2003) found that there is significant heterogeneity in consumers' click-proneness to banner advertisements and that there are significant gains from repeated exposures to banner ads – but mainly for consumers who are not otherwise click-prone. In addition, consumers who are more involved with the product are more likely to click than those who are not (Cho, 2003b). Such findings might suggest that rotating (rather than static) banner ads, which allow for space/time sharing enabling multiple exposures to messages from multiple advertisers, may be an effective way to improve click-through rates and effectiveness of banner advertisements. Recent experimental evidence also confirms that the level of attention and message recall or association of banner advertisements is also a function of position (i.e., top versus bottom) and graphics (Razzouk & Seitz, 2003).

BACKGROUND

Review of Web Advertisement Models

The process of advertising on the Web consists of two parts: delivery of advertisement to a client computer using the Internet, and tracking effectiveness of the delivered advertisement. There are two basic types of advertisement delivery models: delivery-focused and measurement-focused. Delivery-focused models emphasize the advertisement delivery method and do not have the ability to track effectiveness of the advertisement. Measurement-focused models use modified advertisement delivery mechanisms that help in measuring effectiveness.

We consider two delivery-focused models: the static ad model and the dynamic ad model. In the static ad model, when a user requests a page, the Web server responds with the requested page. The page has content and HTML code to insert a banner image into the Web page. This banner image is the advertisement. A server finds the requested banner image for the Web page. The page content and banner image are then transmitted to the user's computer, that is, the client, over the Internet. A Web server log records transfer of the content page as a "hit" in the server's log. When an ad file is sent out to the client, the server also records that the user's browser successfully downloaded the advertisement. In this model each page has only one ad associated with it and this ad is changed in batches, either once per day or once per week.

The dynamic ad model is very similar to the static ad model described previously. In addition to the Web server, there is a separate server called an ad server that stores all the banner advertisements that are delivered to the client. The ad server also has special software that makes a decision regarding which ads should be served to the client or user. A summary of delivery-focused models is provided in Table 1.

We consider two measurement-focused models. The first, cache-measurement, "allows for the appropriate measurements of ads stored and provided from cache by a proxy server or browser, as well as those ads actually provided by the ad server" (Bennett 1998). The second, browser measurement, allows for the recording of ad-related activity using software (e.g., Java) that runs on the requesting browser. A summary of the measurement-focused models is provided in Table 2.

Static and Rotating Banner Advertisements

Static banner advertisements are defined as those in which the banner space is utilized by a single advertiser, whose banner appears along with a Web page through the duration of client's visit. Each such ad provides a link with the advertiser's home page via a "button". We should note that the term *static* simply refers to the fact that the ad belongs to a single advertiser. However, each ad may include moving or animated elements (text, graphics, or both) and other features that attempt to draw attention to the ad.

In contrast, *rotating banner advertisements* refer to ads belonging to different advertisers that can share the same banner space for the duration of the page visit. That is, two or more advertisements appear in succession on the user's screen in the same banner space. Each ad appears on the user's screen for a predetermined duration, and is then replaced by another ad belonging to a different advertiser. This "rotation" continues as long as the page is displayed on the user's screen. Furthermore, similar to static ads, each ad in the rotation provides a link to the advertiser's page for the duration of display.

FUTURE TRENDS

A Framework for Delivery and Tracking of Rotating Banners

In this section we develop a theoretical framework to examine how rotating banner ads may be delivered and evaluated. Figure 1 shows the proposed framework for the delivery and tracking of rotating banners.

The proposed system consists of two components: ad delivery and ad tracking. The following sections describe each in turn.

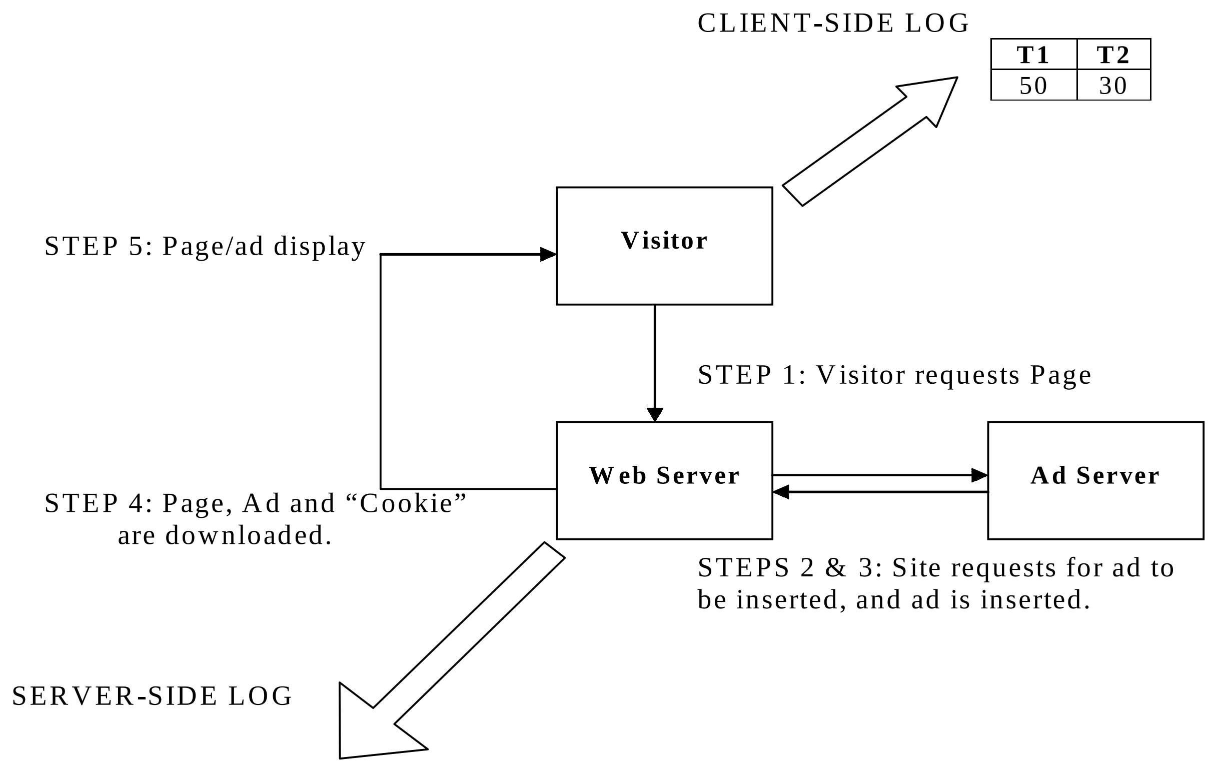
Table 1. Delivery focused models

Model	Content Delivered by	Ad Delivered by	Delivery Mechanism
Static Ad Model	Web server	Web Server	One ad associated with each page. These ads are changed in daily or weekly intervals.
Dynamic Ad Model	Web server	Ad server	Different ads are dynamically associated with each page. This can be done based on the user.

Table 2. Measurement focused models

Model	Content Delivered by	Ad Delivered by	Measurement Mechanism
Cache-measured	Web server	Ad server	Emphasis is on counting ads provided from cache by a proxy server.
Browser-measured	Web server	Ad server	A browser run program keeps track of Ads downloaded.

Figure 1. Ad delivery and tracking system



Client	Time (T)	S1	S2	C1	C2
1	0	1	0	0	0
	30	1	1	0	0
	60	2	1	0	0
	80	2	1	1	0

Note:
T = Time elapsed since page and ads were downloaded
S1 and S2 = Number of opportunities to see ads 1 & 2 respectively
C1 and C2 = Click status of ads 1 & 2 respectively
T1 and T2 = Total time of display of ads 1 & 2 respectively

Ad Delivery

When a Web page is downloaded from the server it downloads the contents of the page (containing the Java Script for the rotation of the ad images), the ad images, and a program to keep track of time spent on the page (T_p) and click status of each ad (C_i). Once the page and the ads have been loaded on the client's browser, the Java Script program that is built into the Web page is executed using the client-computer's resources and provides the ad rotation. This program is crucial to the implementation of the rotating banner system.

Ad Tracking

The tracking system consists of two sub-systems. The one that resides on the Web (or ad) server is called the server side sub-system, and the other, which utilizes the user's computing resources, is called the client side sub-system. Each sub-system is further described next. For explanation purposes we consider a system that consists of two rotating ads: Ad 1 and Ad 2.

Server Side Sub-System

The server-side sub-system is responsible for maintaining a log of the time (T) elapsed since the page was sent (start of the download by client). In addition, it maintains counts (S_1 and S_2) of the number of opportunities that the user has had to see each ad (ads 1 and 2 respectively). S_1 and S_2 are incremented based on the frequency of rotation, that is, how many seconds (t) each ad is displayed for. The log file also maintains a record of the "click status" of each ad using counters C_1 and C_2 for ad 1 and ad 2 respectively. Initially, all counters are set to zero. When the client clicks on a particular ad (say Ad 1), the respective counter (here, C_1) is incremented by one, but C_2 remains unchanged (refer to server side log in Figure 1).

Using this program, the Web server can not only measure the click-through rate of each ad, but can also measure the number of opportunities the client has had to see each ad. The latter measure can be used to determine reach, gross impressions, and other variables that may be used in sophisticated pricing models. This additional information also allows the server to estimate an ad's effectiveness on dimensions other than those that are behavioral in nature. Existing models concern themselves only with click-through rates (see IAB and MB Interactive study, 1997).

Client-Side Sub-system

The client-side sub-system is responsible for maintaining a log on the client's side. This log contains such information as the client code and duration of display for each ad (T1 and T2). The sub-system uses a program that is downloaded to the client's computer along with the Web page requested. The code in the program creates a time stamp when the ad was received using the client's own computer clock and stores it in the hard drive. This mechanism operates like a "cookie," and can be implemented using programs like Java applets.

Consider the scenario when the client clicks on one of the rotating banners. At this time, the data in the cookie (i.e., the entire log from the client's side) are transmitted back to the server log, which then updates the appropriate fields. In this case, the time is noted based on when the click-through was made. Based on the start time and end time transmitted to the server log, the actual time duration (T_1 and T_2) for which each ad was displayed on the client's browser can be calculated and stored in the server log.

Consider another scenario in which the client does not click on any of the ads on the page, but moves to a different page on a different server. In this case, as soon as the user moves to a different page the end time is noted from the computer's internal clock and stored on the hard disk as a "cookie" by the client–side program. The next time the same client connects to the Web site (server), the data in the cookie are transmitted back to the server log, and the actual ad display times are recorded in the log.

It is important to note that there may be differences between the server-side and client-side logs because the server-side log does not consider the time taken to transmit data and images from the server to the client and back. The client program will be more accurate since its time logs are not affected by the time taken to transmit data and images. To reconcile these differences, the client side data are used to calculate the final values of S1, S2, T1 and T2.

CONCLUSIONS

In this article we have presented an overview of models used for delivery and tracking banner advertising on the Web. We introduced the concept of rotating banner advertising and presented a model that can be used for delivery and measurement of such advertising. For advantages and limitations of this model see Dasgupta and Chandrashekaran (2001).

We would like our readers to note that technology in this field is changing rapidly and newer methods of Web advertising are being introduced all the time. But we still believe that this encyclopedia article provides the right overview of technologies issues, marketing concepts, and terms and definitions related to the field of Web-based advertising.

KEY TERMS

Applet: An applet is a program written in the Java™ programming language that can be included in an HTML page, much in the same way an image is included. When you use a Java technology-enabled browser to view a page that contains an applet, the applet's code is transferred to your system and executed by the browser's Java Virtual Machine (JVM) (*http://java.sun.com/applets/*).

Browser: A computer software program that requests Web pages and other associated applications over the Internet and that can display these files using the right format

Browser Log: Browser log is a computer file (program) running on the client's browser that lists all requests for individual files and ads.

Cache: Cache is a storage area on the user computer's hard disk where recently viewed Web pages are stored.

Client: A client refers to a computer that requests and receives data and services from servers on a computer network. Computer users work with clients to access information on the Internet and World Wide Web.

Cookies: A collection of information, usually including a username and the current date and time, stored on the local computer of a person using the World Wide Web, used chiefly by Web sites to identify users who have previously registered or visited the site (*http://dictionary.reference.com*).

HTML: HyperText Markup Language is the language in which most pages on the World Wide Web are written. These pages can be read using a browser.

Java: Java is an object-oriented language that is widely used for Internet or Web-based applications. It was designed specifically for distributed environments.

Javascript: Javascript is Netscape's simple, cross-platform, World Wide Web scripting language. Javascript runs in only three environments – as a server-side scripting language, as an embedded language in server-parsed HTML, and as an embedded language run in Web browsers, where it is the most important part of DHTML (*http://dictionary.reference.com*).

Proxy Server (or Web Cache): This is a server that lies in between the organizational network and the Internet. It has its own disk storage and stores copies of recently requested objects (Kurose & Ross, 2000).

Web Server: A Web server is a computer that is addressable by a URL and that houses objects. Objects include Web pages (HTML files), JPEG images, and other applications or programs.

Web Server Log: Also called an Access log, this is a list of all requests for individual files and ads that users (or clients) have made from a Web site (Whatis.com 2000).

Scenarios for Web-Enhanced Learning

Jane E. Klobas
Bocconi University, Italy and the University of Western Australia, Australia

Stefano Renzi
Bocconi University, Italy

INTRODUCTION

After several years of Internet use in traditional universities, some patterns have emerged, both in the nature of use, and in understanding the conditions associated with successful adoption and application of Web-enhanced learning (WEL). This article summarizes, in the form of nine scenarios, the ways in which the Internet is being used to enhance learning in traditional universities. It also discusses the changes needed if universities are to benefit more widely from WEL.

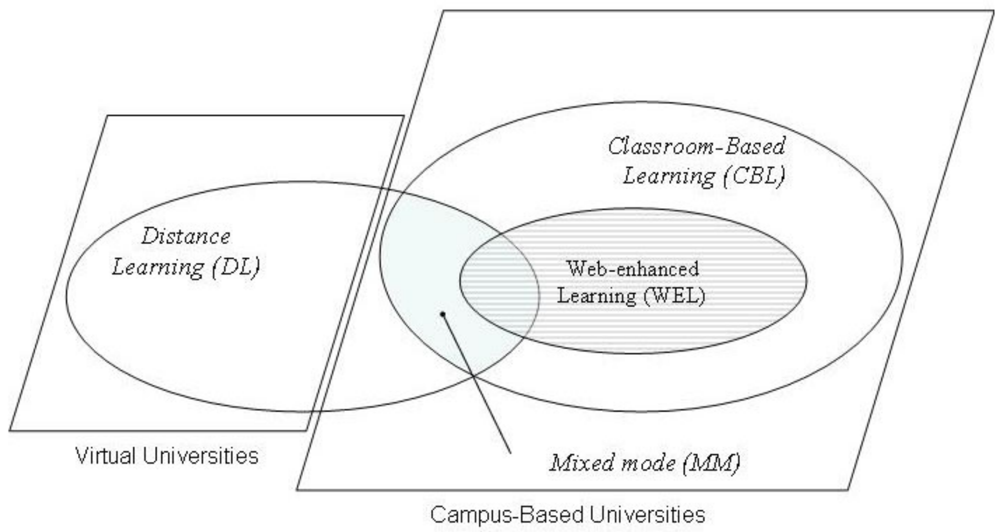
BACKGROUND

The World Wide Web is used by universities to make courses available to students who are distant from campus (*distance learning*, DL) and to enhance learning by students who attend courses on campus (*Web-enhanced learning*, WEL). Universities may be classified on the basis of the modes of learning that they offer. *Virtual universities* offer access to courses by DL only. Traditional, or *campus-based universities*, offer courses that are based on formal lessons held in classrooms or laboratories (*classroom-based learning*, CBL), but may also offer courses by DL or *flexible learning* (FL), which is a combination of DL and CBL.

WEL is the use of the Web to enhance CBL in traditional universities. WEL provides students studying in the classroom with access to electronic resources and learning activities that would not be available to them in traditional classroom-based study. Simple forms of WEL provide access to the Web from within the classroom, using the Web as a platform for real-time demonstration or as a digital library. More sophisticated forms of WEL blend activities in the classroom with Web-enabled learning activities that promote collaborative learning among students, even when they are distant from the classroom.

Figure 1 illustrates the relationship between the modes of learning offered by universities. WEL is represented as that portion of CBL that uses the Web to enhance learning. When it is used to blend in-classroom and out-of-

Figure 1. Relationship between Web-enhanced learning (WEL) and other modes



classroom activities, WEL shares the characteristics of DL and FL.

WEL differs from flexible learning in that the focus of the lesson remains the traditional classroom. With FL, classroom-based learning is mixed with learning at a distance. In the most common form of FL, *distributed learning* (also known as *blended learning* or *mixed mode learning*), students participate in formal lessons both in the classroom and at a distance, according to a schedule prepared by the instructor. Some flexible learning may be enhanced by use of the Web, for example, to provide discussion forums in which students studying at a distance and in the classroom may participate together, but use of the Web is not necessary for flexible learning.

This article is concerned with integration of online learning and classroom-based learning to achieve effective and manageable WEL for campus-based students. The focus is on change across a university system rather than in an individual classroom. We argue that WEL adds most value when it is used to enable new forms of learning, and in particular, online collaborative learning by students working at a distance from the classroom, as well as within it (Rudestam & Schoenholtz-Read, 2002). This value can only be obtained through attention at the institutional level to the organizational transformation required to implement, support, and sustain WEL (Bates, 2000).

WEL SCENARIOS

Nine distinct scenarios for use of WEL can be identified (Table 1, based on Klobas & Renzi, 2003). They can be divided into four groups: *information provision* scenarios, in which the Web is used to provide information to students and others outside the classroom; *classroom*

Table 1. A hierarchy of WEL use scenarios

Scenario	Label	Use
INFORMATION PROVISION SCENARIOS		
1	Catalog	Provision of static, and primarily logistic, information about the course.
2	Notice Board	Distribution of course materials in electronic form.
3	Class Resource	Provision of additional materials and references in response to student and teacher experience in the course as it progresses.
CLASSROOM RESOURCE SCENARIOS		
4	Classroom Resource	Use of the Web for demonstration or as a digital library during classroom sessions.
5	Streaming Video	Broadcast of classroom sessions.
INTERACTIVE LEARNING SCENARIOS		
6	Virtual Classroom	Synchronous interactive classroom sessions that include video and voice communication among instructors and students.
7	Interactive Web	An interactive environment outside the classroom.
8	CSCL	Computer-Supported Collaborative Learning.
EXPERIMENTAL SCENARIO		
9	Experimental	An experimental environment for innovative use of the Web.

resource scenarios, in which the Web is used to extend the classroom, either by providing access to resources in the classroom or by enabling lessons to be broadcast outside the classroom; *interactive learning* scenarios, which range from interactive virtual classrooms to the use of the Web to support collaborative learning among students working at a distance; and an *experimental* scenario, in which the Web is used to experiment with technology and pedagogy in ways not envisaged by the preceding scenarios. Any or all of the scenarios may be used alone or in combination, in a single course or by a whole university.

Information Provision

The first group of scenarios (1 to 3) represent incremental changes to traditional classroom-based learning. In these scenarios, the Web is used as an information delivery mechanism that provides students with some flexibility in the time and place with which they access some of the information required for the course. The scenarios range from simple publication of course catalog information to use of streaming video to permit students to 'attend' classes outside the classroom. The information and communications technology (ICT) infrastructure, training, and skills required for successful use of each scenario is quite simple.

The simplest and most common of WEL scenarios consists of provision of basic *catalog* information about a course: course description, list of textbooks, name of teacher(s), class schedule, allocated classroom(s), and examination procedures. Most university Web sites contain at least a subset of this information. This is a simple scenario to manage. The university needs a Web server and the staff to maintain it. The information posted in such catalogs is often pooled or available from a single source. Because it is static and seldom needs to be updated more than once a semester, the effort involved in maintaining currency is quite low.

In Scenario 2, *notice board*, teachers use the Web to distribute course materials in electronic form. Such material might include: educational material used by teachers in the classroom (slides, case studies, newspaper articles, site URLs related to the course content), past exam scripts and solutions, and official University communication. The content may be made available all at once before the course begins in the online equivalent of a course book, or from time to time during the life of the course (for example, lesson slides may be put online after each lesson).

Use of the Web in Scenario 3, *class resource*, is more dynamic than in Scenario 2. The teacher selects new material to add to the course Web site during the course, in response to questions asked, interest expressed, and other experiences of how the students are responding to the course as it is delivered. In courses with multiple classes (sections), each class may share the material available on the common course notice board, but may have quite different additional resources.

Effective adoption of Scenario 2 and Scenario 3 requires more extensive ICT infrastructure than Scenario 1 to permit students to access the course Web sites on a regular basis. At Scenario 2, some universities make staff available to load materials to the site on behalf of the teacher, but at Scenario 3, the teachers need the IT and the training to be able to load their own materials. This level therefore marks a significant shift in the resources required to support WEL. At the same time, it marks a significant shift in the value added by WEL; at this level, WEL provides the opportunity to quickly and easily provide students with access to current material of direct relevance to their learning and experience in the course as it unfolds.

The Web as a Classroom Resource

In Scenario 4, *classroom resource*, the teacher may use the Web to access reference materials, presentations, and demonstrations from sources outside the classroom. In this scenario, the Web provides convenient access to resources that might previously have been drawn from other sources or accessed in other ways by the teacher. While relatively simple for the teacher, this scenario requires provision of secure access to appropriate IT and Internet infrastructure from within the classroom.

Scenario 5, *streaming video*, requires more substantial investment in technology, including quality recording equipment in classrooms and the staff to operate and maintain it, high-end servers, and high-speed networks to all locations where the video may be watched. For effective use, teachers need to learn how to structure and present visual aids that will be suitable both in the classroom and for presentation by video. The primary uses of streaming video, to allow students the option of 'attending classes' from outside the classroom and to review the teacher's presentation of different material (Creighton & Buchanan, 2001), represent only an incremental change in the nature of education.

Learning Through Interaction

Use of the Web is more dynamic in the interactive learning scenarios, which involve interaction between the teacher and students, and among the students themselves.

In the WEL *virtual classroom* scenario (Scenario 6), the Web is used to transmit complete classroom lessons using synchronous video, voice, whiteboard, and other utilities. Teachers and students from different locations may share lesson components, ask questions, respond, and interact with one another in a variety of ways. For campus-based students, a virtual classroom provides the opportunity to share classroom experiences with teachers and students in classrooms located on other campuses (Hiltz & Wellman, 1997). Universities considering this option for WEL should weigh the considerable costs of investment in ICT infrastructure, training, and course redesign against the return to students.

In Scenario 7, *interactive Web*, the interactions are somewhat passive, based mainly on the use of course forums, resource contributions, self-evaluation tests, delivery of assignments, and secure online exams. This is the most common application of online learning platforms. Teachers require considerable training and support to adopt this scenario effectively. Students also require preparation, both in use of the functions of the technology, and in how to use the provided functions to improve the quality of their course experience and learning.

A more complex interactive scenario is *CSCL* (computer-supported collaborative learning, Scenario 8), an environment where at least the online component of teaching and learning is based primarily on interactions among students working in groups. This scenario includes collaborative group learning activities that go beyond those possible with simple course forums. Such activities may include group projects that involve sharing materials or preparation of joint documents. This scenario offers greater potential for improving the quality of learning at the university than any of the preceding scenarios.

Indeed, the power of WEL to change the quality of education is based on its potential to make collaborative learning possible. WEL makes a difference when it is used to enable students to learn collaboratively (Friedlander, 2002; Klobas & Renzi, 2003; Lammintakanen & Rissanen, 2003; Rudestam & Schoenholtz-Read, 2002). Students, themselves, describe the value of participation in learning communities of peers (Hamilton & Zimmerman, 2002), while educators claim that participation in collaborative learning not only results in better quality learning of course subject matter, but also in changes in the world view of the students and their capacity for lifelong learning and contribution to society (Klobas, Renzi, Francescato & Renzi, 2002; Rudestam & Schoenholtz-Read, 2002). Furthermore, collaborative learning that makes a difference does not need expensive technologies. CSCL does not require the investment in ICT infrastructure of Scenario 6, and can be implemented with simple asynchronous conferencing software (Hazemi & Hailes, 2002; Hiltz & Turoff, 2002).

Experimental Scenario

The final scenario, *experimental* (Scenario 9), provides an environment for teachers to experiment with new applications of the Web in the classroom, new Web-based technologies, new educational strategies, and the interaction between these innovations. While current thinking focuses on CSCL as the most advanced form of WEL, the existence of an experimental scenario reminds us to be open to further changes in learning theory and technology. It also reminds us of the need to evaluate new approaches to learning associated with WEL.

FUTURE TRENDS

Universities across the globe, in developed and developing countries, have been quick to adopt technologies to support WEL, including the infrastructure to support widespread use of the Web as an information resource, and university-wide platforms to support online learning. But this rapid adoption of technology has had relatively little impact on the education of campus-based students (Middlehurst, 2003, as cited in Collis & Van der Wende, 2002; Observatory of Borderless Education, 2002). Those changes that have occurred have been incremental rather than transformational. The Web is most frequently used to provide access to resources—as a substitute for, or complement to, notice boards, distribution of handouts, and use of the library—rather than to provide access to new forms of learning. Thus, the Web is being used to automate rather than to transform university education. Few attempts to go beyond this simple automation have been successful (Pollock & Cornford, 2000). Those universities that are making greater use of the Web are not distinguished from the others by virtue of their information technology infrastructure, but in terms of their focus on students, markets, and policy. Those looking to 'stretch the mould' of the future university emphasize flexibility in the location of learning, and have policies in place for quality, future markets, and costs and efficiency (Collis & Van der Wende, 2002).

Radical changes in our approach to university education are therefore needed if universities are to benefit from WEL. Bates (2000) claims:

"If universities and colleges are successfully to adopt the use of technologies for teaching and learning, much more than minor adjustments in current practice will be required. Indeed, the effective use of technology requires a revolution in thinking about teaching and learning." (p. v)

That revolution, according to Rudestam and Schoenholtz-Read (2002), "demands a reexamination of our core beliefs about pedagogy and how students learn" (p. 4), based on theories of constructivism and collaborative learning (Leidner & Jarvenpaa, 1995). Change on this scale requires vision and leadership, as well as appropriate resources.

Bates (2000) calls for "fundamental change in the way our higher education institutions are organized and managed" (p. 5), because "history dictates that the introduction of new technology is usually accompanied by major changes in the organization of work" (p. 1). This requires leadership, vision, policies, planning, and evaluation that emphasize the educational goals of WEL rather than just its technological characteristics (Bates, 2000; Collis & Van der Wende, 2002; Friedlander, 2002; Klobas & Renzi, 2003; Pollock & Cornford, 2000; Surry, 2002).

While they have put the necessary ICT infrastructure in place, universities have paid relatively little attention to development of the human resources needed for successful adoption of WEL (Collis & Van der Wende, 2002). Financial investment in training and skill development for teachers, students, and technical staff is required. It is not surprising, given arguments for attention to pedagogy rather than technology, that successful adoption of WEL is associated with training to develop teachers' ability to design courses that use WEL to improve pedagogy rather than training that emphasizes the features of specific software (Klobas & Renzi, 2003).

Human resource issues associated with optimization and management of the ICT infrastructure also need to be addressed. This requires attention to engagement with the university's partners in the supply and maintenance of the ICT infrastructure for WEL (Pollock & Cornford, 2000). The ICT infrastructure for WEL involves several layers of technology (internal and external networks, servers, and applications), and successful WEL requires skillful coordination of suppliers (Klobas & Renzi, 2003).

Changes in the reward systems for university staff are necessary to support the changes in work demanded by WEL (Bates, 2000; Collis & Van der Wende, 2002; Klobas & Renzi, 2000, 2003; Surry, 2002). Such changes in reward systems require short-term financial investment, but in the longer term are associated with changes in the nature and structure of work in the university.

CONCLUSION

WEL provides traditional universities with opportunities to enhance the quality of the education they provide to students on campus. While most current approaches to WEL involve incremental changes to classroom teaching, greater value is obtained through application of WEL to improve opportunities for collaborative learning among students. Success therefore requires attention—at the most senior levels—to educational values, financial and human resources, and transformation of educational processes and organizational structure, as well as to technology. WEL will become a natural part of the educational model of those universities with the management commitment and skill to implement and sustain the transformation required.

KEY TERMS

Blended Learning: *See Mixed Mode Learning*.

Collaborative Learning: Learning that occurs through the exchange of knowledge among learners. Collaborative learning is a form of social learning.

Computer-Supported Collaborative Learning (CSCL): Collaborative learning that occurs via the medium of computer-based communication networks such as the Internet.

Distributed Learning: *See Mixed Mode Learning*.

Flexible Learning: Systems in which students may choose to complete some of their learning on campus and some of their learning off campus.

Mixed Mode Learning: Study that combines traditional face-to-face learning with learning at a distance in a structured program. The Web may be used to enhance learning during study by one or both of these modes. Mixed Mode is also known as Blended Learning and Distributed Learning.

Online Learning Activities: Learning activities in which students interact with resources, or other students, or both, using the capabilities of the Internet or other computer-based communication networks.

Social Learning: Learning through social interaction with other people.

Web-Enhanced Learning (WEL): Use of the World Wide Web (Web) to provide students studying in the classroom with access to electronic resources and learning activities that would not be available to them in traditional classroom-based study. The simplest forms of WEL provides information about a course on the Web and access to the Web from within the classroom. More sophisticated forms of WEL blend activities in the classroom with Web-enabled online learning activities, which promote collaborative learning among students even when they are distant from the classroom.

Security and Trust of Online Auction Systems

INTRODUCTION

An auction is a market with an explicit set of rules determining resource allocation and prices on the basis of bids from market participants (McAfee & McMillan, 1987). Generally speaking, an auction is the standard means for performing an aggregation of supply and demand in the marketplace to effectively establish a price for a product or service. It establishes prices according to participants' bids for buying and selling commodities, and the commodities are sold to the highest bidder. Simply stated, an auction is a method for allocating scarce goods, a method that is based upon competition between the participants. It is the purest of markets: a seller wishes to obtain as much money as possible for the commodity offered, and a buyer wants to pay as little as necessary for the same commodity. Traditionally, there are three protagonists in the auction: sellers, buyers, and auctioneers. An auction offers the advantage of simplicity in determining market-based prices. It is efficient in the sense that an auction usually ensures that resources accrue to those who value them most highly and ensures also that sellers receive the collective assessment of the value. Indeed, auctions are conducted in accordance with formal rules for governing market access, trade interaction, price determination, and trade generation (Friedman, 1993). In the case of a traditional physical auction, a seller will choose an auction house based on the service: the form of licensing, the availability of suitable insurance, suitable descriptions and access to the commodities, payment terms, and security of goods before and during the auction process. The buyer or seller needs to come to the market or sends his/her representative.

Online auction systems provide immediate access advantages compared with their physical auction systems counterpart. Participants may join an online auction system, effectively placing bids using a computer on an anywhere-anytime basis. The access is not only limited to desktop computers, but also handheld devices such as mobile phones. In online auctions, transactions take place based on information (product descriptions), and the products move from seller directly to buyers only after online transactions are completed. They facilitate buyers and sellers in: meeting, the listing of items for sale independent of physical location, exchanging information, interacting with each other, and ultimately completing transactions. They offer significant convenience, allowing trading at all hours, and provides continually updated information; and they allow buyers and sellers to trade directly, by bypassing traditional intermediaries and lowering costs for both parties. Online auctions are global in reach, offering buyers a significantly broader selection of goods to purchase, and provide sellers with the opportunity to sell their goods efficiently to a broader base of buyers. Factors that make online auctions attractive may also present disadvantages. Many online auctions simply list the items for sale. No attempt is made to verify and check that the merchandise actually exists or that the description is accurate. Transaction trustworthiness and security are the two most significant problems.

EXISTING PROBLEMS

Online auctions have become very popular. One of the most successful online auctions, eBay (www.ebay.com) purports that the number of active users worldwide has increased from 27.7 million in 2002 to 41.2 million in 2003, and the number of listings was about 292 million in 2003 (eBay, 2004). Nielsen/Netratings, the global standard for Internet audience measurement and analysis, also reports that eBay was one of the top five sites in Germany and the United Kingdom in February 2004 (Nielsen/Netratings, 2004). The research firm, the Aberdeen Group, found that 94% of net market transactions were through auctions, with just 6% through catalog sales (Pritchard, 2002). Most auctions are open to the public. Whatever you want, you can find. Given the rapid success of the virtual market, no de facto standards exist as to the bidding rules and policies governing the online auction business. Although online auctions have been developing for many years, there are still two major problems: trustworthy transaction and security. Regarding the first problem, trustworthy transactions, many auction sites describe themselves merely as meeting places for buyers and sellers. They simply allow sellers to list merchandise offered for trade and do not verify that the merchandise actually exists or is accurately described. They only use an email address to identify the traders—buyers and sellers. After the auction is over, it is the seller's responsibility to deal directly with the buyer concerning payment and delivery. The auction companies do not hold any responsibility for the transaction. Auction fraud is therefore an increasingly difficult problem in the virtual market. The common types of auction fraud are as follows (National Consumer League, 2001):

i) Failure to deliver: Buyers pay for an item, which is never received.
ii) Misrepresentation: Items received do not match up to the original description.
iii) Shill bidding: A seller, or an associate, places a fake bid intended to drive up prices.
iv) Selling black-market goods: The goods are typically delivered without authentic merchandize, warranty, or instructions.

Among the complaints that the Federal Trade Commission (FTC) received about auction fraud, the two most frequent are 'failure to deliver' and 'misrepresentation'. However, in the last few years there is a new trend of increased 'shill bidding'. These problems effectively prevent some Internet users from participating in Internet auctions. According to FTC's Auction Fraud Report, Internet auction fraud entails 64% of all Internet fraud that is reported (Enos, 2001). The total dollar loss for all complaints exceeded US$12.3 million. Internet auction fraud has become a significant problem.

The second problem, security, is naturally a big concern for any business on the Internet. Since data is being transported over public networks, this makes it possible for third parties to snoop and derive critical information. Security and safety is an important topic in conducting business on the Internet; online auctions are no exception. During the auction, buyers and sellers have to submit their personal information to the system, as well as provide electronic payment for their goods. Hundreds and perhaps thousands of credit card numbers, home addresses, and phone numbers were exposed for months through a security hole on many Internet auction sites. Few auction sites provide security features such as SSL and VeriSign security. In the survey of protections on smaller auction sites, there is less than 20% implementing security technology (Selis, Ramasastry & Wright, 2001). Furthermore, most online auctions do not enforce strong authentication, relying instead on a user ID and password, or may be an email account, to establish the validity of a client. Once this minimal information is supplied, people are free to enter into the online auction system and participate in bidding. Moreover, no minimally acceptable standard exists for ensuring that auctioneers protect users against the loss of personal information by the auctioneer. There are no established minimum-security standards or licensing bodies to protect the privacy rights of customers. People are risking their personal information. Ensuring security and trust in electronic communication is a principle requirement for achieving the trust necessary in gaining widespread acceptance of Internet auction systems as a medium for commerce.

SECURITY & CONFIDENTIALITY

The challenge in security is to build an online auction system (OAS) with safe communication and collaboration between legitimate users. The following sums up the fundamental security needs for OAS:

i) The need to identify and authenticate legitimate users, thus identifying and granting access to bid information, content, and supporting services.
ii) Provision of a security system with fine-grained access control that will allow, on the one hand, legitimate users access to resources, while on the other, protecting sensitive information from hackers and unauthorized users (i.e., all other users).
iii) OAS should ensure that private, tamperproof communication channels for auction participants exist. Hence, processing of their transaction is secure.
iv) OAS should provide auditing and logging facilities to track site security and misuse.
v) OAS should provide secure data transactions from sellers to OAS and from OAS to buyers.
vi) Database system security is another consideration in OAS. In order to make sure that no unauthorized or authorized user can access any data in the database system, OAS should clearly identify data held, conditions for release of information, and the duration for which information is held.

Authentication is often considered the single most important technology for OAS. It should be computationally intractable for a person to pretend to be someone else when logging into an OAS. It should be virtually impossible for a third party to alter e-mail addresses, digital signatures, or the content of any document without detection. In addition, it should be equally

Figure 1. E-payment systems

Proprietary Payment Scheme	Third-Party Payment System: P2P	Escrow Service
Buyers pay money to payment company	Seller signs up for P2P Web site	Auction closes
Seller send out goods to buyer	Seller sends money request to buyer	Buyers pays I-escrow
Payment company sends payment to seller	P2P Web site notifies buyer by e-mail	Sellers ships goods
	Buyer signs up	Buyer approves goods
	Buyer sends money to seller	I-escrow pays sellers
	P2P Web site notifies seller by e-mail	
	Seller ships	

difficult for someone to mimic the Internet address of a computer when connecting to the OAS. Various authentication technologies are available for determining and validating the authenticity of users, network nodes, files, and messages; several levels of authentication must be considered. Validating the identity of users during the login process to the system is supported by encryption technologies to support authentication. Encryption is the fundamental technology that protects information as it travels over the Internet. Four properties are used to describe the majority of encryption functions of interest to OAS. These are: *confidentiality, authentication, integrity*, and *non-repudiation*. A cryptosystem comes with two procedures, one for encryption and one for decryption (Garfinkel, 1995). Cryptographic systems include Secure Socket Layer (SSL), Public Key Infrastructure (PKI), and Secure Electronic Transaction (SET).

A consumer-to-consumer (C2C) online auction system is designed for sellers and buyers; the online auction site acts as an intermediary. Sellers and buyers will interact with each other for their payment transaction. In order to prevent trustworthy transaction problems, OAS should provide a mechanism for trustworthiness such that the identity of the parties is established/verified. Almost every online business makes use of registration to identify and classify their customers. However, the difficulty lies in identifying information, which can be readily verified, which is also unique, difficult to fabricate, and does not reduce the potential customer base. Most systems therefore are relatively weak at ensuring the validity of information offered to identify registrants. The limits for ensuring trustworthy online registration are principally set by the availability of online verification services. The OAS may be able to do data field type checking (validate post codes or names). The one verifiable piece of information under current systems might be the customer e-mail address. In practice the only sure way of ensuring customer trustworthiness might be to limit the customer base to a set of certified users.

However, it is not the case in business-to-business (B2B). B2B marketplaces involve the transactions from one business to another via the Internet. No customer is involved in the transaction. A strict and legal entity is required between businesses. Businesses can access sites for procurement and services to obtain multiple bids, issue purchase orders, make payments, and so forth. The bidders are now the purchasing managers of other businesses. All sellers are registered and cleared as a certified business or commercial identity. The problems with B2B mainly arise if the transaction involves multiple countries. 'Cross-border' transactions involve taxes, duties, customs procedures, and satisfaction of legal requirements. For instance, online payments are becoming popular in Europe. However different countries have had different rules on an electronic signature and electronic invoices. At present, the European Committee for Standardization is resolving many issues related to online payments among the members (George, 2004). In Asia, the legal system is weak, inefficient, and corruptive in some countries. Hence it will become difficult to conduct commerce with companies in other countries if the country has no such legislation. Supplier-buyer enablement (B2B) is easy to support in Singapore and Hong Kong, but it is still in its infancy in the Philippines, Indonesia, India, and China (Choy, 2000). The legal framework will need a much longer time to become established in these countries.

Banking plays a critical role in commerce and therefore auction systems, as it typically represents the authority responsible for policing the final settlement of payment. In e-commerce as a whole, however, banks often lag behind the rate of technological change in other sectors of commerce. Buyers may have several payment options, including credit card, debit card, personal check, cashier's check, money order, cash on delivery, and escrow services. Credit cards offer buyers the most protection, including the right to seek a refund from the credit card issuer if the product is not delivered or if the product received is not the product ordered. Many sellers in C2C auctions do not accept credit cards. There are several reasons for this. From the seller's perspective, there will be a charge on them, and the average value of most purchases was US$100 or less (National Consumer League, 2001). The use of a credit card for payment will add cost to the sellers. From the buyer's perspective, it is very dangerous to disclose the credit card information to a person they have never met before. They may use your credit card information for mischief. Payment by check, cashier's check, or money order directly to the seller accounts for 69% of payment methods. However, those methods have no protection for the buyers. Money can be electronically transferred between buyers and sellers in a fast and low-cost way. The e-payment methods are shown in Figure 1. A proprietary payment system is a system in which the buyer pays a payment company rather than the seller, and the payments company pays the sellers. Escrow services allow buyers to deposit money in trust with a company, which will not release the funds to a seller until certain conditions are met or verified. In person-to-person (P2P) payment, it is first necessary for the payer to register with a P2P Web site, giving the payment provider authorization to debit a personal bank or credit card account.

CONCLUSION

Except for some notable large auction systems, most small online auction systems do not implement any security technology, which is the foundation for trusted transactions. Should international legislation be drafted for law enforcement of Internet auctions? It may be likened to legislation for road safety: it is illegal for drivers and passengers to ride in a car without a seat belt. In other words, the online auction systems should only be operated with essential security features such as SSL and privacy policy. Credit cards give the best protection to the customers, however the risk is high as the buyer's information about the seller is limited to an e-mail address. For high-value transactions, bringing in the rules of the traditional auction house may be a trend to maintain the confidence of both buyers and sellers. Consumers have various ways to protect themselves from auction fraud. It is important to educate them about the choices of payment methods related to the degree of protection available. There is always a trade-off between cost and risk. Another major problem facing both C2C and B2B online auction systems is the legal framework under which they operate, since it is not limited to one nation, but is 'cross-border'. In C2C, a perpetrator of fraudulent transactions may be from another country. It may thus be difficult to take legal action against him/her. Meanwhile in B2B, besides the issues of taxation and currency exchange, there are difficult issues relating to legal authority. Who will arbitrate or convene legal hearings in B2B? Online auction systems play a dominant role in e-commerce; it is therefore an important channel for trading. In order to make it a secure and a trusted marketplace, there is an urgent requirement for international management and control.

KEY TERMS

Digital Certificates: Used to authenticate both parties. Certificate authorities (CAs) must issue these certificates. These are trusted third parties that have carried out identity checks on their certificate holders and are prepared to accept a degree of liability for any losses due to fraud. CAs also issue the public and private keys.

Dutch Auction: A popular kind of auction at many sites, commonly used when a seller has a number of the same items to sell, for example, 10 posters. The auctioneer starts with a high asking price. The seller then gradually decreases the offer price, and the first person to bid is the winner.

English Auction: By far the most popular auction method. Bidding takes the form of an ascending price auction where a bid must be higher in price than an existing bid in order to win the auction.

Public Key Infrastructure (PKI): An Internet trust model based on public key cryptography (encryption is conducted with a dual key system: a public key known to everyone and a private key known only to the recipient of the message). PKI offers the advantages of authentication and non-repudiation, which SSL lacks.

Reserve Auction: In this case the seller sets a reserve price, or the lowest price the seller is willing to transact on.

Secure Electronic Transaction (SET): Despite SSL's popularity, MasterCard, Visa, and several other companies developed SET. Released in 1997, SET v1.0 established a standard specifically for handling electronic payments, describing field formats, message types, protocol handshaking, and encryption mechanisms. The key difference between SET and SSL is that SET has digital certificates for all involved parties as an integral part of its design.

Secure Socket Layer (SSL): SSL protocol provides secure links over the Internet between a Web browser and a server. SSL was developed by Netscape Communications in 1995 and is embedded in Web browsers. Its adoption has been widespread as it is relatively inexpensive.

Security Issues in Distributed Transaction Processing Systems

R. A. Haraty
Lebanese American University, Lebanon

INTRODUCTION

Transaction-processing systems (TPS) are becoming increasingly more available as commercial products. However, the approaches to the issues associated with using TPS in multilevel secure environments are still in the research stage. In this article, we address the issues of multilevel security in distributed transaction-processing systems. A distributed transaction-processing system (DTPS) is a collection of a finite number of centralized transaction-processing systems connected by a computer network. Each of these transaction-processing systems is controlled by a software layer and can be accessed both remotely and locally. Properties of a DTPS, such as data replication, may have a substantial effect on the security of the system. The security policies and integrity constraints adopted at each site may result in global security having inconsistent states. We address the issues of achieving a multilevel secure DTPS, and discuss the security constraints and data replication.

In this work, we address the issues of achieving a multilevel secure DTPSs system and discuss the security constraints and the replication of data items. The next section provides some background. Then, next, an overview of a distributed transaction-processing system is presented. In the fourth section, security-related issues are discussed. In the fifth section, a multilevel secure distributed transaction-processing system is presented. Then, in the next section, future trends are presented. The final section concludes the article.

BACKGROUND

Several commercial and military applications require a multilevel secure transaction-processing system (MLS/TPS). In an MLS/TPS, users are assigned classification levels that we denote by "clearances," and data items are assigned sensitivity levels. There are three interesting architectures that have been used to build MLS/TPSs from untrusted ones. These architectures are known as the integrity lock architecture, the kernelized architecture, and the data distribution architecture (Air Force Studies Board, 1983). While most of the techniques for TPS security are developed for traditional centralized TPSs, more TPS researchers are making substantial contributions to the development of a distributed TPS (Getta, 2003; Haraty, 1999; Haraty & Rahal, 2002; O'Connor & Gray, 1988).

A DTPS is a collection of a finite number of TPSs connected by a computer network (Ozsu & Valduriez, 1999). Each of these TPSs is controlled by a transaction management software layer and can be accessed both remotely and locally. A DTPS integrates information from the local TPS and presents remote users with transparent methods to use the total information in the system. An effective TPS system serves to maintain the ACIDity properties (i.e., atomicity, consistency, isolation, and durability) of transactions and must be superimposed on the preexisting local TPSs (Gray & Reuter, 1993).

One proposed architecture for MLS/TPS is the replicated architecture. This approach is being explored in several ongoing research efforts, including the Naval Research Laboratory Secure Information through replicated architecture (SINTRA) project (Thuraisingham, 1987). Data replication in DTPS has several implications for the security of the system. Replication allows data items in different local TPSs to be identified as logically belonging to the same entity. The security policies adopted by each site may result in global security having inconsistent states, because of the difference of local representation and management.

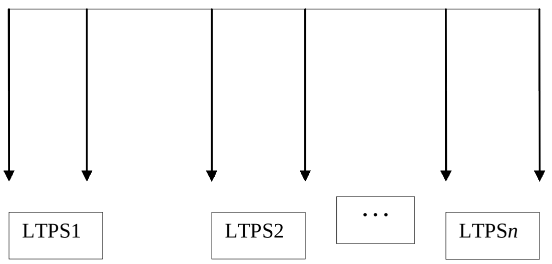
OVERVIEW OF DISTRIBUTED TRANSACTION-PROCESSING SYSTEMS

A DTPS consists of a set of preexisting local TPSs {LTPS*i* | 1 d•*i* d" *m*}, distributed among several interconnected sites. Each LTPS*i* is a software layer on a set of data items D*i*. Figure 1 depicts the architecture of a DTPS.

SECURITY ISSUES

Processes that execute on behalf of users are referred to as subjects. Objects, on the other hand, correspond to a

Figure 1. Distributed transaction-processing system



data item. Objects can be files, records, or even fields. In this section, we present the notion of object classification with emphasis on the problem of conflicting security constraints due to replication.

A security classification is a function that associates each subject and each object with a given level of security. Many classifications, such as the security lattice, exist (Denning, 1976). However, a well-known classification is four-value function (DOD paradigm) that classifies objects into unclassified (U), confidential (C), secret (S), and adopt top secret (TS). A simple policy that can be established using a classification function SL is as follows:

Subject X can access (read) Object Y iff SL (Y) $\leq$ SL(X)

A security constraint consists of a data specification and a security value. The data specification defines any subset of the TPS. The security values can be given by a classification function. Specific values are unclassified, confidential, secret, and top-secret. Thuraisingham (1987) defined two types of security constraints—internal constraints and external constraints:

1. Internal constraints classify the entire TPS as well as relations, attributes, and tuples within a relation. These constraints can be applied to data, as they are actually stored in the TPS.
2. External constraints classify relationships between data and the results obtained by applying operations on the stored data, such as sum, average, and count. Among these constraints are the functional constraints and the dynamic constraints.

These security constraints are subject to inconsistency and conflicting local security constraints. A good global security approach should reject inconsistent security constraints and inconsistent clearance of users. Examples of the inconsistencies encountered include:

- **Conflicting security constraints:** Such constraints classify the same facts into different categories.
- **Overlapped security constraints:** These constraints cover overlapped data domains.
- **Inconsistent security level of replicated data:** Cases where different copies of replicated data may belong to different security cases.
- **Access privileges of users to replicated data:** Instances where a user may have different access rights on replicated data at different sites.

Several solutions have been proposed to solve these inconsistencies and define a global security policy that respects the local ones (Pfleeger, 1989; Thuraisingham, 1987).

There are several ways to combine local policies. The optimal combination should give a policy that defines all component policies and is still secure.

MULTILEVEL SECURE DISTRIBUTED TRANSACTION-PROCESSING SYSTEMS

There are two strategies for building MLS/DTPS from DTPS. These strategies include data replication and per-level-based distribution. The scope of this article does not include the issues associated with network security; but, it is particularly important to have the various local TPSs. Instead, we will assume that interconnection between the various local TPSs is secure and focus attention on security that has to be provided due to replication and other properties specific to the TPS.

The data distribution approach physically replicates low-level data at all higher-level TPSs. The advantage of the replicated architecture is that is fairly secure (McDermott & Sandhu, 1991). No performance overhead is associated with multilevel queries, because they are locally executed. On the other hand, because data is replicated, there is overhead associated with broadcasting updates of lower-level data to higher-level TPSs in a correct and secure manner. This broadcasting mechanism is known as “data synchronization” (Air Force Studies Board, 1983).

In the per-level-based approach, data are physically stored in separate local TPSs according to sensitivity level. Early examples of this approach were presented by Hinke and Schaefer (1975). The advantage of this approach is that updating transactions does not produce inconsistencies. Performance overhead associated with multilevel queries is a major disadvantage.

Global Commitment in Secure Environment

An important aspect of a correct TPS is atomic commitment (Bernstein et al., 1987). Unfortunately, the local TPS in a MLS/DTPS system cannot support atomic commitment, so the two-phase commit (2PC) protocol (Bernstein et al., 1987) cannot be implemented. 2PC is known to introduce covert channels. In order to establish a covert channel, there must be two cooperating agents/subjects in the system and an encoding scheme. There are two main types of covert channels: covert storage channels and covert timing channels.

Covert storage channels disclose information from high to low subjects by manipulating a physical object that can or cannot be seen by the low subjects. For example, suppose there are two subjects of different security levels. Suppose also that these processes share a common resource—the available disk space. The secret subject creates a secret file that takes all of the available disk space to store the file. When the low subject attempts to create a file and store it onto the common disk, its request is denied. Through this denial, the high subject can signal information to the low subject. These signals are in terms of 0 and 1 bits that the low subject has to decode and turn into useful messages.

Covert timing channels can covertly send information by modulating observable delays of a common resource. This delay must be measured by low subjects cleanly; otherwise, the channel becomes noisy. For example, suppose we have two subjects again operating the low and high levels. The high subject can modulate the disk access time of the low subject by issuing numerous disk requests (thus transmitting a bit of 1) or zero disk requests (thus transmitting a zero). A system that is free from any type of covert channel is called covert channel secure.

Several distributed commitment protocols have been defined. A scheduler in MLS/DTPS that produces committable execution guarantees that a distributed transaction (a unit of work with execution sites: TPS1, TPS2, …, TPS*n*) becomes committed after it has been locally committed. The commitment of a distributed transaction means all of its subtransactions are committed. In this article, we follow the definition proposed by Bernstein et al. (1987):

If one subtransaction commits, then all other subtransactions will eventually commit.

We assume, in this article, that each subtransaction of a distributed transaction is designed to be executed in only one container. One can then say that a subtransaction has a security level.

FUTURE TRENDS

Future work will involve taking a closer look at MLS/DTPS and defining new and better ways of handling transaction management as well as query processing. Future work will also involve extending security issues to temporal and multimedia databases.

CONCLUSION

The security issues presented in this article highlight the intricacies required to architect a MLS/DTPS. We hope to address these issues further and to identify potential prototypes and engineering solutions that meet the requirements of MLS for DTPS.

KEY TERMS

Covert Channel: This is a channel that is not meant to route information, but nevertheless does.

Multilevel Secure Transaction-Processing System: This is a system whereby database users are assigned classification levels, and data items are assigned sensitivity levels.

Security Lattice: This is a partial (or total) order of security classes, where there is a least upper bound that dominates all the other security classes and a greatest lower bound that is dominated by all security classes.

Subject: This corresponds to a user or, more correctly, to a process that is running on behalf of a user.

Two-Phase Commit (2PC): This is an atomic commitment protocol that behaves as follows: The coordinator asks the participants to vote on commitment; if any votes No, the coordinator informs all participants to Abort; if all participants voted Yes, then the coordinator informs all participants to Commit.

Self-Organizing Networked Learning Environments

Jon Dron
University of Brighton, UK

INTRODUCTION

The Internet has long been touted as an answer to the needs of adult learners, providing a wealth of resources and the means to communicate in many ways with many people. This promise rarely has been fulfilled, and often, when it is, by mimicking traditional instructor-led processes of education. As a large network, the Internet has characteristics that differentiate it from other learning environments. As Kelly (1998) puts it, "the sum of the value of a network increases as the square of the number of members." Because these interactions are mediated through computers and may be with many users at once, this is a notable underestimate.

Churchill said, "We shape our dwellings and afterwards our dwellings shape us" (Churchill, 1943, p.23). If this is true of buildings, then it is even more applicable of the fluid and ever-changing virtual environments made possible by the Internet. Our dwellings are no longer fixed, but may be molded by the people that inhabit them. This article discusses a range of approaches that makes use of this facility to provide environments that support groups of adult learners by adapting to their learning needs using nothing more than their interactions to provide structure and shape to their learning.

BACKGROUND

Jonathan Darby (2003) identifies three generations of networked learning environments used in adult education. First generation systems are direct analogues of traditional courses, simply translating existing structures and course materials. Like their traditionally delivered forebears, they are dependent on individual authors. Second generation systems tend to be team-built and designed for the medium from pedagogical first principles, but still within a traditional course-based format. Third generation systems break away from such course-led conventions and provide such things as just-in-time learning, guided paths through knowledge management systems, and personalized curricula. This chapter is concerned primarily with third generation environments.

Saba's interpretation of Moore's theory of transactional distance predicts that in an educational system, as structure increases, dialogue decreases and vice versa (Moore & Kearsley, 1996; Saba & Shearer, 1994). What is significant in differentiating learning experiences is not the *physical* distance between learners and teachers, but the *transactional* distance, measured by the degree of interaction between them. Highly structured educational activities have a high transactional distance, while those involving much discussion have a lower transactional distance. This chapter is concerned with the structured variety of educational activity.

In a traditional learning environment, the structure of the experience is provided by the teacher or instructional designer. One of the few justifications for the lecture form is that it provides a framework for understanding a topic, emphasizing the important points and ordering them in a manner that is intended to be beneficial to learners. However, learners will not benefit equally from any given structure, as different learners learn differently (Kolb, 1984). It would be better if learners could select appropriate approaches for their needs. Without a teacher, help with this might be provided by the opinions of other learners. However, eliciting those opinions, assessing their reliability or relevance, actually finding the resources in the first place, and, once found, fitting them into a structured learning experience is difficult. Several approaches to these problems are available, but first it is necessary to introduce a few concepts of self-organization.

Self-Organizing Processes

Self-organization of the kind we are discussing is an emergent process in which the interactions of the participants and the software lead to organization that does not arise as an intentional, programmed, or planned process, but which arises from the nature of the system itself. Such processes are very common in nature and human social systems. Two in particular are of interest here—*evolution* and *stigmergy*.

Based primarily on work following that of Darwin (1872), evolution is one of the most powerful self-organizing principles whereby a process of replication with variation combined with natural selection (survival of the fittest) leads to a finely balanced self-adjusting system. It is important to note that "fittest" does not mean "best" by any other measure than the ability to survive in a given environment.

Stigmergy, a form of indirect communication through signs left in the environment (Grasse, 1959), leads to self-organized behavior, examples of which include everything from ant trails and termite mounds to forest footpaths, money markets, and bank-runs. For example, ants wander randomly until they find food, after which they return to the nest leaving a trail of pheromones. Other ants are more likely to wander where such pheromone trails mark the route. When they, too, find food, they leave a trail of pheromones. The stronger the trail, the more other ants are drawn to it. This positive feedback loop continues until the food runs out, after which the trail slowly dies away.

A full discussion of the many factors that result in a successful self-organizing system is beyond the scope of this chapter. However, the following brief discussion provides a flavor of what is involved.

Self-organizing processes occur through local interactions. For systems to develop any sort of complexity, it is necessary for these interactions to occur at a number of scales. For instance, the interactions of bacteria in an ant's gut affect the ant; groups of ants can affect tree growth; tree growth can affect climate. Local interactions should form small clusters that in turn interact with each other, leading to ever increasing scales of self-organization. A hierarchical scale where the slow moving features of a system shape the faster changing leaf nodes is a common feature of self-organizing systems, from forests to cities (Brand, 1997). Parcellation is also an important feature of such systems (Calvin, 1997). As Darwin found in the Galapagos Islands, isolated populations tend to develop differently and more rapidly than their mainland counterparts. Any self-organizing system relies on interactions between more or less autonomous units. The precise level of interactivity varies, but it is interesting to note that for a system which teeters at the edge of chaos, neither too stable to change nor too changeable to develop, the average number of connections between interacting agents tends to stabilize around just over two (Kauffman, 1995). Systems must be capable of change, being in a more or less permanently unfinished state. Perfect systems cannot evolve (Shirky, 1996). Equally, systems in perpetual flux can never achieve the stability to achieve self-organization.

Some Examples of Self-Organised Learning in Practice

For many seekers of knowledge today, the starting point is often Google (http://www.google.com). Google's PageRank algorithms use as their basis a principle described by Kleinberg (1998) as Latent Human Annotation (LHA). The principle behind LHA is that most Web pages provide links to other sites if those sites are considered in some way "good." A simplified formulation of this is that the more backlinks (links pointing into a site) that point to a given site, the higher its approval rating. Combined with a content-based search for keywords, documents returned often have a high degree of relevance and reliability. This approach is self-organized, incorporating evolution (unlinked sites "die") and stigmergy (more-visited sites get more links pointing to them). It does not rely on a central controlling authority to provide decisions on a resource's usefulness or give a structure to the content that is returned. However, the large number of results returned, problems with term ambiguity, and the lack of a means of identifying relevant resources for specific learner needs (beyond simple content-based searching) makes Google a relatively poor tool for finding resources from which to learn.

Wiki Wiki allows anyone in the whole world to edit any Wiki page. The potential for chaos is enormous, and yet Wikipedia (http://www.wikipedia.org), an encyclopedia generated by thousands of volunteers with no central authority, is not only possible, but hugely successful. In Wikipedia, self-organization largely occurs through the goodwill of the participants. Although anyone may vandalize a page, the community that creates it quickly removes such defacements, leading to a highly reliable and comprehensive source of knowledge. The success of Wikipedia may be ascribed to many factors, not least of which are its strong structure and simple policies. Interestingly, it makes use of a meta-wikipedia where Wikipedians may discuss issues relating to articles to be posted. This parcellation contributes greatly to the evolution of ideas.

Weblog communities form through links provided from one weblog (a kind of easy-to-edit interactive online diary) to another. Links pointing to a weblog may be discovered through Google (using the related: keyword) or explicitly through referrer logs and backlink tools. As links between weblogs grow, they start to form small, stigmergic clusters (Gregorio, 2003). This is in accordance with the principles of small world networks (Watts & Strogatz, 1998) whereby connections between a small number of nodes within a much larger network form natural clusters. As long as an appropriate cluster can be found, such networks provide a powerful means of finding structure in a subject. One way to find such networks is through a recommender system.

PHOAKS (http://www.phoaks.com) is a recommender system. Like Google, it makes use of LHA. It searches for references to Web sites in newsgroup postings and, having filtered out those that are obviously advertisements, matches themes of the newsgroup with the search term entered and provides rankings based on the results (Terveen et al., 1997).

Collaborative filters are recommender systems that make use of implicit and/or explicit preferences to provide recommendations. For instance, if you and I share a liking for nine books, and if you like a further book that I have not read, then it is likely that I will also like that book. Collaborative filters are very useful for matching users' preferences, but tend to be less successful when seeking learning resources because to learn is to change. My previous preferences for particular resources will be a less reliable guide to my future needs than preferences for books, movies, or Web sites, because the act of using a learning resource will (if successful) change me in ways that are likely to differ from how they have changed you. Nonetheless, systems such as Altered Vista (Recker et al., 2000) have achieved some success in this area.

Explicitly Emergent Systems

There are a few systems that explicitly exploit self-organizing principles to the benefit of learners. The selection presented here is a relatively small subset that indicates how this area is developing.

An exception to the rule that collaborative filters cannot cope well with changing needs is the CoFIND system (Dron et al., 2003), which combines both evolutionary and stigmergic principles to provide both social navigation and collaborative filtering. Rather than simple good-bad ratings, it employs a multi-dimensional matrix of "qualities" that loosely translate into those things that learners find useful about a resource (e.g., if it is good for beginners, detailed, exciting, etc.). Because qualities are created by learners and used by other learners to provide explicit ratings, they provide a kind of footprint of the learning needs that led to a particular resource being recommended. This remains even after the learner has moved on. By basing its recommendations on an explicit metadata model rather than a user model, it thus overcomes the problem of changing user models. In keeping with evolutionary principles, not just the resources in the system but the metadata that describe them are in competition with each other. Combined with positive feedback loops generated by social navigation using stigmergy, this means that each CoFIND system develops into a unique ecosystem composed of smaller, interacting ecosystems.

The SEO system also explicitly employs stigmergy, using agents to gather information from experts, which it combines in what is described as a "Kempelen box," named after the Mechanical Turk, an 18th century chess-playing machine that, in reality, contained a human player. These agents leave information trails that provide self-reinforcing paths like ant trails to useful knowledge (Small, 2001). The box provides answers to questions through the use of clusters of agents formed through a combination of stigmergy and evolutionary processes that weed out less useful clusters. Successful agent clusters are those that are most queried. Thus, the structure of the system adapts to the kind of questions being asked of it.

Jaakko Kurhila's (2002) EDUCO system makes use of stigmergy in the form of social navigation features to provide not only visual indicators of the relative popularity of documents within the system, but also real-time indicators of who is currently viewing them. This is combined with a chat system that enables interactions between users, providing a powerful incentive to visit pages that are currently being viewed. A similar principle is employed in Dron's (2003) the *Pavement*, which also makes use of stigmergic self-organizing principles suggested by Jacobs (1961) in "The Death and Life of Great American Cities."

FUTURE TRENDS

Darby's (2003) third generation of learning environments already exists, but by far the majority of effort is still being expended in the construction of first- and (occasionally) second-generation resources. Meanwhile, the huge popularity of systems such as Google demonstrates that there is a demand for discovering information, often in the service of learning. With the ever increasing trend towards meaningful metadata being appended to resources using open, XML-based standards, particularly Resource Description Framework (RDF, the foundation of the Semantic Web), the accuracy of such searches will be immeasurably improved over the coming years. However, to turn such information into useful knowledge and learning, a more sophisticated set of tools is needed. Such tools will combine the knowledge of many people, effectively amplifying intelligence and operating in some senses as a kind of group mind.

CONCLUSION

The World Wide Web is more than a collection of documents. Increasingly, the face presented to the end user is the result of a large amount of processing. The dynamic generation of resources to learn from is moving slowly away from rule-based machine- or human-governed information to a more symbiotic relationship in which the strengths of machines and the strengths of people are combined and, in the process, mutually enhanced. In the process, the high transactional distance of resource-based learning is reduced by glimpses of the footprints of others, a kind of social translucence (IBM_Social_Computing_Group, 2003). In a world where our roles are changing faster than the traditional course-based approaches to the delivery of learning can address, the resulting group mind can adapt itself more readily and effectively to the needs of individual learners than can any single human being.

KEY TERMS

Collaborative filter: A form of recommender system that uses implicit or explicit recommendations of others to provide advice (see Recommender System).

Recommender system: A computer program that recommends some sort of resource based on algorithms that rely on some sort of user model, some sort of content model, and some means of matching the two.

Social navigation: The transformation of an interface (usually Web-based) by using the actions of visitors.

Social translucence: An indirect or oblique indication of the presence of others visiting a Web site.

Stigmergy: A form of indirect communication whereby signs left in the environment influence the behavior of others who follow.

Transactional distance: A measure of the relative amounts of dialogue and structure in an educational activity. Of necessity, as one increases, the other decreases, and vice versa. More autonomous learners require less dialogue than more dependent learners.

Latent Human Annotation (LHA): The unintentional communication of a recommendation or other information as a by-product of another process (e.g., the provision of hyperlinks on a Web page, which are then used by search engines to provide rankings of the linked pages.

Emergent behavior: Behavior that arises out of the interactions between parts of a system and cannot be predicted easily or extrapolated from the behavior of those individual parts.

INTRODUCTION

World Wide Web: A Critical View

The World Wide Web (Berners-Lee, Cailliau, & Groff, 1992; Berners-Lee, 1999) has changed the way people communicate with each other and the way business is conducted. It lies at the heart of a revolution that is currently transforming the developed world toward a knowledge economy (Neef, 1997), and more broadly speaking, to a knowledge society.

Most of today's Web content is suitable for human consumption. Even Web content that is generated automatically from databases is usually presented without the original structural information found in databases. Typical uses of the Web today involve humans seeking and consuming information, searching and getting in touch with other humans, and reviewing the catalogs of online stores and ordering products by filling out forms.

These activities are not particularly well supported by software tools. Apart from the existence of links that establish connections between documents, the main valuable, indeed indispensable, tools are search engines. Keyword-based search engines, such as AltaVista (www.altavista.com), Yahoo (www.yahoo.com), and Google (www.google.com; Page & Brin, 1998), are the main tool for using today's Web. It is clear that the Web would not have been the huge success it was, were it not for search engines. However, there are serious problems associated with their use; the most important ones are listed in Table 1.

BACKGROUND

The Semantic Web Vision

The Semantic Web (Berners-Lee, Hendler, & Lassila, 2001; Davis, Fensel, & van Harmelen, 2002; Fensel et al., 2002; Antoniou & van Harmelen, 2004) proposes to overcome the difficulties listed above by making Web content machine processable. The key point is that the semantics (meaning) of Web content must be explicitly represented and processed. This aim will be achieved by combining the following technologies:

Table 1. A list of problems associated with keyword-based search engines

High recall, low precision Too many, mostly irrelevant pages are retrieved
Low or no recall Key relevant pages are not retrieved
Sensitivity to chosen vocabulary Slight changes in vocabulary may cause significant changes in results
Results are single Web pages Information may be spread across various pages
Human involvement is necessary To interpret retrieved pages, and to combine information

- *Explicit Metadata*: Web content will carry its meaning "on its sleeve" through appropriate semantic markup.
- *Ontologies*: They will describe semantic relationships between terms and will serve as the foundation for establishing shared understanding between applications.
- *Logical Reasoning*: Automated reasoning-enabled tools will make use of the information provided by metadata and ontologies.

More on ontologies and reasoning are found in the following sections. As a simple example, suppose that you are searching for photos of an orange ape in an annotated online collection of digital photos. Suppose that picture 1 is annotated as "playing orangutan." Then this picture can be retrieved on the Semantic Web, although its annotation does not contain the words "orange" or "ape" (so, a keyword-based search would fail). This can be achieved through interplay of (a) the annotation, (b) information contained in an ontology about animals that states that orangutans are apes and are orange, and (c) reasoning that combines the above information to conclude that the picture is relevant to the user's query.

The Semantic Web vision was created by Tim Berners-Lee, the person who created the WWW. The Semantic Web activities are coordinated by the World Wide Web Consortium (http://www.w3.org/2001/sw/). Table 2 collects a few critical issues of Web technologies addressed by the Semantic Web initiative.

FUTURE TRENDS

Ontologies

An ontology is a formalization of a shared conceptualization of a particular domain. It supports interoperability between applications at the semantic level (the meaning of information) and also allows people to talk about objects of common interest. Typically, it describes the objects of the domain and the relationships that hold between them.

Objects of the same kind are organized in so-called classes that are collections of objects sharing certain characteristics. For example, in a university domain, classes may be professors, students, administrative and technical staff, courses, lecture theaters, etc. Individual objects (called *resources* in Web terminology) can be declared to be instances of a certain class.

Once we have defined classes, we can also define relationships between them. One particular kind of relationship is a class hierarchy. A class A is a subclass of a class B (and B is a superclass of A) if every instance of A is also an instance of B. For example, the class of professors is a subclass of the class of all university employees. Figure 1 shows a sample class hierarchy for the university domain.

The subclass relationship is a general-purpose relationship between classes. Further relationships, called *properties*, can be defined by the user. In the university domain, such properties might be that a course is taught by a particular professor, that a student takes a course, and that a professor is head of a department.

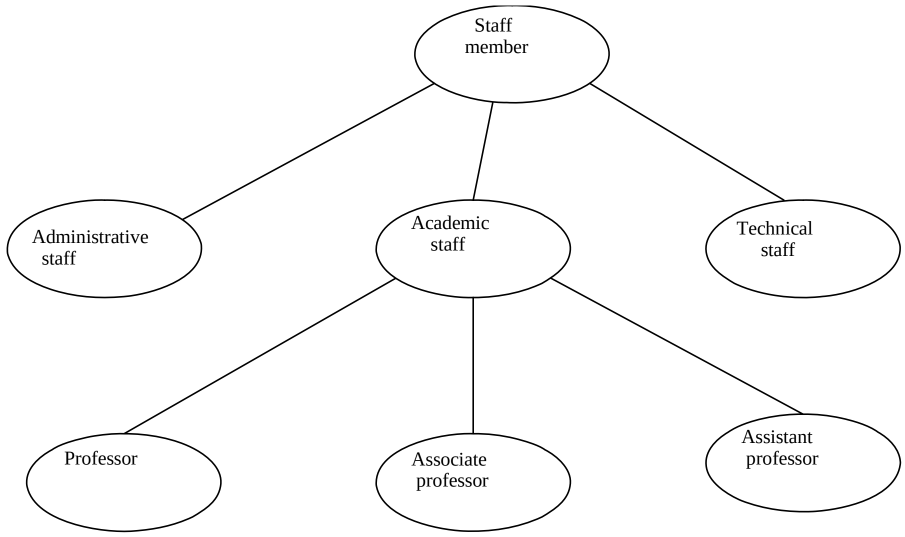
The interplay of classes and properties opens interesting modeling possibilities. For one, it is possible to define domain and range restrictions. For example, one can specify that a course can only be taught by an academic staff member (*range restriction*) and that only a course, and not, say, a lecture theater, can be taught (*domain restriction*).

Moreover, the valuable concept of *inheritance* can be utilized. Suppose that person *X* is declared to be an associate professor. Then *X* is allowed to teach a course, because he inherits this possibility from its superclass academic staff member. This way, we can avoid adding superfluous information to the ontology (*X* is an academic staff member; *X* is a staff member).

Table 2. Critial issues of Web technologies (Khosrow-Pour, 2004) addressed by the Semantic Web

Cyberloafing	Surfing the Internet, wasting time, and accessing inappropriate materials
Flooding of the Web with content	Including information that is not helpful
Having inadequate search facilities on the WWW	Lack of high-level query language search engines for locating, filtering, and presenting information
Maintaining integrity of data	Maintaining up-to-date and accurate information on the site for viewers to use

Figure 1. Class hierarchy in the university domain



Information such as the above can be expressed in an ontology language. Ontology languages can be informal, e.g. thesauri, or formal, when they rely on some kind of logical formalism.

Ontologies have become valuable tools in various domains, for example, in biology (Bodenreider, Mitchell, & McCray, 2003), medicine (Unified Medical Language System, UMLS), and culture (CIDOC/CRM).

Reasoning

When an ontology language is formal, it is possible to reason about the knowledge expressed in a particular ontology. For example, we may reason about the following:

- *Class Membership*: If *x* is an instance of class C, and C is a subclass of D, then we can infer that *x* is an instance of D.
- *Equivalence of Classes*: If class A is equivalent to class B, and B is equivalent to class C, then we can infer that A is equivalent to C.
- *Consistency*: If we declared that classes C and D are disjoint, and *x* is an instance of both C and D, then there is an error.
- *Classification*: If we declared that certain property–value pairs are sufficient conditions for membership in class A, then if an individual *x* satisfies such conditions, we can conclude that *x* must be an instance of A.

Derivation such as the preceding can be made mechanically instead of being made by hand. Such reasoning support is important, because it allows one to do the following:

- Check the consistency of an ontology and the knowledge
- Check for unintended between classes
- Automatically classify instances of classes

Automated reasoning support allows one to check many more classes than could be checked manually. Checks like the preceding ones are valuable for designing large ontologies, where multiple authors are involved, and for integrating and sharing ontologies from various sources.

Relevance to Sample Application Fields

Tables 3 and 4 illustrate the relevance of the Semantic Web vision to the application areas of knowledge management and business-to-consumer (B2C) e-commerce (Fensel, 2001). Other areas that would greatly benefit from the realization of the Semantic Web vision include business-to-business (B2B) e-commerce, e-learning (Nilsson, Palmer, & Naeve, 2002), e-government (Klischewski, 2003), Web services (McIlraith, Son, & Zeng, 2001), and peer-to-peer systems (Nejdl et al., 2002).

S

Table 3. Semantic Web and knowledge management

• Knowledge will be organised in conceptual spaces, that is, according to concepts and their interrelations, not according to keywords or other ad hoc means.
• Automated tools will support maintenance by checking for inconsistencies and extracting new knowledge, hidden in the stored knowledge.
• Keyword-based searching will be replaced by query answering based on what needs to be retrieved (semantic query answering).
• Defining views on certain parts of information (even parts of documents) will be possible. This way, certain pieces of knowledge will be hidden from certain groups of persons, while they will be accessible to others.

Table 4. Semantic Web and B2C e-commerce

• Pricing and product information will be extracted correctly, and delivery and privacy policies will be interpreted and compared to user requirements.
• Additional information about the reputation of online shops will be retrieved from other sources, for example, independent rating agencies or consumer bodies.
• The low-level programming of wrappers, necessary for today's shopbots, will become obsolete.
• More sophisticated shopping agents will be able to conduct automated negotiations, on the buyer's behalf, with shop agents.

CONCLUSION

The Semantic Web is the next step in the development of the WWW. It proposes to dramatically improve the Web's functionality and usability by making the meaning of Web content machine processable.

At present, most of the effort has been placed on the design of formal languages for describing Web resources and for writing Web ontologies. The most important languages are the language of resource description framework (RDF; Lassila & Swick, 1999), which allows one to state simple facts, and the ontology languages RDF Schema (Brickley & Guha, 2003) and OWL (Dean & Schreiber, 2003). The success of the Semantic Web will critically rely on two factors:

1. The development of professional tools for annotating pages and linking them to existing ontologies, for developing ontologies, and for reasoning with them—RDF Suite (Karvounarakis et al., 2002) is a good collection of tools supporting RDF and RDF Schema
2. The uptake by users—initial successes can be expected either in environments with central authority (e.g., in the knowledge management of large organizations) or in the emergence of virtual communities

KEY TERMS

Class: A collection of objects sharing certain characteristics (such as producer, customer, product, company, etc.) Individual objects are called instances of the class. The classes of an ontology describe the important concepts of a particular domain being modeled.

Class Hierarchy: Classes are usually organized in a conceptual space along a generalization/specialization axis. A class A is more general (superclass) than a class B when each instance of B is also an instance of A.

Ontology: A consensual and formal description of shared concepts in a domain. Typically, it organizes the objects of a domain in classes and includes a hierarchy of classes (e.g., printers are hardware devices). Ontologies are used to aid human communication and shared understanding and also communication among software applications.

OWL: The current W3C standard for defining Web ontologies.

Property: Properties are used to establish links between classes. For example, books are published by publishers. The property "publishes" relates a publisher with a particular book.

Property Hierarchy: As with classes, properties can be organized in generalization/specialization taxonomies. For example, the property "is CEO of" relating persons to companies is a more specific property than (subproperty of) "works for."

RDF (Resource Description Framework): This is the basic language of the Semantic Web. It is used for describing Web resources.

RDF (Resource Descrioption Framework) Schema: This is a primitive ontology language that is integrated with RDF. Its basic operations are the definition of classes and properties, their organization in hierarchies, and domain and range restrictions on properties.

XML (Extensible Markup Language): An application-independent meta-language for defining markup languages. It serves as the basis for syntactic interoperability among information systems.

Shaping the Evolution of Mobile Commerce

Andreas Rülke
PRTM, UK

Anand Iyer
PRTM, UK

Greg Chiasson
PRTM, UK

INTRODUCTION

How does a breakthrough technology, or a breakthrough combination of formerly separate technologies, become a viable business? What are the necessary conditions, competencies, and organizing mechanisms? Which enterprises are in the best positions to provide the various competencies and to organize the new business? How will the new business unfold?

Such are the questions posed by mobile commerce (m-commerce) or wireless electronic commerce, the business result of the Internet's convergence with broadband wireless communications. M-commerce's value chain model can help shed light on how this new business will develop and grow in the years to come.

Generally speaking, "value chain" can be defined as a map of the entire set of competencies, investments, and activities required to create, produce, deliver, maintain, and reap the proceeds from a product or service, and the relationships among those investments and activities. The profits and competitive advantages of participation in a given value chain reside dynamically within the chain, accumulating at the positions of greatest value. The enterprises that hold these positions have a great deal of control over how the chain operates and how the benefits are distributed.

The wireless telecommunications industry has changed dramatically since the late 1970s and early 1980s, when the first commercial handsets were launched. Since that time, mobile cellular communications systems have completed two entire generations of development, as have their respective value chains. The first mobile generation, or '1G,' used analog technology for transmitting voice calls, and had a correspondingly simple value chain (see Figure 1). Its value chain was very similar to that of fixed lines.

The second wireless generation ('2G') used digital technology and limited bandwidth. It provided Short Message Service (SMS) text messaging in addition to voice service.

An intermediary step between the second and third generations is 2.5G, which has higher bandwidth than 2G and "always on" wireless access.

BACKGROUND

We are now beginning to see the results of the third generation (3G) of wireless development. The 3G networks operate at a much faster speed than those of its predecessors and feature much greater capabilities: the Multimedia Messaging Service (MMS), which supports simultaneous transmission of various media—images, text, video, and audio clips—along with voice (Rowello, 2001). The 3G-value chain is also considerably more complex, as Figure 3 illustrates.

Figure 1. First-generation value chain: cellular voice service

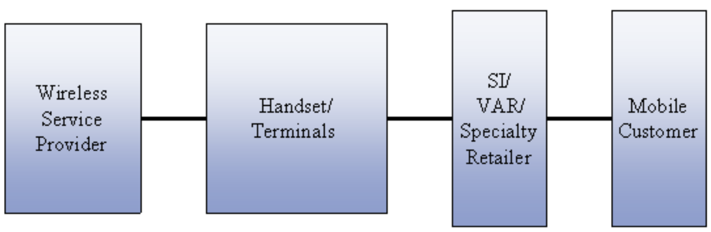

Figure 2. Second-generation value chain: digital voice and data

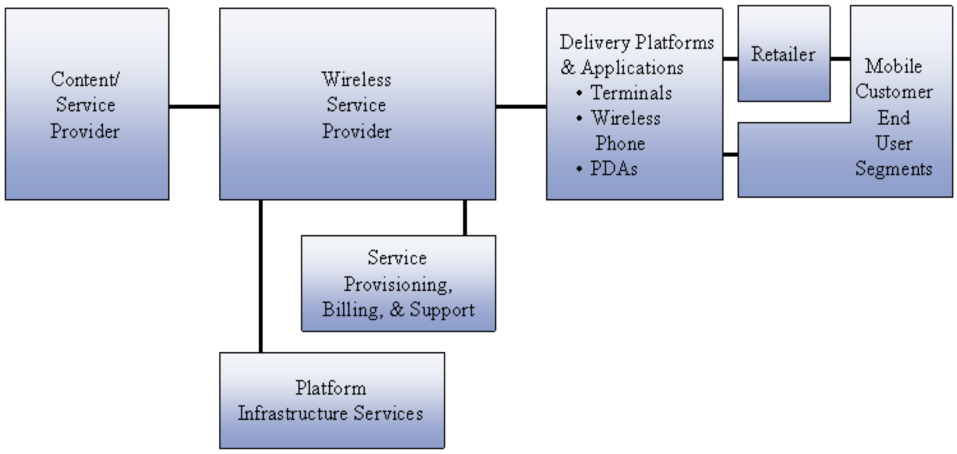

Figure 3. Next-generation value chain: the wireless Internet

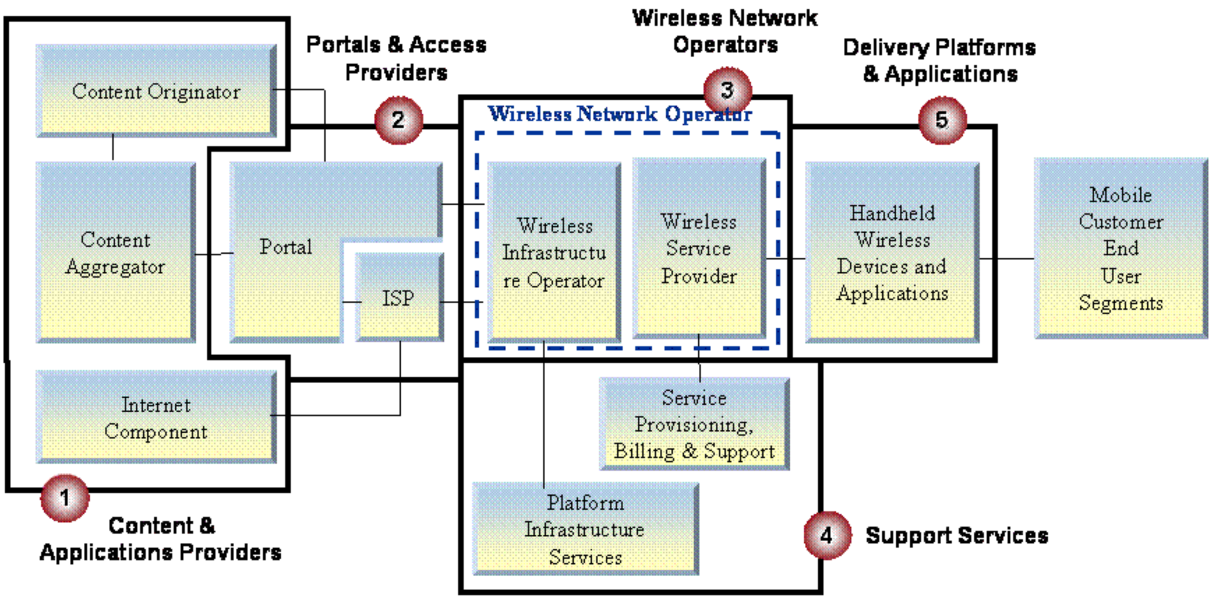

In an article published in 2000, we presented a model of the unfolding '3G' mobile commerce value chain, which groups the participants into five major elements (Rulke & Chiasson, 2000):

- Element 1—Content and Application Providers: e.g., Bloomberg and MapQuest
- Element 2—Portal and Access Providers: e.g., Yahoo! and AvantGo
- Element 3—Wireless Network Operators: e.g., Sprint PCS and Vodafone
- Element 4—Support Services: e.g., SpectraSite and Convergys
- Element 5—Delivery Platforms and Applications: e.g., Nokia and palmOne

This value chain is highly horizontal, and reflects the paths and supporting capabilities required to consummate mobile commerce: to create, aggregate, sell, and deliver content.

The time for 3G is imminent. The network technology is finally sound enough to be introduced to the general public. Traditional defined m-commerce and location-based services were slower to roll out than planned (Carbone, 2003) but are ready now, while 3G content, such as ringtones and music, are becoming increasingly important in the industry. Well-performing handsets are still in short supply (Tanner, 2004) but should be available for a rollout in 2005. For these reasons, this is an apt time to reexamine our 3G value chain and consider its relevance for strategic planning efforts.

MAIN THRUST OF THE CHAPTER

Value chain analysis is predicated on the fact that some forms of participation in horizontally distributed businesses are more advantageous than others. Because wireless network operators are in a position to leverage their existing relationships with their mobile phone customers into m-commerce relationships, they currently occupy one of the strongest positions within the mobile commerce value chain. Moreover, incumbent network operators have cleared the very high capital-investment hurdle facing would-be competitors.

Market history underscores the importance of seizing these two advantages. Many providers of wireline Internet services were slow to press their advantage in developing Internet offerings, only to see their customers migrate to new entities such as Yahoo! and AOL.

Wireless operators' third current advantage within the m-commerce value chain is their information on their subscribers' whereabouts. In the U.S., this information is becoming fairly accurate with the advent of "E911" emergency location-determination requirements. Knowledge of subscribers' locations is invaluable in directing contextual advertising messages, and in providing services such as directions to and phone numbers of nearby businesses. This information provides more than a source of advantage over other m-commerce participants; it affords a significant advantage over wireline ISPs, which do not typically track users' whereabouts.

Wireless operators have other advantages as well. They have extensive billing systems in place, which are generally flexible enough to capture m-commerce as well as access charges. This is of particular advantage in areas of the world where credit cards are less common, or where there is greater reluctance to use them for online transactions.

Value chain analysis also reveals how the positions of advantage within a chain may shift. The key challengers to wireless operators will be the Internet and "dot.com" companies that are part of the World Wide Web. These companies include many thousands of ISPs, business portals, content providers, and other software companies. These entities tend to be extremely quick to react to—or even to create—market changes. They're in the business of being first to market with a product that works. They're also in the business of continuous product improvement, iteratively building customer solutions that are very much on target.

FUTURE TRENDS

As traditional and nontraditional wireless enterprises converge to form content/delivery partnerships in the mobile commerce space, the positions of advantage within the industry's value chain will shift according to emerging patterns of consumer demand and preference. How will the distribution of revenues and profits change over time? What types of service offerings and business structures will be required to manage these changes? How can companies best implement the necessary changes?

In 2001, PRTM conducted a survey in order to get a sense of the wireless industry's expectations associated with the rollout of 3G wireless technologies over the next five years. We used our value chain model as the basis for the survey. A total of 91 respondents participated. Wireless infrastructure manufacturers, terminal and handset makers, wireless operators, content and applications providers, portal companies, and providers of a variety of specialized wireless-related services from more than 80 countries were all represented. A brief overview of the findings was published in the October 15, 2001, issue of *Telephony* magazine (Chiasson & Guyton, 2001).

The responses were quite consistent with the expectations stemming from our value chain model and analysis. Given this consistency and rollout delays, the survey results continue to be a relevant source of information on how the 3G value chain will impact m-commerce.

Companies are looking to capitalize on or compensate for shifts in revenues and profits among the various elements of the wireless value chain through integrated next-generation offerings. Respondents expected a gradual revenue shift away from wireless network operators and toward content and applications providers as the locus of value shifts from transport toward content.

New location-based wireless services, coupled with an improved ability to charge for content (through micro-billing, ASP models, etc.), are the key factors behind the anticipated reapportionment of revenues within the wireless industry. At the same time, wireless operators face both mounting competition and the commoditization of their offerings, much as we saw with land-line long-distance operators.

While the largest share of revenue will continue to accrue to wireless operators over the next five years, the distribution of revenue across the value chain elements will become more equitable. Respondents expected content and applications providers' annual revenues to grow the fastest, doubling from 11% to 22% of the total. This still makes sense, given the coming growth in data-based content and the growing consumer willingness to pay for it.

Today, most of the revenue is generated through voice, and that revenue belongs to the wireless operators. In the future, portals will give customers access to graphics-rich Web sites via mobile handset screens. To limit their decline in revenue share, wireless operators need to avoid becoming mere fungible pipelines.

Respondents expect the wireless industry as a whole to become more profitable over the next five years. Net profit margins are expected to grow, with the largest increases in profitability accruing to content and application providers that are able to take advantage of economies of scale by spreading their fixed costs over wider customer bases. Wireless operators are expected to hold net profit margins constant by focusing on their most profitable customers, and through increasing efficiencies.

For the wireless industry's expected gains to materialize, companies will need to develop offerings that span multiple value chain elements. The large majority of respondents (78%) report that their next-generation business plans focus on multiple value chain elements. Furthermore, companies with superior relative rates of revenue growth attach the greatest importance to integrated offerings. Traditional wireless companies will look to share in the growth and profitability of the new content- and applications-based developments, while companies new to wireless will need to offer solutions that combine delivery with content. Recent telematics ventures such as Wingcast and OnStar are excellent examples of nontraditional players (automotive OEMs in this case) partnering with existing wireless value chain participants to bring new integrated offerings to end consumers.

Multi-element participation in the value chain, both direct and indirect, is expected to increase over the next five years. The largest shift is expected from "one element" to "two element" companies. The number of companies participating in only one value chain element is expected to decrease from 39% in 2001 to 28% by the end of 2005. Given the delayed roll-out of the 3G systems by early 2004, this percentage might have been delayed, but we still expect the same basic trend to take place.

Partnerships will be the preferred means of integrating across the 3-G wireless value chain. The desire to provide integrated offerings, and the expectation of participating in multiple value chain elements, both indicate the transition away from transaction-oriented interactions among value chain participants in favor of more closely coupled business structures. Although the development of cross-chain capabilities in-house is the ultimate in integration, companies generally prefer to partner with holders of existing capabilities. The content and applications providers element, which is expected to enjoy the greatest revenue and profitability growth, is expected to see the most partnering activity. Wireless operators expect to form, on average, 21 partnerships with content and application providers by 2003. Conversely, content and application providers expect to form, on average, two partnerships with wireless operators and three partnerships with delivery platforms and applications by 2003.

PRTM surveyed respondents about a range of anticipated partnership types, including alliances, minority investments, joint ventures, and acquisitions, with varying degrees of coupling and tightness of integration. While the types of partnerships preferred depend on respondents' particular locations within the value chain, strategic/product alliances are the most likely approach to creating partnerships in all value chain elements.

Overall, respondents expect to form "tighter" partnerships (i.e., acquisitions, joint ventures, minority investments) with wireless operators and delivery platforms/applications providers. "Looser" partnerships (i.e., non-exclusive strategy/product alliances and marketing alliances) are favored with content and applications providers, and with portals and access providers. Verizon Wireless, AT&T Wireless, Sprint PCS, and Palm all have alliances with Yahoo! Mobile, for instance, and are listed as official partners on Yahoo!'s Web site.

The two most important reasons cited for forming partnerships are to exploit capabilities not available in-house, and to gain time-to-market advantage. Contributing reasons for partnering are to obtain a cost advantage over in-house capabilities, and to leverage the brands or customer bases of potential partners. Brand and customer leverage were particularly cited by content and applications providers as reasons for partnering.

The highly horizontal, distributed nature of the mobile-commerce value chain makes one fact plain: no single enterprise has the wherewithal to provide a true end-to-end solution that simultaneously optimizes business, shareholder, and customer objectives. But if partnership is vital, what is the right partnership model? Value chain analysis can guide you to the answer.

Each value chain element can be broken down into its constituent links. For instance, delivery platform applications consist of the key hardware, software, operating systems, standards, and so forth that comprise the technological heart of the solution. Support services can be broken down into installation, provisioning, customer care, and billing. Each of those links can, in turn, be subdivided into layers. For example, the hardware link of delivery platform applications can be decomposed into cellular receivers, GPS receivers, processors, logic, and the like.

Once the value chain has been broken down into its underlying elements, it is possible to associate elements with types or classes of candidate alliances. This point raises an important principle: An alliance should be mutually exclusive, yet collectively exhaustive. In other words, it should consist of the minimum number of players (element suppliers) required to deliver the solution, with no overlaps and no gaps. And, of course, the fewer the players, the better: less administrative and governance complexity, and more margin to go around.

We'll use "N" to represent this minimum number of mutually exclusive/collectively exhaustive players. Once you've determined your candidate list of N candidates, the options in terms of business arrangement can be depicted along a simple spectrum. At the far left of the spectrum is the consortium. At the far right is the formation of a new company ("newco"). Along the way are intermediate forms of business arrangement.

While there are no explicit variables that are intended to depict this continuum, one can envision that factors such as degree of management control, investment required, and governance complexity may increase from left to right.

In the context of mobile commerce, it has been our experience that the partnership forms on the right side of the spectrum have worked better than those on the left side.

A set of strategic and operational criteria can be applied to determine the best form for the business alliance from the options along the spectrum. The criteria include:

- Overall ability of the solution to meet customer goals
- Degree of up-front investment required
- Time to market requirement
- Degree of legal/regulatory compliance difficulty
- Degree of public acceptance of the solution offering
- Ability of the partnership form to absorb start-up costs
- Degree of brand leverage potential

In addition to leveraging multiple brands, the newco approach also leverages multiple core competencies, minimizing the new business's learning curve. The approach is well suited to combining best-in-class capabilities to produce a best-in-class offering. If a heavy infusion of capital into the partnership is required, the newco approach has the advantage of being able to draw capital from multiple sources. This approach can also be fastest to market, and has the greatest ability to absorb start-up costs. In addition, this approach has a major advantage when the time comes for market launch. If the newco brings together five companies, then it also brings together five sets of customers, creating a large and well-primed trial market.

CONCLUSION

To describe mobile commerce as an emerging business opportunity, or even as a 'business of businesses," would grossly fail to capture its extraordinary dynamism. M-commerce is a genesis in progress; a new and growing source of value at the confluence of two technological revolutions. The metaphor of a Web is useful in that it conveys the idea of an intricate and purposeful pattern, but the pattern of m-commerce is anything but fixed or final. Its patterns are being woven today, at the interconnections of the many diverse technologies, competencies, investments, and business models that comprise the mobile commerce value chain. M-commerce participation opportunities are value-chain (or "value-Web") participation opportunities, and the key to participation is partnership.

The value chain model presented here, along with the guidance offered on selecting the most appropriate form of partnership, will help companies set appropriate participation strategies, execute their strategies effectively and efficiently, and revise their strategies as circumstances change and opportunities arise. We have identified some clear trends in revenue distribution within the m-commerce value chain: for example, the trend toward a more equitable distribution of revenue across the elements of the chain over the next five years, notably favoring content and applications providers.

The emergence of mobile commerce, in all its complexity and flux, calls some basic business assumptions into question. For instance, to the old question, "Who owns the customer?", m-commerce value chain strategy poses the question, "Who *are* my customers in this Web of entities and partnerships, and to what degree can I own the relationships with value chain partners and end users?" The possibilities for positioning and branding within—and across—the value chain appear boundless. Mobile commerce will become even more complex in the future. The companies that begin proactively carving out their positions now will be best able not just to cope with the value chain's mounting complexities, but to shape the chain's evolution to their advantage.

KEY TERMS

ASP: Application Service Provider.

Content Aggregator: Businesses that transform individuated content into specific and customer-tailored forms.

Content Originators: Businesses that create the highly specific types of content that is enhanced, combined, packaged, transmitted, and sold to customers.

Delivery Platforms and Applications: Handheld wireless device makers, handheld computing devices, personal digital assistants, and mobile handsets.

Internet Service Providers (ISPs): Provide the hardware that connects customers to content and applications providers, usually for a monthly fee.

Mobile Commerce: Wireless electronic commerce.

MMS: Multimedia Messaging Service.

Network Infrastructure Operators: The network-facing elements of wireless networks which provide the software and hardware that enable online communications.

OEM: Original Equipment Manufacturer.

Platform Infrastructure Services: Entities that own portfolios of telecommunication towers in various countries and rent space on the towers to network infrastructure operators.

Portals: A single, convenient point of access to all the products and services produced by the content originators/aggregators.

Service Provisioning, Billing, and Support: Various individual elements of customer service which may be outsourced by wireless service providers.

SMS: Short Message Service.

Wireless Service Providers: The customer-facing elements of wireless networks; the services whose quality is perceived by customers; speed of connection, clarity, and so on.

Sharing Organizational Knowledge through Knowledge Repositories

M. Asim Qayyum
University of Toronto, Canada

INTRODUCTION

Knowledge repositories are increasingly being viewed as a special form of knowledge management in organizational memory information systems (OMISs). Presented in this paper are the design concepts and guidelines for building a knowledge repository, and its practical implementation in the form of a prototype. The needs and the organizational and technical challenges associated with the undertaking of such a project are identified, and recommendations and strategies for overcoming the restrictions are discussed. In light of these repository-building guiding principles, the prototype of such a knowledge management system is envisaged to be a Web-based electronic repository of online pedagogical resources, built to help foster a learning organization that works together to gather and share knowledge. As per the design guidelines, information resources within this prototype are combined with user insights and experience in the form of associated annotations and then categorized within a subject tree to appear as knowledge to the repository users.

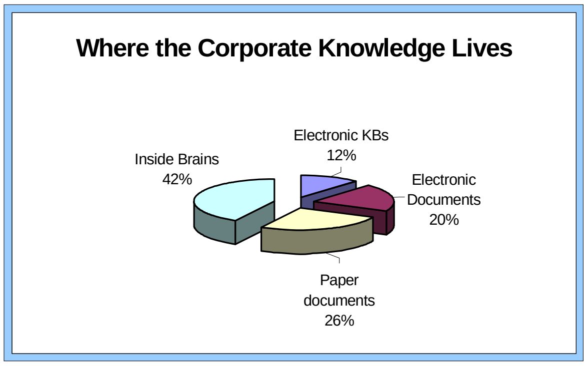
BACKGROUND

"Only 2 percent of information gets written down, the rest is in people's mind," says David Owens, vice president of knowledge management at Unisys Corporation and vice chair of the Conference Board's Learning and Knowledge Management Council (Hickins, 1999). This comment clearly illustrates that knowledge management (KM) places equal emphasis on capturing the tacit knowledge that is in people's heads, rather than targeting just the explicit knowledge that can be stored in a more shareable format. By managing its knowledge an organization would know more, and the more it knows, the more successful it will be. And this comes only after an understanding of the kind of information that is available to the members of an organization, where it is and how it can be accessed (Hackbarth & Grover, 1999).

While the figure quoted by David Owens is probably derived from personal experiences, a study of the empirical division of knowledge in an organization was carried out by the Delphi Group when they looked at KM practices in approximately 700 U.S. companies (Hickins, 1999). The results, presented in Figure 1, illustrate the fact that only a portion of the corporate knowledge is in shareable format while the majority (42%) of any one kind of knowledge resides inside people's heads. However, people leave organizations, taking away the knowledge that is stored in their heads. Therefore, organizations must build knowledge management (KM) systems, such as knowledge repositories, to retain the maximum possible tacit knowledge and make it available to the people who need it. This simple need for KM systems is supported by results from another survey, again by Delphi group, of 370 business professionals which showed that 28% had already begun or completed KM projects, while 93% said that they would undertake such projects by 2000 (Anthes, 1998).

Data and information need to be integrated to arrive at knowledge, and what is data to some may be information for others. Knowledge is, however, information that has been edited and analyzed in such a manner to make it useful. It has the greatest human contribution, stems from people, is the most difficult to manage, and is mostly context-specific (Grover & Davenport, 2001). And when knowledge from the past is brought to bear on present activities and thus affects the level of organizational effectiveness, then it is called organizational memory, or OM (Stein, 1992). A knowledge management system should then manage and expand this organizational memory while retaining a strong organizational learning founda-

Figure 1. Breakdown of knowledge areas within an organization



tion so as to successfully increase an organization's potential for taking effective action (Alavi, 2000; Davenport & Prusak, 1998). Such a knowledge management system would act as an organizational memory information system (OMIS), which provides a coherent integration of dispersed know-how, or OM, from all over the organization (Stein). An important aspect of OMIS is that the projects requiring its use do not involve a simple development of the system but require the incorporation of a concept of organizational development with a focus on enterprise-wide knowledge sharing and learning (Lehner, Mair, & Klosa, 1998). Thus, while an advanced database system will view information as a resource, an OMIS will focus on managing knowledge and contribute to learning ability, flexibility, and mastering of organizational change.

Development of an OMIS is not technology-driven but people-driven (Hickins, 1999), and these systems can firmly be placed as organizational knowledge management systems as they adapt to the social dynamics of the workplace. These social dynamics may include factors such as work habits, perceived benefits, and knowledge sharing. A knowledge repository can then be classified as a special form of OMIS because it embodies the phases of acquisition, retention, maintenance, and retrieval within its knowledge management framework (Hackbarth & Grover, 1999; Maier & Klosa, 1999). Processing of knowledge can be added to this list, and this may involve sorting, filtering, organizing, analyzing, comparing, correlating, mining, or a simple labelling of knowledge so that others can find it (Seng, Zannes, & Pace, 2002). These processes are necessary so that the objective of a knowledge repository can be achieved, which is to capture knowledge for later access by organizational members, and common repository techniques using these concepts include Lotus Notes, Web-based intranets, and document management tools (Grover & Davenport, 2001).

FISKR AS A KNOWLEDGE REPOSITORY

Sharing of tacit knowledge is aimed at gathering knowledge locked in people's heads, their notebooks, or desktops or simply lying in the filing drawer, things that were envisaged to be achieved by this repository. Thus, this was the rationale behind the design of the Faculty of Information Studies Knowledge Repository (FISKR) at FIS in University of Toronto. This repository is capable of acquiring and retaining "structured information," such as resources or pointers to resources of many different kinds, including, but not limited to, electronic or printed material, slide presentations, multimedia files, student papers, theses, reviews, or any other resources that are relevant to the subject matter. Retained in addition to structured information was "informal knowledge," which took the form of user-contributed annotations associated with each resource and provided added value in terms of conveying knowledge. Support was also made available to the faculty members for the creation of course pages and reading lists.

What differentiated FISKR from any other database was the fact that tacit information, which is ordinarily not shared and is deemed useful for the learning community, was made available in a shareable format to its members. Thus, the "implicit" data and information added to this repository consist of not just the resources but the associated contributor's experience, insight, and use context, which was made available to the members of a community in an "explicit" and organized form, or was now knowledge for its users. Such a design was also demonstrated in the conceptual design of a learning organization's KM system (Hall, Paradice, & Courtney, 2003). Nonaka and Takeuchi (1995) addressed this key issue of organizational knowledge creation and labeled it as "knowledge conversion," where human knowledge is created and expanded through social interaction between tacit knowledge and explicit knowledge.

The actual design of repository-based KM projects can be classified in two ways. The top-down approach looks at the knowledge present within a department and seeks to bring that together within a KM system by utilizing the services of a group of specialized personnel. Bottom-up approach on the other hand would tend to identify user needs and create a repository first and then encourage the users to add their knowledge to it. The latter category was chosen for implementing FISKR as it suited an educational environment.

A notable example of building a bottom-up knowledge repository as an OMIS was the Eureka project at Xerox (Hickins, 1999). It was noted at that time that the database housed more than 5,000 user "contributions," which were available to the Xerox employees via the World Wide Web right on their laptops. Docushare was another such Xerox project. Similarly, Hewlett-Packard used Lotus Notes to capture tips. Reviewing FISKR's design in context of the knowledge sharing at these companies, it was noted that success came out of the overall cooperative culture developed there as the management believed that technology must support the distributed sharing of knowledge because the work had become very cooperative in nature. This was in line with recommendations put forward by Davenport, DeLong, and Beers (1998), who suggested that a key success factor for knowledge management project was that knowledge repository creation should be accompanied by encouraging and facilitating communication among organizational members, thereby improving knowledge access and enhancing the knowledge environment. And once this effective communication and learning start occurring within an organization, then they often result in "intelligence" or "knowledge" (Seng et al., 2002). Thus, the system development has to work in parallel with the development of an organization-wide sharing culture. The successful deployment of these two factors is ultimately expected to lead to accelerated learning and innovative sharing environment to an academic setting, such as the one in which this project was implemented.

The other type of repository creation approach, the top-down approach, was demonstrated in the Optical Recorded Information Online Network (ORION) project, which was developed at the Federal Express Corporation. The main objective was to cope with the massive employee documentation requirements of its ever-increasing worldwide workforce, estimated to be at over 90,000 employees (Candler, Palvia, Thompson, & Zeltman, 1996).

PROTOTYPE DEVELOPMENT GUIDELINES

In a learning organization such as FIS, the critical issue was how the individual learning could be transferred to the organization, and this objective was implemented through this project. So when the knowledge transfer is to take place by constructing an OMIS, then a key challenge is to harness as much organizational memory into the OMIS as is feasible and appropriate (Hackbarth & Grover, 1999). To achieve this and to ensure the success of FISKR, it was essential that this repository blended in with the culture of FIS and that the students and faculty used the system without considering it as an additional burden imposed on top of their already overworked schedules. It was realized that if this KM system was viewed as extra work, then it may end up as a straight failure, as people tend to ignore systems which require them to input data (Hickins, 1999). Thus, the need was to develop a system that would be useful to the users in terms of supporting their class work and that they would accept as part of their routines.

In view of the above-mentioned constraints, some guidelines (King, Marks, & McCoy, 2002; Tobin, 1998) adapted during the development of this repository were as follows:

- To act as a useful learning tool, it had to be well organized, kept up-to-date, and be easy to access and search. The users will tend to look for other sources if they find the repository complicated to use.
- The information in the repository had to be kept accurate. If not monitored properly, data that has once been entered could stay there forever, even when it had been outdated or replaced by information that is more accurate. To implement this feature, this repository drew on the services of subject specialists, who classified and verified all user inputs and monitored the quality of contents.
- All members of the organization were given direct access to the repository. While certain portions of this repository were password protected, no other approval was necessary for majority of the users.

The bottom line here was that the information in the repository should be the information that the users need and that it may not be limited to information generated from within the organization. In addition, as the repository grew through user submissions, it amassed the information that users required, and this information came from within or external to the organization. It was only after implementing these conditions that it could be said that the information contained within this repository conveyed knowledge to the community members. Thus, as demonstrated by the project objectives and design and the actual prototype (that will be described in the implementation sections), the standards of a knowledge repository were adequately met in the FISKR implementation as it employed the phases of acquisition, retention, maintenance, processing, and retrieval.

Lastly, the prototype of FISKR has been introduced to students in at least one course and during a couple of presentations and seminars. The interest has been encouraging so far, and over time, the intention is to move out of the prototyping phase to the actual system implementation phase.

The Architectural Representations

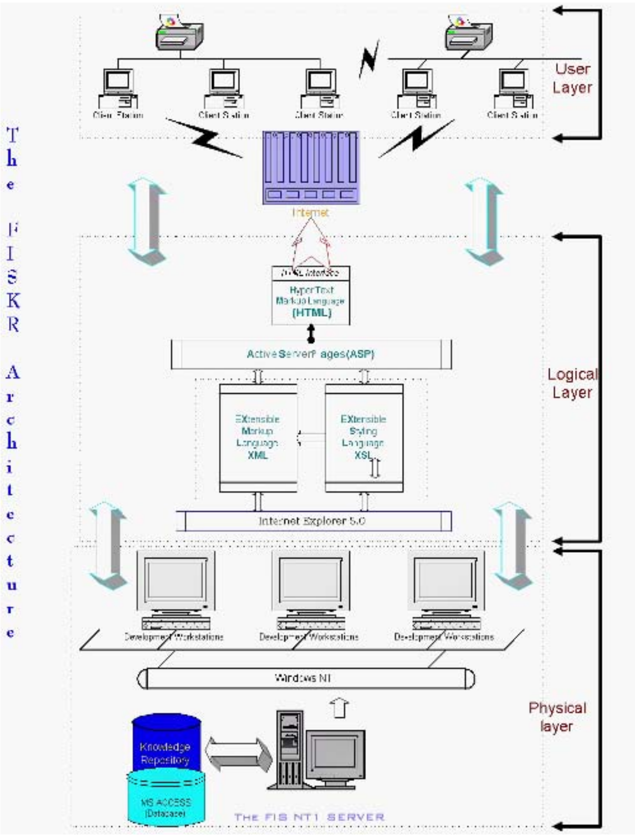
The three-tier physical architecture of the Faculty of Information Studies Knowledge Repository (FISKR) is demonstrated in Figure 2, which shows the various hardware and software components that have been utilized in this prototype. Briefly, the system was Web-based, built upon a Windows NT platform using the test server available at FIS. Microsoft's (MS) Active Server Pages (ASP) was used as the main script language with MS Access acting as the knowledge base at the back-end. Extensible Markup Language (XML) was used to structure the data.

Operational Features

The prototype of FISKR currently provides three options to the user:

1) "Search FISKR" allows an individual to search resources housed in FISKR by keyword, author

Figure 2. FISKR physical architecture



name, title, or type of resource, that is, whether it is a book, journal article, conference paper, research article, etc.

2) "Browse FISKR" allows an individual to browse resources housed in FISKR by various predetermined classification schemes.

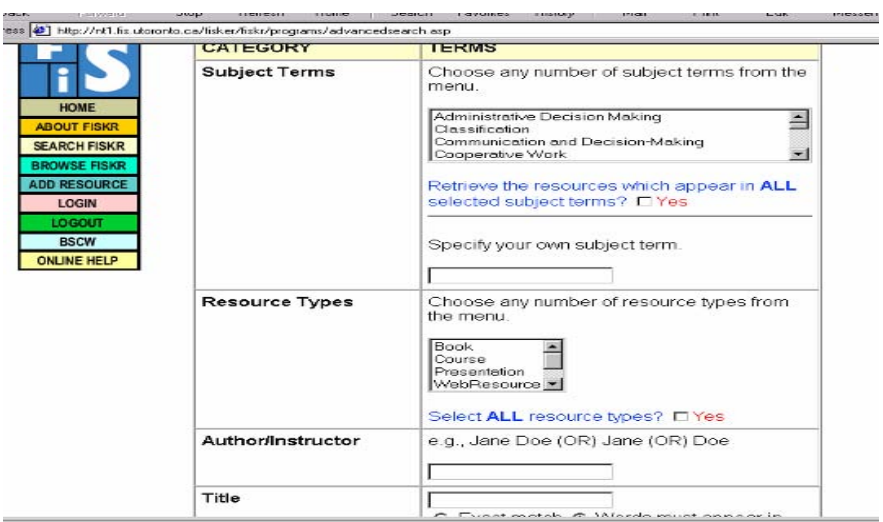
3) "Add a Resource" allows an individual to add resources to FISKR as well as annotations. FIS faculty members are given the additional option of entering a "Course" as a resource.

A typical search screen is shown in Figure 3. This is an advanced search screen, where the user is presented with a basic keyword search option also. A search can also be carried out by date or author information.

When browsing resources according to some subject terms, a typical query will result in a legend at the top, which is present in all search result screens to guide the user in identifying the type of the resource. The user can then drill down to retrieve further information about the resource. When adding a resource, the user is presented with an entry screen, which lists all possible resources that can be entered into the system.

Initial efforts focused on identifying many possible resources within the faculty. However, because of the modular nature of this system, further types of resources can easily be added to the repository without incurring any major design changes. As it is, the resources can be divided into two major virtual categories. The first would be termed as that of containing explicit resources or pointers to them, such as books and other published material. The second category contains the implicit resources, which are comprised of unpublished and little-known personal works, such as student papers, theses, and multimedia files, e.g., the audio and video of some lecture or presentation. The objective was to process categorized information to create knowledge for the repository users (Seng et al., 2002).

Figure 3. FISKR search options



S

FUTURE TRENDS: FISKR-II

FISKR has significant potential for the development and sharing of pedagogical resources within and between schools and departments in the University of Toronto, as well as organizations outside the university. This is mainly because of the structure provided to the data using XML, which will help facilitate data interchange. Commercially, the FISKR framework, as well as its tools and applications would be of great interest to organizations designing and developing their own internal knowledge repositories. The use of XML and object-oriented methodologies to mark up and represent the content of resources permits great breadth and flexibility in the kinds of resources that FISKR can house.

Some future enhancements to this system could be as follows:

- E-mails could be a part of the repository as they play an important role in capturing the elusive tacit knowledge flowing within the organization.
- For retrieving this (implicit) knowledge contained in embedded annotations from the knowledge base, the user can have the option of looking up annotations by made faculty members or renowned researchers, which would lead to availability of more credible information about the resource.
- The use of ontologies will bring about more organized storage within the knowledge base, which can then be exploited by an automated acquisition of explicit resources using Web wrappers.
- A Java-based tree-shaped structure of all the subject taxonomies present in the repository could help the users add nodes to a tree within the subject taxonomies, which have already been created by subject specialists.

CONCLUSION

Presented were the design concepts of a knowledge repository and one completed example. The experiences with this development process helped sum up the repository success factors as being: A repository should be envisioned to be a collection of shared resources, and the greater the information-handling capacity made shareable through the repository, the more valuable the system will be for its community of users. Moreover, the organization implementing such a project should plan to establish a long-standing focus on managing information content and providing "smart, friendly" access to information content. The prototype FISKR is a direct application of these principles to the organizational knowledge base, and benefits from all the areas of expertise that the faculty can bring to bear on it. This helped the project in meeting its ultimate goal of supporting a learning organization by capturing and sharing knowledge.

FISKR prototypes can be viewed at:

KEY TERMS

Annotations: Comments, typographical corrections, hypotheses, or ratings given by a reader playing the role of an author, which makes a statement about the document or some part of it at a certain time.

Knowledge: The most valuable form of content in a continuum, starting at data, encompassing information, and ending at knowledge.

Explicit Knowledge: Knowledge that can be codified in words, numbers, or rules and can take the shape of documents, or perhaps result in the production of some type of equipment.

Implicit Knowledge: Knowledge that has been acquired through experience and task execution, where it helps individuals in performing their work.

Knowledge Management: Identification and analysis of available and required knowledge assets and related processes, and the subsequent planning and control of actions to use these assets and processes to achieve organizational objectives.

Knowledge Repository: A collection of meaningful data and information, including implicit and explicit data, which serves a particular community of practice.

Organizational Memory: When knowledge from the past is brought to bear on present activities, thus affecting the level of organizational effectiveness.

Organizational Memory Information Systems: A coherent integration of dispersed know-how from all over the organization.

ENDNOTE

1. Further information on this topic can be found in Dieng, Corby, Giboin and Ribiere's (1999) article, which provides a useful discussion and survey of methods, techniques, and tools aimed at managing corporate knowledge from a memory designer's perspective.

INTRODUCTION AND BACKGROUND

Web servers have recently become the main source of information on the Internet. Every Web server uses a Web log to automatically record access of its users. Each Web-log entry represents a single user's access to a Web resource (e.g., HTML document) and contains the client's IP address, the timestamp, the URL address of the requested resource, and some additional information. An example log file is depicted in Figure 1. Each row contains the IP address of the requesting client, the timestamp of the request, the name of the method used with the URL of the resource, the return code issued by the server, and the size of the requested object.

Conceptually, Web-log data can be regarded as a collection of clients' access-sequences, where each sequence is a list of Web pages accessed by a single user in a single session. Extraction of user access-sequences is a non-trivial task that involves data cleaning and user session tracking (Cooley, Mobasher & Srivastava, 1999). Figure 2 presents an example client sequence derived from the Web log from Figure 1.

Web logs are typically used to perform Web usage analysis, i.e., to identify and investigate user access-patterns. Such patterns can be discovered by means of popular data-mining algorithms for sequential pattern discovery (Chen, Park & Yu, 1998; Pei, Han, Mortazavi-Asl & Zhu, 2000). Each access pattern is a sequence of Web pages which occurs frequently in a collection of user access-sequences. Sequential access-patterns provide information about typical browsing strategies of users visiting a given Web site, for example, "10% of users

visited the page X, and later the page Y." After some frequently occurring sequences have been discovered, the analyst should be able to search for user access-sequences that contain the patterns. Such queries, called pattern queries, have numerous applications, for example, searching for typical/atypical user access-sequences.

Since Web logs tend to be large, a natural solution to support processing of pattern queries would be indexing Web access-sequences. Unfortunately, traditional indexing techniques for single-valued attributes, such as B-trees (Comer, 1979) or bitmap indexes (O'Neil, 1987), and multidimensional indexes, such as R-trees (Guttman, 1984), are inefficient or even not applicable, as they do not take ordering into consideration. These techniques can be applied merely to locate sequences built from the same set of elements as the query sequence, thus they are likely to introduce many false drops if the actual task is subsequence search. Therefore, novel dedicated indexing methods for Web-log data should be researched.

SEQUENTIAL DATA INDEXING METHODS FOR PATTERN QUERIES

Let I be a set of *items* (e.g., distinct URLs). A *data sequence* X is defined as an ordered list of items (e.g., client's access sequence). Thus, $X = \langle x_1 x_2 \dots x_n \rangle$, where each $x_i \in I$ (x_i is called an *element* of X). We say that a data sequence $X = \langle x_1 x_2 \dots x_n \rangle$ *is contained* in another data sequence $Y = \langle y_1 y_2 \dots y_n \rangle$ if there exist integers $i_1 < i_2 < \dots < i_n$ such that $x_1 = y_{i1}, x_2 = y_{i2}, \dots, x_n = y_{in}$. Given a database D of data sequences (e.g., Web-log file) and a data sequence Q, a *pattern query* consists in finding in D all data sequences that contain Q. In other words, a pattern query formulates a problem of finding all data sequences containing a set of user-defined elements in a specified order.

An *item mapping function* $f_i(x)$, where $x \in I$, is a function that transforms a literal into an integer value. Henceforth it is assumed that literals are mapped to consecutive positive integers starting from 1. An *order mapping function* $f_o(x,y)$, where $x, y \in I$ and $x \neq y \Rightarrow f_o(x,y) \neq f_o(y,x)$, is a function which transforms an item sequence $\langle x\, y \rangle$ into an integer value. It has to be noticed that the intuition for the use of $f_o(x, y)$ is that it takes ordering into account. Henceforth we consider order mapping functions of the form $f_o(x, y) = a * f_i(x) + f_i(y)$, where a is greater than all f_i values. Consequently, f_o values are always greater than f_i values, and the property $x \neq y \Rightarrow f_o(x,y) \neq f_o(y,x)$ is satisfied since $f_o(x,y) = f_o(w,z) \Leftrightarrow x = w \wedge y = z$. Given a sequence $X = \langle x_1 x_2 \dots x_n \rangle$, the *equivalent set* E of X is defined as:

$$E = \left(\bigcup_{x_i \in X} \{ f_i(x_i) \} \right) \cup \left(\bigcup_{x_i, x_j \in X,\, i<j} \{ f_o(x_i, x_j) \} \right)$$

where f_i is an item mapping function and f_o is an order mapping function.

According to the above formula, an equivalent set is the union of two sets: one resulting from considering each element separately, and one resulting from considering pairs of elements. $S(E)$ denotes the former set, consisting of values of f_i, and $P(E)$ denotes the latter set, consisting of values of f_o. A significant property of equivalent sets is that for two sequences Q, P and the corresponding equivalent sets E_Q and E_P, if Q is contained by P, then $E_Q \subseteq E_P$. Therefore, equivalent sets allow us to express a pattern query problem as the problem of finding all sets of items that contain a given subset.

Example 1. For instance, for $I = \{A, B, C, D, E\}$ we have $f_i(A) = 1, f_i(B) = 2, f_i(C) = 3, f_i(D) = 4, f_i(E) = 5$, and $f_o(x, y) = 6 * f_i(x) + f_i(y)$ (e.g., $f_o(A,B) = 8$). Given a sequence $X = \langle A, C, D \rangle$, using the mapping functions that were described above, we get: $E = (\{f_i(A)\} \cup \{f_i(C)\} \cup \{f_i(D)\}) \cup (\{f_o(A, C)\} \cup \{f_o(A, D)\} \cup \{f_o(C, D)\}) = \{1, 3, 4, 9, 10, 22\}$.

Equivalent sets can be efficiently represented with *superimposed signatures*. A signature is a bit string of L bits (L is called signature *length*) and is used to indicate the presence of elements in a set. Each element of a set can be encoded using a hash function into a signature that has exactly m out of L bits equal to '1' and all other bits equal to '0'. The signature of the whole set is defined as the result of the superimposition of all element signatures. In this approach it is assumed that m is equal to one, and the signature of the element x is the binary representation of the number $2^{x \bmod L}$. Given two equivalent sets E_1, E_2 and their signatures $sig(E_1)$, $sig(E_2)$, it holds that $E_1 \subseteq E_2 \Rightarrow (sig(E_1) \,\&\, sig(E_2)) = sig(E_1)$, where & is a bit-wise operator.

Signatures provide a quick filter for testing the subset relationship between sets. Therefore, if there exist any bits of $sig(E_1)$ that are equal to '1' and the corresponding bits of $sig(E_2)$ are not also equal to '1', then E_1 is not a subset of E_2. The inverse of the latter statement, however, does not hold in general. Evidently, *false drops* may result from collisions due to the superimposition. To verify a drop, we have to examine the corresponding sequences with the containment criterion.

Below we describe two selected signature-based sequential data indexing methods to optimize pattern queries: SEQ(C), which uses complete signatures of equivalent sets, and SEQ(A), which uses signatures of approximated equivalent sets.

A Simple Sequential Index (SEQ(C) – "Complete")

Let D be the database of sequences to be indexed. A simple data structure for indexing elements of D is based on the paradigm of the signature file (Faloutsos & Christodoulakis, 1984) and is called SEQ(C). It corresponds to the direct use of signatures of equivalent sets. The construction algorithm for SEQ(C) is given in Figure 3a.

Example 2. Let us consider the following example of SEQ(C) index entry construction. Assume the data sequence to be indexed is $X = \langle A, C, D, E\rangle$. Assume the set I of items and item mapping functions and order mapping functions from Example 1, and L=10.

The equivalent set for the data sequence X is the following: $E = \{f_i(A), f_i(C), f_i(D), f_i(E), f_o(A,C), f_o(A,D), f_o(A,E), f_o(C,D), f_o(C,E), f_o(D,E)\} = \{1, 3, 4, 5, 9, 10, 11, 22, 23, 29\}$.

Therefore, the SEQ(C) index entry will consist of the following signature (starting with the least significant bit): $sig(E) = 1111110001$.

The algorithm for querying the structure for a given sequence Q, is given in Figure 3b. Initially (Step 1), the equivalent set, E_Q, of Q is calculated. Then, each signature in the structure is examined against the signature $sig(E_Q)$ (Step 4). The verification of each drop is applied at Steps 5-7. The result, consisting of the sequences from D that satisfy query Q, is returned in set R.

Using Approximations of Equivalent Sets (SEQ(A) – "Approximate")

In Nanopoulos, Zakrzewicz, Morzy, and Manolopoulos (2003), a different method for organizing equivalent sets is proposed which significantly outperforms SEQ(C) thanks to reduction of the index size. It is based on the observation that the distribution of elements within sequential patterns is skewed, since the items that correspond to frequent subsequences have larger appearance frequency. Therefore, the pairs of elements that are considered during the determination of an equivalent set are not equiprobable.

Due to the above, some pairs have much higher co-occurrence probability than others. The sizes of equivalent sets can be reduced by taking into account only the pairs with high co-occurrence probability. This leads to approximations of equivalent sets, and the resulting method is denoted as SEQ(A). The objective of SEQ(A) is the reduction of the sizes of equivalent sets with a reduction of the lengths of the corresponding signatures.

The construction algorithm for SEQ(A) is depicted in Figure 4, where $supp_D(x, y)$ denotes the support of an ordered pair (x, y) in D (i.e., the normalized frequency of sequence $\langle x\ y\rangle$ (Agrawal & Srikant, 1995)), where $x, y \in I$ and the pair $(x, y) \in P(E)$. SEQ(A) reduces the

9.    endif
10. endfor
```

(b)

sizes of equivalent sets by considering for each element $i \in I$, only k most frequent ordered pairs with i as the first element. In Step 2 of the algorithm, those frequent pairs are discovered and represented in the form of *NN* sets containing k most frequent successors for each element. In Steps 8-10, the *NN* sets are used to filter out infrequent pairs.

Example 3. Let us consider the following example of SEQ(A) index entry construction. Assume the data sequence to be indexed is $X = <A, C, D, E>$. Assume the set I of items and item mapping functions and order mapping functions from Example 1, k=1 and L=10. Given are the following support values for the element pairs: $supp_D(D,E) = 0.280$, $supp_D(E,B) = 0.220$, $supp_D(A,C) = 0.120$, $supp_D(C,E) = 0.101$, $supp_D(A,D) = 0.075$, $supp_D(C,D) = 0.053$, $supp_D(A,E) = 0.040$, $supp_D(B,A) = 0.037$, and for the other pairs, that is, (A,B), (B,C), (B,D), (B,E), (C,A), (C,B), (D,A), (D,B), (D,C), (E,A), (E,C), (E,D), the support values are less than 0.037.

Based on the support values of the element pairs, we construct the *NN* sets for each item. Each *NN* set contains only 1 item (k=1) which forms the strongest pair:

$NN(A) = \{C\}$, $NN(B) = \{A\}$, $NN(C) = \{E\}$, $NN(D) = \{E\}$, $NN(E) = \{B\}$.

The equivalent set will not represent the pairs that are not represented in the *NN* sets:

$E = \{f_i(A), f_i(C), f_i(D), f_i(E), f_o(A,C), f_o(C,E), f_o(D,E)\} = \{1, 3, 4, 5, 9, 23, 29\}$.

Therefore, the SEQ(A) index entry will consist of the following signature:

$sig(E) = 0101110001$.

The search algorithm of SEQ(A) is analogous to that of SEQ(C). However, Step 1 of the algorithm depicted in Figure 3b has to be modified accordingly (identical approximation has to be followed for the equivalent set of a query pattern):

1. E_Q = Equivalent_Set(Q)
1a. **forall** $(x, y) \in P(E_Q)$
1b. **if** *y* Ï*NN*(*x*)
1c. remove pair (x, y) from E_Q
1d. **endif**
1e. **endfor**

During the generation of the approximation of the query's equivalent set, the *NN* sets are used, which implies that they have to be kept in memory. However, this presents a negligible space overhead.

FUTURE TRENDS

Future research on sequence indexing should focus on extending the most promising technique introduced so far—the method based on approximations of equivalent sets. It may be interesting to consider alternative approximation schemes like: (1) global frequency threshold for

Figure 4. SEQ(A) method: construction algorithm

1. **forall** $i \in I$
2. find $NN(i) = \{i_j \mid i_j \in I, 1 \le j \le k, i_j \ne i, \forall\, l \notin NN(i)\ \ supp_D(i, i_j) \ge supp_D(i, l)\}$
3. **endfor**
4. $F = \emptyset$
5. **forall** $P \in D$
6. E = Equivalent_Set(P)
7. **forall** $(x, y) \in P(E)$
8. **if** $y \notin NN(x)$
9. remove pair (x, y) from E
10. **endif**
11. **endfor**
12. $F = F \cup \{<sig(E), \text{pointer}(P)>\}$
13. **endfor**

ordered pairs of elements within a sequence (using most frequent pairs instead of most frequent successors for each item), and (2) information-content measures (considering only pairs that carry more information than others).

CONCLUSION

In this article, the problem of efficient indexing of large Web access logs for pattern queries has been considered. We have described signature-encoding schemes, which are based on equivalent sets. Equivalent sets capture the ordering among the elements of access sequences, which is very important in the case of Web access logs. We have presented selected signature-based indexing methods build upon the concept of equivalent sets. Advanced topics on Web-log indexing, including application of signature trees to organize SEQ(C) and SEQ(A) indexes, can be found in Manolopoulos et al. (2004).

KEY TERMS

Data Mining: A database research area that aims at automated discovery of non-trivial, previously unknown, and interesting regularities, trends, and patterns in large data sets.

Database Index: An auxiliary physical database structure that is used to speed up the retrieval of data objects from the database in response to certain search conditions. Typically, indexes are based on ordered files or tree data structures.

Sequential Pattern: Frequently occurring subsequence in a collection of sequences.

Signature Index: A database index that uses signatures to represent values of the indexed data objects. Signatures are typically encoded as bit strings.

URL: Uniform Resource Locator, the global address of a Web page or other resource on the Internet. A URL has three basic parts: the protocol identifier, IP address or domain name of the server, and the relative path to the resource on the server.

Web Access Log: A text file into which a Web server saves information about every request that it handles.

Web Server: A computer program running on a machine permanently connected to the Internet, dedicated to serving requested Web pages to the user's browser (client).

Similarity Web Pages Retrieval Technologies on the Internet

Rung Ching Chen

Chung Hsun Hsieh
Chaoyang University of Technology, Taiwan

INTRODUCTION

In recent years, due to the fast growth of the Internet, the services and information it provides are constantly expanding. Madria and Bhowmick (1999) and Baeza-Yates (2003) indicated that most large search engines need to comply to, on average, at least millions of hits daily in order to satisfy the users' needs for information. Each search engine has its own sorting policy and the keyword format for the query term, but there are some critical problems. The searches may get more or less information. In the former, the user always gets buried in the information. Requiring only a little information, they always select some former items from the large amount of returned information. In the latter, the user always re-queries using another searching keyword to do searching work. The re-query operation also leads to retrieving information in a great amount, which leads to having a large amount of useless information. That is a bad cycle of information retrieval. The similarity Web page retrieval can help avoid browsing the useless information. The similarity Web page retrieval indicates a Web page, and then compares the page with the other Web pages from the searching results of search engines. The similarity Web page retrieval will allow users to save time by not browsing unrelated Web pages and reject non-similar Web pages, rank the similarity order of Web pages and cluster the similarity Web pages into the same classification.

In this article, we will introduce the technology of similarity Web page retrieval which includes searching Web pages and classifying similarity Web pages. For searching Web pages, we will specify the types of search engines and the policy of ranking search results first. And then, two algorithms used for finding related Web pages, the Cocitation algorithm and Latent Linkage Information (LLI) algorithm, will be introduced. The classification method can make the Web pages with similarity vector attributed will be clustered in the same class, and the user retrieves the related Web pages more effectively.

BACKGROUND

The Web Pages Searching

With the growing information of the Internet, search information efficiently is more important than ever to do. Search engines are used to find the Web pages with the same keyword on the Internet (Chakrabarti, Joshi, & Tawde, 2001; Wen-Syan & Candan, 2002). Only by keypressing a keyword, search engines can return information quickly and easily. Jenkins classifies the search engines into three categories (Barroso, Dean, & Holzle, 2003; Jenkins, Kackson, Burden, & Wallis, 1998).The categories include the classified directories search engines, automated search engines, and metasearch engines. The classified directories search the engines' classification of Web data by human. The automated search engines collect the Web resources from the WWW automatically. The metasearch engines provide interface that receives the user query and merges the searching results from various search engines. For the three types of searching, engines will be described briefly as follows (Madria & Bhowmick, 1999). The classified directories' search engines collect the Web data from the WWW by the editorial staff and describe the Web site with text mention. The editors must classify the Web pages to suitable category. Therefore, a user can find the useful information by classification directory easily (Baeza-Yates, 2003). The automated search engines employ the retrieval programming (called Robot or Spider) to collect the Web data from WWW voluntarily, construct the URL (Uniform Resource Locator) index and title, and provide that to the user (Wen-Syan & Candan, 2002). A metasearch engine uses a concept of a computer agent, between the users and many search engines. Its responsibility is to make the users search more conveniently for various aspects of the search engines (Tirri, 2003). A metasearch engine receives user's query and passes the query to various searching engines, if reformatting the query is needed, and then collects and rearranges the results from the search engines (Madri & Bhowmick, 1999; Baeza-Yates, 2003; Wen-Syan & Candan, 2002). Henzinger, Motwani, and Silverstein indicate a number of reasons why the metasearch engines are needed.

The Web Mining

The mining technology is different from general search work. The mining method can find the data in horizontal relation, and the relation between data and data, that general searching work can not do. When mining technologies are applied to finding Web pages, we called it Web mining. The Web mining framework includes three types which are: Web content mining, Web structure mining, and Web usage mining (shown in Figure1) (Flake, Lawrence, Giles, & Coetzee, 2002; Kao, & Lee, 2000; Madria & Bhowmick, 1999; Sundaresan, & Yi, 2000; Zhang, & Dong, 2002).

In traditional search technologies, the user sends a keyword to a search engine, and then the search engine uses the keyword to find related pages, but it spends too much time and returns too many irrelevant pages. Therefore, the hyperlink analysis and anchor text analysis are proposed to find the related pages. Using the hyperlink structure to find the relative pages can find the related pages quickly and easily, but hyperlink structures have no content information. Hence, there are two assumes in hyperlink study. When a page A links to another page B, indicating page B is recommended by author page A. If two pages have the same links, they might be on the same topic (Henzinger, 2000; Qiu, Hemmje, & Neuhold, 2000; Zhengyu, Qingsheng, & Yukun, 2001). Hence, the hyperlink analysis can be used to ranking pages, Web pages community construction, Web searching improvement, Web clustering and visualization, as well as finding the related pages. Tirri thinks the earlier Web search technologies are not good enough by keyword searching, and he used ontology and hyperlink analysis knowledge to do the searching. He considers the next generation of Web search must have the personal search results, easily find the information that users want and make synonym by itself (Hodgson, 2001; Singh, 2002; Tirri, 2003). We described the similarity Web pages searching technology in the following methods.

(1) Cocitation Method

Dean and Henzinge proposed the Cocitation algorithm that uses the hyperlink structure to find the related pages (Dean,& Henzinger, 1999; Jingyu, & Yanchun, 2003). The algorithm is based on two definitions: (A) The two pages are co-cited if they have a common parent page; (B) The number of their common parent pages, named degree of cocitation. In this algorithm, a user can use a query term for a search engine to find a require page, and then can use a URL of the require page to construct a vicinity graph by hyperlink, and then can analyze the graph to find the related pages of the required page. Hence, the algorithm employed the hyperlink of Web pages to find the related page. It is simple and computes easily, but when two pages have the same degree of cocitation, the system cannot decide which Web pages are actually related pages. Also, it may have a topic drift problem if the anchor of a Web page constructs malice hyperlink purposely. The similarity measures between two pages are shown in Figure 2. The page “u” and page “a” have the same parent page A. They are cocited, and the degree of the cocitation is 1. In the same way, the in degree of Page B is 2. Hence, the degree of all pages that related to pages u can be computed.

(2) Latent Linkage Information (LLI) Algorithm

Although, the Cocitation algorithm can evaluate the similarity of Web pages, it cannot determine which pages are better when the pages have the same degree. Therefore, Hou and Zhang utilize the linkage matrix to express the relevance of the Web page topology. The matrix can reveal the depth relationships of the pages, and then find the

Figure 1.Web mining classification

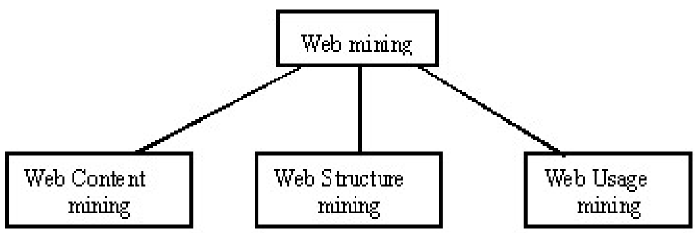

Figure 2. In degree of b is two

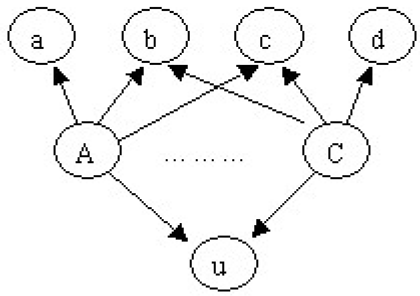

relative pages easily. In order to reveal the deep relationships, the singular value decomposition (SVD) concept is used in linear algebra. In the same way, it extends the Cocitation algorithm to construct the direction graph with parent pages and children pages (FS and BS). The topological relationships between BS and P_u are expressed at a linkage matrix A. The topological relationships between FS and C_u are expressed at a linkage matrix B as follows:

$$A = (a_{ij})_{mxn},$$

$$a_{ij} = \begin{cases} 1, when.page.i.is.a.child.of.page.j,\ page.i \in BS,\ page.j \in P_u \\ 0, otherwise \end{cases}$$

$$B = (b_{ij})_{pxq},$$

$$b_{ij} = \begin{cases} 1, when.page.i.is.a.parent.of.page.j,\ page.i \in FS,\ page.j \in C_u \\ 0, otherwise \end{cases}$$

Hence, the ith row of matrix A can be considered as the coordinate vector of page i (BS) in an n dimensional space; the jth column of matrix A can be considered as the coordinate vector of page j (P_u) in the m dimensional space. In the same way, the ith row of matrix B can be considered as the coordinate vector of page i (FS) in a q dimensional space; the jth column of matrix B can be considered as the coordinate vector of page j (C_u) in a p dimensional space. In other words, it can transfer the matrix A and B to find the topological relationships in different multi-dimensional spaces.

(3) PageRank Agorithm

Brin and Page proposed the PageRank algorithm that uses the in-link structure to rank the results for users (Brin & Page, 1998). When a page B links to page A, it indicates page B is important to page A. For example, if a paper is cited by many other papers, the paper is more important. The PageRank algorithm extends this idea to use the in-link structure to rank the results of search engines. The PageRank is defined as follows:

$$PR(i) = (1-d) + d(PR(T_1)/C(T_1) + ... + PR(T_n)/C(T_n)),$$

where *PR(Ti)* is the page rank of pages *Ti* which links to page A; $C(T_n)$ is the number of the out-link of page T_n and function d is a damping factor which can be set between 0 and 1.

The $PR(i)$ is computed by Web structure, and it can be used to rank the results of Web search. The PageRank algorithm is used to monitor a model of user's behavior. There is a "random surfer" who browses the Web random and goes to another page by links until he gets bored and starts on another page again. The value d is the probability at each page that the "random surfer" will get bored and go to another random page. Therefore, the PageRank can easily compute and rank the result in search engine by hyperlinks (Satronov & Parashar, 2003).

Web Pages Classification

Users usually input a keyword to a search engine to find the related Web pages and often return the massive of Web pages. Users hope to get requiring pages from the returned results, but they contain too many irrelative Web pages; that makes the problem worse. To decide which Web pages are required wastes much time. The data classification method is applied to many fields, it can help user quickly get related information. Previously, WWW was not popular, the Web pages information does not propagate fast, so the system can use artificial method to classify Web pages (Asirvatham & Ravi, 2001). Now, the Web pages expand quickly, so using artificial method to classify Web pages has no efficiency. Therefore, using information technology to automatic classification Web pages is needed. There are many methods using Web pages classification such as Naïve Bayes, k-NN approach, inductive rule learning, neural network, decision tree (Chan, Tokuda, & Akira, 2003; Kwon & Lee, 2003; McCallum, & Nigam, 1998) and support vector machine (Dumais & Chen, 2000). Before the classification operation, the features extraction is necessary. In general, there is the Boolean model, the vector space model, and the probability model (Yates & Ribeiro-Neto, 1999) for features extraction methods. We describe the information retrieval model first.

The information features extraction has three common models: Boolean model, vector space model, and probability model. We will introduce the three models and then weight the keywords through TF-IDF. On the other hand, the method of Web page classification will be a brief specification, too.

(1) Boolean Model

Boolean model is based on fuzzy set theory and Boolean algebra classification (Yates& Ribeiro-Neto, 1999). The weight of a keyword is represented as binary codes.

$W \in \{0,1\}$, 0 stands for keyword W not appeared;
1 stands for keyword W appeared.

A query document q, after the transform Boolean function calculates similarity between classified document d and q, has two results:

1: stands for query document q related to document d.
0: stands for query document q not related to document d.

(2) Vector Space Model

This model uses keywords vector to estimate the angle between query document and classified documents and to determine the query document belonging to which category.

A query vector: $q = (W_{1q}, W_{2q}, .., W_{tq})$
q:query document
t:total of keywords in query document q
Classified document vector: $d = (W_{1d}, W_{2d}, .., W_{td})$
d: already classified document vector.

The similar measure between d and q can be estimated by the cosine angle.

(3) Probability Model

The probability model uses Bayes theorem to determine the documents' category. A query document q is an estimated probability values between document and document. The form is as follows:

$$\frac{P(d\ relate\ to\ q)}{p(d\ non-relate\ to\ q)}$$

For example, if document D have n keywords W_{i1}, W_{i2}, W_{in}, the probability of D belong to C_I is:

$$P(C_I \mid W_{i1}, W_{i2}, .., W_{in})$$

According to Bayesian theorem:

$$P(C_I \mid W_{i1}, W_{i2}, .., W_{in}) = \frac{P(C_I) \times P(W_{i1}, W_{i2}, .., W_{in} \mid C_I)}{P(W_{i1}, W_{i2}, .., W_{in})}.$$

It can calculate the probability of D belonging to each category $C_{I.}$ The category that has maximum of probability value belongs to query document.

(4) TF-IDF

In documents, the more keywords appear, the more important the keywords are. Generally, the importance of a keyword in a document considers two factors. One is the frequency of the keyword in the document, named Term Frequency (TF), the other is the numbers of this keyword appearing in all documents, called Document Frequency (DF). The high value of TF corresponds with the high importance of the keyword in the document. The product of TF and Inverse Documents Frequency (IDF) is used to represent the importance of the keyword in a document, named TF-IDF.

$W_{i,j} = TF_{i.j} \times IDF_i$
$W_{i,j}$: it is the importance of the keyword i in document j.

$$TF_{ij} = \frac{n_j}{n_{all}},$$

where n_j is the times of the keyword *j* appear in thesis *i* and n_{all} is the total TF that is meaningful in thesis *i*. TF_{ij} is the frequency of a keyword *j* in thesis *i*.

$IDF_i = \log\left(\frac{N}{n_i}\right)$, where N is the number of documents and n_i is the frequency of keyword i in all documents.

(5) Web Page Classification Methods

Presently, there are many Web page classification approaches, such as k-NN, neural network method. The k-NN method (Kwon & Lee, 2003) calculates the likelihood between the category and relevant Web page. In order to improve efficiency, have joined the feature selection, used HTML tags and new similarity degree to evaluate the Web page classification. The neural network method (Liu & Zhang, 2001; Selamat & Omatu, 2004) do the preprocessing of the Web page, include stemming and moved the stop words. Then a portion is to reduce the dimension of feature vector (Lam & Lee, 1999), another portion is to each category extraction the keyword and assign the weight. Combine the two types of feature vectors and input to neural network for training. According the neural training results, the system can classify the Web pages into suitable classes.

FUTURE TRENDS

Using the content and the link information features is one of a tendency for finding the related Web pages in the future researches. The content information includes the, tag, and real word and meta information. In WWW, Web pages usually use HTML language to compose the Web pages content which contains tags, out links, and descript terms metadata. The HTML language uses twin tags to represent the characters. However, the Web pages represent the same content with traditional documents when the tags are removed. For HTML tags, each tag has various functions. For examples, the tags pair <title> and </title> stands for the words of title between the tags, as well as the tags pair <table> and </table> stands for a table form between the tags. If these tags are analyzed, we also can get much useful information. The out-links and in-links also contain much information. In HTML file, the metadata described terms that would not appear in Web pages, but it can help the content of the Web pages understand. For example, the metadata of code type description can allow the system to understand which language is used in the Web page. So, how to effectively assemble these features is an interesting topic for the similarity Web pages retrieval.

On the other hand, precisely classifying the Web pages to the correct category also makes the similarity Web pages retrieval effectively. How to correct classification of the Web pages automates by the feature of Web content is also a hot research topic. When we input a keyword in a search engine to do a search, we can get a lot of Web pages. However, the search engine cannot translate the keyword into various languages which make the search results not to stretch out various nation information. Appling the keyword translation technology to a search engine is also a public research direction.

In addition, when two pages have the same present pages, they might be the related pages; we can extend this idea to the Web pages having the same child pages—they might be the related pages. Moreover, the topic discovery is a new technology that finds the related pages. It will automatically cluster the related Web pages together by the representative topics. From representative topics, we can easily determine the related Web pages. Therefore, many of the searching results will be transferred to various classes, and then we find the related pages are easy and do not worry about the return of too much information. Finally, the similarity Web searching will be extended to the functions of multimedia content similarity Web pages retrieval. For example, to do the similarity images retrieves on the Internet.

CONCLUSION

The information on the Internet is growing fast. How to efficiently search is an important research theme. The hyperlink analysis can find the relative pages easily, but it is not precise. Hence, combining the Web content search and the Web structure search finding the relative pages is the trend of study. Many researchers use the hyperlink graph of pages and consider the content of Web pages to find the related pages. In a different way, using the HTML tags to find the related Web pages is also a worthy research direction. The Web pages classification automatically is also a direction to find the similarity Web pages. Many methods are mentioned in the article. The similarity Web pages will be an interesting research topic for scholars to do the research.

KEY TERMS

Classification: A technique dividing a dataset into mutually exclusive groups. Unlike clustering, classification relies on predefined classes.

Clustering: A technique that uses features to find the linking pages of each other automatically. Usually, the Web pages with near features will be clustered together.

Cocited: The Web pages have the same parent page or have the same child pages called the Web pages are cocited.

In Degree: The number of Web pages that link to current Web page.

Information Retrieval: A technology which can retrieve useful information effectively for some themes from the Internet by artificial or automatic method.

k-Nearest Neighbor: A technique that classifies each Web page in a set based on a combination of the classes of the k records most similar to it.

Machine Learning: The purpose of machine learning is how to make computers learning, can let computer to do something. The goal is to make computers improve the performance.

Out Degree: The number of Web pages that current Web page point out.

Simple Methods for Design of Narrowband High-Pass FIR Filters

Gordana Jovanovic-Dolecek
National Institute for Astrophysics, Optics, and Electronics, Mexico

INTRODUCTION

Digital signal processing (DSP) is an area of engineering that "has seen explosive growth during the past three decades" (Mitra, 2001). Its rapid development is a result of significant advances in digital computer technology and integrated circuit fabrication (Smith, 2002; Jovanovic-Dolecek, 2002). Diniz, Silva, and Netto (2002) state that "the main advantages of digital systems relative to analog systems are high reliability, suitability for modifying the system's characteristics, and low cost."

The main DSP operation is digital signal filtering, that is, the change of the characteristics of an input digital signal into an output digital signal with more desirable properties. The systems that perform this task are called digital filters. The applications of digital filters include the removal of the noise or interference, passing of certain frequency components and rejection of others, shaping of the signal spectrum, and so forth (White, 2000; Ifeachor & Jervis, 2001).

Digital filters are divided into finite impulse response (FIR) and infinite impulse response (IIR) filters. FIR digital filters are often preferred over IIR filters because of their attractive properties, such as linear phase, stability, and the absence of the limit cycle (Mitra, 2001; Diniz, Silva & Netto, 2002). The main disadvantage of FIR filters is that they involve a higher degree of computational complexity compared to IIR filters with equivalent magnitude response (Mitra, 2001; Stein, 2000). In past years, many design methods have been proposed to reduce the complexity of FIR filters (Jou, Hsieh & Kuo, 1997; Kumar & Kumar, 1999; Webb & Munson, 1996; Lian & Lim, 1998; Bartolo & Clymer, 1996; Kuo, Chien & Lin, 2000; Abeysekera & Padhi, 2000; Yli-Kaakinen & Saramaki, 2001; Coleman, 2002; Jovanovic-Dolecek, 2003).

We consider high-pass (HP) linear-phase narrowband filters. It is well known that one of the most difficult problems in digital filtering is the implementation of narrowband filters. The difficulty lies in the fact that such filters require a high-order design with a large amount of computation, making them difficult to implement (Mitra, 2001; Grover & Deller, 1999; Stein, 2000).

We propose an efficient design of high-pass linear-phase narrowband digital filters based on the corresponding low-pass (LP) filter. In this design we use the interpolated FIR (IFIR) structure and the sharpening recursive running sum (RRS) filter (Jovanovic-Dolecek, 2003). In the next section we describe the transformation of a low-pass into a high-pass filter, followed by descriptions of an IFIR structure, RRS filter, and the sharpening technique. Finally, we present the design procedure, along with an example.

BACKGROUND

Transformation of LP into HP Filter

Instead of designing a high-pass filter by brute force, we can transform it into a low-pass filter. We replace the desired cutoff frequencies of the high-pass filter ω_p and ω_s, by the corresponding low-pass specifications as follows:

$$\begin{aligned} \omega_p^{'} &= \pi - \omega_p \\ \omega_s^{'} &= \pi - \omega_s \end{aligned} . \quad (1)$$

Given these specifications, a low-pass FIR filter can be designed. From this auxiliary low-pass filter, the desired high-pass filter can be computed by simply changing the sign of every other impulse response coefficient. This is compactly described as:

$$h_{HP}(n) = (-1)^n h_{LP}(n), \quad (2)$$

where $h_{HP}(n)$ and $h_{LP}(n)$ are the impulse responses of the high-pass and the low-pass filters, respectively. In that way the IFIR structure proposed for design of LP filters can also be used for HP filters.

IFIR Structure

The interpolated finite impulse response structure, proposed by Neuevo, Dong, and Mitra (1984), is an efficient realization of a high-order liner-phase LP FIR filter. Instead of designing one high-order liner-phase filter $H(z)$, two lower order liner-phase LP filters are computed. One of them is called the shaping or model filter $G(z)$, and the other one is the interpolator filter $I(z)$.

Suppose that the specifications of the original filter $H(z)$ are: pass-band edge ω_p, stop-band edge ω_s, pass-band ripple R_p, and minimum stop-band attenuation A_s. The specification of the LP filter $G(z)$ can then be expressed as follows:

$$\begin{aligned} \omega_p^G &= M\omega_p \\ \omega_s^G &= M\omega_s \\ R_p^G &= R_p / 2\,, \\ A_s^G &= A_s \end{aligned} \tag{3}$$

where M is the interpolation factor, and the upper index G stands for the filter $G(z)$. The expanded filter $G(z^M)$ is obtained by replacing each delay z^{-1} in the filter $G(z)$ with z^{-M} . In the time domain this is equivalent to inserting M-1 zeros between two consecutive samples of the impulse response of $G(z)$. The expansion of the filter $G(z)$ introduces M-1 images in the range $[0, 2\pi]$, which have to be eliminated. This is why the filter interpolator $I(z)$ is needed. The general low-pass IFIR structure is given in Figure 1.

The high-pass filter design depends on the parity of the interpolation factor. For M even, there is an image at high frequency. If all other images along with the original spectrum are eliminated, the high-pass filter results. Therefore, the interpolator filter is a high-pass filter with the following specifications (Jovanovic-Dolecek, 2003):

$$\begin{aligned} \omega_p^I &= \pi - \omega_p^{'} \\ \omega_s^I &= \frac{2\pi}{M}\frac{M-2}{2} + \omega_s^{'} = \frac{\pi(M-2)}{M} + \omega_s^{'} \\ R_p^I &= R_p / 2 \qquad\qquad , \\ A_s^I &= A_s \end{aligned} \tag{4}$$

where upper index I stands for the interpolator $I(z)$. Now, the resulting IFIR filter is the desired high-pass filter.

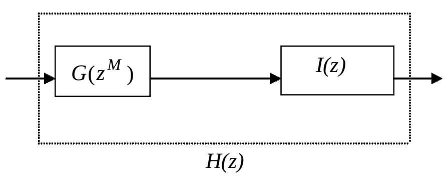
For M odd, however, there are no images at high frequency. In order to obtain the low-pass filter, all images have to be eliminated using the interpolator filter, so that only the original spectrum remains. In this case the interpolator $I(z)$ has the following specifications (Jovanovic-Dolecek, 2003):

$$\begin{aligned} \omega_p^I &= \pi - \omega_p^{'} \\ \omega_s^I &= \frac{2\pi}{M} - \omega_s^{'} \\ R_p^I &= R_p / 2 \qquad . \\ A_s^I &= A_s . \end{aligned} \tag{5}$$

Since the resulting IFIR filter is a low-pass filter, we apply transformation (2) to achieve the desired high-pass filter.

To further simplify the proposed design, a simple RRS filter, described in the next section, is used as the interpolator in the IFIR structure.

Figure 1. IFIR structure



Recursive Running-Sum Filter

The simplest low-pass FIR filter is the moving-average (MA) filter. Its impulse response $g(n)$ is given by:

$$g(n) = \frac{1}{M}\sum_{k=0}^{M-1} g(n-k) . \tag{6}$$

All impulse response coefficients are equal to 1, and so the filter requires no multiplications.

Its transfer function is given by:

$$G(z) = \frac{1}{M}[1 + z^{-1} + ... + z^{-(M-1)}] = \frac{1}{M}\sum_{k=0}^{M-1} z^{-k} \quad . \tag{7}$$

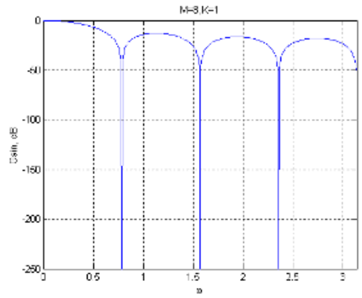
A more convenient form of the above transfer function for realization purposes is given by:

$$H_{RRS}(z) = [G(z)]^K \;= \left[\frac{1}{M}\frac{1-z^{-M}}{1-z^{-1}}\right]^K , \tag{8}$$

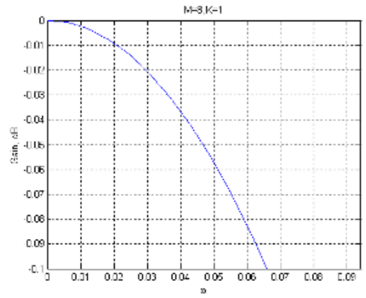
which is also known as a recursive running-sum filter (RRS) (Mitra, 2001), or a boxcar filter. The scaling factor $1/M$ is needed to provide a dc gain of 0 dB, and K is the number of the cascaded sections of the filter. The magnitude response of the filter can be expressed as:

$$\left|H_{RRS}(e^{j\omega})\right| = \left| \; \left[\frac{\sin(\omega M/2)}{M\sin(\omega/2)}\right]^K \right| . \tag{9}$$

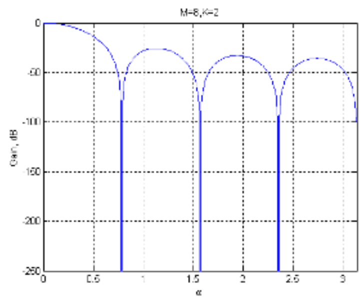
Figure 2. RRS filters for M=8 and K=1, 2, and 4



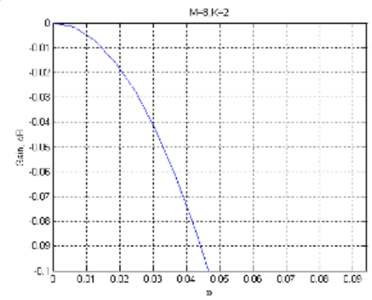
a. Overall magnitude response



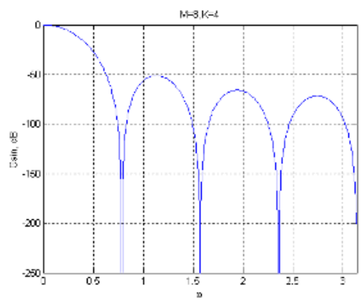
b. Pass-band zoom



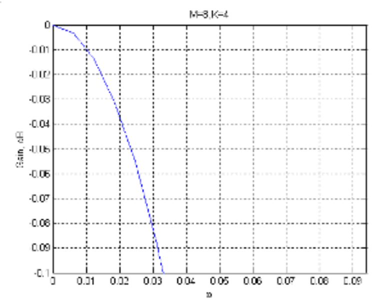
c. Overall magnitude response



d. Pass-band zoom



e. Overall magnitude response



f. Pass-band zoom

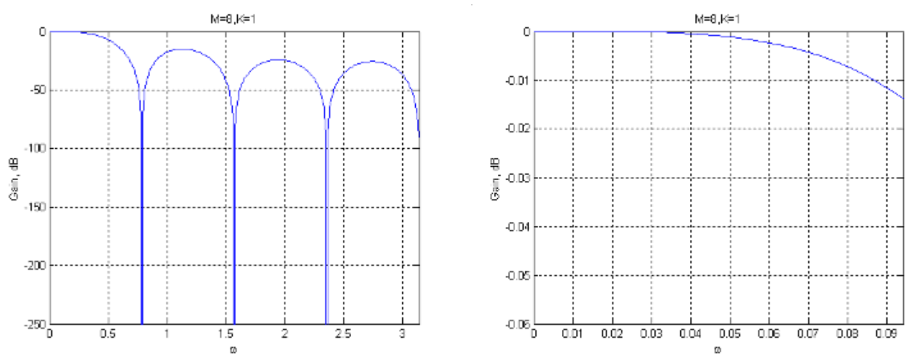
The magnitude response has nulls at integer multiples of ($2\pi/M$). This provides natural alias-rejections introduced by expanding the shaping filter $G(z)$ by factor M. The stop-band attenuation is improved as a result of the increased number of stages K. However, since the pass-band is downgraded, the RRS filter—when used as the interpolator in an IFIR structure—has limited application. Figure 2.a. illustrates the overall magnitude responses and the corresponding pass-band details of the RRS filter for M=8 and K=1, 2, 3, and 4.

In the next section we show how to improve the characteristics of the RRS filter using the sharpening technique.

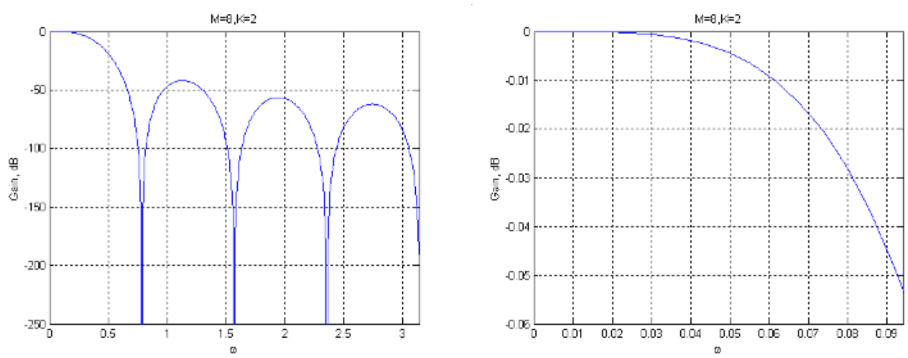
Sharpening RRS Filter

The improved RRS characteristics are based on a technique for sharpening the response of a filter proposed by Kaiser and Hamming (1977) and Kwentus, Jiang, and Willson (1997). This technique improves both the pass-band and stop-band of an RRS filter by using multiple copies of the original filter. The simplest sharpened RRS filter magnitude characteristic $|H_{shRRS}(\omega)|$ is related to the original RRS filter as:

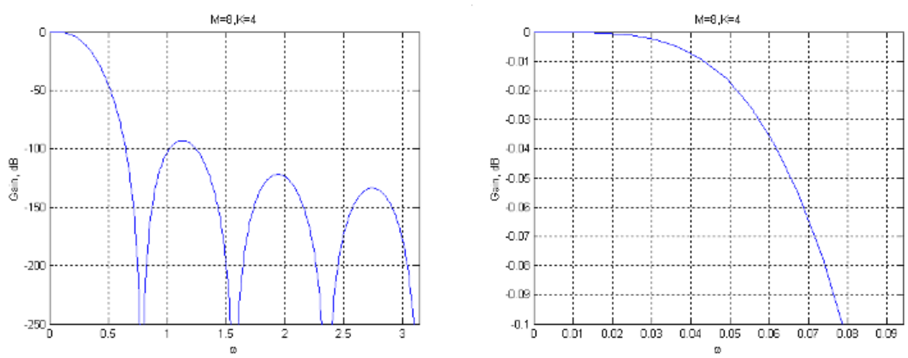
Figure 3. Sharpened RRS filter



a. Overall magnitude response *b. Pass-band zoom*

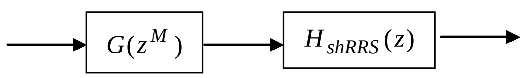


c. Overall magnitude response *d. Pass-band zoom*



e. Overall magnitude response *f. Pass-band zoom*

Figure 4. Sharpening IFIR structure



$$\left| H_{shRRS}(e^{j\omega}) \right| = \left| 3H_{RRS}^2(e^{j\omega}) - 2H_{RRS}^3(e^{j\omega}) \right| , \qquad (10)$$

where the RRS filter magnitude response $H_{RRS}(e^{j\omega})$ is given in Equation (9).

The sharpening RRS filter has improved both pass-band and stop-band characteristics over the ones of the RRS filter, thereby making it a good candidate for the interpolator in an IFIR structure, as illustrated in Figure 3. The corresponding block diagram is shown in Figure 4.

In the following section we outline the design procedure based on the structure in Figure 4 and illustrate it with an example.

Filter Design Procedure

We consider two cases, depending on whether M is even or odd.

The following seven-step procedure may be used to design a sharpening HP IFIR filter when M is an even number:

1. Transform the high-pass specifications into the low-pass ones.
2. Choose the value M.
3. Design the low-pass filter $G(z)$.
4. Expand the filter $G(z)$ M times.
5. Choose the value K and design the low-pass RRS filter. Transform the low-pass RRS filter into a high-pass filter, and design the corresponding sharpening HP RRS filter.
6. Cascade the expanded filter $G(z^M)$ and the sharpening high-pass RRS filter.
7. Check if the specification of the resulting filter is satisfied. If not, choose different values for M and K, and repeat the design.

If the interpolation factor M is an odd number, both filters in the IFIR structure—the shaping filter and the interpolator filter—need to be transformed into high-pass filters. Detailed explanation of the design is presented in the following steps:

1. Transform the high-pass specifications into the low-pass ones.
2. Choose the value M.
3. Design the low-pass filter $G(z)$.
4. Expand the filter $G(z)$ M times.
5. Transform the expanded filter into the high-pass one.
6. Choose the value K and design the LP RRS filter. Transform it into an HP RRS filter and a design HP sharpening RRS filter.
7. Cascade the expanded filter $G(z^M)$ and the sharpening high-pass RRS filter.
8. Check if the specification of the resulting filter is satisfied. If not, choose different values for M and K, and repeat the design.

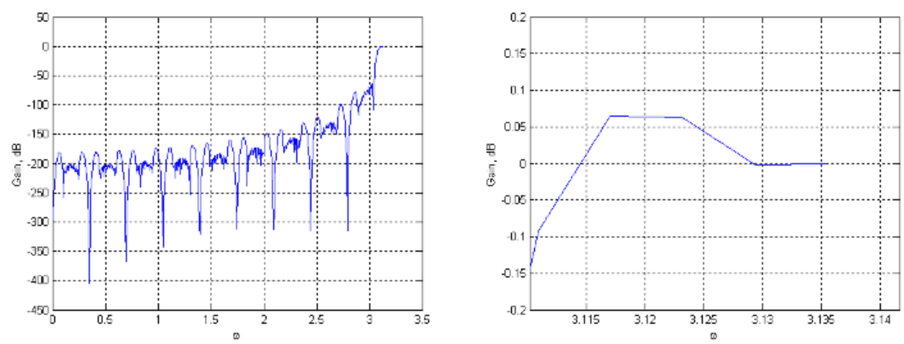
We illustrate the above design in the following example.

Example 1.

Consider a high-pass filter with pass-band edges at $\omega_p = 0.99\pi$ and $\omega_s = 0.97\pi$, pass-band ripple $R_p = 0.2$ dB, and the minimum stop-band attenuation $A_S = -60$ dB.

The high-pass filter that satisfies the specification, when designed using Parks-McClellan algorithm, has an order $N_H = 254$. By choosing $M = 18$ and $K = 3$, the order

Figure 5. Designed filter



a. Overall magnitude response *b. Pass-band zoom* of the shaping filter $G(z)$ is only 16. The magnitude response of the designed filter is shown in Figure 5.

FUTURE TRENDS

Presented here is the low complexity design of narrowband high-pass filters based on the IFIR structure and the sharpening technique. The basic idea behind the frequency masking technique, proposed to reduce the complexity of FIR filters (Lim & Lian, 1993), is to design the overall filter using several less complex sub-filters, including the model filter and its complement, and the corresponding interpolation filters. This technique is the generalization of the IFIR technique and can be also used for the wide-band FIR filters with the narrow transition bands. Indeed, both techniques can be combined if appropriate. Less-complex sub-filters can be designed using the simple filters like cosine and RRS filters. Future work must be dedicated to the problem of the optimization of the design, and the trade-off between the complexity of the sub-filters and the complexity of the sharpening polynomial.

CONCLUSION

The design of low-complexity high-pass narrow-band FIR filters has been presented. The method is based on the use of the IFIR structure where the interpolator is the sharpening RRS filter. The RRS filter requires no multipliers and no storage for the interpolation coefficients. The sharpening technique improves the pass-band and the stop-band characteristics of an RRS filter. The overall result is the lower computational complexity of the resulting designed filter. The method is useful for narrowband HP filter design.

KEY TERMS

Cutoff Frequencies: The frequencies that determine the pass-band (the frequencies that are passed without attenuation) and the stop-band (the frequencies that are highly attenuated).

Frequency Response $H(e^{j\omega})$: The discrete-time Fourier transform of the impulse response of the system; it provides a frequency-domain description of the system. In general, it has a complex value.

High-Pass Digital Filter: Digital filter that passes only high frequencies defined by the pass-band cutoff frequency and attenuates all frequencies from 0 to cutoff stop-band frequency.

IFIR Structure: The cascade of the expanded shaping or model filter $G(z^M)$ and the interpolator $I(z)$.

Impulse Response $h(n)$: The response of a digital filter to a unit sample sequence, which consists of a single sample at index $n = 0$ with unit amplitude.

Low-Pass Digital Filter: Digital filter that passes only low frequencies defined by the pass-band cutoff frequency and attenuates all high frequencies from the cutoff stop-band frequency to p.

Magnitude Response $|H(e^{j\omega})|$**:** Absolute value of the complex frequency response.

Phase Response: Phase of the complex frequency response.

RRS Filter: Recursive running-sum filter is an FIR filter with all coefficients equal to 1 presented in a recursive form.

Sharpening: The procedure for improving both the pass-band and the stop-band of a symmetrical FIR filter by repetition of the original filter according to a chosen polynomial.

Simulation and Gaming in IT Education

Norman Pendegraft
University of Idaho, USA

INTRODUCTION

The rapid change in information technology presents several serious problems to IS educators. In particular, the number of basic ideas that must be mastered is constantly increasing while the time available is not. This makes it essential to use class time efficiently as well as effectively. Simulations and simulation games provide an interesting and useful tool to help in this effort.

BACKGROUND

Simulation, case studies, role playing, and gaming are related teaching methods based on experiential learning. They permit experience or experimentation with a situation modeling the real world (Senge, 1990). On a deeper level, simulation is claimed by some to be a fundamentally new way of studying the world (Pagels, 1998). The idea that students learn better by doing goes back at least to Dewey (1938). The key idea underscoring this approach is that people learn better from experience than from reading or listening (Corbeil, Laveault & Saint-Germain, 1989). By compressing time, the simulation allows the students to experience the consequences of their own actions or to see how a system operates.

Simulation as a teaching tool suggests several approaches. Perhaps most obvious in an information systems curriculum is computer simulation, a tool well known in the information systems community. Using this technique, a computer program is written which exhibits behavior that models the behavior of the system under study. Butterfield and Pendegraft (1998) described a spreadsheet simulation of a Fourier Series, adding sine wave to construct a square wave, thus demonstrating how bandwidth limits data rates. Simulation can be easily used in the information systems classroom by having students operate or create simulations of relevant technology. Campbell (1996) created a simulation of a computer and had his students write assembly language programs to execute on the simulation. Englander (2003) uses Little Man Computer, a simple paper simulation of a CPU, as an example to explain basic CPU architecture, CPU operation, and machine language. In an extension of that idea, Pendegraft and Stone (2003) had their students develop a Visual Basic simulation of a Little Man central processing unit on which they ran programs mandated by the instructor. In addition to having to execute simple programs written in Little Man's machine language, their simulation had to deal with other architectural issues like input and output.

Case studies are a time-honored approach of instruction in strategy courses (see for example, Burgelman, Maidique & Wheelwright, 2001). Barker (2002) suggests that they can also be very valuable for teaching technical skills such as software development. In some sense, a case study is a role play, with the student acting the part of an analyst examining the case situation.

Role playing and simulation gaming are similar approaches in that they use simulated worlds, but instead of creating or observing or analyzing that world, students are immersed in it. Role playing is a method in which students are presented a scenario simulating some real situation, and assigned roles in that scenario. The scenario can be based on real or simulated situations (Barker, 2003). Participants then assume the roles of relevant persons in the scenario and act out the situation to see what happens. Role playing is a commonly and successfully used tool in IS education (for example, Christozov, 2003).

According to Greenblat (1988), simulation gaming includes role playing as an element, Whereas role playing allows participants to play the roles as they please, simulation gaming emphasizes the interactions of the roles and constraints of various types on the players. In some sense, a simulation game strives to teach about a specific situation, while a role play or game may have a more general lesson. The additional structure allows us to focus the students' attention on key issues. Dennis (2002) and Pendegraft (2002, 2003) both developed classroom gaming exercises to help students understand TCP/IP from the inside. Their exercises will be examined in more detail later in this article.

After many years of using such exercises at all levels (undergraduate, graduate, and executive), it is the author's opinion that they are very useful and that major benefit accrues to the instructor in preparing the simulation as well as to the students when they play the game. Simulation and gaming are student-centered learning, that is, the student is actively involved in the learning rather than passively observing the instructor (Greenblat, 1998). The student does the work, makes decisions, and sees the impact of the decisions. Role playing and simulation gaming attempt to take advantage of this by creating a situation in which a student may "play a game" in which time is compressed and attention can be focused on a few key ideas. Finally, these kinds of exercises are fun. The class gets to move around, talk, and frequently laugh. Simulations and games epitomize the idea that learning should be fun.

USING A GAME TO TEACH TCP/IP

TCP/IP is a layered protocol for controlling data flow in a packet switched network. For a more complete discussion of TCP/IP see, for example, Hunt (1998). Figure 1 lists the layers. TCP/IP uses packet switching, which means that each message is broken into pieces (called packets), each of which contains part of the message. Each packet is augmented with a header that contains (among other things) the addresses of the source and destination machines. At each step along the way, a router looks at the header, determines the address of the next host along the way, and forwards the packet to that next host.

Understanding the addressing presents a major hurdle to understanding TCP/IP. There are two types of addresses in each packet. The IP header includes the IP addresses of the source and destination machines. These do not change as the packet moves through the network. DLL layer header includes the MAC addresses of the source and destination machines for the current hop. These change at each hop. Since there are two destination addresses and two source addresses, some students have difficulty understanding how the addressing works. One way to help explain the addresses is to have the students play a game.

As examples of this approach, consider two similar games, one designed by Dennis (2002) and one by Pendegraft (2002, 2003), to help teach how TCP/IP works. Both are published elsewhere and so will not be described in detail here. Both games are designed to be run in one class session in a course on telecommunications. Both seem suitable for undergraduates or graduate students.

Figure 1. TCP/IP layers

Layer		Address
Application		
Transport Control	TCP	Port
Internet Protocol	IP	IP
Data Link Layer	DLL	MAC
Physical Layer		
TCP/IP Layers		

Both could be adapted to class sizes ranging from a dozen to more than 40.

The games have similar structure. The class is divided into teams, each team representing a host. Each player represents one layer on that host. A network map and instructions for each layer are given to the players. Figure 2 shows a sample network, and Figure 3 gives an excerpt from Dennis's instructions for the Data Link Layer.

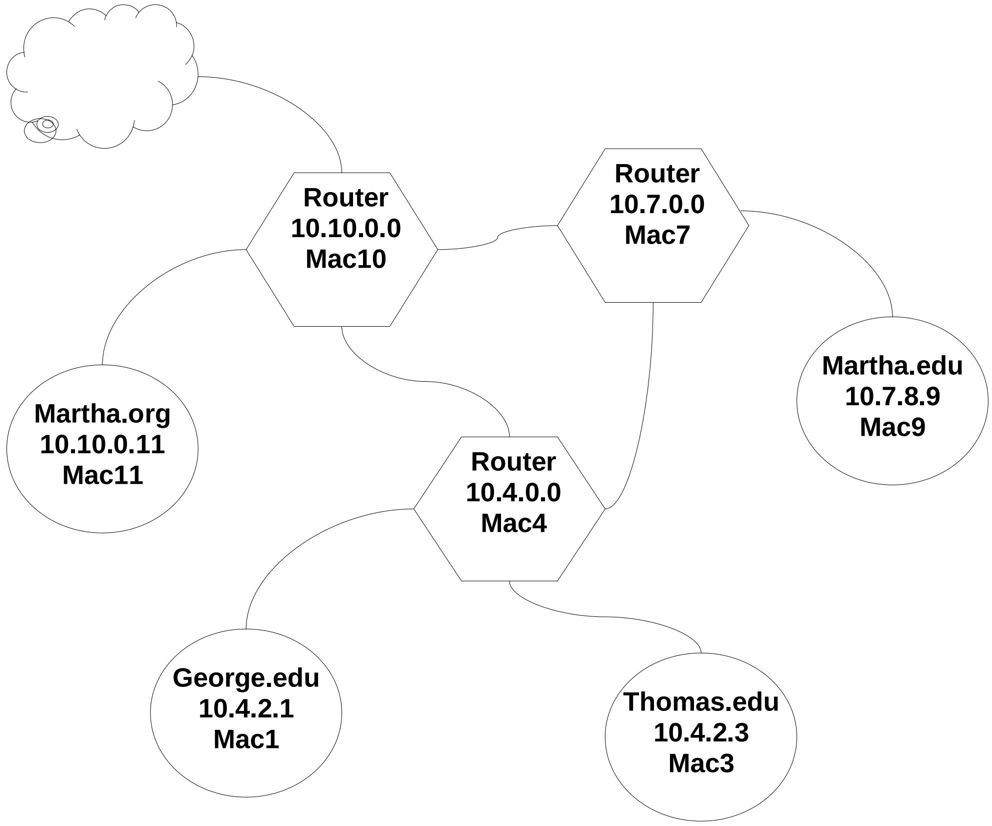
In the play of the simulation, an application layer player writes a message to another application layer player on a paper form. The form is then handed to the TCP player of the sending host. The TCP player adds the TCP header and hands the packet to the IP player. The IP player adds the IP header and hands the packet to the DLL player. The message is then passed to another host where each player strips off the header for that layer and hands the message upward, or in the case of IP forwards it as necessary.

There are several structural differences. Pendegraft gives the IP layer a routing table (see Figure 4 for an example), while Dennis has the IP layer use the network map to determine first hop IP addresses. Pendegraft uses a separate envelope for each layer and its header, while Dennis has different forms for each layer's header data which are taped to the message form. Another difference is that in Pendegraft's game, there is no physical layer player. Instead, the DLL players hold the ends of pieces of wire representing the physical layer. When a DLL player finishes adding the MAC addresses to the packet, he strings the packet on the wire and by raising his hand, sends the packet to the next machine. Such silliness introduces some humor into an otherwise dry subject, and helps keep the students interested and involved.

The games offer different points of view. Dennis's game allows many messages on the network at one time; consequently, it offers a more complete (and hence more complex) model of TCP/IP. In Pendegraft's game only one message is sent at a time and the entire class follows it along the way, immediately discussing problems that may occur such as a player incorrectly addressing a packet. In Dennis's game that sort of error is handled in discussion between the affected players. One result of these two points of view is that in Dennis's game, each player has a different experience that can be shared in the post-game discussion, while in Pendegraft's game, there is a more shared experience.

Both games simplify TCP/IP, ignoring some issues like handshaking or error detection. This is not to say that these issues are unimportant, but that these games focus attention on a limited set of issues of paramount importance, primarily addressing. Pendegraft's game is designed to allow including such complexities "notionally." That is, the instructor can intervene with an external complexity. For example, after a couple of messages have

Figure 2. Network map



been successfully transmitted, the instructor can announce that a packet was garbled in transmission and let the DLL player handle the problem. Or he can announce that at particular data link or router is temporarily out of service, obligating the IP player to reroute traffic.

FUTURE TRENDS

Among the trends in IT that seem relevant is the trend toward increased system complexity, paralleled with efforts to hide that complexity from the user. Examples include third-generation cell phone services, distributed databases, and network-centric systems like Planetnet. These systems raise questions about how to prepare students to deal with a world of increasing complexity. It may be that simulations and games offer a way to let students experience complex systems without having to delve into all the details.

CONCLUSION

Despite their differences, both games have been successfully used to help teach a complex subject. As the two games show, it is possible to design a game to accomplish a specific purpose in a class or to fit the instructor's style. Student response to such exercises is generally favorable for both their educational and entertainment value.

Understanding IT basics will remain an essential part of the education of IT professionals. As technology

Figure 3. DLL instructions (Dennis, 2002, p. 374)

1. Accept outgoing messages from the network layer, format them, add error-control information, and pass them to the physical layer.
2. Accept incoming messages from the physical layer. If they contain no errors, pass them to the network layer. If they contain an error, destroy the message.

Figure 4. Routing table for host 10.4.0.0

Destination	First Hop
10.4.2.1	10.4.2.1
10.4.2.3	10.4.2.3
10.7.*.*	10.7.0.0
*	10.10.0.0

evolves, it will continue to be a challenge to help students understand the basics and prepare themselves to keep learning. Simulation and gaming offer effective and fun tools to help students learn about new technology. They do so in a way that reinforces the need to learn how to learn and to continue learning.

KEY TERMS

Case Study: An instruction tool containing a detailed description of a real-world situation.

Computer Simulation: A simulation built using a computer language.

Experiential Learning: Learning based on experiences rather than listening or reading.

Game: A simulation in which people are part of the model and their decisions partially determine the outcome.

IP (Internet Protocol): The protocol governing the operation of the network layer of the Internet.

Role Playing: An element in gaming which requires the student to assume the role of another.

Simulation: A dynamic model of a system focusing on selected aspects of that system.

TCP (Transport Control Protocol): Protocol governing the operation of the transport layer of the Internet.

S

Simulation for Business Engineering of Electronic Markets

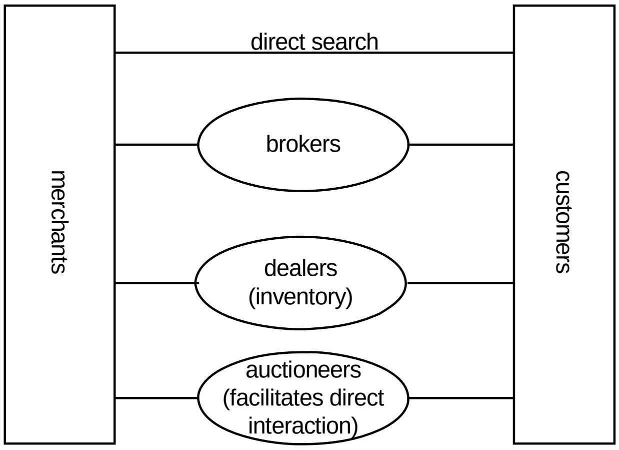
Marijn Janssen
Delft University of Technology, The Netherlands

INTRODUCTION

Information and communication technology (ICT) is applied to support the creation of electronic markets (e-markets). Electronic data interchange (EDI) is the exchange of structured data between information systems of different organizations. EDI is often considered as the first step towards e-markets. In the course of time EDI was extended and interorganizational information systems (IOS) were used to create electronic marketplaces. IOS serve as intermediaries between buyers and sellers. Probably the most well known examples of IOSs are airline reservation systems, which are closed systems having typically a limited number of participants.

With the advent of the Internet e-markets, targeting a global audience at low costs has emerged as a new way of doing business. An e-market system is an interorganizational information system that allows participating buyers and sellers to exchange information about prices and products (Bakos, 1991). Today's e-markets can be used for selling all kinds of products and even services and are typically built around publicly accessible networks, where entrance can be limited based on some kind of conditions. E-markets offer basic market functions and the current base is beginning to emphasize capabilities that aim to satisfy management information, risk management needs and enable integration of information systems (Dai & Kauffman, 2002). E-markets in business-to-business situations are witnessing an evolution towards newer market structures (Tomak & Xia, 2002). It is still unclear what the exact effects of electronic market are, how they emerge, and which markets will eventually turn out to be the most successful in the industry (Fairchild et al., 2004).

Figure 1. Examples of market structures



The value propositions of e-markets often center on two key dimensions (Le, 2002). The first dimensions deals with demand and/or supply aggregation to overcome market fragmentation (through search cost efficiency, price transparency and product-cost savings, market liquidity, network externalities and customer lock-in). The second dimension addresses inter-firm collaboration for greater supply chain performance (through streamlined workflows and process-cost savings, customer lock-on, and business process integration). Design decisions are critical, as they determine the market microstructure influencing liquidity, volatility and business propositions to stakeholders. The development and the introduction of e-markets requires the developer to carefully identify, evaluate, and understand the possible impact of the various design alternatives because they determine the market microstructures (Levecq & Weber, 2002). A business engineering methodology can be of help to design and develop e-markets by providing insight into current market and potential e-markets and by evaluating the implications of potential markets. Simulation can be used to compare the performance of the current and possible "to be" situations in a business engineering methodology. The *objective* of this article is to discuss research issues concerning the simulation of e-markets for business engineering.

BACKGROUND

E-markets can use a large variety of coordination mechanisms and market structures to coordinate demand and supply. A taxonomy of market structures based on how traders search out their counterparts is shown in Figure 1 (Garbade, 1982). In practice, all kinds of market structures and matching mechanisms can be used in accordance with traders' interest (Dai & Kauffman, 2002).

The core of e-markets is the *coordination* of the various interdependent activities performed by autonomous organizations during the information, agreement and settlement phases (Lindemann & Schmid, 1999). There are two opposing views on coordination. In a *coordination of tasks* approach the design of processes is dependent on the coordination mechanisms that manage the dependencies between tasks (Malone & Crowston, 1994). The *coordination of commitments* approach emphasizes networks of commitments that organizations establish through intentional acts of speech (Winograd & Flores, 1987). This coordination approach emphasizes the fulfillment of human commitments and describes activities in terms of contracts and promises. The combination of these two coordination perspectives leads to the definition of an *e-market* as the coordination of interdependent activities performed by autonomous organizations by exchanging data between information systems of buying, selling and facilitating organizations, allowing them to agree on and fulfill commitments.

Requirements of traders on e-markets are not easily elicited and can demand innovative mechanisms or deliberate trade-offs. The timely sharing of information among traders is often a major issue (Christopher, 2002). Information sharing is necessary for efficient coordination of the processes of traders, whereas for example sellers want to avoid information being used to negotiate lower prices or shared with competitors. Another typical issue in the business engineering of e-markets is the selection of matching mechanisms, as buyers and sellers can have different and even opposing requirements. For example one trader might want to minimize trading time, while another might want to maximize the reliability of a chosen trading partner. The most conspicuous opposing requirement is that buyers want to have the lowest price at the best possible trading conditions while sellers want to have the highest possible price to maximize revenue.

In short, a large number of other trade-offs and decisions need to be made before an efficient and effective e-market can be established. A list of business engineering issues is shown in Table 1. Some limitations are coming from the state-of-the-art of the technology and from market and/or product characteristics; others are coming from the opposing requirements and needs of the parties involved. Simulation for business engineering of e-markets can help decision makers to gain insight into these issues. This should support them to make deliberate choices, without having to experiment in real life, which could be costly and even result in a loss of customers.

SIMULATION FOR BUSINESS ENGINEERING

E-markets are by nature complex and analytic methods that can only be applied in a limited way. Analytical techniques analyze market mechanisms in a state of equilibrium and often focus on fair and efficient market mechanism (Mas-Colell, Whinston & Green, 1995). Although these approaches contribute to insight into and design of matching mechanisms, they do not help decision makers to evaluate the impact of e-markets for a practical situation. An e-market should be evaluated prior to implementation on criteria such as costs, utilization, trading time, delivery time, number of bids, matching chance, and so on. Analytical approaches do also not grasp the time-dependent dynamics resulting from the interplay between actors executing business processes.

Simulation of business processes constitutes one of the most widely used applications of operational research, as it allows us to understand the essence of business systems, to identify opportunities for change, and to evaluate the effect of proposed changes on key performance indicators (Law & Kelton, 1991). The philosophy behind a business engineering approach is to develop a simulation model of the current market, experiment with this model, and experiment with alternative market situations (Sol, 1982). An analysis of e-markets needs to begin with understanding of traditional market processes and should investigate how conventional transaction methods are changed as a result of e-market adoption (Lee & Clark, 1997).

Animation is often a standard feature of simulation. An animation model is a graphical representation of a problem situation and includes visualization of the time-ordered dynamics of objects, a static background, an overview of performance indicators and a user-interface (Vreede & Verbraeck, 1996). The purposes of animation are to facilitate decision makers to acquire insight into the dynamic interactions of the modeled system, the performance of the “as is” and “to be” situation and to facilitate communication between parties involved in a dynamic modeling study.

FUTURE TRENDS

Business engineering methodology provides context to the simulation technique (Greasley, 2003). Business engineering approaches proposed by Streng (1994) and Giagles, Paul and Doukidis (1999) tackled the identification of the added value of EDI by making use of discrete-event simulation. Nikolaidou and Anagnostopoulos (2003) use a simulation approach for modeling distributed systems. Janssen (2001) developed a business engineering methodology, including a simulation approach for electronic intermediaries. Business engineering using simulation should be based on the distinguished characteristics of e-markets and provide insight into current and potential markets and should evaluate the added value. Dependent on the characteristics of the market under study, certain issues shown in Table 1 dominate. Business engineering ensures the incorporation of the relevant business engineering issues and simulation can be used to aid conscious decision-making. A business engineering approach should help to focus on those issues most relevant to the particular situation and help to find solutions to those issues (Janssen, 2001). An interesting research direction is about which elements should be included in the business engineering for which type of markets.

A large number of independent organizations with their own strategies and sometimes even opposing aims carry out business with each other. The relations between organizations can change during the trading process, as organizations can enter or leave the playing field. The most powerful abstractions are the ones that minimize the semantic gap between the units of analysis that are intuitively used to conceptualize the problem and the constructs present in the modeling approach. Ideally, organization should be simulated as distributed systems, where each system is represented by an autonomous entity.

Software agents are autonomous entities that can be used for simulating organizations. The so-called agents are autonomous entities with their own interests and goals so they can decide to enter or leave a trading situation. *Agent-based simulation* has appeared for modeling organizations within e-markets (Janssen, 2001; Ramat & Preux, 2003).

In the past, electronic matching mechanisms were primarily used for commodity products (Lee & Lee, 1998). Over time, matching mechanisms became more sophisticated and were able to deal with product characteristics, delivery terms and preferences of buyers and sellers. Current research on mechanisms focuses on supporting semi-competitive matching approaches where agents strive to reach a fair and reasonable agreement for both parties, which nevertheless maximizes their own payoff (Luo et al., 2003). To evaluate the implications of these mechanisms, simulation of e-markets should focus on *emulation*, which means that actual software is written to execute matching mechanisms.

Communication over the Internet using a *Web-based* simulation is preferable for supporting communication between the researcher and persons involved in the design process. Another research issue is to use *distributed* simulation so multiple participants could interact with a simulation environment at the same time. In this way the participants can gain experiences with a hypothetical market situation. This might lead to an increase in insight into the problem situation by participants and might help designers of e-markets to make better decisions.

CONCLUSION

The quest towards innovative forms of e-markets has just started. During the business engineering of e-markets numerous trade-offs and decisions have to be made influencing the performance and possible adoption of an e-market. Business engineering using simulation should help decision-makers to focus on the most relevant issues and to make appropriate decisions and trade-offs without having to experiment in real-life situations. It is still unclear which the most relevant issues are to focus on when engineering e-markets.

Ideally, e-markets should be modeled with the help of a distributed, agent-based simulation environment that makes use of emulated mechanisms. Decision-makers should be able to view the animation over the Internet, manipulate parameters and view the consequences of their actions. The accomplishment of this ideal needs ample research attention in the domain of distributed simulation, agent-based simulation, Web-based animation and emulation of mechanism.

KEY TERMS

Agent-Based Simulation: Simulation of organizations as interacting autonomous entities with their own interests and goals and discrete processes.

Animation Model: An animation model is a graphical representation of a problem situation that can consist of a visualization of the time-ordered dynamics of objects, a static background, an overview of performance indicators and a user interface.

Business Engineering: The integral design of both organizational structures and information systems.

Coordination of Commitments: The actions by humans leading to the completion of work. Coordination is described in terms of contracts and promises consisting of recurring loops of requesting, making and fulfilling commitments.

Coordination of Tasks: The management of dependencies between tasks.

Discrete-Event Simulation: Discrete-event simulation models a system by changing the systems state at discrete points in time.

Electronic Markets: The coordination of interdependent activities performed by autonomous organizations by exchanging data between information systems of buying, selling and facilitating organizations allowing them to agree on and fulfill commitments.

Electronic Market System: An interorganizational information system that allows participating buyers and sellers to exchange information about prices and products.

Emulation: Actual software is written to execute something, instead of simulating it.

Matching Mechanisms: Well-defined set of rules for determining the terms of an exchange of something for money.

Spot Sourcing: Buying based on incidental and last-minute opportunities. Spot sourcing is transaction oriented and often involves short-term and incidental relationships.

Systematic Sourcing: Buying using pre-negotiated contracts with qualified sellers. These contracts are often long-term in nature and tend to have a cooperative nature.

Simulation in Information Systems Research

Chris Coulston
Penn State Erie, USA

INTRODUCTION

Simulation is a standard research technique of the natural sciences, social sciences, and engineering disciplines. The paradigm of simulation provides an accepted mode of development, validation, and verification by which complex, highly dynamic interactions can be probed and analyzed. The approach enables researchers to phrase experiments in a controlled environment where the concepts, variables, and relationships of the domain can be manipulated. Then, employing standard experimental design techniques, the simulation represents the behavior of the underlying system. The behavior can be analyzed statistically for its regularity and critical values where the dynamics may become unstable. Further, once the simulation model is developed, sensitivity analysis can be done to probe the interdependencies of the elements of the underlying system upon one another.

Without the use of computers, the concept of simulation uses physical models to provide the experimental framework examining complex systems. These physical models incorporate dimensions of a real system, abstracted into the model. If one wants to explore a pilot's ability to manage a cockpit's physical controls under different degrees of information loading, one constructs a mock cockpit and offers the pilot different amounts of information to handle. The experiment of the physical simulation relies on the modeler validly abstracting relevant aspects of the real cockpit into the mock cockpit.

Computer-realizable simulation has become an option with the development of computers and the representation of models within a computing environment. Programming known mathematical representations of physical behaviors became a standard use of computers with programming languages such as FORTRAN, designed to numerically analyze mathematical functions within acceptable tolerances. In fact, the disciplines of management science and operations research are defined by their various modeling approaches to represent the behavior of physical systems into mathematical and computational frameworks - simulation being one of the frameworks. In fact, the initiation of these fields are usually traced to their successes in the 1940s with military-related research of dynamic systems using computers and simulation.

Today, simulation continues to be a tool for understanding complex, dynamic systems—but not for proposing optimal solutions to their interactions. Optimization cannot be a mathematical analysis goal of simulation; other mathematical approaches exist for this analysis goal. Typically, the dynamics and interactions of a simulated system are too complex to be captured into a mathematical structure, lending itself to optimization algorithms. Simulation provides a methodical way to describe and to examine the dynamic space of the system's behavior.

The usage of simulation to understand complex systems is not done solely in the natural and physical sciences. Social sciences such as economics and psychology have relied on the concept as a technique to test theories of behavior. Even performing well-defined, "what-if?" analysis in spreadsheet applications to assess supply-and-demand interactions constitutes simulation. Social psychologists might use a simulation framework by developing a research model based on probabilistic structures. The probabilities describe the tendency of elements in a social system such as a crowd to react and change into a mob. In the vernacular of the field, simulation examines the modeled elements, tendencies, and interactions, by manipulating the "stat rats" in order to probe the behavior.

Numerous computational approaches have been developed to handle simulations. General-purpose programming languages such as FORTRAN or C++ can represent the model and realize its execution. General-purpose simulation packages such as SIMAN (Pegden, Shannon & Sadowski, 1990), ARENA (Kelton, Sadowski & Sturrock, 2004), GPSS (Schriber, 1974), or MATLAB (Palm, 2001) have been classically used to represent the model and to facilitate the representation of time for the execution of the model. In addition, special-purpose simulation environments have been developed for specific domains ranging from inventory logistics, chemical manufacturing, to air-traffic control.

Modeling and statistical processes are foundations to simulation. Hannon and Ruth (2001) emphasize dynamic modeling perspectives; Shanbhag and Rao (2003) target stochastic processes as an aspect to simulation; Severance (2001) focuses on the systems-thinking perspective guiding simulation development; Powell and Baker (2004) show how simulation can be realized in easily accessible spreadsheet software; and Chung (2004) captures the general manner of the basics and techniques in a handbook for simulation modeling.

Simulation's advantage stems from the safe, abstract environment invented by the model. Often the underlying system to be understood may be (1) dangerous to manipulate, (2) unavailable for controlled manipulations, or (3) non-existent at the current period of time. The simulation of a proposed new rail-transport system based on a current city's environment captures all three of these conditions.

Simulation also has its down side. A good simulation depends upon a good model of the underlying system. Creating a good model requires analytical, mathematical, and logic skills. Executing the simulation requires computational skills. Understanding the results of the simulation requires knowledge about the underlying system and about the mapping of it into the model. These skills require training and development which are not readily available in the average technical professional.

BACKGROUND

Simulation incorporates experimental design as its underlying paradigm for understanding complex, dynamic systems. By manipulating the input variables and system parameters within acceptable and legal value ranges, the behavior of the system can be mapped as a function of the changes defined by the experimental design. More than one experimental design¾more than one set of experiments, more than set of variable perturbations¾may exist for any modeled system. The modeler determines what aspects of the system need to be captured in the model in order to be probed by the experiments. The process begins with a conceptual model of the system.

A prerequisite to constructing a simulation is to understand the behavior of the system and to represent it sufficiently in a valid model, which can be realized (executed) in a computational format. If the behavior is not well understood, the abstraction into the model may not accurately represent the relationship between the input variables and the output variables. The process of validation examines the correspondence between the modeled input and output pairings, and the actual input and output pairings. This correspondence should show statistical goodness-of-fit. If it does not, the conceptual model needs to be revised. Until this correspondence is valid, proceeding with the experimental design would not be rational.

Models, long a standard of research and engineering, are an abstraction of the significant features and relationships of a system. This abstraction enables the system to be studied for the purpose of prediction or comparison. The experimenter knows the system intimately and defines a level of analysis appropriate in order to enable the prediction of a system's behavior or to compare the effects of change upon the system's behavior.

Generally, models may be represented as linguistic, iconic, or physical representations. The choice depends upon how the modeler expresses the fundamental relationships of the target behavior. Examples of each of these are as follows:

1. A mathematical model of a business's order fulfillment interactions requires equations¾a model based on the language of mathematics.
2. A process model of an organization's enterprise-wide data distribution plan requires diagrams of nodes and connections - a model capturing behavior possibilities by the use of icons.
3. A construction, 3D model of a company's proposed new production plant requires an architectural layout of objects of buildings and land¾a model showing components' interactions based on physical scale.

Although a variety of texts present simulation, classic coverage of the simulation development process from model conceptualization to simulation execution can be found in Banks and Carson (1984), Law and Kelton (2000), Winston (1987), and Zeigler (1984, 1976). Coverage of a variety of classic implementation platforms for simulation can be found in Watson and Blackstone (1989). Aburdene (1988) presents both discrete-event simulation and continuous simulation, and provides examples across a variety of disciplines and applications from information diffusion to modeling the arms race. Pegden et al. (1990, pp. 12-13) identify the simulation process as a set of 12 steps. These steps cover the project management aspects of the simulation study as well as the conceptual management of the experiment.

1. Problem definition: Identifying the goal and purpose to the simulation
2. Project planning: Identifying and coordinating the hardware, software, staff, and management resources required
3. System definition: Identifying the system to be studied—in classical general systems analysis terms
4. Conceptual model formulation: Extending the system definition to incorporate formal variables, relationships, and interaction logic
5. Preliminary experimental design: Identifying an experimental framework by which to assess the study,

that is, which control variables, output variables, factors to vary

6. Input data preparation: Identifying and collecting data to configure parameters and probability distributions
7. Model translation: Representing the system and experiment in the language of a software application designed for simulation
8. Verification and validation: Confirming the accuracy, integrity, and credibility of the model's parameters, distributions, and output
9. Final experimental design: Finalizing the structure of the experiment to test a specific, stated hypothesis
10. Experimentation: Executing the simulation according to the experimental design
11. Analysis and interpretation: Examining the output of the simulation study in light of the hypothesis of the experiment
12. Implementation and documentation: Using the results of the analysis to drive action as a consequence of study

These 12 steps give a researcher an environment to manipulate, repeatedly, in order to explore any relationships appropriately captured by the model of the system. Since the simulation can be used to explore conditions that have not yet occurred, but which are plausible within the definition of the model, the simulation enables a researcher to pose problems and to experience solutions to the problems before they are needed. The reliability and credibility of the simulation are powerful reasoning tools for research.

The value of Step 8 is directly based on the goal of Step 11, interpretation. Simulation requires the model to be executed under statistical conditions, mimicking the concept of "in the long run." One run of a simulation cannot give statistically significant results and cannot prove the validity of the model. Simulation requires the model to have its statistical elements manipulated appropriately so that the tendency to respond to an input is correctly captured by the parameters used for the statistical elements. For instance, if a researcher has analyzed a system and has assessed that according to a normal distribution with a mean of σ and a standard deviation of μ, users will request services from an information help desk, and if the simulation is being constructed to assess the need for expanded staffing of the help desk, then the validity—the truthfulness of description—of the parameters to the normal distribution describing users' requests-for-services will influence the final interpretation of the staffing question. If the parameters are wrong—or if the assessment of a normal distribution is wrong—then the validity of the interpretation and the value of the simulation is lost.

THE CURRENT ROLE FOR SIMULATION IN INFORMATION SYSTEMS RESEARCH

While simulation as a technique for examining complex and dynamic systems is widely accepted in the physical and social sciences, the approach is not used, understood, or taught as a tool for information systems (IS) research. As such, its use as a tool for information systems management by IS professionals is limited. The fundamental gist of creating good simulations is to know the underlying system being modeled. IS professionals known their systems intimately, and yet, are not using a general-systems theoretic approach such as simulation for assessing their research or their problems.

IS research has not taken advantage of simulation to examine complex situations as other domains have. A variety of reasons exist for the limited use of simulation in IS research.

- The field is relatively young compared to the other domains using simulation.
- The formalization of the problems and systems within the IS field has not reached the level of maturity and understanding existing in other domains. Much IS research has focused on capturing and describing the behavior of IS systems, not on predicting the expression of the behavior.
- The technical competencies to develop a valid and verified simulation are not standard components of IS curriculums. IS curriculums do not provide the mathematical and analytical emphasis required to construct a robust simulation. IS curriculums stress the technical competencies to plan, to build, and to deploy systems, but not to predict the ramifications of incorporating new processes into an organization from a scientific perspective.

IS professionals who understand and build decision support systems for the traditional functional areas of industry have incorporated simulation as a modeling environment for assessing a variety of management decisions. Yet, the field has not embraced the same modeling approach to support management concerns of an IS's nature. Ironically, IS professionals are asked to build simulation environments and applications, but may not be trained in the basics of such tools.

However, as the field of IS matures, IS professionals will want better understanding and control of the systems they build, manage, and modify. Also, the organizations relying on the systems will require the IS professionals to do these tasks better. The use of simulation by IS researchers can be used to address the need for accountability and prediction. The problem domains for the application of simulation will come from the industrial settings of IS professionals. The understanding of the components of the problem domain and how they could be expressed by simulation are tasks for IS researchers.

From risk management in project development to security assessment in IS operations, IS professionals require quantitative appraisals that are reliable indicators of performance and expectations. While the language of "indicators of performance and expectations" is common to marketing, production, and human resources efforts, the incorporation of these indicators into a model is not as common. If an IS researcher wants to assess how effective different change management techniques would be for a development project, the elements of the development project, the character of the change management techniques, and the different response tendencies of the users and project coordinators could be modeled and simulated. The simulation could be probed, suggesting an effective technique and its timing, reflecting the needs of the organization and of the project. Currently, IS professionals might use a technique at hand which need not necessarily fit the project.

As IS executives embrace the concept of portfolio management of IS efforts in an organization, the concept requires quantitative grounding. If a CIO is to define the appropriate mix of on-going projects and strategic initiatives, some rational basis for promoting one mix over another is required. By building a simulation of the IS efforts of an organization, a CIO could examine how different project mixes could influence the work and future of the organization. IS research could support the portfolio management by defining suitable mappings of organizations and projects into model components to be incorporated by the CIOs into a specific model. Specific models would then be simulated.

IS tactical management wants to add knowledge management to its repository of intellectual assets. While an organization has multiple sources of knowledge, IS management needs to define a rationale to identify which sources should be captured, how to capture the source(s), and what aspects of the source(s) to capture. Without an environment to assess these decisions, knowledge management efforts could simply become a burden to the IS professionals and useless to the organization. Simulation can provide the environment, once again, to quantitatively view the value of the knowledge asset in light of its potential to the organization. IS research could examine the questions of knowledge management

IS operations - like any other department of operations - can benefit from simulation, as it has been used historically in manufacturing, logistics, or facilities layout. This aspect is an accepted concept of information resources management. However, the use of classical operations management techniques to IS operations has been less common, but is changing. The assessment of network capabilities provides situations for simulation (for usage of simulation to review network capabilities, see Bagrodia, Gerla, Kleinrock, Short & Tsai, 1995; Lee, Gerla & Toh, 1999). Requirements assessment as part of the development of information systems has also proposed the use of simulation (see Rozenblit & Liu, 1990). The trend towards incorporating total cost of ownership (TCO) assessments into information systems management is another example area of operations where simulation would be a viable tool.

FUTURE TRENDS

Traditionally, IS research gives the IS profession insight into methodologies, techniques, and technologies. IS professionals can benefit from an analytical framework for examining the use, need, and character of IS at the strategic, tactical, and operational level of analysis. Simulation could provide this analytical framework for reviewing the efficiency and effectiveness of proposed and operational systems. The simulation results would provide comparisons between proposals or explanations of problematic events.

The reasons for simulation not being more common in IS research can be attributed to four points: the structure of IS curriculums, the modeling approaches driving current research, the separation of IS project development from review after deployment, and the newness of the IS field. Each of these reasons impose limitations upon IS research and its potential use of simulation. The conditions of these reasons, however, are changing. As the IS field matures and moves away from ad hoc techniques, and moves towards repeatable, sustainable processes, more scientific techniques will be sought to assess situations. This trend is occurring now in the profession. The trend will also influence IS curriculums to change in order to promote the scientific exploration of the situations.

CONCLUSION

Researchers in the natural sciences, social sciences, and engineering have relied on the methodology of simulation in order to represent, assess, and predict behavior in systems. Simulation requires a variety of skills from systems analysis to mathematical modeling to logical construction in order to create, verify, validate, and execute a simulation model. All of these skills are not common to all IS professionals, and the methodology of simulation is not widely known or taught to them either. However, the problems IS professionals and researchers address can benefit from the use of simulation. If IS curriculums include the skill sets needed for simulation and include simulation in their learning objectives, then simulation can be used as one of the quantitative techniques for addressing IS problems and research questions.

KEY TERMS

Conceptual Model: The abstraction of relevant aspects of a target—usually physical—system into a representation system consisting of symbols, logic, and mathematical constructs.

Continuous System: A system whose state variables show its behavior change continuously with respect to time. Hence, the behavior of the system is seen as changing continuously over time. Such systems are usually modeled using differential equations.

Discrete System: A system where the state variables showing its behavior change only at isolated, discernible points of time. Hence, the behavior of the system is seen as changing in distinct, separate moments of time. Such systems can be modeled using difference equations or incremental event analysis.

Experimental Design: The process of defining dependent and independent variables of the underlying model and acceptable ranges for these variables. In terms of input, output, and model, the experimental design describes which input variables and parameters to manipulate and according to what range of changes. As these elements are manipulated, specific output variables will be assessed. The connection between the input- and output-set pairings is embodied in the description of the model. Identifying what items to manipulate and which correspondence should reveal the effect of the manipulation describes the plan of the experiment.

Simulation: (1) An analysis technique capturing the behavior of a system as mathematical and logical algorithms into a model. The model is represented and realized in an environment where the resultant behavior of the model can be captured, analyzed, and used to further the understanding of the system. Simulation is not an optimization technique, but can be used with sensitivity analysis to probe the parameter space of the underlying system. (2) The computational execution of a simulation model in a simulation environment according to an experimental design.

Simulation Environment: A computing environment for realizing and executing a simulation model, giving output values corresponding to states of behavior in the physical, real system.

Simulation Model: The representation of a system in terms of the fundamental components, relationships, and interactions of its behavior, captured as mathematical and logical algorithms.

Validation: The process of showing the correspondence between the physical system and the simulated system is within acceptable tolerances of output performance. Validation relies on statistical confirmation of the simulated output to fit the behavior exhibited by target, physical system.

Verification: The process of determining the correctness of the programmed components in terms of typographical errors, numerical accuracy, algorithm completeness, and logical unity. Verification covers all aspects of logical, syntactic, and semantic debugging of computer programs.

Small Business Transformation Through Knowledge Management

Nory B. Jones
University of Maine Business School, USA

Jatinder N. D. Gupta
University of Alabama in Huntsville, USA

INTRODUCTION

In the last decade, the importance of knowledge as a source of sustainable competitive advantage has gained widespread acceptance. Business practitioners and academics alike recognize that what is "between the ears" (Tiwana, 2000) of their employees represents the source of creativity and innovation that nourishes and sustains the organization. Furthermore, the ability to harness the intellectual capital in an organization probably represents the most important aspect relating to the creation of an intelligent enterprise.

However, most research on the topic of knowledge management (KM) and intellectual capital has focused on larger organizations. Because small businesses account for a major portion of the total number of businesses, jobs, and growth in many world economies (Wong & Radcliff, 2000), it is important to understand the impact of knowledge management on small businesses as well. We need to understand the correlation between knowledge management practices, the ability of a small business to transform itself into an intelligent enterprise and any resulting performance or competitive improvements KM may provide.

Because a "build it and they will come" approach to knowledge management usually does not work, this article discusses and integrates the concepts of adoption and diffusion of innovations with knowledge management theories to help transform a small business into an intelligent enterprise. The ultimate goal of this chapter is to provide small businesses with some consistent theories and practices that may help improve their competitiveness in a turbulent world.

KNOWLEDGE MANAGEMENT IN SMALL BUSINESS

What is Knowledge Management?

Karl Wigg is credited with coining the term "knowledge management" (KM) at a 1986 Swiss Conference sponsored by the United Nations International Labor Organization. He defined KM as "the systematic, explicit, and deliberate building, renewal, and application of knowledge to maximize an enterprise's knowledge-related effectiveness and returns from its knowledge assets" (Wigg, 1999). Thus, KM represents an organization's ability to capture, organize, and disseminate knowledge to help create and maintain competitive advantage. It is becoming widely accepted as a key part of the strategy to use expertise to create a sustainable competitive advantage in today's business environment. It enables the organization to maintain or improve organizational performance based on experience and knowledge. It also makes this knowledge available to organizational decision-makers and for organizational activities (Beckman, 1999; Pan & Scarbrough, 1999). Therefore, we can assert that knowledge management represents a key strategy in creating and sustaining an intelligent enterprise, capable of outperforming its competitors.

Using KM in Small Business

Why is it important for small businesses to use knowledge management to become "learning organizations" or "intelligent enterprises"? According to Wong et al. (1997), "Many of the factors which have promoted the growth of SMEs also require their managers to acquire new skills. In fast-growing small firms, the management team will be constantly developing and the skills needed will change as both cause and effect of the development of the firm itself." The bottom line is that for a small business to succeed and thrive in a changing world, it must continually learn and adapt better and faster than its competitors. Knowledge management provides the tools and strategies to achieve this (Anderson & Boocock, 2002).

Guimaraes (2000) further suggests that small businesses face greater pressures from chains owned by large corporations, increased regulations and politics, and greater competition due to increasing business globalization. He asserts that innovation, facilitated by knowledge management, may be the key to their survival and success in difficult times. Chaston et al. (2001) support this view in their statement: "Organizational learning [knowledge management] is increasingly being mentioned in the literature as a mechanism for assisting small firm survival". It is "the most effective and practical way through which to increase Small and Medium-Size Enterprise (SME) sector survival rates during the early years of the new millennium". They contend that by assisting employees and facilitating their learning and knowledge sharing, they can creatively develop new products, better and more efficient processes, and identify new ways of building better relationships with customers. Thus, it appears that knowledge management techniques of acquiring, sharing and effectively using knowledge may represent a crucial means of transforming a small business into an intelligent enterprise, resulting in improved performance by facilitating innovation, idea creation, and operating efficiencies.

Influence of Adoption and Diffusion

How do adoption and diffusion factors influence KM in small businesses and their goal of becoming an intelligent enterprise? By understanding factors that facilitate the adoption and diffusion of innovations, small businesses may improve their chances of success in a knowledge management initiative. Based on many years of adoption and diffusion of innovations research, Rogers (1995) developed a model often considered the foundation for the adoption and diffusion of innovations. We include strategies and processes in the definition of "innovations" in the context of this chapter. This model proposes three main elements influencing the adoption and diffusion of innovations, including: the innovation, communication channels, and social systems.

Based on the research of Rogers and others, the factors that appear to significantly influence adoption and diffusion include the relative advantage of an innovation (the degree to which the innovation is perceived as better than what it supercedes), which is positively related to its rate of adoption and continued and effective use and the influence of culture and social systems. The social systems similarly influence people's attitudes and willingness to adopt new processes or technologies. Finally, communication channels such as mass communication and interpersonal channels have been found to be effective promotional avenues to facilitate the successful awareness and use of a new process or technologies. Other studies propose that technological change within organizations represents a cumulative learning process where firms will seek to improve and diversify their technology in areas that enable them to build upon their current strategies in technology (Alange et al., 1998). Thus, prior experience appears to influence the willingness to adopt and the rate of adoption and diffusion in addition to Rogers' variables. The concept of absorptive capacity (Cohen & Levinthal, 1990) further suggests that an organization's ability to absorb new knowledge or for an innovation to diffuse throughout is based on its prior experience with this knowledge or innovation. In terms of creating a learning organization or an intelligent enterprise, this theory says that the greater the absorptive capacity of the organization, the greater is the ability of its employees to absorb and use new knowledge effectively.

APPLICATIONS TO SMALL BUSINESS

How can these theories be applied to a small business for transformation into an intelligent enterprise? First, relying on Rogers' classic theories, a small business can easily communicate the advantages of these new technologies and practices using mass media channels, such as company newsletters, e-mail, or company meetings. After making people aware of the new KM system, the business can use interpersonal channels to effectively persuade people to try them and continue using them. By using homophilous colleagues (individuals with similar attributes such as common beliefs, education, social status and values), a small business can more effectively persuade people to adopt and then use the KM systems. These "knowledge champions" represent very important motivators and influencers because they are trusted and respected by their peers (Jones et al., 2003). This is very important because the literature is replete with cases of companies investing in new technologies and new management strategies, which are simply viewed with skepticism as the "latest fad". However, by carefully selecting peers who are trusted and respected, the adoption and diffusion process can be greatly facilitated.

Similarly, the literature describes the huge influence of culture on the effectiveness of KM systems and the development of a learning organization (intelligent enterprise). Rogers' theories can be effectively applied to the cultural aspect as well. The effect of norms, opinion leaders, and change agents can exert a profound influence on the adoption and diffusion of an innovation throughout a social system. This is because norms (culture) can exert a powerful influence on people's willingness to accept or reject an innovation depending on whether it is compatible with their existing values and norms. Therefore, by using change agents as cultural influencers, small businesses can greatly enhance the transition to becoming a learning organization/ intelligent enterprise while using knowledge management systems to provide competitive advantages. Finally, in an organizational social system, such as within a small business, a powerful individual within the organization, such as the business

Table 1. Contributing factors to the adoption & diffusion of innovations

Success Factor	Characteristic
Innovation:	
o Relative advantage	o The perceived benefit from the innovation that makes it superior to existing tools or processes.
o Compatibility	o How well the innovation is perceived as consistent with the existing values, past experiences, and needs of potential adopters.
o Complexity	o How difficult it is to understand and use.
o Triability	o Ability to experiment with the innovation.
o Observability	o Ability to see tangible results from using it.
Communication Channels:	
o Type of communication channel	o **Communication Type:** Mass media: used for initial awareness of innovation versus interpersonal: used to persuade potential people about benefits.
o Type of individual	o **Individual Type:** Homophilous; opinion leader, knowledge champion.
Social Systems (Culture):	
o Organizational Leaders (Change Agents)	o People in a position of authority who can make the adoption decision.
o Opinion Leaders (Peers)	o Those individuals who can exert a positive influence on others to adopt and use an innovation; individuals who have similar attributes such as common beliefs, education, social status and values, who can persuade their peers to adopt the new system and change values and norms within the culture.
o Prior knowledge/ experience/attitude towards innovation	o Attitudes and prior experience and knowledge may influence the adoption and diffusion of an innovation. The theory of absorptive capacity tells small businesses that the more knowledge they provide their employees, the greater their capacity to absorb more and become a more proactive learning organization/intelligent enterprise.

owner, can also exert a strong influence on the adoption and diffusion of a KM system as well as facilitating a cultural shift to becoming a learning organization. Table 1 summarizes these factors.

FUTURE TRENDS

As mentioned, small businesses often face major challenges of coping with resource deprivation. This includes not only fewer technological resources, but also less focused expertise to enable them to make critical decisions or improve products or processes. They need to learn how to learn, change, and adapt better and faster than their competitors and better meet the needs of their customers. By understanding how they can facilitate a knowledge sharing initiative, a small business may be able to make better use of scarce resources and become more intelligent than their competitors; become better at learning, innovation and creativity. For a small business to increase the speed and effectiveness of the diffusion process for a knowledge management initiative or other processes/technologies, it may be important for them to understand the components of an innovation, communication channels, and/or social systems within the context of a small business environment.

Therefore, incorporating a knowledge management strategy holds some promise as a mechanism for small businesses to improve performance. However, the “build it and they will come” philosophy may be simplistic and an investment in knowledge sharing technologies may be wasteful if the systems are not used effectively. Therefore, small businesses should be aware of the issues associated with adoption and diffusion of knowledge management practices.

Similarly, small businesses should understand that creating a learning organization/ intelligent enterprise potentially involves huge cultural changes. Thus, a major challenge is whether a small business owner is interested in fundamentally changing the culture of the organization, including the reward and recognition structures. For example, Pan and Scarbrough (1999, 2000) found that the major challenge to implementing a knowledge management initiative was successfully overcome when the CEO initiated cultural changes that actively promoted and rewarded knowledge acquisition, knowledge sharing, and knowledge use. This led to significant performance improvements such as considerably reduced time in process for product development, reduced costs and improved customer satisfaction. However, this involved a complete commitment to cultural change by a new CEO, who made dramatic changes in the culture and the reward/recognition structures and company policies.

CONCLUSION

With respect to opportunities and challenges for SMEs, knowledge management appears to represent a mechanism for survival, growth and prosperity. As knowledge management continues to diffuse throughout the global business world, the competitive pressures may necessitate some form of KM as a pre-requisite for survival. Therefore, implementing these diffusion methods should prove beneficial to small business owners and operators.

Small businesses can benefit from understanding the factors associated with diffusion, including Roger's five major elements. Another important consideration for small businesses is the cultural issues surrounding their organizations and resources issues that will prove important to employees. By understanding these issues, small businesses may be able to tailor the adoption and diffusion of technologies or a knowledge sharing system to their unique situation, thus improving their chances for success.

While the small business studied represents only one situation, it is interesting that several consistencies with the literature emerged, lending some possible connections and conclusions between the effective diffusion of knowledge management systems and a causal relationship with improved performance. The implication is that knowledge management can facilitate the creation of a learning organization or an intelligent enterprise. This improves creativity and innovation that further enhances productivity, problem solving and customer satisfaction. By promoting a culture that continually learns and improves, organizations can develop a sustainable competitive advantage that is not easily imitated by competitors.

KEY TERMS

Absorptive Capacity: An organization's ability to absorb new knowledge; often based on the prior experience and knowledge base of its employees. The greater the absorptive capacity of an organization, the greater its ability to learn and adapt to changing market forces.

Adoption: Changes in employee attitudes, perceptions, and actions that lead them to try new practices, activities, or innovations that are different from their normal routines or behaviors.

Diffusion: The process by which new behaviors, innovations, or practices spread through the organization as people learn about them from other employees and try them out.

Intelligent Enterprise: An organization that is able to understand changing environments, and adapt with agility and resourcefulness in order to outperform competitors.

Knowledge Management: An organization's ability to capture, organize and disseminate knowledge to help create and maintain competitive advantage.

Learning Organization: An organization that continually strives to create a culture and environment that promotes learning, exploration, and innovation and that continuously transforms itself to achieve superior competitive performance.

Organizational Culture: The set of shared values and norms within an organization that shape its behaviors, attitudes, and actions.

Relative Advantage: The degree to which an innovation or process is perceived as being superior to that which preceded it.

SMEs Amidst Global Technological Changes

Nabeel A. Y. Al-Qirim
United Arab Emirates University, UAE

BACKGROUND AND IMPLICATIONS

In small countries such as New Zealand, small to medium-sized enterprises (SMEs) are defined as enterprises employing 19 or fewer employees. Small enterprises are defined as those employing zero to five full-time employees (FTEs) (often called microbusinesses), and medium-sized enterprises as those employing six to nineteen FTEs. Other countries, such as the United States and European countries, define their SMEs as having a much larger number of employees (200–500 or fewer).

SMEs contribute significantly to the economies and to the employment levels of different countries in the world. For example, SMEs constitute around 95 percent of enterprises and account for 60–70 percent of employment within the countries of the Organisation for Economic Cooperation and Development (OECD, 1997) and other countries across the globe, including the United States. Not to forget that SMEs are usually the source of most of the profound inventions and innovations (Iacovou, Benbasat, & Dexter, 1995).

Historically, SMEs have been accused of being uncritical about the strategic importance of IT and its use in their businesses. This laggardness in adopting or using IT in business was attributed to various organisational, technological, and environmental deficiencies in SMEs. The recent emergence of the Internet, in general, and the Web, in particular, revolutionises business activities (Abell & Lim, 1996) and promises to provide unprecedented opportunities to SMEs to expand in scope and in market reach.

However, despite the apparent media hype (Premkumar & Roberts, 1999) and the enthusiasm among academicians (Adam & Deans, 2000; Abell & Lim, 1996; *Infotech Weekly*, 1997; Poon & Swatman, 1999a) and professionals (Deloitte, 2000; IDC, 1998; PWHC, 1999) about electronic commerce (EC), the published EC research portrayed a gloomy picture about EC uptake and use by SMEs. Thus, investigating reasons behind such laggardness in adopting and in using EC effectively is essential. This research attempts to highlight some of the important issues that could assist in bridging the existing divide between SMEs and EC. These issues could be of interest to SMEs and to other stakeholders interested in SMEs and EC.

ELECTRONIC COMMERCE SUCCESS IN SMES

In the SMEs scenario, different research emphasised the different EC advantages to SMEs (Abell & Black, 1997; Abell & Lim, 1996; Adam & Deans, 2000; Deloitte, 2000; Poon & Swatman, 1997, 1998, 1999a,b; PWHC, 1999):

1. The Internet is an efficient communication medium and a vast resource for information. The SMEs could use e-mail technology to communicate efficiently with their buyers and suppliers, reducing communication costs, including the buying of expensive equipment (e.g., fax/telex).
2. The Internet provides added-value services to customers/partners/suppliers by providing different primary/supplementary information about the organisation's industry, products, and services on their Web sites. This could result in increasing the loyalty and the stickiness of their customers (customer resource management; CRM). The preceding tangible and intangible tactics are of strategic importance in retaining and increasing customer bases by increasing switching costs.
3. The Internet would provide new opportunities to SMEs, otherwise not possible before the introduction of the Internet, such as the ability to reach global markets and the ability to mass-customise products and services to appeal to the different tastes of global consumers.
4. SMEs would adopt EC for image-enhancement purposes. Having an Internet account (URL, dot-com, Web page) and printing an e-mail address on business cards and letterhead were reported as major drivers as well. Whether the SMEs were able to elevate from such initial depiction to a more strategic posture in adopting more strategic EC initiatives, such as selling and buying online, is worth further investigation from the perspective of the different countries.

On the other hand, the EC research highlighted the following impediments:

1. Technological impediments: e.g., security (privacy concerns, viruses, e-payments), legalities (enforceability of contracts, confirmations of receipt, prosecutions), policies (lack of global or unified standards), telecommunication services [bandwidth, convergence, reliability and quality of services (QoS)]
2. Organisational impediments: cost, busy nature, small size and limited resources, lack of knowledge/expertise about EC
3. Environmental impediments: Relating to the lack of regulatory frameworks pertinent to the above technological impediments highlighted in (1), above, either at the one-country level or even at the global level.

In the light of the above advantages and impediments, most of the existing EC research found most of the SMEs not witnessing real benefits (direct sales and tangible profits) in the short term due to difficulties in selling products over the Internet (Adam & Deans, 2000; Poon & Swatman, 1998, 1999a). Face-to-face interactions with customers and buyers proved to be more dominating than electronic interfaces (Ba et al., 1999; Poon & Swatman, 1997). They found the key motives for SMEs to adopt EC are the long-term indirect benefits, e.g., ongoing business transformation and new business initiatives (new opportunities), which could resemble a preparatory stage (infrastructure) for the long-run direct benefits stage (secure returning customers and form long-term business partnerships) (Poon & Swatman, 1998, 1999a). However, the biggest challenge for the SMEs here is to succeed in moving from such simple and preparatory EC initiatives (driven mostly by hype from the media, professionals, and researchers) to more sophisticated and strategic initiatives (e.g., efficiency à effectiveness à strategic advantage).

On the one hand, having EC requires an apparent investment in different areas: technological infrastructure upgrades or replacement, EC integration with existing IT systems, EC consultants, investments in bandwidth and applications (Web site, intranet, extranet, etc.). However, this considerable investment in the EC infrastructure is necessary to make it possible to process information efficiently, handle heavy traffic, and deliver satisfactory performance. SMEs would perceive this to be an expensive endeavour and, hence, represent a barrier to EC adoption (MOED, 2000; PWHC, 1999). It is worth mentioning here that unlike the investment in information science/information technology (IS/IT), which requires high initial investment and smaller ongoing maintenance and support costs, EC would require considerable continued investments in upgrading, overhauling, and replacing the whole EC system with an innovation or new designs, etc. Most probably, the investment in EC would materialise in the long term only as highlighted earlier (Poon & Swatman, 1998, 1999). However, this depends on different factors, such as the ability to develop economies of scale (Ba et al., 1999; Poon, 2000), e.g., having a well-established online customer base and ongoing business that enables the firm to sell massively and cheaply at the same time.

With the introduction of new EC technology like the intranet, Internet electronic data interchange (EDI), extranet, Web site, etc., there would be some fundamental changes in work processes and current practices (Alexander, 1999; Behrendorff & Rahman, 1999). EC is not only a new way of selling and marketing, but also a new way of thinking, which requires a change of mindset. Teo, Tan, and Buk (1998) pointed to the fact that organisations attempting to adopt the Internet should expect a possible change in communication and culture patterns. EC is changing the way business is conducted, even with individual customers. Firms that are able to streamline their products or processes or delivery agents on the Internet will be able to shift entirely to the pure EC arena (Choi et al., 1997). The success stories of small businesses using the Internet are apparent and are publicised and reported by the media. However, most of the businesses existing on the Internet are not necessarily transacting information-based products only, but rather complementing the sale and the delivery of a physical product with such things as publishing information about the usability of a physical product (e.g., user manuals), tracking the shipment, etc. (Teo et al., 1998).

Most of the IS literature on SMEs (Blili & Raymond, 1993; Cragg & King, 1992, 1993; Harrison et al., 1997; Jarvenpaa & Ives, 1991; Thong, 1999; Thong & Yap, 1995, 1996) and EC in SMEs (Poon & Swatman, 1998, 1997, 1999a, 1999b) emphasises the role and the characteristics of the manager (usually the owner) as a product champion. Poon and Swatman (1998, 1999a) pointed to the manager's role in their EC study, where they found direct management involvement was the norm in the different cases. Although the managers of small business lack formal IT qualifications and training, they were champions in adopting EC, specifically in microbusinesses, where the sole decision maker was the director of the business.

Due to the recent nature of EC, it is expected that the adoption decision for EC would include some sort of high-risk elements. Hence, the adoption decision for EC would require a risk-taking manager. Poon and Swatman (1997, 1998, 1999a) found that the entrepreneurial perspective differed between the different firms in their study. Managers/owners embraced EC technology and attempted to exploit it to the maximum. The managers who championed Internet adoption in their organisations demonstrated an innovative and risk-taking attitude toward EC, despite lacking formal IT training.

Adam and Deans (2000) and Poon and Swatman (1998) pointed to the market scope of small business, where SMEs transacting with international markets would perceive many advantages from the Internet, such as cost savings and market communication in comparison with other SMEs operating in local markets. In this scenario, EC is perceived to increase global competition and provide different opportunities to SMEs. Poon and Swatman (1999a) asserted that if a small business retained a high percentage of customers and competitors online, this would increase the chances of adopting EC.

The field of EC is relatively new, and the actual functioning and utilisation of EC technologies are still unknown to most organisations (Teo et al., 1998), including SMEs. Therefore, it is expected that SMEs planning to adopt EC would seek assistance from consultants and vendors in the industry in different areas, such as planning and strategy, training, development, and implementation (Deloitte, 2000). Determining how efficient the technology vendors are in providing feasible and well-integrated EC products and services to SMEs is worth investigating in different countries.

CONCLUSION

SMEs contribute significantly to the national economies and to the employment levels of different countries and represent a viable source for inventions and innovations. The emergence of EC in the early 1990s could provide different opportunities to the small business sector to overcome its inadequacies. However, in review of the electronic commerce/business (EC) literature in organisations, in general, and in SMEs, specifically, it was observed that the available research portrayed a gloomy picture about EC uptake and use by SMEs. Therefore, this research attempted, by reviewing recent EC research, to depict an agenda for EC success in SMEs. By following the suggested guidelines in this research, SMEs could be in a better position to assess the viability of the new EC phenomenon to their survivability in the long term. Specifically, these points are addressed to the managers/owners of the SMEs in identifying the different perspectives surrounding the new innovations. These factors are of high importance to researchers, SMEs, professionals (including educational institutions), and policy makers in driving SMEs and EC forward.

INTRODUCTION

Today's Information Age is having a dramatic effect on businesses as well as on the life styles of people. Globalization, rapid technological change and the importance of knowledge in gaining and sustaining competitive advantage characterize this information age. Traditionally, economists have seen capital, labor, and natural resources as the essential ingredients for economic enterprise. The new economy of the 21st century is increasingly based on knowledge with information, innovation, creativity and intellectual capitalism as its essential ingredients (Persaud, 2001). Today's modern economy then, is based more on intangibles, information, innovation, and creativity, and their abilities to facilitate expanding economic potential (Persaud, 2001) and the exploitation of ideas rather than material things. Many new terms have been coined for this new economy such as "knowledge-based economy", "borderless economy", "weightless economy". and "digital economy" to name a few (Woodall, 2000). This new economy seems to defy the basic economic law of scarcity which means, if a physical object is sold, the seller ceases to own it. In this new economy, however, when an idea is sold, the seller still possesses it and can sell it over and over again (Woodall, 2000). Traditional economic theory assumes that most industries run into "diminishing returns" at some point because unit costs start to rise, so no one firm can corner the market. In the new economy, knowledge-based products and services have "increasing returns" because knowledge-based products are expensive to produce for the first time, but cheap to reproduce. High fixed costs and negligible variable costs give these industries vast potential for economies of scale (Sharma, Wickramasinghe & Gupta, 2003; Woodall, 2000).

The shift to a knowledge-based economy results largely from developments in information and communications technologies. A company's knowledge assets are inherent in the creativity of its knowledge workers combined with technological and market know-how (Halliday, 2001). Information can now be delivered with such speed that companies must develop their knowledge assets to solve competitive problems. Knowledge-based economies offer huge opportunities for small and medium-sized enterprises (SMEs) to develop entirely new high-value products and services, add value to existing products and services, reduce costs, develop new export markets, and add value to existing activities. Implicit promises include access to world markets, low cost entry into new markets, and the ability to gain efficiencies in business processes. However, these promises may be illusory for most SMEs. Technological, organizational, and marketing hurdles are also making it more difficult for SMEs to succeed in knowledge-based economies (Acs, Carlsson, & Karlsson, 1999; Persaud, 2001). This article identifies those major factors that are hindering the success of SMEs in knowledge-based economies.

THE KNOWLEDGE-BASED ECONOMY

In a knowledge-based economy, knowledge drives the profits of the organizations for gaining and sustaining competitive advantage. Intellectual capital, that is, employees, their knowledge of products and services, and their creativity and innovity, is a crucial source of knowledge assets. The knowledge-based economy is all about adding ideas to products and turning new ideas into new products. Thus, the knowledge-based economy is all about adding ideas to products and turning new ideas into new products. Realizing the importance of knowledge assets, many companies have changed their traditional organization's structures. The traditional command and control model of management is rapidly being replaced by de-centralized teams of individuals motivated by their ownership in the companies (McGarvey, 2001; Sharma et al., 2003).

The new structure of the economy is emerging from the convergence of computing, communications and content. Products are becoming digital and markets are be-

Table 1. Key factors for SMEs

Factors	Description
Lack of Sustained Technology Developments	While borderless electronic trade and online trading hubs are opening up, many more opportunities for small- and medium-sized enterprises (Jordan, 2000), is proving to be a difficult task for SMEs in ever increasing technological environments. Only 35% of small businesses have an Internet Web site, and of those only 2% have sites with e-commerce transactions (Kleindl, 2000). Asian SMEs are even further behind the times due to poor penetration of Internet technologies and slow growth of electronic commerce infrastructure (Jordan, 2000).
Lack of Proper Information	SMEs require proper guidance in making the right choice of technology suited to their needs. Many SMEs do not have the ability, time or energy to shift to new technology either due to lack of expertise at their own level or absence of proper guidance, advice and support from big companies. Not only do they lack information about the availability and sources of the new technology, but they also lack a resource base for searching for partners (Jordan, 2000).
Inertia to Change	Many small businesses are too content to change, despite the often-surprising rewards of taking that step into the future. For example, SMEs can benefit from powerful enterprise resource planning (ERP) tools and customer relationship management (CRM) software technology solutions without investing in them, because they can rely upon rental-based enterprise solutions such as application service providers (ASPs) to provide these solutions.
Slow to Adapt E-commerce	The Internet and the Web environments are bringing fundamental changes in traditional business models. SMEs often lack the resources of larger firms and may not have the brand name recognition of Internet first movers.
Encroachment by Big Corporations into Niche Areas	The Internet and the online environments are having a major impact on how businesses operate. The Web environments allow customers to easily search and find competitive information and new sources of supply (Kleindl, 2000). SMEs have traditionally been able to gain the advantage over larger competitors by developing personalized relationships with customers, customizing their offerings, and efficiently targeting niche markets (Kleindl, 2000).
Commoditization of Suppliers	SMEs face additional pressure due to the commoditization of suppliers. This occurs when the customer can find a large number of suppliers with relatively similar offerings and then have them bid for the sale.
Competition from First Movers	SMEs face competition with online competitors who have first mover advantages. Firms that are Web pioneers already have cost advantages as they move along experience curves that relate to personnel training and management in Web practices.
Weak Supply Chains	Online communication and developing links with suppliers are impacting almost all businesses including SMEs.
Lack of Expertise	The Internet allows SMEs to communicate and transact business at any time. SMEs can use the Internet and information technologies to create unique products and services for their customers that differ from the competition.

Table 1. Key factors for SMEs (continued)

Barriers to International Trade	Export and internationalisation are important to the survival of many SMEs because of their tremendous potential for enhancing sales growth, increasing efficiency and improving quality (Masurel, 2001). SMEs find it difficult to form international partnerships, or may lack managerial experience and competence, and have difficulty in gathering information.
Lack of Awareness of Management Processes	As our economy becomes more connected to the global marketplace, SMEs need awareness of management processes and tools to create competitive advantage (Monk, 2000).
Long Lead Times	The rapid economic and technological developments in the globally-oriented business world make the strategic use of information technology (IT) essential yet SMEs are somewhat behind regarding the application of IT (Knol & Stroeken, 2001).
Poor Management and Accounting Practices	The role of finance has been viewed as a critical element for the development and participation of small and medium-sized enterprises (Cook, 2001). Levy has highlighted the limited access to financial resources available to smaller enterprises compared to larger organizations and the consequences for their growth and development (Levy, 1993).
Intense Market Competition in International Trade	Many SMEs are relatively inexperienced operators in international trade. SMEs face the challenge of intense market competition for trade promotion. Adapting to a new global trading environment presents a challenge to SMEs.
Inefficient Value Chains	The rapid development of the World Wide Web as a communication and marketing medium offers small and medium-sized enterprises tremendous opportunities of access to world markets, low-cost entry into new markets, and the ability to gain efficiencies in business processes (Kleindl, 2000). However, SMEs require restructuring of value chains because business models of a knowledge-based economy are very different than the earlier traditional businesses.

coming electronic. In the old economy, information flow was physical: cash, checks, invoices, bills, reports, face-to-face meetings, analog telephone calls, radio or television transmissions, and so forth. Relationships with trading partners, customers and suppliers, distribution networks, intellectual property, patents, image, and so forth, are all elements of a knowledge economy. These elements represent intellectual capital. The knowledge-based economy is based on the application of human know-how to everything we produce; and hence, in this new economy, human expertise and ideas create more and more of the economy's added value. The knowledge content of products and services is growing significantly, as consumer ideas, information, and technology become part of products. In the new economy, the key assets of the organization are intellectual assets in the form of knowledge (Anonymous, 2001; Cowey, 2000; Gold, Malhotra, & Segars, 2001; Granstrand, 2000; McGarvey, 2001; Sharma et al., 2003).

KEY ISSUES AFFECTING PARTICIPATION AND SUCCESS OF SMES IN THIS ECONOMY

It is not enough just to highlight the critical elements of today's knowledge-based economy; we must now understand the various factors affecting the participation and success of SMEs in this economy. We identify 15 important factors which are summarized in Table 1.

CONCLUSION

We believe that SMEs should find many more new opportunities in today's knowledge-based economy, but at the same time, may be threatened in competitive environments that can force SMEs to modify or completely abandon many current business practices. SMEs must consider new business models that take advantage of existing and emerging Internet-based technologies in order to stay competitive. SMEs have to introduce new technologies to enter into global markets and find ways to attract customers if they want to compete in global scenarios. As larger organizations are entering into Internet-enabled businesses, SMEs have to upgrade their tools and techniques to equip themselves with the abilities to compete with large organizations. In addition, more has to be done to encourage stability and growth in the small to medium-sized business sector, and to establish globally competitive firms. Many small manufacturers do not have the resources required to transform their businesses in response to the digital economy's rapid evolution. It may be necessary for SMEs to redesign many of their traditional business processes to compete in the new economy. SMEs face the challenges of fast changing technology and business scenarios in the knowledge-based economy. Combining the right business strategy along with the most effective technology tools would improve the chances of SMEs participation in knowledge-based economy.

KEY TERMS

Customer Relationship Management (CRM): Simply stated, customer relationship management (CRM) is about finding, getting, and retaining customers. CRM are those aspects of a business strategy which relate to techniques and methods for attracting and retaining customers.

E-Commerce: The conduct of buying and selling of products and services by businesses and consumers over the internet. E simply means anything done electronically, usually via the Internet. E-commerce is the means of selling goods on the Internet, using Web pages.

Knowledge Economy: The knowledge-based economy is all about adding ideas to products and turning new ideas into new products. Relationships with trading partners, customers and suppliers, distribution networks, intellectual property, patents, image, and so forth, are all elements of a knowledge economy. These elements represent intellectual capital.

Learning Organizations: Those that have in place systems, mechanisms and processes, that are used to continually enhance their capabilities and those who work with it or for it, to achieve sustainable objectives " for themselves and the communities in which they participate.

Small and Medium-sized Enterprises (SMEs): As per European Commission definition, small and medium-sized enterprises, referred as "SMEs", are defined as enterprises which: have fewer than 250 employees; and have either an annual turnover not exceeding 40 million EURO, or an annual balance-sheet total not exceeding 27 million EURO as shown in Table 2.

Web Portal: Commonly referred to as simply a *portal*. Web portal is a Web site or service that offers a broad array of resources and services, such as e-mail, forums, search engines, and online shopping malls. The first Web portals were online services, such as AOL, that provided access to the Web, but now most of the traditional search engines have transformed themselves into Web portals to attract and keep a larger audience.

Table 2. SMEs

	Medium-sized	Small	Micro-enterprise

Max. turnover (in million ECU)	40	7	-
Max. balance-sheet total (in million ECU)	27	5	-

Social Responsibility and the Technology Paradigm in Latin America

Herberto Ochoa-Morales
University of New Mexico, USA

INTRODUCTION

In Latin America, regional as well as multilateral integration schemes have a predominant role within integration agreements. A representation of this includes MERCOSUR: Brazil, Argentina, Uruguay and Paraguay. The Andean Community of Nations (CAN) is composed of Bolivia, Ecuador, Colombia, Peru, and Venezuela and the Group of Three (G3): Colombia, Mexico, and Venezuela. Another regional pact is the CARICOM, composed of English speaking countries within the Caribbean Basin. These organizations have the intent to establish, among other components, free trade areas, customs unions, common markets, and economic unions; all covenants that, in the future, may evolve into a political union (S.C.A. et al., 1998).

Under the scheme of regional integration, a high flow of goods, services, and investments between countries will be originated primarily under the format of foreign direct investments (FDIs). From the economic perspective, the outcome is trade and, therefore, stimulus to economic growth. By the year 2000, Latin America's regional agreements CAN and MERCOSUR, without considering other regional pacts with Chile, had a potential market of 310 million consumers (UN-CEPAL, 1999a). Chile's contribution alone is 15.2 million potential customers. It should be emphasized that the CAN countries will have, by the period 2000-2005, an average increase in population rate of 17.98 per thousand, while MERCOSUR will have 13.96 and Chile 11.8 per thousand increases respectively (UN-CEPAL, 1999b).

The research literature concurs on the importance of technology as main factor embedded in the productivity equation. The "digital gap" between developed countries (DC) and the less developed ones (LDC) is greater than the one built by economic indicators such as productivity; and socio-economic ones like "standard of living". In March 2000, the number of users on the Internet was approximately 304 million. The United States of America and Canada have 45%, Europe 27%, the Asia-Pacific region 23%, and Africa and the Middle East 1.5%. Latin America and the Caribbean hold 8% of the world population, but only 3.5% of Internet users and less than 1% of the global e-commerce, but at the same time the growth rate has been the highest in the world, and the number of users was 14-fold within the 1995 to 1999 period (UIT, 2000).

The literature emphasized the growth of e-commerce in the decade of the 90s that has occurred by improvement of computer-based power and convergence taking place with telecommunications. Nevertheless, there are other factors associated with the developments that include, but are not limited to, the role and social responsibilities of the public and private sectors in driving and sustaining infrastructure development. E-commerce has shown a rapid development in Latin America. Brazil reached 4 million users in 1999. This represents 50% of the interconnected population - Argentina 12%, and Chile 4%. It is necessary to emphasize the fact that 80% of electronic commerce is realized within six realms: supermarkets, books, hardware and software, electronic equipment, music, and financial services (UN-CEPAL, 2000b).

Another "gap" present in Latin America that has a great repercussion on the digital economy is the one that could be defined by its components: socio-economics and technology. Further, there is an uneven distribution of wealth between countries, and within them. A large price differential regarding telecommunications cost and coverture exists. The governments of the region have accomplished basic strides so the mass population will have access to the Internet. Peru has created The Peruvian Scientific Network, known by its Spanish abbreviation, RCP. The network is composed of 1,000 public centers that provide service to 40% of the network. In Argentina, the program argentina@internet.todos has approximately 1,000 tele-centers located in low income and remote areas (UIT, 2000).

The position of the Latin American countries within the framework of a knowledge-based society could be described as a transitional one. To acquire the objective of one, state intervention through laws and regulations, and furthermore, private and public actions will be essential in view of the peculiar contrasts in the region. It will be wearisome to expect the market forces alone to furnish the needed mechanisms. Also, the implementation of adequate legal framework that determines the rules and regulations, not only for the suppliers of services, but to compensate power concentration generated by the technology in the hands of the industrialized countries and multinational enterprise (MNE) are imperative (Katz & Ventura-Dias, 2000).

The literature concurs that computer information systems is a function of various parameters, and among them, the ones that could be identified as related to communication and diffusion are: cost of telephone service, and the structure and behavior of the market that compose the Internet services. There are least five relevant parameters in the market of information transmission that will be identifiable, which contribute to shape the Internet: 1) the carriers, 2) the access providers, 3) the service providers, 4) the content providers and 5) the end users. These schemes generate conflict and competition. International firms cover the first two levels; meanwhile, the rest are national enterprises within country members of regional or multilateral agreements (UN-CEPAL, 2000b).

BACKGROUND

In the last decade, the telecommunication sector in Latin America has grown enormously. Privatization and the development of new technologies have performed a critical role in this process. During the decade of the 90s, 2/3 of the countries of the region totally or partially privatized the telecommunication domain. At the same time, the arrival of new technologies such as cellular telephones and cable television has generated substantial changes in the sector. The case of Venezuela and Paraguay deserves special attention due to the fact that there are more cell phones than conventional ones (UIT, 2000).

In Latin America only 1/3 of all homes have telephone service. The growth and covertures of the telecommunication sector are functions of the regulatory framework in which they are developed. In many cases, monopolies have been created. Other good indicators of improvement in the sector are the digitalization of the telephone systems, an increase in the number of public telephones, and the improvement of repair time (UIT, 2000). Social factors have to be taken in consideration regarding the infrastructure of telecommunications; 25% of the region population lives on an income of $1 a day. The access to the Internet services in absolute terms is less than the U.S., although it is prohibited to the great majority of the population due to poverty. Government involvement could provide a solution to the problem of subsidizing services and the necessary hardware and software (UN-CEPAL, 2000b). A notion exists that the Internet revolution would narrow the gap between the world's rich and poor. The evidence shows that the opposite could happen and many developing countries are located on the wrong side of a widening knowledge gap if they do not act almost immediately. The DCs use different approaches to deal with the digital divide. The U.S. approach comes out of the "trade vector" because U.S. firms have large investments in the New Economy. They aggressively seek market expansions. The "state vector" represented by European firms emphasizes the state responsibility and sustainable development. The northern hemisphere countries', "donor states," approach is to find the best way to penetrate foreign markets and use their investments in the most cost-effective mode. The southern hemisphere countries, "host states," are concerned with how to attract investments that could generate growth and therefore jobs and wealth that will assist in the struggle to reduce social inequities (Conhaim, 2001).

Across the literature, authors agree on a definition of social responsibility as moral obligation of business organizations to seek goals that will provide common good for the communities that are beyond those required by business itself. According to Adams (2000), the business' main responsibility is the shareholders concern; therefore, society should not expect large investment or involvement within the communities where they function. Also, the author stated that business organizations look forward for the government to provide and maintain the necessary infrastructure for them to operate. Epstein (1998) confirmed that corporations are institutions that exist to fulfill societal purpose and the common good of the community is the underlying principle for their continued existence. The author defined corporate social policy process (CSPP) as a concept to provide the tools and operational framework to assist business managers in the consideration of social policies in the decision-making process. The foundation of CSPP is the internalization within business organizations' key elements from business ethics, corporate social responsibility and corporate social responsiveness (Epstein, 1998). The latter eliminates a vacuum in the decision-making process that could have as a result the instance that the literature recognized as "bounded rationality," which is the "good enough solution" for a particular problem.

Brazil has the privilege to count within its information technology assets The Committee for Democracy in Information Technology (CDI). This not-for-profit organization has as its goal to reduce the digital gap affecting individuals of low-income communities not only in the country but also throughout the world. In addition to bringing information technology (IT) to the less privileged, CDI promotes notions of human rights, literacy, ecology, health, and non-violence, among other important social teachings that will help to cover the social responsibility vacuum created by the lack of involvement of domestic businesses, MNEs, and public and private institutions. Currently, Brazil has 19 regional CDI centers with 311 schools of information technology and citizenship. Internationally, CDI operates 25 centers located in

Chile, Colombia, Japan, Mexico and Uruguay, for a grand total of 336 schools. The Japan Center located in Tokyo is mainly used to collect hardware that later is sent to LDCs. CDI was created in 1993 by a young professor of information technology, Rodrigo Baggio, with an initial slogan of "Computers for everyone" (*htpp://cdi.org.br*).

United Nations' Economic and Social Council, based on the decision 1999/281, resolved that the high level segment of the agenda for the year 2000 would be dedicated to "The Development and International Cooperation in the XXI Century: The Function of Information Technology in the Context of a World Economy Based in Knowledge". Therefore, representatives of Latin American and Caribbean Countries met in the town of Florianopolis, Santa Catarina, Brazil on June 20 to 21, 2000 to issue the guidelines to design and implement the necessary mechanism to move these countries into the "knowledgeable society" (UN-CEPAL, 2000a).

The mechanism of social responsibility will need to be based on an agenda that will contain several public policies to increase the efficiency and equity during the transition to a knowledge-based society. These include, but are not limited to, cost of telecommunication services, access to the digital network, and cost and accessibility to the computational structure. Education of the users at any level is necessary and access must be provided to the mass population with scarce financial resources for the information society. To reach the latter, the establishment of terminals in public places and community centers is necessary. All of these have to be performed within a legal framework that provides the essential elements to guarantee electronic transactions and therefore the ability to generate a large volume of trade using these media.

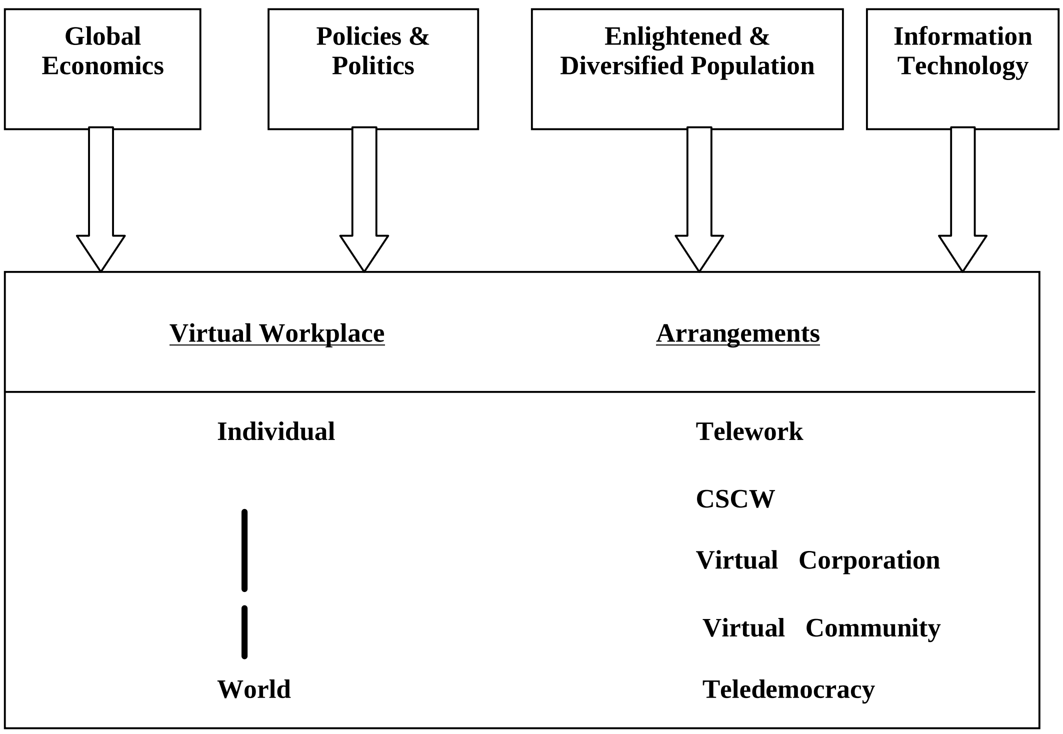
FUTURE TRENDS

The synergism generated by countries, members of regional and/or multilateral agreements allows them to obtain the necessary endowment to develop the infrastructure required for a virtual society. Also, this synergism contributes to dissipate the concentration of power originated by the technology in the hands of the DC and MNEs, and provides the necessary significance to establish policies that eliminated the vacuum created by the lack of involvement of business organizations regarding the social implications caused by the virtual society.

CONCLUSION

Driving Forces Model (Figure 1) depicts the framework in which the virtual society evolved (Igbaria, 1999). The

Figure 1. Driving Forces, 1999 ACM, Inc. Reprinted by permission



regional trading block already in place in Latin America will generate an expansion of business into global markets, creating a global economy in which new standards for trade will be present that include, but are not limited to, electronic payments like e-cash, and electronic data interchange (EDI) among businesses located elsewhere. Due to economic and social factors in Latin America, the role of regional governments to provide oversight for this new arrangement is not only preponderant but could be controversial. Elements such as the amount of control to be adopted by the government, regulations, and privatization will be relevant to the development of the knowledge-based society within the legal framework - same as the education and exposure of the population to the new virtual society (Ochoa-Morales, 2001). The Peruvian case portrays the importance of privatization versus a state monopoly in the telecommunication industry. It shows that privatization not only increases the amount of investments and the growth of many parameters within the telecommunication area, but also allows the mass population to have access to the technology (Ochoa-Morales, 2002). Any new policies should contain essential provisions addressing the importance of social responsibility and accountability. This will aid in reaching the goals of helping in the realm of social inequalities. Pertaining to the technology sector, a component that will exert large influence is the volatility of the communication segment due to the availability of new technology and changes thereof. The workplace arrangements such as tele-work, computer-supported cooperative work (CSCW), among others described in the model (Figure 1), are elements that will change the way business is done conventionally and will cause a great impact in social and cultural values within the context of society.

KEY TERMS

Convergence: The occurrence taking place with computing and telecommunications that emphasizes the preeminence of computer-based information and telecommunications networks.

Digital Gap: The disparity or breach among countries generated by the lack of communication infrastructure and computer-based power that contribute to accentuate socio-economic differences.

Knowledge-Based Society: The UN Economic and Social Council decision 1999/281 defines the "function of information technology in the context of a world economy based in knowledge". This decision determines the importance of information technology in conjunction with knowledge to create a society in which these parameters will contribute to disseminate knowledge, create participation among countries and therefore among individuals, and generate economic growth. All the latter will take place within a societal framework that helps to preserve and increase the social and economic well-being of the inhabitants of the world.

Latin America: The part of the American continent located south of the United States border, which extends to the Patagonia.

Privatization: The transfer of government, public owned, or controlled institutions and entities to private enterprise. This was a common public policy in Latin America during the 90s to generate hard currency and support deregulation.

Social Responsibility: The moral obligation of business organizations to seek goals that will provide common good for the communities that are beyond those required by business itself.

Telecommunications: The transmission of data, text, sound, and images over long distances, and the physical infrastructure that supports such endeavor.

Socio–Cognitive Model of Trust

Rino Falcone
Institute for Cognitive Sciences and Technology, National Research Council of Italy, Italy

Cristiano Castelfranchi
Institute for Cognitive Sciences and Technology, National Research Council of Italy, Italy

INTRODUCTION

Humans have learned to cooperate in many ways and in many environments, on different tasks, and for achieving different and several goals. Collaboration and cooperation in their more general sense (and, in particular, negotiation, exchange, help, delegation, adoption, and so on) are important characteristics - or better, the most foundational aspects - of human societies (Tuomela, 1995).

In the evolution of cooperative models, a fundamental role has been played by diverse constructs of various kinds (purely interactional, technical-legal, organizational, socio-cognitive, etc.), opportunely introduced (or spontaneously emerged) to support decision making in collaborative situations.

The new scenarios we are destined to meet in the third millennium transfigure the old frame of reference, in that we have to consider new channels and infrastructures (i.e., the Internet), new artificial entities for cooperating with artificial or software agents, and new modalities of interaction (suggested/imposed by both the new channels and the new entities). In fact, it is changing the identification of the potential partners, the perception of the other agents, the space-temporal context in which interaction happen, the nature of the interaction traces, the kind and role of the authorities and guarantees, etc.

For coping with these scenarios, it will be necessary to update the traditional supporting decision-making constructs. This effort will be necessary especially to develop the new cyber-societies in such a way as not to miss some of the important cooperative characteristics that are so relevant in human societies.

BACKGROUND

Trust (Ganbetta, 1990; Luhmann, 1990; Dasgupta, 1990), in the general frame described above, might be considered as a socio-cognitive construct of main importance. In particular, trust building is always more recognized as a key factor for using and developing the new interactional paradigm.

Trust should not be made indistinct with security. The latter can be useful to protect – in the electronic domain - from the intrusiveness of an unknown agent, to guarantee an agent in the identification of its partner, to identify the sender of a message (for example, by verifying the origin of a received message; by verifying that a received message has not been modified in transit; by preventing that an agent who sent a message might be able to deny later that it sent the message [He, Sycara & Su, 2001]). With sophisticated cryptographic techniques, it is possible to give some solution to these security problems.

However, more complex is the issue of trust, that must give us tools for acting in a world that is in principle insecure (that cannot be considered 100% secure), where we have to make the decision to rely on someone in risky situations. (Consider the variety of cases in which it is necessary or useful to interact with agents whose identity, history or relationships are unknown, and/or it is only possible to make uncertain predictions on their future behaviors.)

Trust should not be made indistinct with reputation, too. In fact, communicated reputation (Conte & Paolucci, 2002) is one of the possible sources on which the trustier bases its decision to trust or not.

The more actual and important example of the usefulness of trust building is electronic commerce, but we must also consider other important domains of Multi Agent Systems and Agent Theory such as Agent Modeling, Human-Computer Interaction, Computer Supported Cooperative Work, Mixed Initiative and Adjustable Autonomy, Pervasive and Ubiquitous Computing. In fact, today many computer applications are open distributed systems (with many autonomous components that are spread throughout a network and interacting with each other). Given the impossibility to rule this kind of system by a centralized control regime (Marsh, 1994), it becomes essential to introduce local tools in order to choose the right partnership and at the same time reduce the uncertainty (deriving from the nature of an open distributed system) associated with that choice.

S

TRUST IN THE NEW TECHNOLOGICAL SCENARIOS

In fact, various different kinds of trust should be modeled, designed, and implemented:

- Trust in the environment and in the infrastructure (the socio-technical system)
- Trust in personal agents and in mediating agents
- Trust in potential partners
- Trust in sources
- Trust in warrantors and authorities.

Part of these different kinds of trust have a complementary relation with each other, that is, the final trust in a given system/process can be the result of various trust attributions to the different components. An exemplary case is one's trust in an agent that must achieve a task (and more specifically in its capabilities for realizing that task) as different from one's trust in the environment (hostile versus friendly) where that agent operates, or again as different from one's trust in a possible third party (arbitrator, mediator, normative systems, conventions, etc.) able to influence/constrain the trustee and representing a guaranty for the trustier (Castelfranchi & Falcone, 1998; Falcone & Castelfranchi, 2001).

Therefore, the "sufficient" trust value of one single component cannot be established before evaluating the value of the other components. In this regard, it is very interesting to characterize the relationships between trust and (partial) control (Castelfranchi & Falcone, 2000).

It is important to underline how trust is in general oriented towards not directly observable properties. It is, in fact, based on the ability to predict these properties and to rely or not to rely on them. Thus, it is quite complex to assess the real trustworthiness of an agent/system/process, not only because - as we have seen - there are many different components that contribute to this trustworthiness, but also because the latter is not directly observable (see [Bacharach & Gambetta, 2001] about signs of trust). The important thing is the perceived trustworthiness that is, in its turn, the result of different modalities of the trustier's reasoning about direct experience; categorization; inference, and communicated reputation.

SOCIO-COGNITIVE MODEL OF TRUST

The Socio-Cognitive model of trust is based on a portrait of the mental state of trust in cognitive terms (beliefs, goals). This is not a complete account of the psychological dimensions of trust. It represents the most explicit (reason-based) and conscious form. The model does not account for the more implicit forms of trust (for example, trust by default, not based upon explicit evaluations, beliefs, derived from previous experience or other sources) or for the affective dimensions of trust, based not on explicit evaluations but on emotional responses and an intuitive, unconscious appraisal (Thagard, 1998).

The word *trust* means different things, but they are systematically related with each other. In particular, three crucial concepts have been recognized and distinguished not only in natural language but also in the scientific literature. Trust is at the same time:

- A mere *mental attitude* (prediction and evaluation) toward another agent, a simple *disposition*;
- A *decision* to rely upon the other, i.e., an *intention* to delegate and to trust, which makes the trustier "vulnerable"(Mayer, Davis, & Schoorman, 1995);
- A *behavior*, i.e., the intentional *act* of trusting, and the consequent *relation* between the trustier and the trustee.

In each of the above concepts, different sets of cognitive ingredients are involved in the trustier's mind. The model is based on the BDI (Belief-Desire-Intention) approach for modeling mind that is inspired by Bratman's philosophical model (Bratman, 1987). First of all, in the trust model only an agent endowed with both goals and beliefs can "trust" another agent. Let us consider the trust of an agent X towards another agent Y about the (Y's) behavior/action α relevant for the result (goal) g when:

- *X is the (relying) agent, who feels trust; it is a cognitive agent endowed with* internal explicit goals and beliefs (the *trustier*)
- Y is the agent or entity that is trusted (the *trustee*)
- X trusts Y about g/α and for g/α.

In the model Y is not necessarily a cognitive agent (for instance, an agent can - or cannot - trust a chair as far as to sustain his weight when he is seated on it). On the contrary, X must always be a cognitive agent: so, in the case of artificial agents we should be able to simulate these internal explicit goals and beliefs.

For all the three notions of trust defined above (*trust disposition*, *decision to trust*, and *trusting behavior*), we claim that someone trusts some other one only relatively to some goal (here the goal is intended as the general, basic teleonomic notion, any motivational representation in the agent: desires, motives, will, needs, objectives, duties, utopias, are kinds of goals). An unconcerned agent does not really "trust": he just has opinions and forecasts. Second, trust itself *consists of* beliefs.

Since *Y*'s action is useful to *X* (trust disposition), and *X* has decided to rely on it (decision to trust), this means that *X* might delegate (act of trusting) some action/goal in his own plan to *Y*. This is the strict relation between trust disposition, decision to trust, and delegation.

The model includes two main basic beliefs (we are considering the trustee as a cognitive agent, too):

- *Competence Belief*: a *sufficient evaluation* of *Y*'s abilities is necessary. *X* should believe that *Y* is useful for this goal, that *Y* can produce/provide the expected result, and that *Y* can play such a role in *X*'s plan/action.
- *Willingness Belief*: *X* should think that *Y* not only is able and can do that action/task, but *Y* actually will do what *X* needs (under given circumstances). This belief makes the trustee's behavior predictable.

Another important basic belief for trust is:

- *Dependence Belief*: *X* believes -to trust *Y* and delegate to it- that either *X* needs it, *X* depends on it (*strong dependence*), or at least that it is better to *X* to rely on it, rather than not to rely on it (*weak dependence*). In other terms, when *X* trusts someone, *X* is in *a strategic situation*: *X* believes that there is interference and that his rewards, the results of his project, depend on the actions of another agent *Y*.

Obviously, the willingness belief hides a set of other beliefs on the trustee's reasons and motives for helping. In particular, *X* believes that *Y* has some motives for helping it (for adopting its goal), and that these motives will probably prevail -in case of conflict- on other motives, negative for it. Notice that motives inducing adoption are of several different kinds: from friendship to altruism, from morality to fear of sanctions, from exchange to common goal (cooperation), and so on. This is why, for example, it is important to have common culture, shared values, and the same acknowledged authorities between trustier and trustee.

Another important characteristic of the socio-cognitive model of trust is the distinction between trust "in" someone or something that has to act and produce a given performance thanks to its *internal characteristics*, and the global trust in the global event or process and its result, which is also affected by *external factors* like opportunities and interferences.

Trust in *Y* (for example, "social trust" in strict sense) seems to consists in the first two prototypical beliefs/evaluations identified as the basis for reliance: *ability/competence* (that with cognitive agents includes knowledge and self-confidence*)*, and *disposition* (that with cognitive agents is based willingness, persistence, engagement, etc.). Evaluation about external opportunities is not really an evaluation about *Y* (at most the belief about its ability to recognize, exploit and create opportunities is part of our trust in *Y*). We should also add an evaluation about the probability and consistence of obstacles, adversities, and interferences.

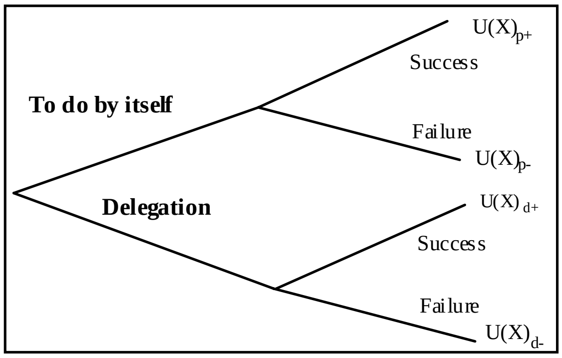
Trust can be said to consist of or better to (either implicitly or explicitly) imply the *subjective probability* of the successful performance of a given behavior a, and it is on the basis of this subjective perception/evaluation of risk and opportunity that the agent decides to rely or not to rely on *Y*. However, the probability index is based on, and derives from those beliefs and evaluations. In other terms, the global, final probability of the realization of the goal *g*, i.e., of the successful performance of a, should be decomposed into the probability of *Y* performing the action well (*internal attribution*) and the probability of having the appropriate conditions (*external attribution*) for the performance and for its success, and of not having interferences and adversities (*external attribution*). This decomposition is important because:

a) The trustier's decision might be different with the same global probability or risk, depending on its composition (for example, for personality factors);
b) Trust composition (internal vs. external) produces completely different intervention strategies: to manipulate the external variables (circumstances, infrastructures) is completely different from manipulating internal parameters.

The idea that trust is gradable is usual (in common sense, in social sciences, in Artificial Intelligence). However, since no real definition and cognitive characterization of trust is given, the quantification of trust is quite *ad hoc* and arbitrary, and the introduction of this notion or predicate is semantically empty. On the contrary, in the socio-cognitive model of trust there is a strong coherence between the cognitive definition of trust, its mental ingredients, and, on the one side, its value, on the other side, its social functions. More precisely the latter are based on the former.

A degree of trust of *X* in *Y* is grounded on the cognitive components of *X*'s mental state of trust. More precisely *the degree of trust is a function of the subjective certainty of the pertinent beliefs*. The degree of trust is used to formalize a rational basis for the decision of relying and betting on *Y*. A "quantitative" aspect of another basic ingredient is relevant: the value or importance or utility of the goal (g). In sum, *the quantitative dimensions of trust are based on the quantitative dimensions of its cognitive constituents*.

Figure 1



If we call $DoT_{XY\tau}$ the degree of trust of an agent *X* about *Y* on the task $\tau=(\alpha,g)$ we have:

- $DoT_{XY\tau} = DoC_X[Opp_Y(\alpha,g)] * DoC_X[Ability_Y(\alpha)] * DoC_X[WillDo_Y(\alpha,g)]$

Where:

- $DoC_X[Opp_Y(\alpha,g)]$, is the degree of credibility of *X's* beliefs about *Y's* opportunity of performing α to realize *g;*
- $DoC_X[Ability_Y(\alpha)]$, the degree of credibility of *X's* beliefs about *Y's* ability/competence to perform α*;*
- $DoC_X[WillDo_Y(\alpha,g)]$, the degree of credibility of *X's* beliefs about *Y's* actual performance*;*
- $DoC_X[WillDo_Y(\alpha,g)] = DoC_X[Intend_Y(\alpha,g)] * DoC_X[Persist_Y(\alpha,g)]$
(Given that *Y* is a cognitive agent)

In any circumstance, an agent *X* endowed with a given goal, has three main choices:

i) To try to achieve the goal by itself;
ii) To delegate the achievement of that goal to another agent, *Y*;
iii) To do nothing (relatively to this goal), renouncing.

Considering the simplified scenario in which only (i) and (ii) are the possible choices we have the Figure1.

Where if *U(X)* is the agent *X*'s utility function, more specifically:

- ***U(X)p+***, the utility of the *X*'s success performance;
- ***U(X)p-***, the utility of the *X*'s failure performance;
- ***U(X)d+***, the utility of a successful delegation (the utility due to the success of the delegated action);
- ***U(X)d-***, the utility of a failure delegation (the damage due to the failure of the delegated action).

In the previous scenario, in order to delegate we must have:

$$DoT_{XY\tau} * U(X)_{d^+} + (1 - DoT_{XY\tau})\, U(X)_{d^-} > DoT_{XX\tau} * U(X)_{p^+} + (1 - DoT_{XX\tau})\, U(X)_{p^-}$$

where $DoT_{XX\tau}$ is the *selftrust* of *X* about τ.

More precisely, we have: $U(X)_{p^+}$ *= Value(g) + Cost [Performance(X)],*

U(X)p- = Cost [Performance(X)] + Additional Damage for failure

$U(X)_{d^+}$ *= Value(g) + Cost [Delegation(X Y)],*

$U(X)_{d^-}$ *= Cost [Delegation(X Y)]+ Additional Damage for failure*

Where it is supposed that it is possible to attribute a quantitative value (importance) to goals and where the costs of the actions (delegation and performance) are supposed to be negative.

FUTURE TRENDS

One of the main aspects that should be analyzed in the next few years is the dynamics of trust and the possibility of introducing all the dynamic aspects in the computational setting in which humans and machines will work together. Trust is a dynamic phenomenon in its intrinsic nature (Falcone & Castelfranchi, 2001). Trust changes with experience, with the modification of the different sources it is based on, with the emotional state of the trustier, with the modification of the environment in which the trustee is supposed to perform, and so on. But, trust is also influenced by trust, itself, in the same specific interaction: for example, how trust creates a reciprocal trust; how the fact that A trusts B can actually increase B's trustworthiness; and so on. In other words, in a computational model of trust relationships we have to consider all the dynamical aspects of the trust phenomenon.

CONCLUSION

The Socio-Cognitive model of trust analyzes the basic elements on which trust is founded in terms of the cognitive ingredients of the trustier. In fact, the richness of the referred model (trust is based on many different beliefs) allows us to distinguish between internal and external attributions (to the trustee) and for each of these two attributions it allows us to distinguish among several other sub-components such as: competence, disposition, un-harmfulness, and so on.

The model introduced a degree of trust instead of a simple probability factor since it permits us to evaluate trustfulness in a rational way.

In other words, if we understand what precisely the basic ingredients of trust are, we would be able to better model and build artificial systems in which this attitude should be present.

KEY TERMS

Cyber-societies: The set of natural, artificial, and virtual agents connected and interacting with each others through natural and artificial infrastructures within virtual institutions.

Reputation: the estimated trustworthiness in an agent as derived from the communicated opinions of other parts (directly or indirectly received); the resulting and emergent "common opinion" about the agent's trustworthiness.

Task: An action and/or a goal an agent has to realize as delegated by another agent; thus – in the opposite perspective - the couple action/goal that an agent intentionally delegates to another agent; where at least the delegating agent knows one between the action and the goal.

Trust: The attitude of an agent to delegate a part of its own plan/goal to another agent and rely upon it in a risky situation (possible failure) on the basis of its own beliefs about the other agent and on the environment in which it operates.

Trustee: the trusted agent in the trust relationship.

Trustier: the trusting agent in the trust relationship.

Ubiquitous Computing: The trend of the technological development to integrate into any kind of object information processing and communication capabilities.

Softening the MIS Curriculum for a Technology-Based Profession

Glenn Lowry
United Arab Emirates University, UAE

Rodney Turner
Victoria University of Technology, Australia

INTRODUCTION

Information systems[1] (IS) professionals help to achieve business and organizational goals through the use of information technology. The information systems profession is team oriented and project based.

Students are first and foremost concerned with future employability. Employers, on the other hand, often indicate that they want new graduates who can be immediately productive in their environment.

Are the aspirations of students and employers fundamentally incompatible? How can IS educators help to find a workable and satisfying balance? How can information systems educators soften and refine the design of information systems curricula to achieve a better fit between the workplace and the university 'studyplace'?

BACKGROUND: BALANCING THE MIX OF HARD AND SOFT SKILLS IN THE IS/IT CURRICULUM

The preparation of information systems (IS) professionals must encompass a body of knowledge and a repertoire of technical and 'soft' skills identified by various professional bodies (Cheney, Hale & Kasper, 1990; Davis, Gorgone, Feinstein & Longenecker, 1997; Gorgone & Gray, 1999; Underwood, 1997; Lidtke, Stokes, Haines & Mulder, 1999; Cohen, 2000; Mulder & van Weert , 2000; ACM-AIS, 2002).

The persistent research finding that employers want graduates who possess better business skills is often interpreted by academics to mean that more traditional, formal business subjects such as accounting, economics, business finance, and marketing should be taught alongside traditional technical or 'hard' skill subjects such as systems analysis/design and programming in particular languages (Trauth, Farwell & Lee, 1993; Van Slyke, Kittner & Cheney, 1997). On the other hand the 'soft' areas such as teamwork, communication skills, ability to accept direction, and others are somehow 'picked up' along the way through an unspecified, osmotic process and not addressed as part of a curriculum.

The past few decades have been characterized by a rapidly and constantly changing business environment. Lee, Trauth, and Farwell (1995) argued that technological and sociological developments facilitated by evolving information technology and changing business needs has made it necessary for IS professionals to develop a wider range of non-technical skills than was previously the case. Similar views have been expressed by many others, including Burn, Ng, and Ma (1995), Cafasso (1996), Lowry, Morgan, and FitzGerald, (1996), and Morgan, Lowry, and FitzGerald (1998).

The work presented here is part of an ongoing research program that investigates the views of major IS curriculum stakeholders, including employers, IS practitioners, currently enrolled students, and academics. The data were gathered from a survey of IS practitioners and IS decision makers in Australia, and covered all industry sectors as well as business unit sizes. We argue that IS practitioners, employers, and students see little value in some of the more formal business subject areas that often form the core of an IS degree offered in a business or commerce faculty. These stakeholder groups see more value in the development of 'soft skills' useful in client interaction. The findings have serious implications for IS educators and IS curriculum design (Turner & Lowry, 1999a, 1999b, 2000, 2001, 2002, 2003).

IS CURRICULUM CONTENT AND DELIVERY IN THE FIRST DECADE OF THE 21ST CENTURY

In a 1999 study, the authors began to suspect that the 'other business skills' desired of new IS graduates were not synonymous with traditional business curriculum subjects. Study results indicated that of nine business subjects that are typically included in IS curricula, only three—*Accounting*, *Business Ethics*, and *Management*—were judged to be important by students and employers.

Follow-up studies were conducted in 2001 and 2002 to further explore the 'other business skills' aspect of the IS curriculum (Turner & Lowry, 1999b, 2001, 2002, 2003). Tables 1 and 2 show comparative ratings of 'hard' or traditional IS and business subjects, and of 'soft' skills by information systems and technology professionals and employers.

COMPARATIVE RATINGS OF ACADEMIC SUBJECTS BY IS PRACTITIONERS AND EMPLOYERS

The research instruments contained two sections pertaining to academic preparation of graduates. These two sections separately covered the technical areas of an IS business degree and the other academic areas that are not specific to IS. Subjects responded to each question using a seven-point Likert scale (1= irrelevant, 7 = essential). Table 1 shows the mean and standard deviation of ratings of academic subjects and soft skills by *Information Systems/Information Technology (IS/IT) Professionals* and *IS/IT Employers.*

Of the 14 subjects/skills in Table 1 that achieved a mean rating of 5.0 or more, the highest rating by both practitioners and employers was achieved by *Communications & Report Writing,* a soft skill. *Analysis and Design,* a core IS academic subject, was rated highly by both IS/IT professionals and employers. The value placed on these two subjects is consistent with earlier (1999) findings by the authors.

Eleven technical subjects and two 'other business subjects'—management and business ethics—achieved mean ratings of 5.0 or more. These higher ratings suggest

that these subjects should be included in IS curricula, ahead of other subjects that received lower ratings by practitioners and employers.

COMPARATIVE IMPORTANCE OF SOFT SKILLS BY IS/IT PROFESSIONALS AND EMPLOYERS

A third section in the survey solicited rankings of the importance of a range of so-called ‘soft skills’. The results are presented in Table 2, which shows the ratings by IS/IT professionals and employees for ‘soft’ business skills.

Table 2 shows a marked similarity between practitioners and employers in their ratings of the importance of ‘soft’ business skills. Only the ability to prepare multimedia presentations failed to achieve a mean rating of 5.0. All other soft business skills were highly rated by both IS practitioners and employers.

Unlike the academic subjects in Table 1, many of the soft skills can be identified, grouped together, and developed through formal ‘professional development’ units in IS curricula or specifically taught and assessed as part of formal coursework.

FUTURE TRENDS AND SOME CRITICAL ISSUES IN IS CURRICULUM DESIGN AND DELIVERY

Barriers to meaningful reform and evolution of the IS curriculum include confusion, tradition and inertia, scarcity of resources, and vested interests. Table 3 summarizes these issues and offers recommendations, in increasing order of difficulty.

Table 3. Issues and recommendations for IS curriculum refinement

Confusion: Research results that call for more 'business skills' have handily and traditionally been interpreted as meaning exposure of students to additional, formal business subjects. While an IS student may well gain knowledge and skill in marketing, economic analysis, or international business in that way, our findings suggest that it is the 'soft' skills, rather than formal academic skill, that is wanted by IS/IT practitioners and employers.	**To reduce confusion:** Local course advisory and professional bodies can provide invaluable insight into the mix of technical and non-technical formal courses and 'soft' skills appropriate for a given institution's service area. Focus groups and local replication of available studies should provide targeted, timely, and authoritative guidance for ongoing curriculum evolution**.**
Tradition and Inertia—Content: It is easy to offer traditional business subjects as they are already being taught anyway. In many institutions, the existing IS academic staff would have to acquire the additional academic background and skills needed to introduce a substantive 'soft skills' emphasis into the IS curriculum. In most instances, there may be insufficient time or interest to do so. **Tradition and inertia—Delivery Method:** Many, if not most, subjects are taught in a familiar lecture-practical mode. As a project- and team-oriented profession, information systems programs may well achieve a better match between the workplace *through* the 'study place' through the adoption of active-learning, student-centered delivery methods such as Problem-Based Learning (PBL) and Work-Integrated Learning (WIL) (Bentley, Sandy & Lowry, 2002).	**Overcoming Tradition and Inertia:** To some extent, prospective students have taken matters into their own hands by opting in larger numbers to bypass traditional university courses in favor of industry-sponsored/sanctioned entry gateways such as those offered by Microsoft, Oracle, SAP, and others. It is possible that students electing the non-academic alternative see more value in industry-focused training than in academic education that they see as irrelevant to their career aspirations. A large number of traditional business subjects were rated low in importance by IS practitioners and employers in Tables 1 and 2. Tertiary educators will need to reconsider the value of these traditional business subjects, and will have to develop and deliver revitalized curricula that squarely address the expressed desire for 'soft' skills that have been identified in a number of studies.
Resources: If a substantial portion of an undergraduate degree program were shifted from traditional business subjects to the acquisition and development of 'soft skills', who would develop, teach, and assess the new 'soft skills' curriculum component? We must learn to master what we teach about building client ownership to enlist influential industry partners.	**Finding Resources:** Resources are easier to obtain from a body of satisfied clients, such as the firms who employ our graduates. If we are seen to consult with, listen to, and serve the interests of those firms, they will follow their self-interest and become rich sources of guidance in curriculum planning and development, work experience for students, consultancies for academics, equipment, money, and political weight in our own institution.
Vested Interest: Some academic institutions supplement the enrollment in less relevant or popular subjects through inclusion of those subjects in a popular curriculum such as information systems. In many institutions, economic incentives exist for students to be enrolled in subjects within a single administrative unit, such as a business or IT faculty**.**	**Neutralizing Vested Interests:** Senior university managers may oppose substantive IS curriculum reform such as that discussed in this chapter for a number of reasons, including loss of revenue if students enroll in 'soft' skill courses provided by another administrative unit. It is up to IS educators to develop strategies to address the turf issues that preoccupy some administrators. Building effective partnerships with the appropriate industries in our service area can provide a powerful voice to speak on our behalf to senior management. Accrediting bodies can also help in this way.

CONCLUSION

There has long been agreement that the IS curriculum should be comprised of some combination of technical subjects and non-technical business subjects, and that graduates also need 'soft' business skills. There is far less agreement about what the mix between these should be and how best to prepare students in some areas, notably in the development of 'soft' business skills.

While we agree with the general view that 'soft' skills have become increasingly important, we argue that the traditional business subjects are *not* the business skills primarily sought in studies of the IS marketplace. Does the study of traditional business subjects such as marketing, business law, or economics directly help the students to develop a repertoire of 'soft' business skills? The findings suggest that in reality it is not more core business subjects that are needed, but an appreciation of business processes and activities that are not always covered in IS degree programs.

Some formidable barriers exist to substantive revision of IS curricula to emphasize acquisition and development of 'soft' business skills. In increasing order of difficulty, Table 3 summarizes some of the issues and barriers to meaningful reform, and evolution of the IS curriculum might be surmounted over time and with sufficient dedication. There are, of course, no easy solutions to resolve these issues.

While study after study has called for 'soft' skills acquisition and development by IS students, some IS programs have a clearer and better-developed vision than others of what those skills are, and how they may be introduced and cultivated. The growing emphasis on 'soft' skills in IS education is an indication that what began as a fundamentally technology-oriented discipline is, indeed, evolving into a technology-based profession. We can watch someone else claim that knowledge and the opportunities that it offers, or we can embrace it ourselves, while we have the initiative.

KEY TERMS

Hard Skills: Measurable capabilities and academic knowledge acquired through traditional tertiary study. Current MIS curriculum examples include communications and report writing, systems analysis and design, client/server applications, and business applications.

Inquiry-Based Learning (IBL): A student-centered, active learning approach focusing on questioning, critical thinking, and problem solving. IBL is expressed by the idea "involve me and I understand." The IBL approach is more focused on using and learning content as a means to develop information-processing and problem-solving skills. The system is more student centered, with the teacher as a facilitator of learning. There is more emphasis on "how we come to know" and less on "what we know." Students are involved in the construction of knowledge through active involvement. The more interested and engaged students are by a subject or project, the easier it will be for them to construct in-depth knowledge of it. Learning becomes easier when it reflects their interests and goals, and piques their natural curiosity.

Problem-Based Learning: An active learning strategy that may be suitable for better preparing information systems students for professional practice. In the problem-based approach, complex, real-world problems or cases are used to motivate students to identify and research concepts and principles they need to know in order to progress through the problems. Students work in small learning teams, bringing together collective skill at acquiring, communicating, and integrating information in a process that resembles that of inquiry.

Project-Based Learning: An active learning approach that focuses on developing a product or creation. The project may or may not be student centered, problem based, or inquiry based. Project-based learning uses open-ended assignments that provide students with a degree of choice, and extend over a considerable period of time. *Teachers* act as facilitators, designing activities and providing resources and advice to students. Instruction and facilitation are guided by a broad range of teaching goals. *Students* collect and analyze information, make discoveries, and report their results. *Projects* are often interdisciplinary.

Soft Skills: Cultivated elements of professionalism that derive from example, reflection, imitation, and refinement of attitudes, personal capabilities, work habits, and interpersonal skills, and are expressed in consistent and superior performance, characterized by a customer service and team orientation. Current MIS curriculum examples include ability to work as a member of a team, well-developed oral and written presentation skills, and the ability to work independently.

Student-Centered/Active Learning: Places the student into active, self-directed learning, learning by enquiry, and ownership of the learning goals. Active-learning strategies include Problem-Based Learning (PBL), Project-Based Learning, Inquiry-Based Learning, and Work-Integrated Learning.

Teacher-Centered Learning: Characterized by didactic teaching, passive learning, and the teacher as the 'expert'. Control of learning rests with the instructor. The learning of the students is directed by the instructor and is often based on what the instructor believes the student needs to learn. This approach can lead to students focusing on determining what knowledge they require to pass the subject, rather than the instructional objectives of the program, a phenomenon well-known to educators.

Work-Integrated Learning: A hybrid approach that achieves learning outcomes through a combination of alternating periods of traditional academic pedagogy, with extended periods of practical experience in the professional workplace. Work-Integrated Learning is a mature pedagogical strategy that is often referred to as 'sandwich' and 'end-on' courses.

ENDNOTE

1 The term "information systems" will be used to mean "management information systems" and "informatics" throughout this article.

Software Agents in E-Commerce Systems

Juergen Seitz
University of Cooperative Education Heidenheim, Germany

INTRODUCTION

The Internet introduces a new global marketplace for a large number of relatively unknown and often small companies often offering substitutive or complimentary products and services. The merchants profit from reduced costs, reduced time, and unsold stocks. Customers are attracted by increasing convenience and fast fulfillment.

Merchants offering these products and services on this new marketplace need to acquire new customers and sustain ongoing relationships. Nowadays, most merchants' sites are passive catalogs of products and prices with mechanisms for orders (Dasgupta et al., 1998). The pull strategy is also applied in auctions available over the Internet, where the seller waits passively for bids. The new push technologies for electronic commerce, like software agents, enable customers to compare a bewildering array of products efficiently, effectively, and automatically (Jennings et al., 1998). Switching costs for customers and, thereby, their loyalty to previous suppliers in the marketplace decline.

Using the Internet, the producers profit from reduced cost through direct, non-intermediated sales. The key elements to successful long-term relationships between merchants and customers will be the offering of personalized and value-added services, like one-to-one marketing services, discounts, guarantees, and savings coupons (Seitz et al., 2002, p. 209).

In this article, we will analyze possible consequences of new push and pull technologies in electronic commerce for customers' loyalty. The active technologies enable customers to purchase efficiently and the merchants to offer highly personalized, value added, and complimentary products and services. We will discuss some examples of such services and personalization techniques sustaining one-to-one relationships with customers and other actors involved.

BACKGROUND

The World Wide Web provides a great opportunity to compare products and services. Customers as well as competitors may quickly gain detailed and up-to-date data. Especially, suppliers of digital goods are in fear of declining customers' loyalty. Customers compare catalogs of products of merchants and producers, and conduct transactions independently of their geographic localization. The crucial basic factors responsible for a limited loyalty of customers are convenience, time, and cost of fulfillment. So, an electronic commerce system should support the ability to embed intelligence to automate the decision process (Dasgupta et al., 1998). The system should not only compare products and prices, but also negotiate and finally purchase products (Teuteberg & Kurbel, 2002). Nowadays, most systems still involve a substantial human element that is from the consumer's perspective neither convenient nor efficient. The human involvement should be limited to transaction specification at the beginning of the process and to the buying or refusal decision at the end of the process (Chen, 2000). This means that an appropriate technology is necessary in the intermediate stages to coordinate between customers and suppliers (d'Inverno & Luck, 2003). Mobile software agents emerge as ideal mediators in electronic commerce and thereby as an appropriate technology for an automated procurement process. Customers may specify constraints on the features of products that enable mobile agents to select products from the merchant's catalogs and finally to determine the terms of the transaction. Otherwise, software agents may be used by suppliers as market surveyors to determine the current demand and an appropriate price for the good. Software agent technology also abolishes the problem of different technological standards, like hardware platforms and operating systems of remote computers. This means that geographical or technological barriers for customers are of no significant importance anymore. The key factors are convenience, time and cost of the procurement process.

AGENT MEDIATED ELECTRONIC COMMERCE

Software agents are computer programs showing the following characteristics (Joshi & Ramesh, 1998):

- Reactivity: Agent perceives and reacts to environmental changes.

- Autonomy: Agent has its own program code, data and execution state.
- Proactivity: Agent initiates changes to the environment.

The ability of an agent to travel around in networks enhances it to a mobile agent (Brenner, Zarnekow & Wittig, 1998). Mobile software agents may be classified based on their attributes, like mobility, type of cooperation and level of interactivity (see Figure1) (Joshi & Ramesh, 1998). For further possible classifications see, for example, Nwana (1996), Sycara et al. (1996) or Kurbel and Loutchko (2001).

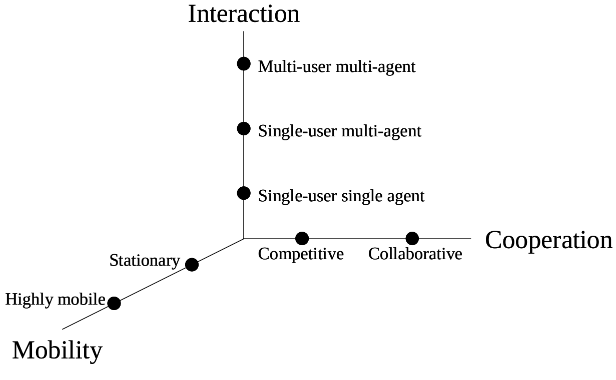
Competitive agents, mostly single-agents, maximize the interests of their owners. Collaborative agents, on the contrary, share their knowledge and try to maximize benefits of the community on the whole (Joshi & Ramesh, 1998). Mobile agents differ also in terms of the ease of the mobility between remote computers. A continuously traveling nomadic agent, like mobile sales agents (containing information of the total quantity of the product to be sold, the initial price of the product and the list of potential customers to visit), arrives at a customer's site and communicates with a stationary customer agent, which determines the quantity to be purchased at a given price (Dasgupta et al., 1998). The customer agent uses market values and demand curves of the product for its decision. The sales agent has to adjust the price dynamically during negotiations in order to maximize the gross returns. The price for the product may not be settled too low (an agent sells all of his stock at a bargain price) or too high (a given quantity of the goods may be unsold). Such a supplier-driven electronic commerce system enables merchants to maximize their gross return, but also to identify quickly the customers' needs and finally to cultivate long-term relationships with them. The architecture of the supplier-driven system was presented by Dasgupta et al. (1998).

From a customer's perspective, software agents should be highly personalized, continuously-running and autonomous mediators, that have to delegate some process management tasks (Guttman et al., 1998). A software agent should identify customers' needs at first, then retrieve information about the product from the merchants' sites, compare the offers and finally determine the terms of the transaction (Castro-Schez et al., 2004). Nowadays, customer agents are mostly used for product and merchant brokerage and for negotiation (Guttman et al., 1998).

The price of a product may also be dynamically negotiated instead of being fixed. For example, tête-à-tête agents cooperatively negotiate multiple terms of a transaction, like warranties, return policies, delivery times, and loan options (Guttman et al., 1998). The buyer agent in a tête-à-tête system negotiates towards a pareto-optimal deal with the sales agent (Fatima et al., 2004). A system like this does not maximize gross returns to suppliers or price discounts for customers (Excelente-Toledo & Jennings, 2004; Rahwan et al., 2004). However, it takes into consideration the important value-added merchant's services.

Summarizing, software agents are helping customers to compare and to purchase goods on the Internet. Most of them are agents for a simple online product price comparison or for competitive negotiation over price without considering the value-added and post-purchase services from merchants. Such agents decrease customers' loyalty to a merchant towards zero. However, additional services, like guarantees, return policies, loans, gifts, discounts and insurance are of interest to customers. Therefore, they should rather use agents for comparing or negotiation over multiple terms of a transaction (tête-à-tête). Otherwise, merchants may also send their own sales agents to potential buyers in order to acquire new customers and remind the previous customers of new sales offerings (Dutta et al., 2003).

Figure 1. Classification of software agents (Joshi & Ramesh, 1998).



FUTURE TRENDS

In general, software agents helping customers in the procurement process may minimize their loyalty to merchants. Suppliers who do not want to compete solely on the basis of price provide their customers with highly personalized and value-added services to sustain a long-term relationship.

Personalization and Privacy

Personalization is defined as the customization of a Web site to meet the particular needs of individual users (Chaffey et al., 2000; Dean, 1998). The goal of personalization technology is to encourage repeated visits and to enhance user loyalty. The identification of customers' needs occurs through the observation of their behavior and the collection of data (filling out forms or following decision-tree sets of questions).

There exist some advanced techniques supporting personalization of Web site contents, like rule-based matching and collaborative filtering. Using rule-base matching, users have to answer a set of yes/no or multiple-choice questions to settle a set of users' criteria. Collaborative filtering methods combine the personal preferences of a user with preferences of like-minded people (Dean, 1998). In regard to personalization techniques, one-to-one-marketing should be noticed. This strategy enables targeting unique offers to specific customers (Chaffey et al., 2000). Institutions offering such individualized services have to dispose of accurate user profiles before.

A critical factor of personalization is the privacy issue. Filtering and customization techniques entail the collection and the use of personal data, like name, e-mail address, postal address, age, gender, income, Internet connection, and employment status, that must be protected from abuse (Dean, 1998). Furthermore, a lot of suppliers on the Internet deriving revenues mainly from advertising need to identify their users in order to better customize the content and to attract the advertisers that might be interested. Hence, the user should be informed by suppliers how they use the personal data and how the protect them. Nowadays, there are several initiatives and standardization projects for the privacy of personal data usage. Such initiatives increase user trust and confidence in electronic commerce. However, no organization or institution has the power to enforce it to the wide usage of suppliers.

Value-Added Services

Merchants who do not want to compete solely on the basis of prices often offer their customers value-added or complimentary services. Complimentary products imply higher benefits to the customer in the case that he or she only buys the product he or she is looking for (Seitz et al., 1999). Such products or services increase the value of the primary good to the customer. Examples for value-added services in electronic commerce are sales discounts, savings coupons, additional insurance and guarantees, gifts, but also free software to test. In general, value-added services enable customers to trade at favorable terms and with confidence. They increase the attractiveness of the merchant to present customers and attract new customers.

Reduced Financial Transaction Costs

Internet merchants might achieve additional reduction of transaction costs using electronic payment systems. Electronic payment systems reduce cash handling costs for merchants and improve speed and convenience for customers. The aggregated cost of each payment consists of transformation costs, for example, the fees for conversion from assets to cash and vice versa, transport and storage costs, costs for safety measures, and search and time costs (Hakenberg, 1996).

CONCLUSION

This article discusses consequences of electronic commerce on customers' loyalty. Electronic commerce on the Internet offers the possibility to create a perfect marketplace. The intermediation in distribution will be reduced. This means lower costs for both suppliers and customers.

Software agents may be classified into different types with regard to their use on supporting electronic commerce. Most of the software agents only perform simple product price comparisons; some support the purchase of products. These software agents reduce customers' loyalty because the price is the only parameter. Quality and added values are not considered. Therefore, multi-agent systems allowing negotiation might be useful from a customer's perspective. Merchants may also send their own sales agents to potential buyers in order to remind previous customers of new sales offerings or to suppliers in order to maximize their gross return.

Personalization and customization of Web sites, value-added services and the reduction of transaction costs are instruments for increasing customers' loyalty. Personalization techniques, like rule-based matching and collaborative filtering, provide contents on Web sites that are appropriate to the customer's preferences or analyze past purchases and prior suggestions of other customers. One-to-one-marketing may be especially useful for sophisticated products demanding explanations or to enable cross-selling of other products and services. User profiles allow merchants to make customer-oriented offers or build special offers including additional services. Value-added services attract the customer to trade at favorable terms. The usage of electronic payment systems may reduce transactions costs.

KEY TERMS

Collaborative Filtering: Collaborative filtering methods combine personal preferences of a user with preferences of like-minded people to guide the user.

Customer Loyalty: Because there is no existing ownership to service products, suppliers have to make special efforts to get long-standing customers.

Customer Profiling: Usage of the Web site to get information about the specific interests and characteristics of a customer.

Customization: The adjustment of products or services to individual needs. Basic characteristics are implemented in the product or service and may be controlled by parameters.

Disintermediation: The elimination of agents, like wholesale dealers or brokers, who built the former relationship between producer and consumer. Disintermediation allows the direct supply of the consumer.

One-to-One-Marketing: One-to-one-marketing means the direct dialog between a producer and an individual consumer or a group of consumers with similar needs.

Personalization: Web-based personalization means providing customized content to individual users using Web sites, e-mails and push technologies.

Software Agents: Computer programs that are characterized by reactivity, autonomy and proactivity. Therefore, the software agent interacts with its environment.

Software and Systems Engineering Integration

Rick Gibson
American University, USA

INTRODUCTION

With software an increasingly significant component of most products, it is vital that teams of software and systems engineers collaborate effectively to build cost effective, reliable products. This article will identify the key aspects of software engineering and systems engineering in an effort to highlight areas of consensus and conflict to support current efforts by practitioners and academics in the both disciplines in redefining and integrating their professions and bodies of knowledge.

In response to increasing concerns about software development failures, the Software Engineering Institute (SEI) pioneered a software process improvement model in 1988, with the fully developed version of their Capability Maturity Model for Software (SW- CMMâ) appearing in 1993. Since the early nineties, there have been comparable improvement models introduced in the systems engineering community as well, some of which have been published and widely accepted include: Systems Engineering Capability Maturity Model (SE-CMM), also known as the Electronic Industries Alliance Interim Standard (EIA/IS) 731, Systems Engineering Capability Model (SECM), and the Integrated Product Development Capability Maturity Model (IPD-CMM). The resulting avalanche of models and standards has been described by Sarah Sheard (Software Productivity Consortium) as a "Framework Quagmire". In December of

Table1. Software and system engineering similarities and differences

Similarities	Differences
Definition and analysis involves manipulation of symbols.	Software is not subject to physical wear or fatigue.
Highly complex aggregation of functions, requiring satisfying (though not optimizing) multiple criteria.	Copies of software are less subject to imperfections or variations.
Decisions driven by need to satisfy quality attributes such as reliability, safety, security, and maintainability.	Software is not constrained by the laws of physics.
Easy and dangerous to suboptimize solutions around individual subsystem functions or quality attributes.	Software interfaces are conceptual, rather than physical—making them more difficult to visualize.
Increasing levels of complexity and interdependency.	Relative to hardware, software testing involves a larger number of distinct logic paths and entities to check.
	Unlike hardware, software errors arrive without notice or a period of graceful degradation.
	Hardware repair restores a system to its previous condition; repair of a software fault generally does not.
	Hardware engineering involves tooling, manufacturing, and longer lead times, while software involves rapid prototyping and fewer repeatable processes.

2000, the SEI initiated the Capability Maturity Model–Integrated (CMMI^{SM}) project, which combines best practices from the systems and software engineering disciplines. (Note: CMMâ and CMMI^{SM} are copyrights and service marks of the Software Engineering Institute.)

Recent studies (Carter et al., 2003; Goldenson & Gibson, 2003) have validated the SEI's assertion the each of the disciplines benefit from incorporation of principles from the other. Moreover, there appears to be no fundamental differences between the disciplines that would prevent their integration.

BACKGROUND

There is great hope that the SEI imitative will provide the impetus to overcome some long-standing discipline boundaries. The nature of the systems and software engineering work has led to terminology differences rooted in the very descriptions of the disciplines. One important problem with software is the difficulty in understanding its inherent level of quality.

Issues and concerns regarding such an integration were articulated by Barry Boehm and Fred Brooks as early as 1975. Boehm suggested that the adoption of systems engineering reliability techniques by software engineers was counterproductive. Moreover, Brooks' Law suggests that a common systems engineering solution to schedule slippage (add more people) will only make late software projects even later.

More recently, Boehm (1994) expressed concerns that, in spite of the central function of software in modern systems, the two engineering disciplines have not been well integrated. Boehm articulated similarities and differences as shown in Table 1.

Software engineering, as defined by the Institute of Electrical and Electronics Engineers (IEEE, 2001), is: (1) the application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software; that is, that application of engineering to software; (2) The study of approaches as in (1)—and further identifies the body of knowledge for software engineering to be: software requirements, software design, software construction, software testing, software maintenance, software configuration management, software engineering management, software engineering process, software engineering tools and methods, and software quality.

A useful definition of systems engineering resides in an in-process body of knowledge document by the International Council on Systems Engineers (Leibrandt, 2001, p. 3), which defines systems engineering in terms of product and process: "…product oriented engineering discipline whose responsibility is to create and execute an interdisciplinary process to ensure that customer and stakeholder needs are satisfied in a high quality, trustworthy, cost effective and schedule compliant manner throughout a system's lifecycle". The process starts with customer needs, and consists of stating the problem, investigating alternatives, modeling, integrating, launching the system, and assessing performance. Moreover, the system engineer is responsible for pulling together all the disciplines to create a project team to meet customers' needs. The complete systems engineering process includes performance, testing, manufacturing, cost, schedule, training and support, and disposal. The body of knowledge recognizes that systems engineering processes often appear to overlap software and hardware development processes and project management. Thus, systems engineering is a discipline that focuses on processes; it develops structure, and efficient approaches to analysis and design to solve complex engineering problems. In response to concerns about integrated development of products, the system engineer plans and organizes technical projects and analyzes requirements, problems, alternatives, solutions and risks. Systems engineering processes are not specific to a particular discipline; they can be applied in any technical or engineering environment.

In short, software engineering is defined by IEEE Standard 610.12 as the application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software—that is, the application of engineering to software. Eisner (2002) adopts the International Council on Systems Engineering (INCOSE) definition of systems engineering as an interdisciplinary approach and means to enable the realization of successful systems.

When different process models are in place within developer groups, say for systems engineering and software engineering of an organization, the organizations will have communication problems, be unable to improve their processes, and if the combined performance of one advances beyond the other in capability, then the problems are even more profound (Johnson, 1998).

In 2002, the SEI released a single integrated capability model for systems engineering and software engineering, integrated product and process development and supplier sourcing. The new model, Capability Maturity Model Integrated (CMMI), is intended to improve organizations' development and maintenance of products. The CMMI will eventually replace the SEI's Software Capability Maturity Model (Phillips, 2002). In the integrated model (SEI, 2002), CMMI, the categories and processes are:

One purpose of the CMMI was to evolve the software CMM while integrating the best features of the systems engineering capability models. The combination of the

practices of the models into one single framework required more than just combining practices because of differences in interpretation, focus, and terminology. Compromises and intentional inefficiencies were required in order to integrate these models.

With the arrival of the CMMI, a wider continuum of the product life cycle has been targeted for possible enhancement, no longer limiting process improvement only to the development of software. This integrated approach provides a reduction in the redundancy and intricacy resulting from the use of multiple, separate process improvement models. For organizations that wish to assess their process improvement efforts against multiple disciplines, the CMMI provides some economies of scale in model training and assessment training. This one evaluation method can provide separate or combined results for the fields of software and systems engineering. Furthermore, software organizations can also focus on the amplifications for software engineering within the engineering shared process areas and take advantage of any systems engineering amplifications that are helpful. Although still subject to debate, a distinction is made between base and advanced engineering practices as model constructs. Adopting the continuous representation of CMMI not only forces software organizations to define business goals and choose process areas that should be implemented first to focus on these goals, but it also forces companies who are choosing a new subcontractor to do the same. One of the claimed benefits of a staged representation is that it facilitates comparisons among organizations (Shrum, 2000). While it may simplify comparisons, it does so at the loss of additional details. Using a continuous representation, the comparison can be done based on the process areas that are judged by the organization as important rather than simply comparing the organization's maturity score. When using a continuous representation, there is less likelihood that organizations will try to attain a specific level without reasons within their business to do so. It provides an incentive to address processes that would have the greatest impact on their business goals.

FUTURE TRENDS

Despite anticipated problems, bringing systems engineering best practices into the established software process improvement models is expected to be very beneficial. Boehm (1994) reminds us that an important reason to overcome or bridge these differences is to establish an adequate supply of people who can deal with complex systems problems. The Bureau of Labor Statistics (1997) estimates of anticipated growth in information technology jobs, shown in Table 2, provides further support for this concern.

The final job type, managers, is a significant concern addressed by Jerry Weinberg in an interview (Layman, 2001). Weinberg explains that the software development problems are growing faster than individuals' levels of competence. Moreover, he asserts that the current state of practice is one where we need to apply a few fundamentals (e.g., requirements, reviews, configuration management); that is, things known to be useful, but not adopted in the sense of consistent application. Soloman (2002) provides guidelines for using the CMMI to improve earned value management.

Table 2. Anticipated employment growth 1996-2006

Type of Job	1996 Employment	2006 Employment	% Change
Database Administrators and Computer Support	212,000	461,000	118%
Computer Engineers	216,000	451,000	109%
Systems Analysts	506,000	1,025,000	103%
Data Processing Equipment Repair	80,000	121,000	52%
Engineering, Science, and Computer Systems *Managers*	343,000	498,000	45%

It has been suggested that the systems engineering—hardware engineering interfaces have matured nicely over many years, but that the systems engineering—software engineering interface is not as mature as the various hardware engineering interfaces.

Meanwhile, the dependency on the systems engineering-software engineering interface has increased faster than it has matured. Specific concerns by discipline include:

The State of Systems Engineering

- Most successful projects rely on expertise established with similar systems.
- Lack of documented processes makes repeatability difficult.
- Development efforts for unprecedented or significantly different systems often encounter problems.

The State of Software Engineering

- The brief history of software development has been filled with problems of cost overruns, schedule slippage, and failure to achieve performance goals.
- Systems are increasingly dependent on software, yet hardware typically gets the most visibility.

CONCLUSION

Although Pierce (2000) suggests that the CMMI is more of a merged model than an integrated one, which may serve to prolong the separation of the disciplines, Rassa (2001) summarizes the benefits of the CMMI project as follows:

- Common, integrated vision of improvement for all organizational elements;
- Means of representing new discipline-specific information in a standard, proven process improvement context;
- Efficient, effective assessment and improvement across an organization's multiple process disciplines;
- Reduced training and assessment costs.

Although many software-only organizations remain adamant that they do not do systems engineering, all software must run on some computer system, and interface with others. This perceived separation of concerns exacerbates the difficulties associated with hardware/software/system tradeoff decisions, which are further complicated by terminology differences and disparate mental models. Interpretive guidance for CMMI implementation has been provided (e.g., Chrissis et al., 2003)

However, the integration potential of the CMMI℠ can allow the system and software engineering communities to get the most out of their similarities. The CMMI℠ allows organizations to tailor the model to mesh with their own mission and goal statements as well as their business objectives. Each individual project can use CMMI℠ models for individual disciplines and discipline combinations because the architecture of the CMMI℠ does not force the employment of every discipline for every organization implementing it. Before the CMMI℠, the systems engineering models shared many of the same principles as the software version of CMM, but were written to address the needs and terminology of the systems engineering community. Because the CMMI℠ includes the common and shared elements and best features of both software and system engineering together with discipline-specific elements, an organization can generate integrated capability maturity models or discipline-specific capability models. With CMMI℠, an organization can still capitalize on these similarities and improve the efficiency of and the return on investment for process improvement. The resulting integrated capability models will adapt to an organization's business purposes.

The concept of an architecture continues to serve as a theoretical link for both the software/system tradeoffs and the integration of process improvement efforts. While respecting the legitimate differences in areas such as reliability testing, it is important to sustain the hope that overlapping or underlying theories will emerge regarding areas of common concern such as: requirements, security, safety, and performance.

In order to achieve true integration of software and system engineering practices into one process improvement model, the remaining differences of terminology and model construction have to be addressed. These two communities have well-developed disparate languages and methodologies that are reflected in their different origins, models and perspectives; differences that have become entrenched in their organizational cultures. With the adoption of an integrated process improvement model, an organization can assess both software and systems engineering functions, reduce conflict and increase consensus.

KEY TERMS

Capability Maturity Model (CMM): Contains the essential elements of effective processes for one or more disciplines. It also describes an evolutionary improvement path from ad hoc, immature processes to disciplined, mature processes with improved quality and effectiveness.

Process Architecture: Describes the ordering, interfaces, interdependencies, and other relationships among the process elements in a standard process. Process architecture also describes the interfaces, interdependencies, and other relationships between process elements and external processes (CMMI).

Process Improvement: A program of activities designed to improve the performance and maturity of the organization's processes, and the results of such a program.

Quality: The ability of a set of inherent characteristics of a product, product component, or process to fulfill requirements of customers.

Software Engineering: The software engineering discipline covers the development of software systems.

Software engineers focus on applying systematic, disciplined, and quantifiable approaches to the development, operation, and maintenance of software.

Systems Engineering: The systems engineering discipline covers the development of total systems, which may or may not include software. Systems engineers focus on transforming customer needs, expectations, and constraints into product solutions and supporting those product solutions throughout the product life cycle.

Software Contracts for Component–Based Web Engineering

Martin Gaedke
University of Karlsruhe, Germany

Martin Nussbaumer
University of Karlsruhe, Germany

Emma Tonkin
University of Karlsruhe, Germany

INTRODUCTION

As an emerging technology, the Web is full of unique challenges for developers, designers – and engineers. Its use for increasingly complex applications such as e-commerce and banking, involving connection to many data sources, highlighted a number of common difficulties. During the design phase, good modeling of complex sites is difficult; during implementation, the design models are often found to be difficult to translate into an implementation model; afterwards, maintenance and long-term management of the site's evolution offer problems of their own. Qualities such as integrity, security, and usability are often afterthoughts, or left unconsidered – most particularly during the site's post-deployment evolution. Many organizations working for the Web still use ad-hoc, chaotic development and maintenance methods, even though the issues surrounding development are now widely known.

Solving these issues called for software engineering – a discipline covering design, development and use of computer software (Weik, 1989) – to be applied to the Web. Researchers in the field noticed a gap between the granularity of design models and that of implementation models for the Web (Gellersen, Wicke & Gaedke 1997) – that is to say, the models that worked best for designers did not provide the right levels of detail for the implementation stage.

BACKGROUND

Software engineering approaches have been brought to the Web through design models especially suited for Web and other hypermedia technologies, for example OOHDM (Schwabe, Rossi & Barbos, 1996), RMM (Isakowitz, Stohr & Balasubramaninan, 1995), and UML (Conallen, 1999). Nevertheless, the lack of representation of higher-level concepts in the implementation remains.

A proposed solution to this issue came from *compositional design and reuse*, a concept from the software engineering domain within which components are designed such that they may be reused as building blocks. An application may then be developed – composed – from the available components. Should additional components be required, they are developed; they may then be reused in future compositions. This concept resulted in a new sub-discipline: component-based Web engineering (CBWE) (Gaedke & Turowski, 2002).

Components seem to solve the granularity problem, as components can be described in whatever granularity suits both parties. For example, a component might represent a formatted paragraph of text, a navigational menu, an active component such as a calendar – or a single link. Components can represent a workflow as a set of pages, forms, and underlying "business logic". Once developed, such components can be stored and reused. Components can even represent an assemblage of smaller components.

The advantages of this approach, christened the *WebComposition* approach (Gaedke, 2000), were demonstrated by the development of proof-of-concept language WCML, the Web-Composition Markup Language (Gaedke, Schempf & Gellersen, 1999), which offers a convenient way to define and represent components. It uses the eXtensible Markup Language (XML), an almost ubiquitous standard, for this purpose. WCML permits XML-based definition of components, associated typed attributes (name-value pairs) referred to as *properties*, and relationships between components. Components are stored in a *repository*, a dedicated data store, and referred to by a unique ID (UUID). These component assemblies provide WebComposition services or in short services – for example, an ordering service is made up of a form interface and a product database. Additional components provide business logic to control the order process, thus enabling the concept of constructing Web applications based on the services they provide. This abstract definition allows for different implementations of the

WebComposition service concept, for example using components, Web services, or even the secretary phone in the office.

WCML was developed as part of a complete approach, which defined a disciplined procedure of composing Web applications with components based on the WebComposition component model (Gaedke, 2000). It is a synthesis of a component-oriented process model with a dedicated Web application framework, reuse management, and dedicated component technology. The details of the reuse model are discussed in Gaedke and Turowski (2002).

DROWNING IN INFORMATION – AND STARVING FOR KNOWLEDGE?

Just as in R.D. Roger's popular quotation, one component in a repository resembles a small needle in a big haystack. A designer looking for an appropriate component in the repository needs a good way to find it, so that he or she can retrieve it using its unique ID. What methods exist to sort or index components within a repository, and what techniques permit components to be most usefully described and specified?

WebComposition services, and the components of which they are built, can be represented in several ways that use searchable indexes to direct the user to the UUID of likely components: controlled indexing, uncontrolled indexing, and methods containing semantic information. Controlled indexing refers to the use of controlled vocabularies or categorizations, such as hierarchical or taxonomical classification or *faceted* classification, where objects are described by characteristic. For example, facets of this encyclopedia entry include its publication date, the expected knowledge of its readers, and its subject type. Uncontrolled indexing refers to methods without the constraint of a controlled vocabulary, such as free-text keywords added to the object's description by a human or a computer, or attribute-value pairs. Examples of both are shown in Figure 1. Controlled and uncontrolled indexing methods were compared (Frakes & Pole, 1994) and both were found to be useful – but, the authors concluded, no single method is perfect. A good result often comes from mixing several methods.

Unlike most types of data, components have an additional property – behavior. As elements in a software application, they have to perform a task, and they must work reliably and accurately – and they must interoperate correctly with other components. In order to ensure this, *software contracts* were introduced in 1988 by Meyer, as part of the Eiffel programming language (Meyer, 1988). Software contracts may include information on many levels, depending on the context of the agreement; configurable values may be negotiated as part of the contract.

Software components are obligations to which a service provider (a component) and a service consumer (a client) agree. The provider guarantees that a service it offers, under certain conditions – such as the provision of appropriate data – will be performed to a guaranteed quality. Furthermore, it also provides information about certain external characteristics, such as its interfaces. The following sections will discuss the different levels for specifying a component, as shown in Figure 2.

Figure 1. Classifying an article

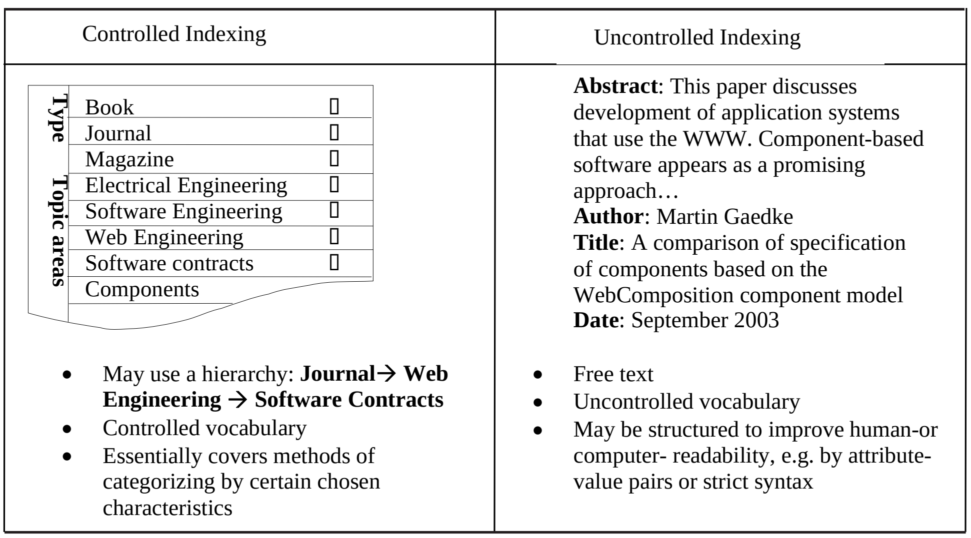

Figure 2. Software contract levels – specifications of a component

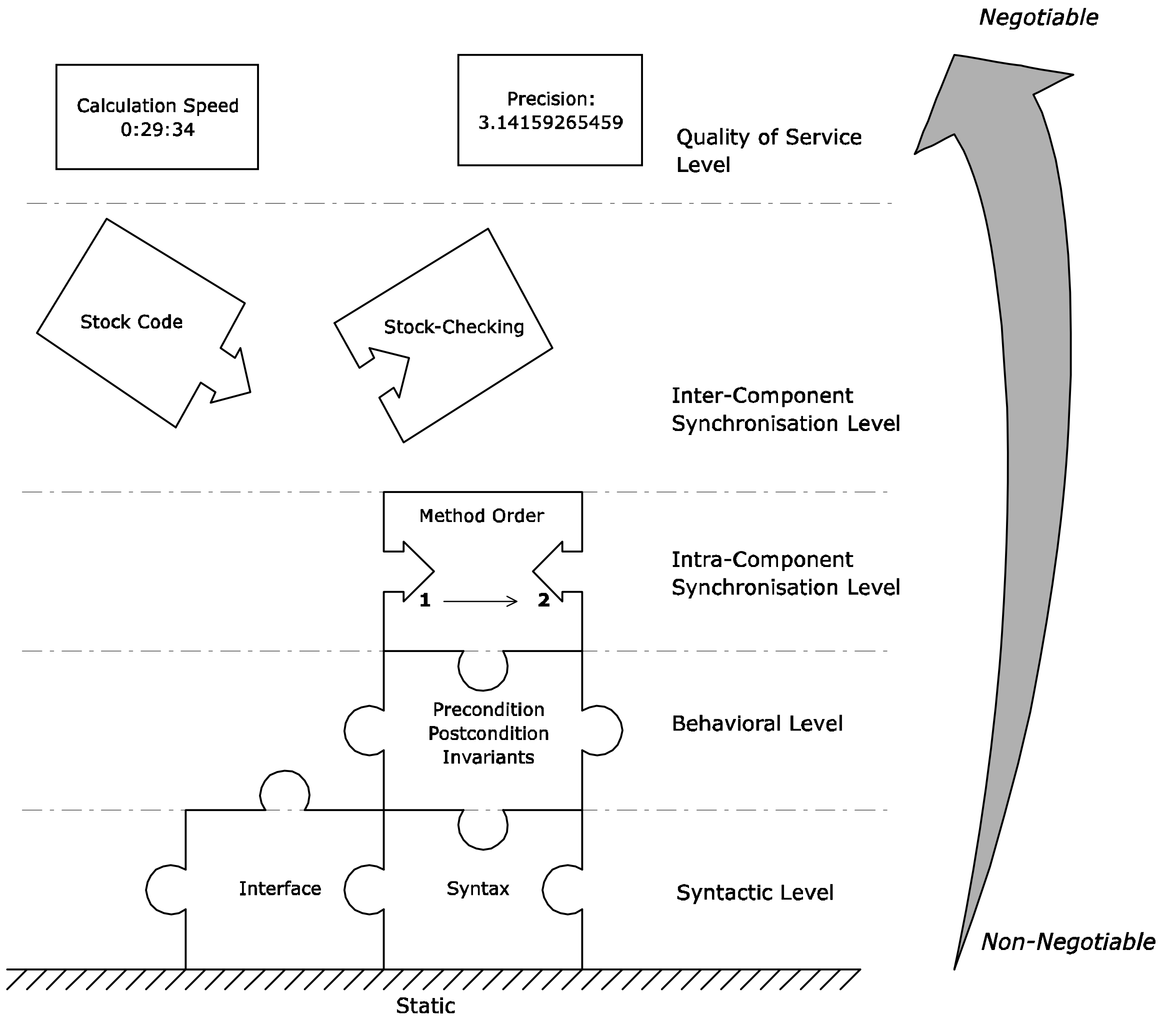

Syntactic and Behavioral Information Levels

On the most fundamental level, software contracts specify the interface and behavior of a component. This offers a way for components to provide information about what their functions are, in what ways they may be addressed, the prerequisites of use, on what data they may operate and what outputs they should provide. Components can use software contracts to describe their interfaces, to describe their behavior, and to set pre-and post-conditions on use.

Intra- and Inter-Component Synchronization Levels

The technique can also be used to describe synchronization issues, both internally and with relation to other contracts. The correct execution of a component, accessed concurrently from multiple sources, may depend on synchronization rules – or policies – ensuring that an entire transaction is correctly executed before another is begun. Externally, components may be mutually dependent; the order in which component services are executed may be controlled by software contract. A component could stipulate that another component be run before itself, such as, "Before you access the stock-checking component, you must first retrieve the stock code from the search tool".

Quality of Service Level – Negotiable Properties

Finally, software contracts could be used to negotiate the properties of a component in detail. Components may provide options, such as a trade-off between calculation speeds and result precision or, in the context of the Web, the bandwidth demanded may be traded against properties of the returned object, such as image size, resolution or detail. These are often classed as *non-functional* characteristics.

The WCML is able, by making use of several companion technologies, to include the contract levels described here. The Interface Definition Language (IDL) proposed by the Object Management Group (ISO International Standard 14750) permits the definition of component behavior on the syntactic level (OMG, 2003), to complement the interface definition capabilities provided by WCML itself on the semantic level by WCML schemas. Several IDLs permit definition of the interface between client and server processes.

The Object Constraint Language (OCL) specification (OCL, 1997) builds on the Unified Modeling Language (UML), providing a useful notation for specification of facts at the behavioral level. A temporal extension, Temporal OCL, was developed (Ziemann & Gogolla, 2002) for the purpose of describing synchronization on the inter-component and intra-component levels. Other graphical notations may be used for the purpose, such as Petri nets. Appropriate alternative notations include process algebras, developed as an algebraic approach to the study of concurrent processes (Van Glabbeek, 1987), and process calculi. Several process calculus languages exist, designed to permit descriptions or specifications of software that consists of multiple interactive elements.

Natural language may be used for many specifications at the quality of service level – for example, the details of a component's level of accessibility to the visually impaired may be specified in this way. Other services require more specialized constraints to be specifiable, in which case alternative notations should be considered (mathematics or scientific notation, for example).

FUTURE TRENDS

At this time, we envisage the next steps in software component design to begin with development of a component referencing system that combines the concepts of software contracts and traditional metadata with the Universal Description, Discovery and Integration (UDDI) protocol (UDDI, 2002). This standard, introduced in September 2000 as the result of a joint industry effort by 36 major companies, provides a standard for development of an electronically searchable directory of services, such as Web services. Web services are definable as a special case of the Web component concept, software components that communicate via the XML-based standard Simple Object Access Protocol (SOAP). UDDI, designed to enable efficient business-to-business exposure of Web services, is considered to be adaptable to the general case of software components. Once combined and adapted, the technologies are expected to provide a powerful method supporting component discovery, either manually or in an automated fashion – self-discovery.

Reflection, in the sense of the ability to discover interfaces of previously unknown components and therefore inform oneself on components' abilities and provided services, is also an interesting technique in the context of CBWE. This approach paves the way to implementation of software contracts on the Web, as well as a greater degree of automation and fact and error checking.

Thirdly and finally, a group of techniques considered to be of importance to component specification is the addition of information and processes that contribute towards successful and transparent digital rights management (DRM). Issues surround the use, deployment and control of components, which may be at least partially solved by implementing a form of rights management within the component discovery process and underlying runtime environment.

CONCLUSION

Component-based Web engineering helps to solve the problems in representing abstract design ideas in code. This raises the problem of specifying components so that they can be located in a large data repository. WCML has provided a method by which the concepts behind CBWE can be demonstrated and has been used to illustrate the principle. Furthermore, the WebComposition approach has successfully been applied to several real-world applications, and its advantages verified in a 4-year project for a large international Web-application: "E-Victor Procurement Portal" at Hewlett-Packard.

Recent efforts within Web engineering have focused on specifying components by means of software contracts. By combining this method with other classifications, and perhaps with additional information such as digital rights management markers, components may be made available and discovered by means of the various specifications. The range of information available about each component may be such that it is useful for users, developers – in the technical and in the business contexts – and even for computer-based automatic discovery of components.
