**With a foreword by Brendan Eich, JavaScript's creator**

**WILEY**

Wiley Publishing, Inc.

## Praise for Danny Goodman's *JavaScript™ Bible*

"*JavaScript™ Bible* is the definitive resource in JavaScript programming. I am never more than three feet from my copy."

— Steve Reich, CEO, PageCoders

"This book is a must-have for any web developer or programmer."

— Thoma Lile, President, Kanis Technologies, Inc.

"Outstanding book. I would recommend this book to anyone interested in learning to develop advanced Web sites. Mr. Goodman did an excellent job of organizing this book and writing it so that even a beginning programmer can understand it."

— Jason Hensley, Director of Internet Services, NetVoice, Inc.

"Goodman is always great at delivering clear and concise technical books!"

— Dwayne King, Chief Technology Officer, White Horse

"*JavaScript™ Bible* is well worth the money spent!"

— Yen C.Y. Leong, IT Director, Moo Mooltimedia, a member of SmartTransact Group

"A must-have book for any internet developer."

— Uri Fremder, Senior Consultant, TopTier Software

"I love this book! I use it all the time, and it always delivers. It's the only JavaScript book I use!"

— Jason Badger, Web Developer

"Whether you are a professional or a beginner, this is a great book to get."

— Brant Mutch, Web Application Developer, Wells Fargo Card Services, Inc.

"I never thought I'd ever teach programming before reading your book [*JavaScript™ Bible*]. It's so simple to use—the Programming Fundamentals section brought it all back! Thank you for such a wonderful book, and for breaking through my programming block!"

— Susan Sann Mahon, Certified Lotus Instructor, TechNet Training

"Danny Goodman is very good at leading the reader into the subject. *JavaScript™ Bible* has everything we could possibly need."

— Philip Gurdon

"An excellent book that builds solidly from whatever level the reader is at. A book that is both witty and educational."

— Dave Vane

"I continue to use the book on a daily basis and would be lost without it."

— Mike Warner, Founder, Oak Place Productions

"*JavaScript™ Bible* is by far the best JavaScript resource I've ever seen (and I've seen quite a few)."

— Robert J. Mirro, Independent Consultant, RJM Consulting

# About the Authors

**Danny Goodman** is the author of numerous critically acclaimed and best-selling books, including *The Complete HyperCard Handbook*, *Danny Goodman's AppleScript Handbook*, *Dynamic HTML: The Definitive Reference*, and *JavaScript & DHTML Cookbook*. He is a renowned authority and expert teacher of computer scripting languages. His writing style and pedagogy continue to earn praise from readers and teachers around the world. To help keep his finger on the pulse of real-world programming challenges, Goodman frequently lends his touch as consulting programmer and designer to leading-edge World Wide Web and intranet sites from his home base in the San Francisco area.

**Michael Morrison** is a writer, developer, toy inventor, and author of a variety of books covering topics such as Java, Web scripting, game development, ActiveX, and Pocket PCs. Some of Michael's notable writing projects include *Faster Smarter HTML and XML*, *Teach Yourself XML in 24 Hours*, and *The Complete Idiot's Guide to Java 2*. Michael is also the founder of Stalefish Labs ([www.stalefishlabs.com](http://www.stalefishlabs.com)), an entertainment company specializing in traditional games and toys.

# Foreword

---

**A**s JavaScript's creator, I would like to say a few words about where JavaScript has been, where it is going, and how the book you're holding will help you to make the most of the language.

JavaScript was born out of a desire to let HTML authors write scripts directly in their documents. This may seem obvious now, but in the spring of 1995 it was novel and more than a little at odds with both the conventional wisdom (that HTML should describe static document structure only) and the Next Big Thing (Java applets, which were hyped as the one true way to enliven and extend Web pages). Once I got past these contentions, JavaScript quickly shaped up along the following lines:

- ◆ “Java-lite” syntax. Although the “natural language” syntax of HyperTalk was fresh in my mind after a friend lent me *The Complete HyperCard Handbook* by some fellow named Goodman, the Next Big Thing weighed heavier, especially in light of another goal: scripting Java applets. If the scripting language resembled Java, then those programmers who made the jump from JavaScript to Java would welcome similarities in syntax. But insisting on Java's class and type declarations, or on a semicolon after each statement when a line ending would do, were out of the question — scripting for most people is about writing short snippets of code, quickly and without fuss.
- ◆ Events for HTML elements. Buttons should have `onClick` event handlers. Documents load and unload from windows, so windows should have `onLoad` and `onUnload` handlers. Users and scripts submit forms: thus the `onSubmit` handler. Although not initially as flexible as HyperCard's messages (whose handlers inspired the `onEvent` naming convention), JavaScript events let HTML authors take control of user interaction from remote servers and respond quickly to user gestures and browser actions. With the adoption of the W3C DOM Level 2 event handling recommendations, JavaScript in modern browsers has fully flexible control over events.
- ◆ Objects without classes. The Self programming language proved the notion of prototype-based inheritance. For JavaScript, I wanted a single prototype per object (for simplicity and efficiency), based by default on the function called using the `new` operator (for consonance with Java). To avoid distinguishing constructors from methods from functions, all functions receive the object naming them as the property that was called in the parameter. Although prototypes didn't appear until Navigator 3, they were prefigured in Version 2 by quoted text being treated as an object (the Strong object prototype, to which users could attach methods).
- ◆ Generated HTML. Embedding JavaScript in HTML gave rise to a thought: Let the script speak HTML, as if the emitted text and markup were loaded in place of the script itself. The possibilities went beyond automating current or last-modified dates, to computing whole trees of tables where all the repeated structure was rolled up in a scripted loop, while the varying contents to be tabulated came in minimal fashion from JavaScript objects forming a catalog or mini-database.

At first, I thought JavaScript would most often find use in validating input to HTML forms. But before long, I was surprised to see how many Web designers devised compelling applications by way of script-generated HTML and JavaScript objects. It became clear from user demonstration and feedback that Web designers sought to build significant applications quickly and effectively with just a few images, HTML, and JavaScript. Eventually they demanded that the browser support what is now known as “Dynamic HTML” (one fun link: <http://www.javascript-games.org/>).

As legions of Web authors embraced the authoring power of JavaScript, they, in turn, demonstrated the crucial advantages of a scripting environment over old-school application development. Not only were the HTML and JavaScript languages comparatively easy to use, but development did not require the programming expertise needed to light all pixels and handle all events as in a big, traditional application.

The primacy of JavaScript on the Web today vindicates our early belief in the value of a scripting language for HTML authors. By keeping the “pixel-lighting” bar low, HTML with images has made Web designers out of millions of people. By keeping the “event-handling” bar low, JavaScript has helped many thousands of those designers become programmers. Perhaps the ultimate example of Web development’s convergence with application development is the Mozilla browser, wherein all of the user-interface and even some custom widgets and modular components are implemented entirely using JavaScript, Cascading Style Sheets (CSS), custom XML-based markup languages, and images.

JavaScript is also a general language, useful apart from HTML and XML. It has been embedded in servers, authoring tools, browser plug-ins, and other kinds of browsers (for such things as 3D graphical worlds). Its international standard, ECMA-262 (ISO 16262), has advanced to a Third Edition. But compared to languages such as Perl and even Java, it is still relatively young. Work toward a Fourth Edition of the language, supporting optional types, classes, and versioning facilities progresses within the ECMA technical committee (see the “JS2” proposal to the ECMA technical committee documented at <http://www.mozilla.org/js/language/js20/>).

It is clear to me that JavaScript would not have survived without a creative, loyal, and patient community of developers; I owe them each a huge debt of thanks. Those developers who took up the beta releases of Navigator 2, and disseminated vital workarounds and feature requests by e-mail and net-news, are the language’s godparents. Developer support and feedback continue to make JavaScript the eclectic, rambunctious success it is.

The book in your hands compiles thousands of those “developer miles” with the insight of an expert guide and teacher. Danny didn’t know at the time how much inspiration I found in his HyperCard book, but it was on my desk throughout the development of JavaScript in 1995. His energy, compassion, and clear prose helped me keep the goal of “a language for all” in mind. It is enormously gratifying to write the foreword to the fourth edition of this book, which has earned so many “satisfied reader miles.”

I highly recommend Danny Goodman’s *JavaScript Bible* to anyone who wants to learn JavaScript, and especially to those HTML authors who’ve so far written only a few scripts or programs — you’re in for a lifetime of fun on the “scripting road” with a trusty guide at your side.

*Brendan Eich*  
*The Mozilla Organization (<http://www.mozilla.org>)*

# Preface

---

**F**or over 20 years, I have written the books I wished had already been written to help me learn or use a new technology. Whenever possible, I like to get in at the very beginning of a new authoring or programming environment, feel the growing pains, and share with readers the solutions to my struggles. This fifth edition of the *JavaScript™ Bible* represents knowledge and experience accumulated over eight years of daily work in JavaScript and a constant monitoring of newsgroups for questions, problems, and challenges facing scripters at all levels. My goal is to help you avoid the same frustration and head scratching I and others have experienced through multiple generations of scriptable browsers.

While the earliest editions of this book focused on the then predominant Netscape Navigator browser, the swing of the browser market share pendulum currently favors Microsoft Internet Explorer on the Windows platform. But the more important trend is the Web developer community's demand for browser compliance with a growing body of industry standards. Potential conflicts arise when the dominant browser on the Internet does not fully support existing standards, but instead provides proprietary alternatives. The job of a book claiming to be the "bible" is not only to present both the standard and proprietary details when they diverge, but also to show you how to write scripts that blend the two so that they work on as many browsers as possible. Empowering you to design and write good scripts is my passion, regardless of browser. It's true that my bias is toward industry standards, but not to the exclusion of proprietary features that may be necessary to get your content and scripting ideas flowing equally well on today's and tomorrow's browsers.

## Organization and Features of This Edition

Like the previous fourth and Gold editions of the *JavaScript Bible*, this fifth edition contains far more information than can be printed and bound into a single volume. The complete contents can be found in the electronic version of this book (in Adobe Acrobat form) on the CD-ROM that accompanies the book. This new edition is structured in such a way as to supply the most commonly needed information in its entirety in the printed portion of the book. Thus, numerous complete code listings, which had been diverted to CD-ROM in the previous editions, are now readily available in the printed pages. Content that you use to learn the fundamentals of JavaScript and reference frequently are at your fingertips in the printed version, while chapters with advanced content are in the searchable electronic version on the CD-ROM. Here are some details about the book's structure.

## Part I

Part I of the book begins with a chapter that shows how JavaScript compares with Java and discusses its role within the rest of the World Wide Web. The Web browser and scripting world have undergone significant changes since JavaScript first arrived on the scene. That's why Chapter 2 is devoted to addressing challenges facing scripters who must develop applications for both single- and cross-platform browser audiences amid rapidly changing standards efforts. Chapter 3 provides the first foray into JavaScript, where you get to write your first practical script.

## Part II

All of Part II is handed over to a tutorial for newcomers to JavaScript. Nine lessons provide you with a gradual path through browser internals, basic programming skills, and genuine browser scripting with an emphasis on industry standards as supported by most of the scriptable browsers in use today. Exercises follow at the end of each lesson to help reinforce what you just learned and challenge you to use your new knowledge (you'll find answers to the exercises in Appendix C). The goal of the tutorial is to equip you with sufficient experience to start scripting simple pages right away while making it easier for you to understand the in-depth discussions and examples in the rest of the book. By the end of the final lesson, you'll know how to create the mouse-rollover image swapping effect that is popular in a lot of Web pages these days, and modify the content of a Web page dynamically.

## Part III

Part III, the largest section of the book, provides in-depth coverage of the document object models as implemented in today's browsers. In all reference chapters, a compatibility chart indicates the browser version that supports each object and object feature. One chapter in particular, Chapter 15, contains reference material that is shared by most of the remaining chapters of Part III. To help you refer back to Chapter 15 from other chapters, a dark tab along the outside edge of the page shows you at a glance where the chapter is located. Additional navigation aids include guide words near the tops of most pages to indicate which object and object feature is covered on the page.

## Part IV

Reference information for the core JavaScript language fills Part IV. As with reference chapters of Part III, the JavaScript chapters display browser compatibility charts for every JavaScript language term. Guide words near the tops of pages help you find a particular term quickly.

## Part V

Several appendixes at the end of the book provide helpful reference information. These resources include a JavaScript and Browser Objects Quick Reference in Appendix A, a list of JavaScript reserved words in Appendix B, answers to Part II's tutorial exercises in Appendix C, and Internet resources in Appendix D. In Appendix E, you also find information on using the CD-ROM that comes with this book, which includes numerous bonus chapters and examples.

## CD-ROM

The CD-ROM is a gold mine of information. It begins with an Adobe Acrobat (PDF) version of the entire contents of this fifth edition of the *JavaScript Bible*. This version includes not only the unprinted advanced material from Parts III and IV, but also 23 bonus chapters covering:

- ◆ Advanced DOM, XML, and JavaScript objects
- ◆ Dynamic HTML, data validation, plug-ins, and security
- ◆ Techniques for developing and debugging professional Web-based applications
- ◆ Nine full-fledged JavaScript real-world applications

Another treasure trove on the CD-ROM is the Listings folder where you'll find over 300 ready-to-run HTML documents that serve as examples of most of the document object model and JavaScript vocabulary words in Parts III and IV. All of the bonus chapter example listings are also included. You can run these examples with your JavaScript-enabled browser, but be sure to use the `index.html` page in the Listings folder as a gateway to running the listings. This page shows you the browsers that are compatible with each example listing. I could have provided you with humorous little sample code fragments out of context, but I think that seeing full-fledged HTML documents (simple though they may be) for employing these concepts is important. I intentionally omitted the script listings from the tutorial part (Part II) of this book to encourage you to type the scripts. I believe you learn a lot, even by aping listings from the book, as you get used to the rhythms of typing scripts in documents.

Be sure to check out the Chapter 13 listing file called `evaluator.html`. Many segments of Parts III and IV invite you to try out an object model or language feature with the help of an interactive workbench, called The Evaluator — a *JavaScript Bible* exclusive! You see instant results and quickly learn how the feature works.

The Quick Reference from Appendix A is in PDF format on the CD-ROM for you to print out and assemble as a handy reference, if desired. Adobe Acrobat Reader is also included on the CD-ROM, in case you don't already have it, so that you can read both of these PDF files.

## Prerequisites to Learning JavaScript

Although this book doesn't demand that you have a great deal of programming experience behind you, the more Web pages you've created with HTML, the easier you will find it to understand how JavaScript interacts with the familiar elements you normally place in your pages. Occasionally, you will need to modify HTML tags to take advantage of scripting. If you are familiar with those tags already, the JavaScript enhancements will be simple to digest.

Forms and their control elements (text fields, buttons, and selection lists) play an especially important role in much of typical JavaScript work. You should be familiar with these elements and their HTML attributes. Fortunately, you won't need to know about server scripting or passing information from a form to a server. The focus here is on client-side scripting, which operates independently of the server after the JavaScript-enhanced HTML page is fully loaded into the browser.

The basic vocabulary of the current HTML standard should be part of your working knowledge. You should also be familiar with some of the latest document markup standards, such as XHTML and Cascading Style Sheets (CSS). You don't need to be an expert, by any means. Web searches for these terms will uncover numerous tutorials on the subjects.

## If you've never programmed before

To someone who learned HTML from a slim guidebook a few years ago, the size of this book must be daunting. JavaScript may not be the easiest language in the world to learn, but believe me, it's a far cry from having to learn a full programming language, such as Java or C. Unlike developing a full-fledged monolithic application (such as the productivity programs you buy in the stores), JavaScript lets you experiment by writing small snippets of program code to accomplish big things. The JavaScript interpreter built into every scriptable browser does a great deal of the technical work for you.

Programming, at its most basic level, consists of nothing more than writing a series of instructions for the computer to follow. We humans follow instructions all the time, even if we don't realize it. Traveling to a friend's house is a sequence of small instructions: Go three blocks that way; turn left here; turn right there. Amid these instructions are some decisions that we have to make: If the stoplight is red, then stop; if the light is green, then go; if the light is yellow, then floor it. Occasionally, we must repeat some operations several times (kind of like having to go around the block until a parking space opens up). A computer program not only contains the main sequence of steps, but it also anticipates what decisions or repetitions may be needed to accomplish the program's goal (such as how to handle the various states of a stoplight or what to do if someone just stole the parking spot you were aiming for).

The initial hurdle of learning to program is becoming comfortable with the way a programming language wants its words and numbers organized in these instructions. Such rules are called syntax, the same as in a living language. Because computers generally are dumb electronic hulks, they aren't very forgiving if you don't communicate with them in the specific language they understand. When speaking to another human, you can flub a sentence's syntax and still have a good chance of the other person's understanding you fully. Not so with computer programming languages. If the syntax isn't perfect (or at least within the language's range of knowledge that it can correct), the computer has the brazenness to tell you that you have made a syntax error.

The best thing you can do is to just chalk up the syntax errors you receive as learning experiences. Even experienced programmers make them. Every syntax error you get — and every resolution of that error made by rewriting the wayward statement — adds to your knowledge of the language.

## If you've done a little programming before

Programming experience in a procedural language, such as BASIC, may almost be a hindrance rather than a help to learning JavaScript. Although you may have an appreciation for precision in syntax, the overall concept of how a program fits into the world is probably radically different from JavaScript. Part of this has to do with the typical tasks a script performs (carrying out a very specific task in response to user action within a Web page), but a large part also has to do with the nature of object-oriented programming.

In a typical procedural program, the programmer is responsible for everything that appears on the screen and everything that happens under the hood. When the program first runs, a great deal of code is dedicated to setting up the visual environment. Perhaps the screen contains several text entry fields or clickable buttons. To determine which button a user clicks, the program examines the coordinates of the click and compares those coordinates against a list of all button coordinates on the screen. Program execution then branches out to perform the instructions reserved for clicking in that space.

Object-oriented programming is almost the inverse of that process. A button is considered an object—something tangible. An object has properties, such as its label, size, alignment, and so on. An object may also contain a script. At the same time, the system software and browser, working together, can send a message to an object—depending on what the user does—to trigger the script. For example, if a user clicks in a text entry field, the system/browser tells the field that somebody has clicked there (that is, has set the focus to that field), giving the field the task of deciding what to do about it. That's where the script comes in. The script is connected to the field, and it contains the instructions that the field carries out after the user activates it. Another set of instructions may control what happens when the user types an entry and tabs or clicks out of the field, thereby changing the content of the field.

Some of the scripts you write may seem to be procedural in construction: They contain a simple list of instructions that are carried out in order. But when dealing with data from form elements, these instructions work with the object-based nature of JavaScript. The form is an object; each radio button or text field is an object as well. The script then acts on the properties of those objects to get some work done.

Making the transition from procedural to object-oriented programming may be the most difficult challenge for you. When I was first introduced to object-oriented programming a number of years ago, I didn't get it at first. But when the concept clicked—a long, pensive walk helped—so many light bulbs went on inside my head that I thought I might glow in the dark. From then on, object orientation seemed to be the only sensible way to program.

## If you've programmed in C before

By borrowing syntax from Java (which, in turn, is derived from C and C++), JavaScript shares many syntactical characteristics with C. Programmers familiar with C will feel right at home. Operator symbols, conditional structures, and repeat loops follow very much in the C tradition. You will be less concerned about data types in JavaScript than you are in C. In JavaScript, a variable is not restricted to any particular data type.

With so much of JavaScript's syntax familiar to you, you will be able to concentrate on document object model concepts, which may be entirely new to you. You will still need a good grounding in HTML to put your expertise to work in JavaScript.

## If you've programmed in Java before

Despite the similarity in their names, the two languages share only surface aspects: loop and conditional constructions, C-like “dot” object references, curly braces for grouping statements, several keywords, and a few other attributes. Variable declarations, however, are quite different, because JavaScript is a loosely typed language. A variable can contain an integer value in one statement and a string in the next (though I'm not saying that this is good style). What Java refers to as methods, JavaScript calls methods (when associated with a predefined

object) or functions (for scripter-defined actions). JavaScript methods and functions may return values of any type without having to state the data type ahead of time.

Perhaps the most important aspects of Java to suppress when writing JavaScript are the object-oriented notions of classes, inheritance, instantiation, and message passing. These aspects are simply non-issues when scripting. At the same time, however, JavaScript's designers knew that you'd have some hard-to-break habits. For example, although JavaScript does not require a semicolon at the end of each statement line, if you type one in your JavaScript source code, the JavaScript interpreter won't balk.

## If you've written scripts (or macros) before

Experience with writing scripts in other authoring tools or macros in productivity programs is helpful for grasping a number of JavaScript's concepts. Perhaps the most important concept is the idea of combining a handful of statements to perform a specific task on some data. For example, you can write a macro in Microsoft Excel that performs a data transformation on daily figures that come in from a corporate financial report on another computer. The macro is built into the Macro menu, and you run it by choosing that menu item whenever a new set of figures arrives.

Some modern programming environments, such as Visual Basic, resemble scripting environments in some ways. They present the programmer with an interface builder, which does most of the work of displaying screen objects with which the user will interact. A big part of the programmer's job is to write little bits of code that are executed when a user interacts with those objects. A great deal of the scripting you will do with JavaScript matches that pattern exactly. In fact, those environments resemble the scriptable browser environment in another way: They provide a finite set of predefined objects that have fixed sets of properties and behaviors. This predictability makes learning the entire environment and planning an application easier to accomplish.

## Formatting and Naming Conventions

The script listings and words in this book are presented in a `monospace` font to set them apart from the rest of the text. Because of restrictions in page width, lines of script listings may, from time to time, break unnaturally. In such cases, the remainder of the script appears in the following line, flush with the left margin of the listing, just as they would appear in a text editor with word wrapping turned on. If these line breaks cause you problems when you type a script listing into a document yourself, I encourage you to access the corresponding listing on the CD-ROM to see how it should look when you type it.

As soon as you reach Part III of this book, you won't likely go for more than a page before reading about an object model or language feature that requires a specific minimum version of one browser or another. To make it easier to spot in the text when a particular browser and browser version is required, most browser references consist of an abbreviation and a version number. For example, WinIE5 means Internet Explorer 5 for Windows; NN6 means Netscape Navigator 6 for any operating system; Moz stands for the relatively new browsers now under the stewardship of The Mozilla Foundation; and Safari is Apple's own browser for MacOS X. If a feature is introduced with a particular version of browser and is supported in subsequent versions, a plus symbol (+) follows the number. For example, a feature marked WinIE5.5+ indicates that Internet Explorer 5.5 for Windows is required at a minimum, but the feature is also available in

WinIE6 and probably future WinIE versions. Occasionally, a feature or some highlighted behavior applies to only one browser. For example, a feature marked NN4 means that it works only in Netscape Navigator 4.x. A minus sign (e.g., WinIE-) means that the browser does not support the item being discussed.

The format of HTML and code listings in this edition has changed radically from previous editions. To emphasize the Web developer community's trend toward the latest Web standards, the HTML examples in this edition follow XHTML coding conventions, which dictate all-lowercase tag and attribute names, as well as self-closing tags that do not act as containers (such as the XHTML `<br />` tag in place of the HTML `<br>` tag). Another pervasive style change is the explicit inclusion of semicolons at the end of JavaScript statement lines. Semicolons are still optional in the language, but I have changed my personal coding style, as demonstrated throughout this book.

**Note****Tip****Caution**

Note, Tip, and Caution icons occasionally appear in the book to flag important points.

# Acknowledgments

---

**B**ringing this 1750-page edition up to the current state of the art was a task greater than one author could possibly handle in a timely manner. While I busied myself with updating the tutorial and validating terminology and listings with the latest browsers, I was fortunate to have the tireless help of Michael Morrison — a first-rate author in his own right — who carefully pruned obsolete content, modernized tens of thousands of lines of code, restored linearity to the previous edition’s maze, and kept the project on track at a breakneck pace. David Wall, a long-time *JavaScript Bible* helper, thankfully contributed his time and expertise to this effort as well. Many thanks to the hard-working folks at Wiley Publishing: Debra Williams Cauley, Mary Beth Wakefield, Angela Smith. Above all, I want to thank the many readers of the earlier editions of this book for investing in this ongoing effort. I wish I had the space here to acknowledge by name so many who have sent e-mail notes and suggestions: Your input has been most welcome and greatly appreciated.

# Contents at a Glance

---

Foreword . . . . .	vii
Preface . . . . .	ix
Acknowledgments . . . . .	xvii

## **PART I: Getting Started with JavaScript . . . . . 1**

Chapter 1: JavaScript's Role in the World Wide Web and Beyond . . . . .	3
Chapter 2: Authoring Challenges Amid the Browser Wars . . . . .	9
Chapter 3: Your First JavaScript Script . . . . .	17

## **PART II: JavaScript Tutorial . . . . . 25**

Chapter 4: Browser and Document Objects . . . . .	27
Chapter 5: Scripts and HTML Documents . . . . .	47
Chapter 6: Programming Fundamentals, Part I . . . . .	59
Chapter 7: Programming Fundamentals, Part II . . . . .	69
Chapter 8: Window and Document Objects . . . . .	83
Chapter 9: Forms and Form Elements . . . . .	97
Chapter 10: Strings, Math, and Dates . . . . .	111
Chapter 11: Scripting Frames and Multiple Windows . . . . .	121
Chapter 12: Images and Dynamic HTML . . . . .	131

## **PART III: Document Objects Reference . . . . . 141**

Chapter 13: JavaScript Essentials . . . . .	143
Chapter 14: Document Object Model Essentials . . . . .	163
Chapter 15: Generic HTML Element Objects . . . . .	201
Chapter 16: Window and Frame Objects . . . . .	359
Chapter 17: Location and History Objects . . . . .	485
Chapter 18: The Document and Body Objects . . . . .	509
Chapter 19: Link and Anchor Objects . . . . .	591
Chapter 20: Image, Area, and Map Objects . . . . .	601
Chapter 21: The Form and Related Objects . . . . .	629
Chapter 22: Button Objects . . . . .	651
Chapter 23: Text-Related Form Objects . . . . .	673
Chapter 24: Select, Option, and FileUpload Objects . . . . .	695
Chapter 25: Event Objects . . . . .	719
Chapter 26: Style Sheet and Style Objects . . . . .	793

**PART IV: JavaScript Core Language Reference . . . . . 847**

Chapter 27: The String Object . . . . . 849  
Chapter 28: The Math, Number, and Boolean Objects . . . . . 877  
Chapter 29: The Date Object . . . . . 891  
Chapter 30: The Array Object . . . . . 909  
Chapter 31: Control Structures and Exception Handling . . . . . 931  
Chapter 32: JavaScript Operators . . . . . 961  
Chapter 33: Functions and Custom Objects . . . . . 981  
Chapter 34: Global Functions and Statements . . . . . 1009  
Chapter 35: Body Text Objects . . . . . 1023

**PART V: Appendixes . . . . . 1105**

Appendix A: JavaScript and Browser Object Quick Reference . . . . . 1107  
Appendix B: JavaScript Reserved Words . . . . . 1121  
Appendix C: Answers to Tutorial Exercises . . . . . 1123  
Appendix D: JavaScript and DOM Internet Resources . . . . . 1139  
Appendix E: What's on the CD-ROM . . . . . 1143

Index . . . . . 1147  
End-User License Agreement . . . . . 1243

**PART VI: Bonus Chapters . . . . . On the CD-ROM**

Chapter 36: HTML Directive Objects  
Chapter 37: Table and List Objects  
Chapter 38: The Navigator and Other Environment Objects  
Chapter 39: Positioned Objects  
Chapter 40: Embedded Objects  
Chapter 41: XML Objects  
Chapter 42: The Regular Expression and RegExp Objects  
Chapter 43: Data-Entry Validation  
Chapter 44: Scripting Java Applets and Plug-Ins  
Chapter 45: Debugging Scripts  
Chapter 46: Security and Netscape Signed Scripts  
Chapter 47: Cross-Browser Dynamic HTML Issues  
Chapter 48: Internet Explorer Behaviors  
Chapter 49: Application: Tables and Calendars

Chapter 50: Application: A Lookup Table

Chapter 51: Application: A “Poor Man’s” Order Form

Chapter 52: Application: Outline-Style Table of Contents

Chapter 53: Application: Calculations and Graphics

Chapter 54: Application: Intelligent “Updated” Flags

Chapter 55: Application: Decision Helper

Chapter 56: Application: Cross-Browser DHTML Map Puzzle

Chapter 57: Application: Transforming XML Data

# Contents

Foreword . . . . .	vii
Preface . . . . .	ix
Acknowledgments . . . . .	xvii

## Part I: Getting Started with JavaScript 1

<b>Chapter 1: JavaScript's Role in the World Wide Web and Beyond . . . . .</b>	<b>3</b>
Competing for Web Traffic . . . . .	4
Other Web Technologies . . . . .	4
JavaScript: A Language for All . . . . .	6
JavaScript: The Right Tool for the Right Job . . . . .	8
<b>Chapter 2: Authoring Challenges Amid the Browser Wars . . . . .</b>	<b>9</b>
Leapfrog . . . . .	9
Duck and Cover . . . . .	10
Compatibility Issues Today . . . . .	11
Developing a Scripting Strategy . . . . .	14
<b>Chapter 3: Your First JavaScript Script . . . . .</b>	<b>17</b>
The Software Tools . . . . .	17
Setting Up Your Authoring Environment . . . . .	18
What Your First Script Will Do . . . . .	20
Entering Your First Script . . . . .	21
Examining the Script . . . . .	22
Have Some Fun . . . . .	24

## Part II: JavaScript Tutorial 25

<b>Chapter 4: Browser and Document Objects . . . . .</b>	<b>27</b>
Scripts Run the Show . . . . .	27
JavaScript in Action . . . . .	28
The Document Object Model . . . . .	34
When a Document Loads . . . . .	36
Object References . . . . .	39
Node Terminology . . . . .	41
What Defines an Object? . . . . .	42
Exercises . . . . .	46

<b>Chapter 5: Scripts and HTML Documents</b> . . . . .	<b>47</b>
Where Scripts Go in Documents . . . . .	47
JavaScript Statements . . . . .	51
When Script Statements Execute . . . . .	51
Viewing Script Errors . . . . .	54
Scripting versus Programming . . . . .	55
Exercises . . . . .	56
<b>Chapter 6: Programming Fundamentals, Part I</b> . . . . .	<b>59</b>
What Language Is This? . . . . .	59
Working with Information . . . . .	59
Variables . . . . .	60
Expressions and Evaluation . . . . .	62
Data Type Conversions . . . . .	64
Operators . . . . .	66
Exercises . . . . .	67
<b>Chapter 7: Programming Fundamentals, Part II</b> . . . . .	<b>69</b>
Decisions and Loops . . . . .	69
Control Structures . . . . .	70
About Repeat Loops . . . . .	71
Functions . . . . .	72
About Curly Braces . . . . .	76
Arrays . . . . .	76
Exercises . . . . .	80
<b>Chapter 8: Window and Document Objects</b> . . . . .	<b>83</b>
Top-Level Objects . . . . .	83
The window Object . . . . .	84
Window Properties and Methods . . . . .	87
The location Object . . . . .	89
The navigator Object . . . . .	90
The document Object . . . . .	90
Exercises . . . . .	95
<b>Chapter 9: Forms and Form Elements</b> . . . . .	<b>97</b>
The form Object . . . . .	97
Form Controls as Objects . . . . .	100
The Button Object . . . . .	102
The Checkbox Object . . . . .	102
The Radio Object . . . . .	103
The select Object . . . . .	104
Passing Form Data and Elements to Functions . . . . .	106
Submitting and Prevalidating Forms . . . . .	108
Exercises . . . . .	110

<b>Chapter 10: Strings, Math, and Dates</b> . . . . .	<b>111</b>
Core Language Objects . . . . .	111
String Objects . . . . .	111
The Math Object . . . . .	115
The Date Object . . . . .	116
Date Calculations . . . . .	117
Exercises . . . . .	119
<b>Chapter 11: Scripting Frames and Multiple Windows</b> . . . . .	<b>121</b>
Frames: Parents and Children . . . . .	121
References among Family Members . . . . .	123
Frame Scripting Tips . . . . .	125
About iframe Elements . . . . .	125
Controlling Multiple Frames — Navigation Bars . . . . .	126
References for Multiple Windows . . . . .	128
Exercises . . . . .	130
<b>Chapter 12: Images and Dynamic HTML</b> . . . . .	<b>131</b>
The Image Object . . . . .	131
The javascript: Pseudo-URL . . . . .	137
Popular Dynamic HTML Techniques . . . . .	137
Exercises . . . . .	140

## Part III: Document Objects Reference 141

<b>Chapter 13: JavaScript Essentials</b> . . . . .	<b>143</b>
JavaScript Versions . . . . .	143
Core Language Standard — ECMAScript . . . . .	144
Embedding Scripts in HTML Documents . . . . .	144
Browser Version Detection . . . . .	148
Designing for Compatibility . . . . .	155
Language Essentials for Experienced Programmers . . . . .	158
Onward to Object Models . . . . .	161
<b>Chapter 14: Document Object Model Essentials</b> . . . . .	<b>163</b>
The Object Model Hierarchy . . . . .	163
How Document Objects Are Born . . . . .	165
Object Properties . . . . .	166
Object Methods . . . . .	167
Object Event Handlers . . . . .	168
Object Model Smorgasbord . . . . .	169

### Chapter 3

Your First JavaScript Script

# JavaScript's Role in the World Wide Web and Beyond

---

**M**any of the technologies that make the World Wide Web possible have far exceeded their original goals. Envisioned at the outset as a medium for publishing static text and image content across a network, the Web is forever being probed, pushed, and pulled by content authors. By taking for granted so much of the “dirty work” of conveying the bits between server and client computers, content developers and programmers dream of exploiting that connection to generate new user experiences and practical applications. It's not uncommon for a developer community to take ownership of a technology and mold it to do new and exciting things. But with so many Web technologies — especially browser programming with JavaScript — being within reach of everyday folks, we have witnessed an unprecedented explosion in turning the World Wide Web from a bland publishing medium into a highly interactive, operating system-agnostic authoring platform.

The JavaScript language, working in tandem with related browser features, is a Web-enhancing technology. When employed on the client computer, the language can help turn a static page of content into an engaging, interactive, and intelligent experience. Applications can be as subtle as welcoming a site's visitor with the greeting “Good morning!” when it is morning in the client computer's time zone — even though it is dinnertime where the server is located. Or applications can be much more obvious, such as delivering the content of a slide show in a one-page download while JavaScript controls the sequence of hiding, showing, and “flying slide” transitions while navigating through the presentation.

Of course, JavaScript is not the only technology that can give life to drab Web content. Therefore, it is important to understand where JavaScript fits within the array of standards, tools, and other technologies at your disposal. The alternative technologies described in this chapter are HTML, Cascading Style Sheets (CSS), server programs, and plug-ins. In most cases, JavaScript can work side by side with these other technologies, even though the hype around some make them sound like one-stop shopping places for all your interactive needs. That's rarely the case. Finally, you learn about the origins of JavaScript and what role it plays in today's advanced Web browsers.

## In This Chapter

How JavaScript blends with other Web-authoring technologies

The history of JavaScript

What kinds of jobs you should and should not entrust to JavaScript

## Competing for Web Traffic

Web page publishers revel in logging as many visits to their sites as possible. Regardless of the questionable accuracy of Web page *hit* counts, a site consistently logging 10,000 dubious hits per week is clearly far more popular than one with 1,000 dubious hits per week. Even if the precise number is unknown, relative popularity is a valuable measure. Another useful number is how many links from outside pages lead to a site. A popular site will have many other sites pointing to it—a key to earning high visibility in Web searches.

Encouraging people to visit a site frequently is the Holy Grail of Web publishing. Competition for viewers is enormous. Not only is the Web like a fifty million-channel television, but the Web competes for viewers' attention with all kinds of computer-generated information. That includes anything that appears onscreen as interactive multimedia.

Users of entertainment programs, multimedia encyclopedias, and other colorful, engaging, and mouse finger-numbing actions are accustomed to high-quality presentations. Frequently, these programs sport first-rate graphics, animation, live-action video, and synchronized sound. In contrast, the lowest common denominator Web page has little in the way of razzle-dazzle. Even with the help of Dynamic HTML and stylesheets, the layout of pictures and text is highly constrained compared with the kinds of desktop publishing documents you see all the time. Regardless of the quality of its content, an unscripted, vanilla HTML document is flat. At best, interaction is limited to whatever navigation the author offers in the way of hypertext links or forms whose filled-in content magically disappears into the Web site's server.

## Other Web Technologies

With so many ways to spice up Web sites and pages, you can count on competitors for your site's visitors to do their darndest to make their sites more engaging than yours. Unless you are the sole purveyor of information that is in high demand, you continually must devise ways to keep your visitors coming back and entice new ones. If you design for an intranet, your competition is the drive for improved productivity by colleagues who use the internal Web sites for getting their jobs done.

These are all excellent reasons why you should care about using one or more Web technologies to raise your pages above the noise. Let's look at the major technologies you should know about.

### Hypertext Markup Language (HTML and XHTML)

As an outgrowth of *SGML* (*Standard Generalized Markup Language*), *HTML* is generally viewed as nothing more than a document formatting, or *tagging*, language. The tags (inside <> delimiter characters) instruct a viewer program (the *browser* or, more generically, the *client*) how to display chunks of text or images.

Relegating HTML to the category of a tagging language does disservice not only to the effort that goes into fashioning a first-rate Web page, but also to the way users interact with the pages. To my way of thinking, any collection of commands and other syntax that directs the way users interact with digital information is *programming*. With HTML, a Web page author controls the user experience with the content just as the engineers who program Microsoft Excel craft the way users interact with spreadsheet content and functions.

Version 4.0 and later of the published HTML standards endeavor to define the purpose of HTML as assigning context to content, leaving the appearance to a separate standard for stylesheets. In other words, it's not HTML's role to signify that some text is italic, but rather to signify *why*

it is italic. For example, you would tag a chunk of text that conveys emphasis (via the `<em>` tag) regardless of how the stylesheet or browser sets the appearance of that emphasized text.

XHTML is a more recent adaptation of HTML that adheres to stylistic conventions established by the XML (eXtensible Markup Language) standard. No new tags come with XHTML, but it reinforces the notion of tagging to denote a document's structure and content.

## Cascading Style Sheets (CSS)

Specifying the look and feel of a Web page via stylesheets is a major trend taking over the modern Web. The basic idea is that given a document's structure spelled out by its HTML or XHTML, a stylesheet defines the layout, colors, fonts, and other visual characteristics to present the content. Applying a different set of CSS definitions to the same document can make it look entirely different, even though the words and images are the same.

Mastery of the fine points of CSS takes time and experimentation, but the results are worth the effort. The days of using HTML tables and transparent "spacer" images to generate elaborate multicolumn layouts are on the wane. Every Web developer should have a solid grounding in CSS.

## Server scripting

Web sites that rely on database access or change their content very frequently incorporate programming on the server that generates the HTML output for browsers and/or processes forms that site visitors fill out on the page. Even submissions from a simple login or search form ultimately trigger some server process that sends the results to your browser. Server programming takes on many guises, the names of which you may recognize from your surfing through Web development sites. PHP, ASP, .Net, JSP, and Coldfusion are among the most popular. Associated programming languages include Perl, Python, Java, C++, C#, Visual Basic, and even server-side JavaScript in some environments.

Whatever language you use, the job definitely requires the Web page author to be in control of the server, including whatever *back-end* programs (such as databases) are needed to supply results or massage the information coming from the user. Even with the new, server-based Web site design tools available, server scripting often is a task that a content-oriented HTML author will need to hand off to a more experienced programmer.

As powerful and useful as server scripting can be, it does a poor job of facilitating interactivity in a Web page. Without the help of browser scripting, each change to a page must be processed on the server, causing delays for the visitor and an extra burden on the server for simple tasks. This wastes desktop processing horsepower, especially if the process running on the server doesn't need to access big databases or other external computers.

## Of helpers and plug-ins

In the early days of the World Wide Web, a browser needed to present only a few kinds of data before a user's eyes. The power to render text (tagged with HTML) and images (in popular formats such as GIF and JPEG) was built into browsers intended for desktop operating systems. Not wanting to be limited by those data types, developers worked hard to extend browsers so that data in other formats could be rendered on the client computer. It was unlikely, however, that a browser would ever be built that could download and render, say, any of several sound file formats.

One way to solve the problem was to allow the browser, upon recognizing an incoming file of a particular type, to launch a separate application on the client machine to render the

content. As long as this helper application was installed on the client computer (and the association with the helper program set in the browser's preferences), the browser would launch the program and send the incoming file to that program. Thus, you might have one helper application for a MIDI sound file and another for an animation file.

Beginning with Netscape Navigator 2 in early 1996, software *plug-ins* for browsers enabled developers to extend the capabilities of the browser without having to modify the browser. Unlike a helper application, a plug-in can enable external content to blend into the document seamlessly.

The most common plug-ins are those that facilitate the playback of audio and video from the server. Audio may include music tracks that play in the background while visiting a page or live (streaming) audio, similar to a radio station. Video and animation can operate in a space on the page when played through a plug-in that knows how to process such data.

Today's browsers tend to ship with plug-ins that decode the most common sound file types. Developers of plug-ins for Internet Explorer for the Windows operating system commonly implement plug-ins as ActiveX controls—a distinction that is important to the underpinnings of the operating system but not to the user.

Plug-ins and helpers are valuable for more than just audio and video playback. A popular helper application is the *Adobe Acrobat Reader*, which displays Acrobat files that are formatted just as if they were being printed. But for interactivity, developers today frequently rely on Macromedia Corporation's *Flash* plug-in. Created using the Macromedia Flash authoring environment, a Flash document can have active clickable areas and draggable elements. Some authors even simulate artistic video games and animated stories in Flash. A browser equipped with the Flash plug-in displays the content in a rectangular area embedded within the browser page.

One potential downside for authoring interactive content in Flash or similar environments is that if the user does not have the correct plug-in version installed, it can take some time to download the plug-in (if the user even wants to bother). Moreover, once the plug-in is installed, highly graphic and interactive content can take longer to download to the client (especially on a dial-up connection) than some users are willing to wait. This is one of those situations in which you must balance your creative palette with the user's desire for your interactive content.

Another client-side technology—the Java applet—was popular for a while in the late 1990s but has fallen out of favor for a variety of reasons (some technical, some corporate-political). But this has not diminished the use of Java as a language for server and even cellular telephone programming, extending well beyond the scope of the language's founding company, Sun Microsystems.

## JavaScript: A Language for All

Sun's Java language is derived from C and C++, but it is a distinct language. Its main audience is the experienced programmer. That leaves out many Web page authors. I was dismayed at this situation when I first read about Java's preliminary specifications in 1995. I would have preferred a language that casual programmers and scripters who were comfortable with authoring tools, such as Apple's once-formidable HyperCard and Microsoft's Visual Basic, could adopt quickly. As these accessible development platforms have shown, nonprofessional authors can dream up many creative applications, often for very specific tasks that no professional programmer would have the inclination to work on. Personal needs often drive development in the classroom, office, den, or garage. But Java was not going to be that kind of inclusive language.

My spirits lifted several months later, in November 1995, when I heard of a scripting language project brewing at Netscape Communications, Inc. Initially born under the name LiveScript, this language was developed in parallel with a new version of Netscape's Web server software. The language was to serve two purposes with the same syntax. One purpose was as a scripting language that Web server administrators could use to manage the server and connect its pages to other services, such as back-end databases and search engines for users looking up information. Extending the "Live" brand name further, Netscape assigned the name LiveWire to the database connectivity usage of LiveScript on the server.

On the client side—in HTML documents—authors could employ scripts written in this new language to enhance Web pages in a number of ways. For example, an author could use LiveScript to make sure that the user had filled in a required text field with an e-mail address or credit card number. Instead of forcing the server or database to do the data validation (requiring data exchanges between the client browser and the server), the user's computer handles all the calculation work—putting some of that otherwise wasted computing horsepower to work. In essence, LiveScript could provide HTML-level interaction for the user.

## LiveScript becomes JavaScript

In early December 1995, just prior to the formal release of Navigator 2, Netscape and Sun Microsystems jointly announced that the scripting language thereafter would be known as JavaScript. Though Netscape had several good marketing reasons for adopting this name, the changeover may have contributed more confusion to both the Java and HTML scripting worlds than anyone expected.

Before the announcement, the language was already related to Java in some ways. Many of the basic syntax elements of the scripting language were reminiscent of the Java style. For client-side scripting, the language was intended for very different purposes than Java—essentially to function as a programming language integrated into HTML documents rather than as a language for writing applets that occupy a fixed rectangular area on the page (and that are oblivious to anything else on the page). Instead of Java's full-blown programming language vocabulary (and conceptually more difficult to learn object-oriented approach), JavaScript had a small vocabulary and a more easily digestible programming model.

The true difficulty, it turned out, was making the distinction between Java and JavaScript clear to the world. Many computer journalists made major blunders when they said or implied that JavaScript provided a simpler way of building Java applets. To this day, some new programmers believe JavaScript is synonymous with the Java language: They post Java queries to JavaScript-specific Internet newsgroups and mailing lists.

The fact remains that client-side Java and JavaScript are more different than they are similar. The two languages employ entirely different interpreter engines to execute their lines of code.

## Enter Microsoft and others

Although the JavaScript language originated at Netscape, Microsoft acknowledged the potential power and popularity of the language by implementing it (under the JScript name) in Internet Explorer 3. Even if Microsoft might prefer that the world use the VBScript (Visual Basic Script) language that it provides in the Windows versions of IE, the fact that JavaScript is available on more browsers and operating systems makes it the client-side scripter's choice for anyone who must design for a broad range of users.

With scripting firmly entrenched in the mainstream browsers from Microsoft and Netscape, newer browser makers automatically provided support for JavaScript. Therefore, you can count on fundamental scripting services in browsers such as Opera or the Apple Safari

browser (the latter built upon an Open Source browser called KHTML). Not that all browsers work the same way in every detail—a significant challenge for client-side scripting that is addressed throughout this book.

## JavaScript: The Right Tool for the Right Job

Knowing how to match an authoring tool to a solution-building task is an important part of being a well-rounded Web site author. A Web designer who ignores JavaScript is akin to a plumber who bruises his knuckles by using pliers instead of the wrench from the bottom of the toolbox.

By the same token, JavaScript won't fulfill every dream. The more you understand about JavaScript's intentions and limitations, the more likely you will be to turn to it immediately when it is the proper tool. In particular, look to JavaScript for the following kinds of solutions:

- ♦ Getting your Web page to respond or react directly to user interaction with form elements (input fields, text areas, buttons, radio buttons, checkboxes, selection lists) and hypertext links
- ♦ Distributing small collections of database-like information and providing a friendly interface to that data
- ♦ Controlling multiple-frame navigation, plug-ins, or Java applets based on user choices in the HTML document
- ♦ Preprocessing data on the client before submission to a server
- ♦ Changing content and styles in modern browsers dynamically and instantly in response to user interaction

At the same time, it is equally important to understand what JavaScript is *not* capable of doing. Scripters waste many hours looking for ways of carrying out tasks for which JavaScript was not designed. Most of the limitations are designed to protect visitors from invasions of privacy or unauthorized access to their desktop computers. Therefore, unless a visitor uses a modern browser and explicitly gives you permission to access protected parts of his or her computer, JavaScript cannot surreptitiously perform any of the following actions:

- ♦ Setting or retrieving the browser's preferences settings, main window appearance features, action buttons, and printing
- ♦ Launching an application on the client computer
- ♦ Reading or writing files or directories on the client or server computer
- ♦ Capturing live data streams from the server for retransmission
- ♦ Sending secret e-mails from Web site visitors to you

Web site authors are constantly seeking tools that will make their sites engaging (if not "cool") with the least amount of effort. This is particularly true when the task is in the hands of people more comfortable with writing, graphic design, and page layout than with hard-core programming. Not every Webmaster has legions of experienced programmers on hand to whip up some special, custom enhancement for the site. Nor does every Web author have control over the Web server that physically houses the collection of HTML and graphics files. JavaScript brings programming power within reach of anyone familiar with HTML, even when the server is a black box at the other end of a telephone line.

# Authoring Challenges Amid the Browser Wars

---

If you are starting to learn JavaScript at this point in the brief history of scriptable browsers, you have both a distinct advantage and disadvantage. The advantage is that you have the wonderful capabilities of mature browser offerings from Microsoft, Netscape, The Mozilla Foundation, Apple, and others at your bidding. The disadvantage is that you have not experienced the painful history of authoring for older browser versions that were buggy and at times incompatible with one another due to a lack of standards. You have yet to learn the anguish of carefully devising a scripted application for the browser version you use only to have site visitors sending you voluminous e-mail messages about how the page triggers all kinds of script errors when run on a different browser brand, generation, or operating system platform.

Welcome to the real world of scripting Web pages with JavaScript. Several dynamics are at work to help make an author's life difficult if the audience for the application uses more than a single type of browser. This chapter introduces you to these challenges before you type your first word of JavaScript code. My fear is that the subjects I raise may dissuade you from progressing further into JavaScript and its powers. But as a developer myself — and as someone who has been using JavaScript since the earliest days of its public pre-release availability — I dare not sugarcoat the issues facing scripters today. Instead, I want to make sure you have an appreciation of what lies ahead to assist you in learning the language. I believe if you understand the big picture of the browser-scripting world as it stands in the year 2004, you will find it easier to target JavaScript usage in your Web application development and be successful at it.

## Leapfrog

Browser compatibility has been an issue for authors since the earliest days of the Web gold rush — long before JavaScript. Despite the fact that browser developers and other interested parties voiced their opinions during formative stages of standards development, HTML authors could not produce a document that appeared the same pixel by pixel on all client machines. It may have been one thing to establish a set of standard tags for defining heading levels and line

### In This Chapter

How leapfrogging browser developments hurt Web developers

Separating the core JavaScript language from document objects

The importance of developing a cross-browser strategy

breaks, but it was rare for the actual rendering of content inside those tags to look identical on different brands of browsers on different operating systems.

Then, as the competitive world heated up — and Web browser development transformed itself from a volunteer undertaking into profit-seeking businesses — creative people defined new features and new tags that helped authors develop more flexible and interesting looking pages. As happens a lot in any computer-related industry, the pace of commercial development easily surpassed the studied progress of standards. A browser maker would build a new HTML feature into a browser and only then propose that feature to the relevant standards body. Web authors were using these features (sometimes for prerelease browser versions) before the proposals were published for review.

When the deployment of content depends almost entirely on an interpretive engine on the client computer receiving the data — the HTML engine in a browser, for example — authors face an immediate problem. Unlike a standalone computer program that can extend and even invent functionality and have it run on everyone's computer (at least for a given operating system), Web content providers must rely on the functionality built into the browser. This led to questions such as, "If not all browsers coming to my site support a particular HTML feature, then should I apply newfangled HTML features for visitors only at the bleeding edge?" and "If I do deploy the new features, what do I do for those with older browsers?"

Authors who developed pages in the earliest days of the Web wrestled with these questions for many HTML features that we today take for granted. Tables and frames come to mind. Eventually, the standards caught up with the proposed HTML extensions — but not without a lot of author woe along the way.

Despite the current dominance of Microsoft's Internet Explorer browser on the dominant Windows operating system, the number of browsers that people use is not shrinking. Several recent browsers, including the modern Netscape 7 and Firebird browsers, are based on an Open Source browser called Mozilla. The Macintosh operating system now includes its own Apple-branded browser, Safari (released in 2003). And the independent Opera browser also has a home on some users' computers. All of these non-Microsoft browser makers obviously believe that they bring improvements to the world to justify their development — building better mousetraps you might say.

## Duck and Cover

Today's browser wars are fought on different battlegrounds than in the early days of the Web. The breadth and depth of established Web standards have substantially fattened the browser applications — and books that developers read to exploit those standards for their content. On the one hand, most developers clamor for deeper standards support in new browser versions. On the other hand, everyday users care little about standards. All they want is to have an enjoyable time finding the information they seek on the Web. Most users are slow to upgrade their browsers, holding out until their favorite sites start breaking in their ancient browsers.

Industry standards don't necessarily make the Web developer's job any easier. For one thing, the standards are unevenly implemented across the latest browsers. Some browsers go further in their support than others. Then there are occasional differences in interpretation of vague standards details. And sometimes the standards don't provide any guidance in areas that are vital to content developers. At times we are left to the whims of browser makers who fill the gaps with proprietary features, in the hope that those features will become de facto standards.

As happens in war, civilian casualties mount when the big guns start shooting. The browser battle lines shifted dramatically in only a few years. The huge market share territory once

under Netscape's command now lies in Microsoft hands. The Netscape brand, itself, is fading as a result of corporate dealings; but the spirit continues in the populist, Open Source Mozilla effort. While a fair amount of authoring common ground exists between the latest versions of today's browsers, uneven implementation of the newest features causes the biggest problems for authors wishing to deploy on all browsers. Trying to define the common denominator may be the toughest part of the authoring job.

## Compatibility Issues Today

Allow me to describe the current status of the compatibility situation among the top three browser families: Microsoft's Internet Explorer, browsers based on Mozilla, and Apple's Safari. The discussion in the next few sections intentionally does not get into specific scripting technology very deeply—some of you may know very little about programming at this point. In many chapters throughout Parts III and IV, I offer scripting suggestions to accommodate a variety of browsers.

### Separating language from objects

Although early JavaScript authors initially treated client-side scripting as one environment that permitted the programming of page elements, the scene has changed as the browsers have matured. Today, a clear distinction exists between specifications for the core JavaScript language and for the elements you script in a document (for example, buttons and fields in a form).

On one level, this separation is a good thing. It means that one specification exists for basic programming concepts and syntax, which could become the programming language in any number of other environments. You can think of the core language as basic wiring. Once you know how electric wires work, you can connect them to all kinds of electrical devices. Similarly, JavaScript today is used to wire together elements in an HTML document. Tomorrow, operating systems could use the core language to enable users to wire together desktop applications that need to exchange information automatically.

At the ends of today's JavaScript wires are the elements on the page. In programming jargon, these items are known as *document objects*. By keeping the specifications for document objects separate from the wires that connect them, you can use other kinds of wires (other languages) to connect them. It's like designing telephones that can work with any kind of wire, including a type of wire that hasn't been invented yet. Today the devices can work with copper wire or fiber optic cable. You get a good picture of this separation in Internet Explorer, whose set of document objects can be scripted with JavaScript or VBScript. They're the same objects, just different wiring.

The separation of core language from document objects enables each concept to have its own standards effort and development pace. But even with recommended standards for each factor, each browser maker is free to extend the standards. Furthermore, authors may have to expend more effort to devise one version of a page or script that plays on multiple browsers unless the script adheres to a common denominator (or uses some other branching techniques to let each browser run its own way).

### Core language standard

Keeping track of JavaScript language versions requires a brief history lesson. The first version of JavaScript (in Netscape Navigator 2) was Version 1.0, although that numbering was not part of the language usage. JavaScript was JavaScript. Version numbering became an

issue when Navigator 3 was released. The version of JavaScript associated with that Navigator version was JavaScript 1.1. The first appearance of the Navigator 4 generation increased the language version one more notch with JavaScript 1.2.

Microsoft's scripting effort contributes confusion for scripting newcomers. The first version of Internet Explorer to include scripting was Internet Explorer 3. The timing of Internet Explorer 3 was roughly coincidental to Navigator 3. But as scripters soon discovered, Microsoft's scripting effort was one generation behind. Microsoft did not license the JavaScript name. As a result, the company called its language JScript. Even so, the HTML tag attribute that lets you name the language of the script inside the tags could be either JScript or JavaScript for Internet Explorer. Internet Explorer 3 could understand a JavaScript script written for Navigator 2.

During this period of dominance by Navigator 3 and Internet Explorer 3, scripting newcomers were often confused because they expected the scripting languages to be the same. Unfortunately for the scripters, there were language features in JavaScript 1.1 that were not available in the older JavaScript version in Internet Explorer 3. Microsoft improved JavaScript in IE3 with an upgrade to the .dll file that gives IE its JavaScript syntax. However, it's hard to know which .dll is installed in any given visitor's IE3. The situation smoothed out for Internet Explorer 4. Its core language was essentially up to the level of JavaScript 1.2 as in early releases of Navigator 4. Microsoft still officially called the language JScript. Almost all language features that were new in Navigator 4 were understood when you loaded the scripts into Internet Explorer 4.

While all of this jockeying for JavaScript versions was happening, Netscape, Microsoft, and other concerned parties met to establish a core language standard. The standards body is a Switzerland-based organization originally called the European Computer Manufacturer's Association and now known simply as ECMA (commonly pronounced ECK-ma). In mid-1997, the first formal language specification was agreed on and published (ECMA-262). Due to licensing issues with the JavaScript name, the body created a new name for the language: ECMAScript.

With only minor and esoteric differences, this first version of ECMAScript was essentially the same as JavaScript 1.1 found in Navigator 3. Both Navigator 4 and Internet Explorer 4 officially supported the ECMAScript standard. Moreover, as happens so often when commerce meets standards bodies, both browsers went beyond the ECMAScript standard. Fortunately, the common denominator of this extended core language is broad, lessening authoring headaches on this front.

JavaScript version 1.3 was implemented in Netscape Navigator 4.06 through 4.7x. This language version is also the one supported in IE 5, 5.5, and 6. A few new language features are incorporated in JavaScript 1.5, as implemented in Mozilla-based browsers (including Navigator 6 and later).

In practice, so many browsers in use today support all but a few leading-edge features of the Mozilla browsers that JavaScript version numbers are mostly irrelevant. Other compatibility issues with older browsers will likely get in your way before core language problems. The time has come to forget about elaborate workarounds for inadequacies of the oldest browsers.

## Document object model

If prevalent browsers have been close to each other in core JavaScript language compatibility, nothing could be further from the truth when it comes to the document objects. Internet Explorer 3 based its document object model (DOM) on that of Netscape Navigator 2, the same

browser level it used as a model for the core language. When Netscape added a couple of new objects to the model in Navigator 3, the addition caused further headaches for neophyte scripters who expected those objects to appear in Internet Explorer 3. Probably the most commonly missed object in Internet Explorer 3 was the image object, which lets scripts swap the image when a user rolls the cursor atop a graphic — *mouse rollovers*, they're commonly called.

In the Level 4 browsers, however, Internet Explorer's document object model jumped way ahead of the object model that Netscape implemented in Navigator 4. The two most revolutionary aspects of IE4 were the ability to script virtually every element in an HTML document and the instant reflow of a page when the content changed. This opened the way for HTML content to be genuinely dynamic without requiring the browser to fetch a rearranged page from the server. NN4 implemented only a small portion of this dynamism, without exposing all elements to scripts or reflowing the page. It introduced a proprietary layering concept that was abandoned in future Navigator versions. Inline content could not change in NN4 as it could in IE4. Suffice it to say IE4 was an enviable implementation.

At the same time, a DOM standard was being negotiated under the auspices of the World Wide Web Consortium (W3C). The hope among scripters was that once a standard was in place, it would be easier to develop dynamic content for all browsers that supported the standard. The resulting standard — the W3C DOM — formalized the notion of being able to script every element on the page, as in IE4. But it also invented an entirely new object syntax that no browser had used previously. The race was on for browsers to support the W3C DOM standards.

An arm of the Netscape company, called Mozilla.org, was formed to create an all-new browser dedicated to supporting industry standards. The engine for the Mozilla browser became the foundation for the all-new Navigator 6. It incorporated all of the W3C DOM Level 1 and a good chunk of Level 2. Mozilla 1.01 became the basis for the Netscape 7 browser, while Netscape 7.1 was built on the Mozilla 1.4 generation. In the summer of 2003, Netscape's parent company, AOL Time Warner, decided to end further Netscape-branded browser development. The work on the underlying Mozilla browser, however, continues under an independent organization called The Mozilla Foundation. Mozilla-branded browsers, and others using the same engine, continue to be upgraded and released to the public. The Mozilla engine offers arguably the most in-depth support for the W3C DOM Level 2 standard.

Even though Microsoft participated in the W3C DOM standards development, IE5 and 5.5 implemented only some of the W3C DOM standard — in some cases, just enough to allow simple cross-browser scripting that adheres to the standard. Microsoft further filled out W3C DOM support in IE6, but chose to omit several important parts. DOM support in Apple's Safari 1.0 lies in between that of Mozilla and IE6. Of course, the standard is not perfect either, lacking some practical features that IE offered back in IE4.

Despite this seemingly tortuous history of DOM development and browser support, you may wonder how anyone can approach DOM scripting with hope of success. Yet you'd be amazed at how much you can accomplish with today's browsers. You'll certainly encounter compatibility issues along the way, but this book will guide you through the most common problems and equip you to tackle others.

## Cascading Style Sheets

Navigator 4 and Internet Explorer 4 were the first browsers to claim compatibility with a W3C recommendation called *Cascading Style Sheets Level 1 (CSS1)*. This specification provided designers an organized way to customize the look and feel of a document (and thus minimized the HTML in each tag). As implementations go, NN4 had a lot of rough edges, especially when

trying to mix stylesheets and tables. But IE4 was no angel, either, especially when comparing the results of stylesheet assignments as rendered in the Windows and Macintosh versions of the browser (developed by two separate teams).

CSS Level 2 adds more style functionality to the standard, and IE6, Mozilla-based browsers, and Safari support a good deal of Level 2 (albeit unevenly). Rendering of styled content is more harmonious among browsers, largely thanks to guidelines about how styles should render. Complex layouts, however, still need careful tweaking from time to time because of different interpretations of the standard.

JavaScript plays a role in stylesheets in IE4+, Mozilla, and Safari because those browsers' object models permit dynamic modification to styles associated with any content on the page. Stylesheet information is part of the object model and is therefore accessible and modifiable from JavaScript.

## Dynamic HTML

Perhaps the biggest improvements to the inner workings of the Level 4 browsers from both Netscape and Microsoft revolved around a concept called *Dynamic HTML (DHTML)*. The ultimate goal of DHTML was to enable scripts in documents to control the content, content position, and content appearance in response to user actions. To that end, the W3C organization developed another standard for the precise positioning of HTML elements on a page as an extension of the CSS standards effort. The CSS-Positioning recommendation was later blended into the CSS standard, and both are now part of CSS Level 2. With positioning, you can define an exact location on the page where an element should appear, whether the item should be visible, and what stacking order it should take among all the items that might overlap it.

IE4+ adheres to the positioning standard syntax and makes positionable items subject to script control. Navigator 4 followed the standard from a conceptual point of view, but it implemented an alternative methodology involving an entirely new, and eventually unsanctioned, tag for layers. Such positionable items were scriptable in Navigator 4 as well, although a lot of the script syntax differed from that used in Internet Explorer 4. Fortunately for DHTML authors, Mozilla, by its adherence to the CSS standard, is more syntactically in line with DHTML style properties employed in IE4+. Numerous issues still surround the IE implementation because of Microsoft's shift with IE6 to a more accurate interpretation of certain measurement systems in CSS. The new system can be switched on in IE6 to be more in sync with the CSS standard as implemented in Mozilla and Safari browsers. Cross-browser DHTML scripting can be challenging, yet it is certainly possible if you understand the limitations imposed by following a common denominator.

## Developing a Scripting Strategy

Browsers representing the latest generation contain a hodgepodge of standards and proprietary extensions. Even if you try to script to a common denominator among today's browsers, your code probably won't take into account the earlier versions of both the JavaScript core language and the browser document object models.

The true challenge for authors these days is determining the audience for which scripted pages are intended. You learn techniques in Chapter 13 that enable you to redirect users to different paths in your Web site based on their browser capabilities. In Chapter 14, you discover the alternatives you can take depending on the object model version(s) and specific features you need to support. Each new browser generation not only brings with it new and exciting features you are probably eager to employ in your pages, it also adds

to the fragmentation of the audience visiting a publicly accessible page. With each new browser upgrade, fewer existing users are willing to download megabytes of browser merely to have the latest and greatest browser version. For many pioneers — and certainly for most nontechie users — there is a shrinking imperative to upgrade browsers, unless that browser comes via a new computer or operating system upgrade.

At this stage in the history of scriptable browsers, I take the stand that we should assume that a Web surfer arrives with a browser equipped with support for at least simple W3C DOM and DHTML capabilities. That certainly won't be the case 100 percent of the time, so it is also your obligation to apply scripting in an additive, or value-added manner. By this I mean that your pages should convey their primary information to the most brain-dead browser; but visitors with recent scriptable browsers will have a more enjoyable experience — better interactivity, faster performance, and a more engaging presentation. You will not only be contributing to the state of the art, but also carrying on the original vision of scripting in the browser.

# Your First JavaScript Script

---

In this chapter, you set up a productive scriptwriting and previewing environment on your computer, and then you write a simple script whose results you can see in your JavaScript-compatible browser.

Because of differences in the way various personal computing operating systems behave, I present details of environments for two popular variants: Windows (95 through XP) and MacOS X. For the most part, your JavaScript authoring experience is the same regardless of the operating system platform you use—including Linux or UNIX. Although there may be slight differences in font designs depending on your browser and operating system, the information remains the same. Most illustrations of browser output in this book are made from the Windows XP version of Internet Explorer 6. If you run another browser or version, don't fret if every pixel doesn't match with the illustrations in this book.

## The Software Tools

The best way to learn JavaScript is to type the HTML and scripting code into documents in a text editor. Your choice of editor is up to you, although I provide you with some guidelines for choosing a text editor in the next section.

### Choosing a text editor

For the purposes of learning JavaScript in this book, avoid WYSIWYG (What You See Is What You Get) Web-page authoring tools, such as FrontPage and DreamWeaver, for now. These tools certainly will come in handy afterward when you can productively use those facilities for molding the bulk of your content and layout. But the examples in this book focus more on script content (which you must type in anyway), so there isn't much HTML that you have to type. Files for all complete Web page listings in this book (except for the tutorial chapters) also appear on the companion CD-ROM.

An important factor to consider in your choice of editor is how easy it is to save standard text files with an .html filename extension. In the case of Windows, any program that not only saves the file as text by default but also enables you to set the extension to .htm or .html prevents a great deal of problems. If you use Microsoft Word, for

### In This Chapter

How to choose basic JavaScript authoring tools

How to set up your authoring environment

How to enter a simple script to a Web page

example, the program tries to save files as binary Word files — something that no Web browser can load. To save the file initially as a text or .html extension file requires mucking around in the Save As dialog box. This requirement is truly a nuisance.

Nothing's wrong with using bare-essentials text editors. In Windows, that includes the WordPad program or a more fully featured product such as the shareware editor called TextPad. For MacOS X, TextEdit is also fine. A favorite among Mac HTML authors and scripters is BBEdit (Bare Bones Software), which includes a number of useful aids for scripters, such as optional line numbers (which help in debugging JavaScript).

## Choosing a browser

The other component that is required for learning JavaScript is the browser. You don't have to be connected to the Internet to test your scripts in the browser. You can perform all testing offline. This means you can learn JavaScript and create cool, scripted Web pages with a laptop computer — even on a boat in the middle of an ocean.

The browser brand and version you use is up to you. Because the tutorial chapters in this book teach the W3C DOM syntax, you should be using a recent browser. Any of the following will get you through the tutorial: Internet Explorer 5 or later (Windows or Macintosh); any Mozilla-based browser (including Netscape 7 and later); and Apple Safari.

**Note**

Many example listings in Parts III and IV of this book demonstrate language or document object model (DOM) features that work on only specific browsers and versions. Check the compatibility listing for that language or DOM feature to make sure you use the right browser to load the page.

## Setting Up Your Authoring Environment

To make the job of testing your scripts easier, make sure that you have enough free memory in your computer to let both your text editor and browser run simultaneously. You need to be able to switch quickly between editor and browser as you experiment and repair any errors that may creep into your code. The typical workflow entails the following steps:

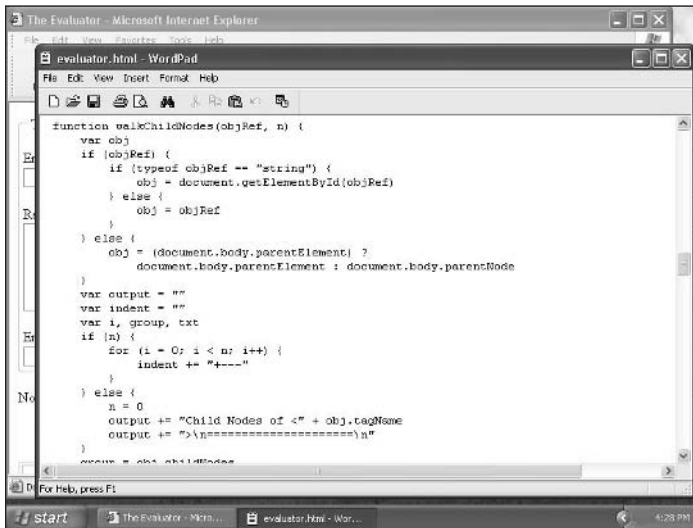

1. Enter HTML and script code into the source document in the text editor.
2. Save the latest version to disk.
3. Switch to the browser.
4. Do one of the following: If this is a new document, open the file via the browser's Open menu. If the document is already loaded, reload the file into the browser.

Steps 2 through 4 are the key ones you will follow frequently. I call this three-step sequence the save-switch-reload sequence. You will perform this sequence so often as you script that the physical act quickly will become second nature to you. How you arrange your application windows and effect the save-switch-reload sequence varies according to your operating system.

## Windows

You don't have to have either the editor or browser window maximized (at full screen) to take advantage of them. In fact, you may find them easier to work with if you adjust the size

and location of each window so both windows are as large as possible while still enabling you to click a sliver of the other's window. Or, you can leave the taskbar visible so you can click the desired program's button to switch to its window (see Figure 3-1). A monitor that displays more than 800 × 600 pixels certainly helps in offering more screen real estate for the windows and the taskbar.

**Figure 3-1:** Editor and browser window arrangement in Windows XP.

In practice, however, the Windows Alt+Tab task-switching keyboard shortcut makes the job of the save-switch-reload steps outlined earlier a snap. If you run Windows and also use a Windows-compatible text editor (which more than likely has a Ctrl+S file-saving keyboard shortcut), you can effect the save-switch-reload sequence from the keyboard all with the left hand: Ctrl+S (save the source file); Alt+Tab (switch to the browser); Ctrl+R (reload the saved source file).

As long as you keep switching between the browser and text editor via Alt+Tab task switching, either program is always just an Alt+Tab away.

## MacOS X

In MacOS X you can change between your text editor and browser applications via the Dock or, more conveniently, by typing ⌘-Tab. As long as you stay strictly in those two applications, the other program is only one ⌘-Tab away (see Figure 3-2).

With this setup, the save-switch-reload sequence is a simple affair:

1. Press ⌘-S (save the source file).
2. Press ⌘-Tab (switch to the browser).
3. Press ⌘-R (reload the saved source file).

To return to editing the source file, press ⌘-Tab again.

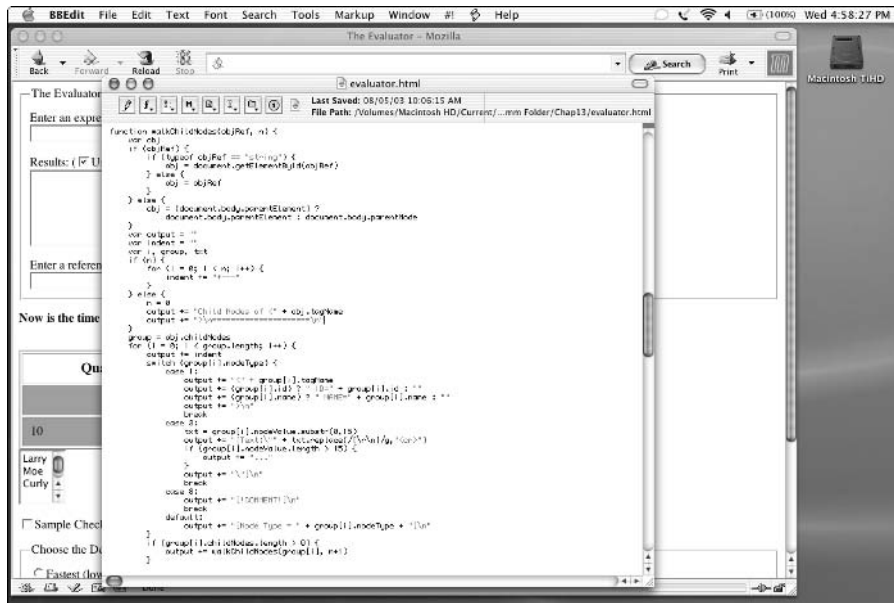

Figure 3-2: Editor and browser window arrangement on the Macintosh screen.

## Reloading issues

For the most part, a simple page reload is enough to let you test a revised version of a script right away. But sometimes the browser's cache (with its default settings) can preserve parts of the previous page's attributes when you reload, even though you have changed the source code. To perform a more thorough reload, hold down the Shift key while clicking the browser's Reload/Refresh button. Alternatively, you can turn off the browser's cache in the preferences area, but that setting may negatively affect the overall performance of the browser during your regular Web surfing.

## What Your First Script Will Do

For the sake of simplicity, the kind of script you look at in the next section is the kind that runs automatically when the browser loads the HTML page. Although all scripting and browsing work done here is offline, the behavior of the page is identical if you place the source file on a server and someone accesses it via the Web.

Figure 3-3 shows the page as it appears in the browser after you're finished. (The exact wording differs slightly if you run your browser on an operating system platform other than Windows XP or if you use a browser other than Internet Explorer.) The part of the page that is defined in regular HTML contains nothing more than an `<h1>`-level header with a horizontal rule under it. If someone does not use a JavaScript-equipped browser, all he or she sees is the header and horizontal rule (unless that person has a truly outmoded browser, in which case some of the script words appear in the page).

Below the rule, the script displays plain body text that combines static text with information about the browser you use to load the document. The script writes a stream of HTML

information to the browser, including a tag that applies a stylesheet to render a portion of the information in boldface. Even though two lines of code are writing information to the page, the result is rendered as one line — just as it is when all the text is hard-coded in HTML.

Figure 3-3: The finished page of your first JavaScript script.

## Entering Your First Script

It's time to start creating your first JavaScript script. Launch your text editor and browser. If your browser offers to dial your Internet service provider (ISP) or begins dialing automatically, cancel or quit the dialing operation. If the browser's Stop button is active, click it to halt any network searching it may try to do. You may receive a dialog box message or page indicating that the URL for your browser's home page (usually the home page of the browser's publisher — unless you've changed the settings) is unavailable. That's fine. You want the browser open, but you needn't be connected to your ISP. If you're automatically connected to the Internet via a local area network in your office or school, or via cable modem or DSL, that's also fine. However, you don't need the network connection for now. Next, follow these steps to enter and preview your first JavaScript script:

1. Activate your text editor and create a new, blank document.
2. Type the script into the window exactly as shown in Listing 3-1.

### Listing 3-1: Source Code for script1.html

```
<html>
<head>
<title>My First Script</title>
<style type="text/css">
.highlight {font-weight: bold}
</style>
</head>
```

*Continued*

**Listing 3-1 (continued)**

```
<body>
<h1>Let's Script...</h1>
<hr>
<script type="text/javascript">
<!-- hide from old browsers
document.write("This browser is version " + navigator.appVersion);
document.write(" of <span class='highlight'" + navigator.appName + "</span>.");
// end script hiding -->
</script>
</body>
</html>
```

3. Save the document with the name `script1.html`.
4. Switch to your browser.
5. Choose Open (or Open File on some browsers) from the File menu and select `script1.html`. (On some browsers, you have to click a Browse button to reach the File dialog box.)

If you typed all lines as directed, the document in the browser window should look like the one in Figure 3-3 (with minor differences for your computer's operating system and browser version). If the browser indicates that a mistake exists somewhere as the document loads, don't do anything about it for now. (Click the OK button if you see a script error dialog box.) Let's first examine the details of the entire document so you understand some of the finer points of what the script is doing.

## Examining the Script

You do not need to memorize any of the commands or syntax discussed in this section. Instead, relax and watch how the lines of the script become what you see in the browser. In Listing 3-1, all of the lines up to the `<script>` tag are very standard HTML with one Cascading Style Sheet (CSS) rule in the head portion.

### The `<script>` tag

Any time you include JavaScript verbiage in an HTML document, you must enclose those lines inside a `<script>...</script>` tag pair. These tags alert the browser program to begin interpreting all the text between these tags as a script. Because other scripting languages (such as Microsoft's VBScript) can take advantage of these script tags, you must specify the kind of language in which the enclosed code is written. Therefore, when the browser receives the signal that your script is of the type `text/javascript`, it employs its built-in JavaScript interpreter to handle the code. You can find parallels to this setup in real life: If you have a French interpreter at your side, you need to know that the person with whom you're conversing also knows French. If you encounter someone from Russia, the French interpreter can't help you. Similarly, if your browser has only a JavaScript interpreter inside, it can't understand code written in VBScript.

Now is a good time to instill an aspect of JavaScript that will be important to you throughout all your scripting ventures: JavaScript is case-sensitive. Therefore, you must enter any item in your script that uses a JavaScript word with the correct uppercase and lowercase letters. Your HTML tags (including the `<script>` tag) can be in the case of your choice, but everything in JavaScript is case-sensitive.<sup>1</sup> When a line of JavaScript doesn't work, look for the wrong case first. Always compare your typed code against the listings printed in this book and against the various vocabulary entries discussed throughout it.

## A script for all browsers

The next line after the `<script>` tag in Listing 3-1 appears to be the beginning of an HTML comment tag. It is, but the JavaScript interpreter treats comment tags in a special way. Although JavaScript dutifully ignores a line that begins with an HTML comment start tag, it treats the next line as a full-fledged script line. In other words, the scripting machinery inside the browser begins interpreting the next line after a comment start tag. If you want to put a comment inside JavaScript code, the comment must start with a double slash (`//`). Such a comment may go near the end of a line (such as after a JavaScript statement that is to be interpreted by the browser) or on its own line. In fact, the latter case appears near the end of the script. The comment line starts with two slashes.

Step back for a moment and notice that the entire script (including comments) is contained inside a standard HTML comment tag (`<!--comment-->`). The value of this containment is not clear until you see what happens to your scripted HTML document in a non-JavaScript-compatible browser. Such a browser blows past the `<script>` tag as being an advanced tag it doesn't understand. But it treats a line of script as regular text to be displayed in the page. If you enclose script lines between HTML comment tags, most older browsers don't display the script lines.

Remember, too, that some users don't have access to modern browsers or graphical browsers. (They use the Lynx text-oriented UNIX Web reader software or lightweight browsers in handheld computers.) By embracing your script lines within these comments, your Web pages don't look completely broken in relatively modern, non-JavaScript browsers.

**Note**

Notice that the comment lines that shield older browsers from your scripts go *inside* the `<script>...</script>` tags. Do not put these comment lines above the `<script>` tag or below the `</script>` tag and expect them to work.

One more issue about the script-hiding comment lines in this book. To save space on the page, most examples do not have comment lines inserted in them. But as you can see in the full-fledged application examples from Chapters 48 through 57 on the CD-ROM, the comment lines are where they should be. For any pages you produce for public consumption, always encase your script lines inside these comments.

## Displaying some text

Both script lines in Listing 3-1 use one of the possible actions a script can ask a document to perform (`document.write()`, meaning display text in the current document). You learn more about the `document` object in Chapter 18.

---

<sup>1</sup> XHTML style, if you intend to follow its conventions, requires all lowercase tags and attribute names. This is the style observed throughout this book.

Whenever you ask an object (a document in this case) to perform a task for you, the name of the task is always followed by a set of parentheses. In some cases—the `write()` task, for example—JavaScript needs to know what information it should act on. That information (called a *parameter*) goes inside parentheses after the name of the task. Thus, if you want to write the name of the first U.S. president to a document, the command to do so is

```
document.write("George Washington");
```

The line of text that the script writes starts with some static text (“This browser is version”) and adds some evaluated text (the version of the browser) to it. The writing continues with more static text that includes an HTML tag (“ of `<span class='highlight'>`”), more evaluated text (the name of the browser application), and an HTML closing tag and the sentence’s period (“`</span>.`”). JavaScript uses the plus symbol (+) to join (*concatenate*) text components into a larger, single string of text characters to be written by the document. Neither JavaScript nor the + symbol knows anything about words and spaces, so the script is responsible for making sure that the proper spaces are passed along as part of the parameters. Notice, therefore, that an extra space exists after the word “version” in the first `document.write()` parameter, and extra spaces exist on both sides of “of” in the second `document.write()` parameter.

To fetch the information about the browser version and name for your parameters, you call upon JavaScript to extract the corresponding properties from the `navigator` object. You extract a property by appending the property name to the object name (`navigator` in this case) and separating the two names with a period. If you’re searching for some English to mentally assign to this scheme as you read it, start from the right side and call the right item a property “of” the left side: the `appVersion` property of the `navigator` object. This dot syntax looks a great deal like the `document.write()` task, but a property name does not have parentheses after it. In any case, the reference to the property in the script tells the JavaScript interpreter to insert the value of that property in the spot where the call is made. For your first attempt at the script, JavaScript substitutes the internal information about the browser as part of the text string that gets written to the document.

Finally, notice the semicolon characters at the end of each JavaScript statement. Trailing semicolons are purely optional. There is no penalty for leaving them out. If you intend to investigate other programming languages, such as Java or C++, for example, you’ll find those semicolons are required. Program listings in this book use semicolons.

## Have Some Fun

If you encounter an error in your first attempt at loading this document into your browser, go back to the text editor and check the lines of the script section against Listing 3-1, looking carefully at each line in light of the explanations. There may be a single character out of place, a lowercase letter where an uppercase one belongs, or a quote or parenthesis missing. Make necessary repairs, switch to your browser, and click Reload.

To see how dynamic the script in `script1.html` is, go back into the text editor and replace the word “browser” with “client software.” Save, switch, and reload to see how the script changes the text in the document. Feel free to substitute other text for the quoted text in the `document.write()` statement. Or, add more text with additional `document.write()` statements. The parameters to `document.write()` are HTML text, so you can even write “`<br>`” to make a line break. Always be sure to save, switch, and reload to see the results of your handiwork.

# Browser and Document Objects

---

**T**his chapter marks the first of nine tutorial chapters tailored to Web authors who have at least basic grounding in HTML concepts. In particular, you should already be familiar with common HTML tags and their attributes, as well as the fundamentals of Cascading Style Sheets (CSS). In this chapter, you see several practical applications of JavaScript and begin to see how a JavaScript-enabled browser turns familiar HTML elements into objects that your scripts control. This tutorial teaches concepts and terminology that apply to modern browsers with special focus on standards-compatibility to equip you to work with today's and tomorrow's browsers. You should study this tutorial in conjunction with any of the following browsers: Internet Explorer 5 or later (Windows or Macintosh), any Mozilla-based browser, or Apple's Safari.

## Scripts Run the Show

If you have authored Web pages with HTML, you are familiar with how HTML tags influence the way content is rendered on a page when viewed in the browser. As the page loads, the browser recognizes angle-bracketed tags as formatting instructions. Instructions are read from the top of the document downward, and elements defined in the HTML document appear onscreen in the same order in which they appear in the document's source code. As an author, you do a little work one time and up front — adding the tags to text content — and the browser does a lot more work every time a visitor loads the page into a browser.

Assume for a moment that one of the elements on the page is a text input field inside a form. The user is supposed to enter some text in the text field and then click the Submit button to send that information back to the Web server. If that information must be an Internet e-mail address, how do you ensure the user includes the “@” symbol in the address?

One way is to have a Common Gateway Interface (CGI) program on the server inspect the submitted form data after the user clicks the Submit button and the form information is transferred to the server. If the user omits or forgets the “@” symbol, the CGI program sends the page back to the browser — but this time with an instruction to include the symbol in the address. Nothing is wrong with this

### In This Chapter

What client-side scripts do

What happens when a document loads

How the browser creates objects

How scripts refer to objects

What distinguishes one object from another

exchange, but it means a significant delay for the user to find out that the address does not contain the crucial symbol. Moreover, the Web server has to expend some of its resources to perform the validation and communicate back to the visitor. If the Web site is a busy one, the server may try to perform hundreds of these validations at any given moment, probably slowing the response time to the user even more.

Now imagine that the document containing that text input field has some intelligence built into it that makes sure the text field entry contains the “@” symbol before ever submitting one bit (literally!) of data to the server. That kind of intelligence would have to be embedded in the document in some fashion — downloaded with the page’s content so it can stand ready to jump into action when called upon. The browser must know how to run that embedded program. Some user action must start the program, perhaps when the user clicks the Submit button. If the program runs inside the browser and detects a lack of the “@” symbol, an alert message should appear to bring the problem to the user’s attention. The same program also should be capable of deciding if the actual submission can proceed or if it should wait until a valid e-mail address is entered into the field.

This kind of pre-submission data entry validation is but one of the practical ways JavaScript adds intelligence to an HTML document. Looking at this example, you might recognize that a script must know how to look into what is typed in a text field; a script must also know how to let a submission continue or how to abort the submission. A browser capable of running JavaScript programs conveniently treats elements such as the text field as *objects*. A JavaScript script controls the action and behavior of objects — most of which you see on the screen in the browser window.

## JavaScript in Action

By adding lines of JavaScript code to your HTML documents, you control onscreen objects in whatever way your applications require. To give you an idea of the scope of applications you can create with JavaScript, I show you several applications on the CD-ROM (in the Listings folders for Chapters 48 through 57). I strongly suggest you open the applications and play with them in your browser as they are described in the next several pages. You can find links to the application files for these chapters via the `index.html` file located in the Listings folder on the CD-ROM.

### Interactive user interfaces

HTML hyperlinks do a fine job, but they’re not necessarily the most engaging way to present a table of contents for a large site or document. With a bit of JavaScript, you can create an interactive, expandable table of contents listing that displays the hierarchy of a large body of material (see Figure 4-1). Just like the text listings (or *tree views*) in operating system file management windows, the expandable table of contents lets the user see as much or as little as possible while displaying the big picture of the entire data collection.

Click a gray widget icon to expand the items underneath. An endpoint item has an orange and black widget icon. Items in the outline can be links to other pages or descriptive information. You also maintain the same kind of font control over each entry, as expected from HTML. While such outlines have been created with the aid of server programs in the past, the response time between clicks is terribly slow. By placing all of the smarts behind the outline inside the page, it downloads once and runs quickly after each click.

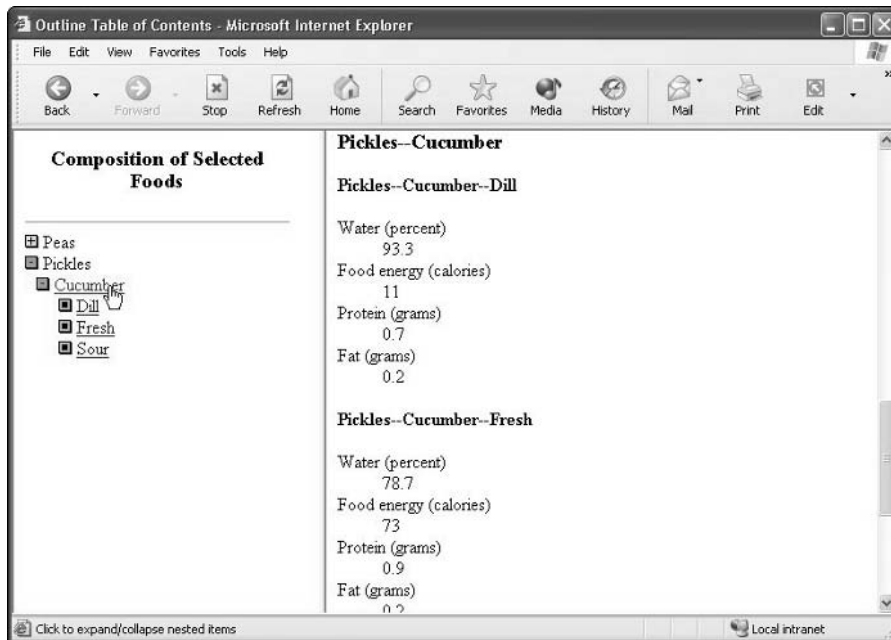

Figure 4-1: An expandable table of contents.

## Small data lookup

A common application on the Web is having a server program present a page that visitors use to access large databases on the server. Large data collections are best left on the server where search engines and database technologies are the best fit. But if your page acts as a *front end* to a small data collection lookup, you can consider embedding that data collection in the document (out of view) and letting JavaScript act as the intermediary between user and data.

I do just that in a Social Security prefix lookup system shown in Figure 4-2. I convert a printed table of about 55 entries into a JavaScript list that occupies only a few hundred bytes. When the visitor types the three-character prefix of his or her Social Security number into the field and clicks the Search button, a script behind the scenes compares that number against the 55 or so ranges in the table. When the script finds a match, it displays the corresponding state of registration in a second field.

If the application were stored on the server and the data stored in a server database, each click of the Search button would mean a delay of many seconds as the server processed the request, got the data from the database, and reformulated the page with the result for the user. Built instead as a JavaScript application, once the page downloads the first time, scripts perform all lookups instantaneously.

Figure 4-2: Looking up data in a small table.

## Forms validation

I've already used data entry form validation as an example of when JavaScript is a good fit. In fact, the data entry field in the Social Security lookup page (see Figure 4-2) includes scripting to check the validity of the entered number. Just as a server program for this task has to verify that the entry is a three-digit number, so, too, must the JavaScript program verify the entered value. If a mistake appears in the entry—perhaps a finger slips and hits a letter key—the visitor is advised of the problem and directed to try another entry. The validation script even preselects the text in the entry field for the visitor so that typing a new value replaces the old one.

## Interactive data

JavaScript opens opportunities for turning static information into interactive information. Figure 4-3 shows a graphical calculator for determining the value of an electrical component (called a *resistor*) whose only markings are colored bars.

**Figure 4-3:** An interactive graphical calculator.

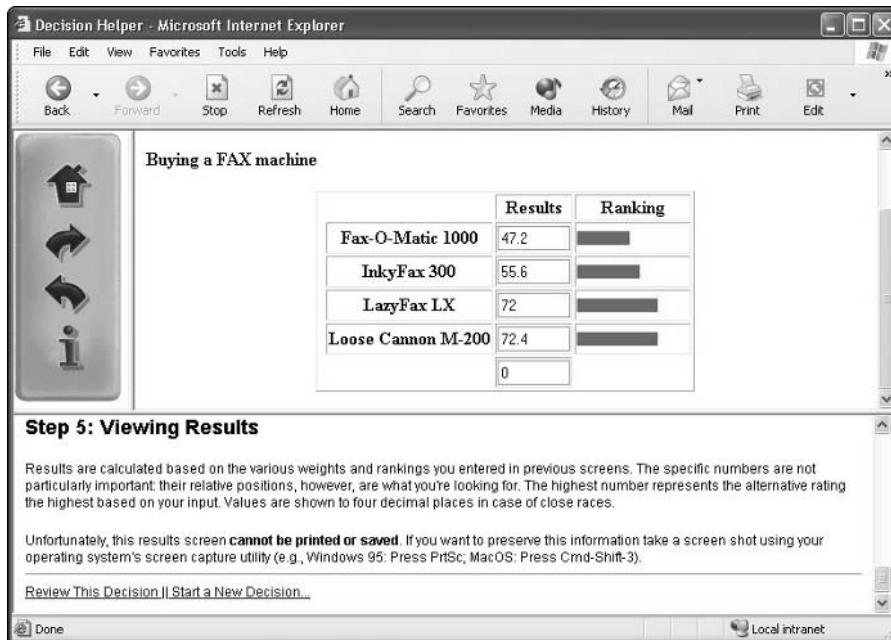

The image in the bottom half of the page is composed of seven images in vertical slices all bunched up against each other. Four slices display the colored bands, while the remaining three slices contain the ends of the resistor and the spacer between groups of bands. As the visitor selects a color from a pop-up list near the top, the associated image slice changes to the selected color and the resistance value is calculated and displayed.

Again, once the page is loaded, response time is instantaneous. Conversely, a server-based version of this calculator would take many seconds between color changes. Moreover, JavaScript provides the power to preload all possible images into the browser cache while the main page loads. Therefore, with only a slight extra delay to download all images with the page, no further delay occurs when a visitor chooses a new color. Not only is the application practical (for its intended audience), but it's just plain fun to play with.

## Multiple frames

While frames are the domain of HTML, they suddenly become more powerful with some JavaScript behind them. The Decision Helper application shown in Figure 4-4 takes this notion to the extreme.

The Decision Helper is a full-fledged application that includes four input screens and one screen that displays the results of some fairly complex calculations based on the input screens. Results are shown both in numbers and in a bar graph form, as displayed in Figure 4-4.

**Figure 4-4:** The Decision Helper.

Interaction among the three frames requires JavaScript. For example, suppose the user clicks one of the directional arrows in the top-left frame. Not only does the top-right frame change to another document, but the instructions document in the bottom frame also shifts to the anchor point that parallels the content of the input screen. Scripting behind the top-right frame documents uses various techniques to preserve entry information as the user navigates through the sequence of input pages. These are the same techniques you might use to build an online product catalog and shopping cart—accumulating the customer's selections from various catalog pages and then bringing them together in the checkout order form.

Certainly you could fashion this application out of a CGI program on the server. But the high level of interaction and calculation required would turn this now speedy application into a glacially slow exchange of information between user and server.

## Dynamic HTML

Starting with the version 4 browsers from both Netscape and Microsoft, you can modify more and more content on the page with the help of client-side scripts. In Figure 4-5, for example, scripts in the page control the dragging of map pieces in the puzzle. Highlighted colors change as you click the state maps, instruction panels fly in from the edge of the screen, and another item appears when you place all the states in their proper positions.

Applying scripts to modify HTML content or position on the fly is commonly called *Dynamic HTML (DHTML)*. JavaScript becomes the vital connection between the user and dynamically repositionable elements on the screen. Not even a program on the server could help this application because you need immediate programmatic control in the page to respond to user mouse motion and instantaneous changes to screen elements.

Figure 4-5: A map game in scriptable Dynamic HTML.

## When to use JavaScript

The preceding examples demonstrate a wide range of applications for JavaScript, but by no means do they come close to exhausting JavaScript's possibilities. When faced with a Web application task, I look to client-side JavaScript for help with the following requirements:

- ♦ **Data entry validation:** If form fields need to be filled out for processing on the server, I let client-side scripts prequalify the data entered by the user.
- ♦ **Serverless CGIs:** I use this term to describe processes that, were it not for JavaScript, would be programmed as CGIs on the server, yielding slow performance because of the interactivity required between the program and user. This includes tasks such as small data collection lookup, modification of images, and generation of HTML in other frames and windows based on user input.
- ♦ **Dynamic HTML interactivity:** It's one thing to use DHTML's capabilities to position elements precisely on the page—you don't need scripting for that. But if you intend to make the content dance on the page, scripting makes that happen.
- ♦ **CGI prototyping:** Sometimes you may want a CGI program to be at the root of your application because it reduces the potential incompatibilities among browser brands and versions. It may be easier to create a prototype of the CGI in client-side JavaScript. Use this opportunity to polish the user interface before implementing the application as a CGI.
- ♦ **Offloading a busy server:** If you have a highly trafficked Web site, it may be beneficial to convert frequently used CGI processes to client-side JavaScript scripts. Once a page

is downloaded, the server is free to serve other visitors. Not only does this lighten server load, but users also experience quicker response to the application embedded in the page.

- ♦ **Adding life to otherwise dead pages:** HTML by itself is pretty “flat.” Adding a blinking chunk of text doesn’t help much; animated GIF images more often distract from, rather than contribute to, the user experience at your site. But if you can dream up ways to add some interactive zip to your page, it may engage the user and encourage a recommendation to friends or repeat visits.
- ♦ **Creating “Web pages that think”:** If you let your imagination soar, you may develop new, intriguing ways to make your pages appear “smart.” For example, in the application Intelligent “Updated” Flags (Chapter 54 on the CD-ROM), you see how (without a server CGI or database) an HTML page can “remember” when a visitor last came to the page. Then any items that have been updated since the last visit — regardless of the number of updates you’ve done to the page — are flagged for that visitor. That’s the kind of subtle, thinking Web page that best displays JavaScript’s powers.

## The Document Object Model

Before you can truly start scripting, you should have a good feel for the kinds of objects you will be scripting. A scriptable browser does a lot of the work of creating software objects that generally represent the visible objects you see in an HTML page in the browser window. Obvious objects include form controls (text boxes and buttons) and images. However, there may be other objects that aren’t so obvious by looking at a page but which make perfect sense when you consider the HTML tags used to generate a page’s content — paragraph objects or frames of a frameset, for example.

To help scripts control these objects — and to help authors see some method to the madness of potentially dozens of objects on a page — the browser makers define a *document object model (DOM)*. A model is like a prototype or plan for the organization of objects on a page.

Evolution of browser DOMs has caused much confusion and consternation among scripters due to a lack of compatibility across succeeding generations and brands of browsers. Fortunately, the DOM world is stabilizing around a formal specification published by the World Wide Web Consortium (W3C). Today’s modern browsers continue to support some of the “old ways” of the earliest DOM because so much existing script code on the Web relies on these traditions continuing to work (you’ll see some of these in Chapter 9). But with the vast majority of browsers in use today supporting the basic W3C DOM syntax and terminology, scripters should aim toward standards compatibility whenever possible.

### HTML structure and the DOM

An important trend in HTML markup is applying markup solely to define the structure of a document and the context of each piece of content in the document. The days of using HTML tags solely to influence the appearance of a chunk of text are drawing to a close. It is no longer acceptable to enclose a line of text in, say, an `<h1>` tag because you want the line to appear in the text size and weight that browsers automatically apply to text tagged in that way. An `<h1>` element has a special context within a document’s structure: a first-level heading. In today’s HTML world, if you wish to display a standalone line of text with a particular style, the text would likely be in a simple paragraph (`<p>`) tag; the precise look of that paragraph would be

under the control of a Cascading Style Sheet (CSS) rule. Current practice even frowns upon the application of `<b>` and `<i>` tags to assign boldface and italic styles to a span of text. Instead surround the text in a contextual tag (such as the `<em>` element to signify emphasis) and define the CSS style you wish applied to any emphasized text in the document.

The result of applying strict structural design to your HTML tagging is a document that has a well-defined *hierarchy* of elements based on their nesting within each other. For example, an empty HTML document has the following minimum elements:

```
<html>
  <head></head>
  <body></body>
</html>
```

The `html` element contains two nested elements, `head` and `body`. The hierarchy of elements can be charted like a corporate organizational chart, as shown in Figure 4-6. For the sake of upcoming terminology lessons, however, it is more convenient to visualize the chart in Figure 4-6 as a family tree—except that, unlike most real family trees each point that spawns children is a single-parent. In the empty HTML document, the `html` element is the parent of two child elements: `head` and `body`. The `html` element is, in turn, a child of the document.

**Figure 4-6:** Element hierarchy of an empty HTML document.

## The DOM in a browser window

As its name implies, the formal Document Object Model focuses primarily on the HTML document and the content nested inside it. From a practical standpoint, however, scripters often need to control the environment that contains the document: the window. The `window` object is the top of the hierarchy that browser scripts work with. The basic structure of the object model in modern browsers (given an empty HTML document) is shown in Figure 4-7.

**Figure 4-7:** Basic object model for all modern browsers.

It's not important to memorize the model. But to give you a sense of the relationships among these top-level objects, the following describes their respective roles:

- ♦ **window object:** At the very top of the hierarchy is the window. This object represents the content area of the browser window where HTML documents appear. In a multiple-frame environment, each frame is also a window (but don't concern yourself with this just yet). Because all document action takes place inside the window, the window is the outermost element of the object hierarchy. Its physical borders contain the document.
- ♦ **navigator object:** This is the closest your scripts come to accessing the browser program, primarily to read the brand and version of browser that holds the current document. This object is read-only, protecting the browser from inappropriate access by rogue scripts.
- ♦ **screen object:** Another read-only object lets scripts learn about the physical environment in which the browser is running. For example, this object reveals the number of pixels high and wide available in the monitor.
- ♦ **history object:** While the browser maintains internal details about the browser's recent history (such as the list available under the Back button), scripts have no access to the details. At most this object assists a script in simulating a click of the Back or Forward button.
- ♦ **location object:** This object is the primary avenue to loading a different page into the current window or frame. URL information about the window is available under very controlled circumstances so that scripts cannot track access to other Web sites.
- ♦ **document object:** Each HTML document that gets loaded into a window becomes a document object. The document object contains the content that you are likely to script. Except for the `html`, `head`, and `body` element objects that are found in every HTML document, the precise makeup and structure of the element object hierarchy of the document depends on the content you put into the document.

## When a Document Loads

Programming languages, such as JavaScript, are convenient intermediaries between your mental image of how a program works and the true inner workings of the computer. Inside the machine, every word of a program code listing influences the storage and movement of bits (the legendary 1s and 0s of the computer's binary universe) from one RAM storage slot to another. Languages and object models are inside the computer (or, in the case of JavaScript and the DOM, inside the browser's area of the computer) to make it easier for programmers to visualize how a program works and what its results will be. The relationship reminds me a lot of knowing how to drive an automobile from point A to point B without knowing exactly how an internal combustion engine, steering linkages, and all that other internal "stuff" works. By controlling high-level objects such as the ignition key, gearshift, gas pedal, brake, and steering wheel, I can get the results I need.

Of course, programming is not exactly like driving a car with an automatic transmission. Even scripting requires the equivalent of opening the hood and perhaps knowing how to check the transmission fluid or change the oil. Therefore, now it's time to open the hood and watch what happens to a document's object model as a page loads into the browser.

## A simple document

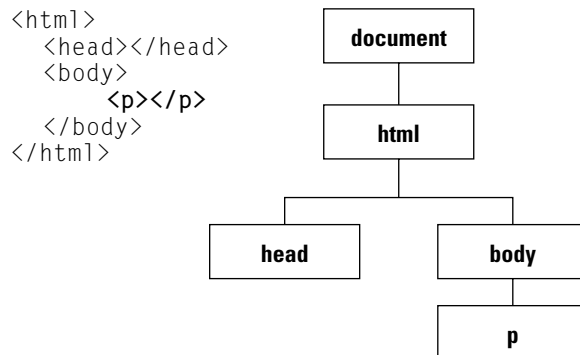

Figure 4-8 shows the HTML and corresponding object model for a document that I'll be adding to in a moment. The figure shows only the `document` object portion—the `window` object and its other top-level objects (including the `document` object) are always there, even for an empty document. When this page loads, the browser maintains in its memory a map of the objects generated by the HTML tags in the document. At this point, only three objects exist, one for the outermost `html` element and its two nested elements.

**Figure 4-8:** Object map of an empty document.

## Add a paragraph element

Now, I modify the HTML file to include an empty paragraph element and reload the document. Figure 4-9 shows what happens to both the HTML (changes in boldface) and the object map as constructed by the browser. Even though no content appears in the paragraph, the `<p>` tags are enough to tell the browser to create that `p` element object. Also note that the `p` element object is contained by the `body` element object in the hierarchy of objects in the current map. In other words, the `p` element object is a child of the `body` element object. The object hierarchy matches the HTML tag containment hierarchy.

**Figure 4-9:** Adding an empty paragraph element.

## Add paragraph text

I modify and reload the HTML file again, this time inserting the text of the paragraph between the element's start and end tags, as shown in Figure 4-10. A run of text extending between tags is a special kind of object in the DOM, called a *text node*. A text node always has an element acting as its container. Applying the official genealogy metaphor to this structure, the text node is a child of its parent *p* element. We now have a branch of the document object tree that runs several generations: document->html->body->p->text node.

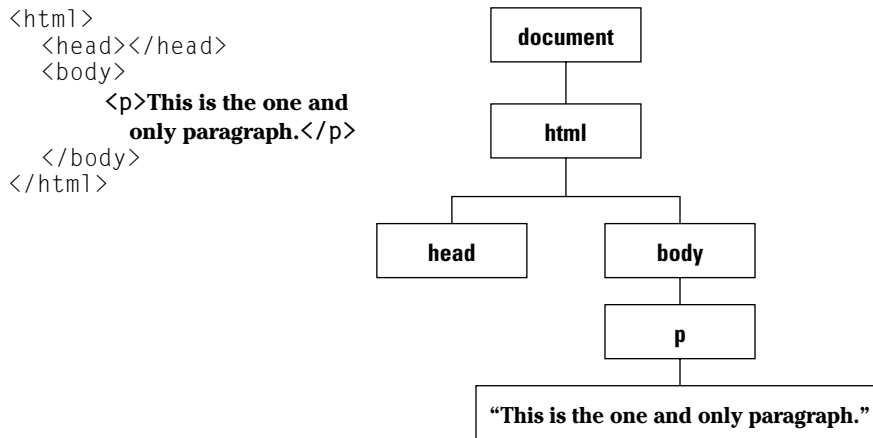

Figure 4-10: Adding a text node to the *p* element object.

## Make a new element

The last modification I make to the file is to wrap a portion of the paragraph text in an `<em>` tag to signify emphasis for the enclosed text. This insertion has a large effect on the hierarchy of the *p* element object, as shown in Figure 4-11. The *p* element goes from having a single (text node) child to having three children: two text nodes with an element between them. In the W3C DOM, a text node cannot have any children and therefore cannot contain an element object. The bit of the text now inside the *em* element is no longer a child of the *p* element, but rather a child of the *em* element. That text node is now a grandchild of the *p* element object.

Now that you see how objects are created in memory in response to HTML tags, the next step is to figure out how scripts can communicate with these objects. After all, scripting is mostly about controlling these objects.

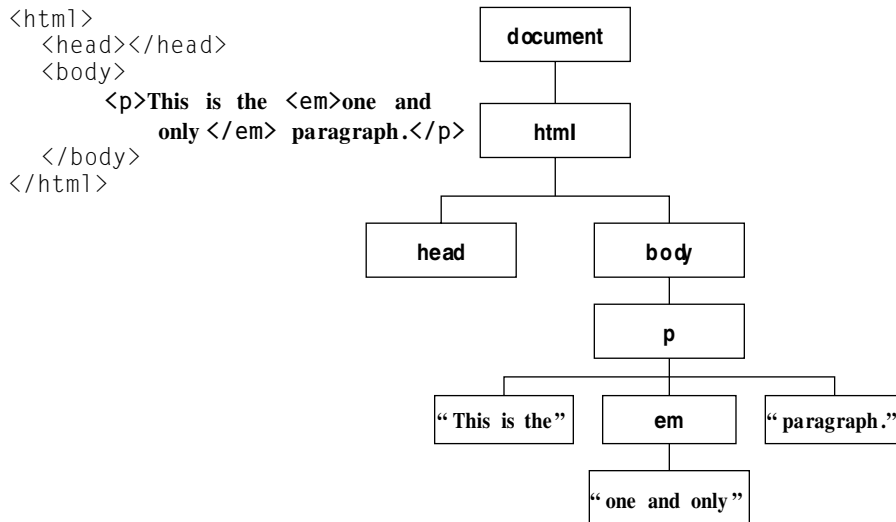

Figure 4-11: Inserting an element into a text node.

## Object References

After a document is loaded into the browser, all of its objects are safely stored in memory in the containment hierarchy structure specified by the browser's document object model. For a script to control one of those objects, there must be a way to communicate with an object and find out something about it such as, "Hey, Mr. Text Field, what did the user type?" To let your scripts "talk to" an object, you need a way to refer to that object. That is precisely what an *object reference* in a script does for the browser.

### Object naming

The biggest aid in creating script references to objects is assigning a name to every scriptable object in your HTML. In the W3C DOM (and current HTML specification), the way to assign a name to an element is by way of the `id` attribute. This attribute is optional, but if you plan to use scripts to access an element in the page, it is most convenient to assign a name to that element's `id` attribute directly in the HTML code. Here are some examples of `id` attributes added to typical tags:

```

<p id="firstParagraph" >

<div class="draggable" id="puzzlePiece">

```

The only rules about object IDs (also called *identifiers*) are that they

- ♦ May not contain spaces
- ♦ Should not contain punctuation except for the underscore character
- ♦ Must be inside quotes when assigned to the `id` attribute
- ♦ Must not start with a numeric character
- ♦ May not occur more than once in the same document

Think of assigning IDs as the same as sticking nametags on everyone attending a conference meeting. To find a particular conference attendee whose name you know, you could wait at the entrance and scan each nametag until you find the name you're looking for; or you could bump around the attendees at random in the hope that you'll find a known name. But it would be more efficient if you had a way to immediately target an attendee by name—like broadcasting the name on the public address system to the whole crowd.

## Referencing a particular object

The W3C DOM provides that kind of instant access to any named element in the document. If you haven't programmed before, the syntax for this access command may be intimidating by its length—a hazard when a standard such as the W3C DOM is designed by programmers. Like it or not, we're stuck with this syntax. Here is the syntax you will use frequently in your browser scripting:

```
window.document.getElementById("elementID")
```

You substitute the ID of the element you wish to reference for *elementID*. For example, if you want to reference the paragraph element whose ID is `firstParagraph`, the reference would be:

```
window.document.getElementById("firstParagraph")
```

Be careful! JavaScript is case-sensitive. Be sure you use uppercase for the three uppercase letters in the command, and use a lowercase “d” at the end, and that you capitalize the ID accurately as well.

The `getElementById()` command belongs to the `document` object, meaning that the entire document's collection of elements is subject to this instantaneous search for a matching ID. The dot—a traditional period character—is the JavaScript way of indicating that the item to the left of the dot (the `document` object here) has the item to the right of the dot (`getElementById()` here) as a resource to call upon whenever needed. Each type of object has a list of such resources, as you'll see in a moment (and as summarized in Appendix A).

## id versus name Attributes

Prior to the HTML 4.0 specification's introduction of the `id` attribute, scripts could access a handful of elements that also supported the `name` attribute. Elements supporting the `name` attribute are predominantly related to forms, images, and frames. You will see how `name` attributes work in forms in Chapter 9. In fact, most browsers still require the `name` attribute for forms and form controls (text fields, buttons, and select lists) for their data to be submitted to a server. It is permissible to assign the same identifier to both the `id` and `name` attributes of an element.

## Node Terminology

W3C DOM terminology uses metaphors to assist programmers in visualizing the containment hierarchy of a document and its content. One concept you should grasp early in your learning is that of a *node*; the other concept is the family relationship among objects in a document.

### About nodes

While the English dictionary contains numerous definitions of “node,” the one that comes closest to its application in the W3C DOM is the one that implies a knob or bump on a tree branch. Such nodules on a branch usually lead to one of two things: a leaf or another branch. A leaf is a dead end in that no further branches emanate from the leaf; but the branch kind of node leads to a new branch that can, itself, have further nodes, whether they be leaves or more branches. When you define the structure of an HTML document, you also define a node structure (also called a *node tree*) whose placement of branches and leaves depends entirely on your HTML elements and text content.

In the W3C DOM, the fundamental building block is a simple, generic node. But inside an HTML document, we work with special kinds of nodes that are tailored to HTML documents. The two types of nodes that scripts touch most often are element nodes and text nodes. These node types correspond exactly to HTML elements and the text that goes between an element’s start and end tags. You’ve been working with element and text nodes in your HTML authoring, and you didn’t even know it.

Look again at the simple document assembled earlier, along with its containment hierarchy diagram in Figure 4-12. All of the boxes representing HTML elements (`html`, `head`, `body`, `p`, and `em`) are element nodes; the three boxes containing actual text that appears in the rendered document are text nodes. You saw in the transition from one long text node (Figure 4-10) to the insertion of the `em` element (Figure 4-11) that the long text node divided into three pieces. Two text node pieces stayed in the same position in the hierarchy relative to the containing `p` element. The new `em` element bullied its way into the tree between the two text nodes, and shifted the third text node one level away from the `p` element.

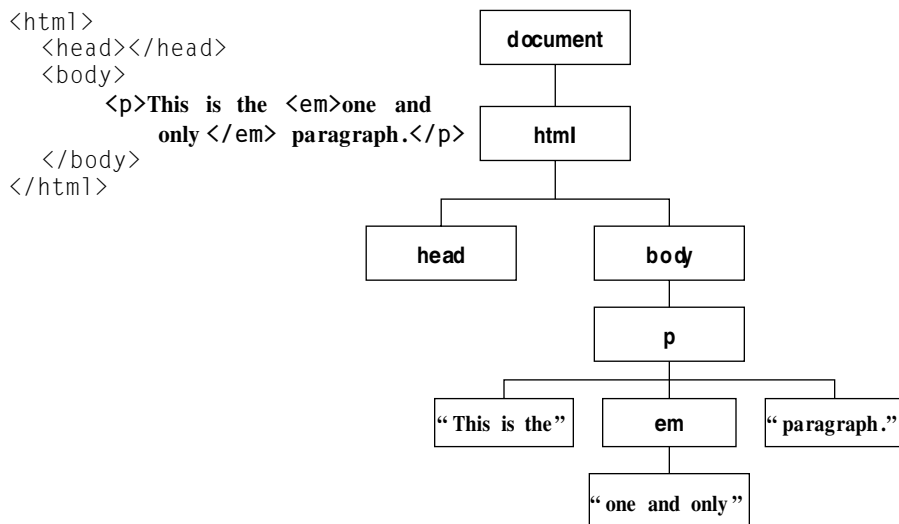

Figure 4-12: A simple HTML document node tree.

## Parents and children

Looking more closely at the `p` element and its content in Figure 4-12, you can see that element has three *child* nodes. The first and last are of the text node type, while the middle one is an element node. When an element contains multiple child nodes, the sequence of child nodes is entirely dependent upon the HTML source code order. Thus, the first child node of the `p` element is the text node containing the text “This is the “. In the case of the `em` element, a single child text node is the sole descendant of the element.

Element node children are not always text nodes, nor do branches always end in text nodes. In Figure 4-12, the `html` element has two child nodes, both of which are element nodes; the `body` element has one child node, the `p` element. Even though the `head` element node appears to be at the end of a branch, it is still an element node because it is capable of containing other nodes (such as a `title` element). A tag in the HTML indicates an element node, whether or not it has any child nodes. In contrast, a text node can never contain another node—it’s one of those dead-end leaf type of nodes.

Notice that a child node is always contained by one element node. That container is the *parent* node of its child or children. For example from the point of view of the `em` element node, it has both one child (a text node) and one parent (the `p` element node). A fair amount of W3C DOM terminology (which you’ll meet in Chapter 14) concerns itself with assisting scripts to start at any point in a document hierarchy and obtain a reference to a related node if necessary. For instance, if a Dynamic HTML script wants to modify the text inside the `em` element of Figure 4-12, it would typically do so by starting with a reference to the `em` element via the `document.getElementById()` command (assuming the `em` element has an ID assigned to it) and then modifying the element’s child node.

In case you’re wondering, the `document` object at the top of the node tree is, itself, a node. Its place in the tree is special and is called, simply, the *document node*. Each document contains a single document node, and that node becomes the scripter’s gateway to the rest of the document’s nodes. It’s no accident that the syntax for referencing an element node—`document.getElementById()`—begins with a reference to the `document` object.

## What Defines an Object?

When an HTML tag defines an object in the source code, the browser creates a slot for that object in memory as the page loads. But an object is far more complex internally than, say, a mere number stored in memory. The purpose of an object is to represent some “thing.” In the browser and its Document Object Model, the most common objects are those that correspond to elements, such as a text input form field, a table element, or the whole HTML document. Outside of the pared-down world of the DOM, an object can also represent abstract entities, such as a calendar program’s appointment entry or a layer of graphical shapes in a drawing program. It is common for your browser scripts to work with both DOM objects and abstract objects of your own design.

Every type of DOM object is unique in some way, even if two or more objects look identical to you in the browser. Three very important facets of an object define what it is, what it looks like, how it behaves, and how scripts control it. Those three facets are properties, methods, and event handlers. They play such key roles in your future DOM scripting efforts that the Object Quick Reference in Appendix A summarizes the properties, methods, and event handlers for each object in the object models implemented in various browser generations.

## Properties

Any physical object you hold in your hand has a collection of characteristics that defines it. A coin, for example, has shape, diameter, thickness, color, weight, embossed images on each side, and any number of other attributes that distinguish it from, say, a feather. Each of those features is called a *property*. Each property has a value of some kind attached to it (even if the value is empty or null). For example, the shape property of a coin might be “circle”—in this case, a text value. In contrast, the denomination property is most likely a numeric value.

You may not have known it, but if you’ve written HTML for use in a scriptable browser, you have set object properties without writing one iota of JavaScript. Tag attributes are the most common way to set an HTML element object’s initial properties. For example, the following HTML tag defines an `input` element object that assigns four property values:

```
<input type="button" id="clicker" name="clicker" value="Hit Me...">
```

In JavaScript parlance, then, the `type` property holds the word “button,” the `id` and `name` properties hold the same word, “clicker,” and the `value` property is the text that appears on the button label, “Hit Me. . .” In truth, a button input element has more properties than just these, but you don’t have to set every property for every object. Most properties have default values that are automatically assigned if nothing special is set in the HTML or later from a script.

The contents of some properties can change after a document has loaded and the user interacts with the page. Consider the following text input tag:

```
<input type="text" id="entry" name="entry" value="User Name?">
```

The `id` and `name` properties of this object are the same word, “entry.” When the page loads, the text of the `value` attribute setting is placed in the text field—the automatic behavior of an HTML text field when the `value` attribute is specified. But if a user enters some other text into the text field, the `value` property changes—not in the HTML, but in the memory copy of the object model that the browser maintains. Therefore, if a script queries the text field about the content of the `value` property, the browser yields the current setting of the property—which isn’t necessarily the one specified by the HTML.

To gain access to an object’s property, you use the same kind of dot notation addressing scheme you saw earlier for objects. A property is a resource belonging to its object, so the reference to it consists of the reference to the object plus one more extension naming the property. Therefore, for the button and text object tags just shown, references to various properties are

```
document.getElementById("clicker").name  
document.getElementById("clicker").value  
document.getElementById("entry").value
```

You may wonder what happened to the `window` part of the reference. It turns out that there can be only one document contained in a window, so references to objects inside the document can omit the `window` portion and start the reference with `document`. You cannot omit the `document` object, however, from the reference.

## Internet Explorer References

Before the W3C DOM came into existence, Microsoft had created its own way of referencing element objects by way of their `id` attributes. You will find many instances of this syntax in existing code that has been written only for Internet Explorer 4 or later. The syntax uses a construction called `document.all`. Although there are a few different ways to use this construction, the most commonly applied way is to continue the dot notation to include the ID of the element. For example, if a paragraph element's ID is `myParagraph`, the IE-only reference syntax is:

```
document.all.myParagraph
```

You can also completely omit the lead-in parts of the reference, and simply refer to the ID of the element:

```
myParagraph
```

Be aware, however, that none of these approaches is supported in the W3C DOM standard. Both the IE-specific and W3C DOM reference syntax styles are implemented in IE5 or later. Going forward, you should migrate existing code to the W3C DOM style to be compatible with more browsers.

## Methods

If a property is like a descriptive adjective for an object, then a method is a verb. A *method* is all about action related to the object. A method either does something to the object or with the object that affects other parts of a script or document. They are commands of a sort, but whose behaviors are tied to a particular object.

An object can have any number of methods associated with it (including none at all). To set a method into motion (usually called *invoking a method*), a JavaScript statement must include a reference to it — via its object with a pair of parentheses after the method name — as in the following examples:

```
document.getElementById("orderForm").submit()  
document.getElementById("entry").focus()
```

The first is a scripted way of sending a form (named `orderForm`) to a server. The second gives focus to a text field named `entry`.

Sometimes a method requires that you send additional information with it so that it can do its job. Each chunk of information passed with the method is called a *parameter* or *argument* (you can use the terms interchangeably). You saw examples of passing a parameter in your first script in Chapter 3. Two script statements invoked the `write()` method of the `document` object:

```
document.write("This browser is version " + navigator.appVersion)  
document.write(" of <B>" + navigator.appName + "</B>.")
```

As the page loaded into the browser, each `document.write()` method sent whatever text was inside the parentheses to the current document. In both cases, the content being sent as a parameter consisted of straight text (inside quotes) and the values of two object properties: the `appVersion` and `appName` properties of the `navigator` object.

Some methods require more than one parameter. If so, the multiple parameters are separated by commas. For example, version 4 and later browsers support a `window` object method that

moves the window to a particular coordinate point on the screen. A coordinate point is defined by two numbers that indicate the number of pixels from the left and top edges of the screen where the top-left corner of the window should be. To move the browser window to a spot 50 pixels from the left and 100 pixels from the top, the method is:

```
window.moveTo(50,100)
```

As you learn more about the details of JavaScript and the document objects you can script, pay close attention to the range of methods defined for each object. They reveal a lot about what an object is capable of doing under script control.

## Event handlers

One last characteristic of a DOM object is the *event handler*. *Events* are actions that take place in a document, usually as the result of user activity. Common examples of user actions that trigger events include clicking a button or typing a character into a text field. Some events, such as the act of loading a document into the browser window or experiencing a network error while an image loads, are not so obvious.

Almost every DOM object in a document receives events of one kind or another — summarized for your convenience in the Object Quick Reference of Appendix A. What determines whether the object does anything in response to the event is an extra attribute you enter into the object's HTML definition. The attribute consists of the event name, an equal sign (just like any HTML attribute), followed by instructions about what to do when the particular event fires. Listing 4-1 shows a very simple document that displays a single button with one event handler defined for it.

### Listing 4-1: A Simple Button with an Event Handler

```
<html>
<body>
<form>
<input type="button" value="Click Me" onclick="window.alert('Ouch!')">
</form>
</body>
</html>
```

The form definition contains what, for the most part, looks like a standard `input` element. But notice the last attribute, `onclick="window.alert('Ouch!')"`. Button input objects, as you see in their complete descriptions in Chapter 22, react to mouse clicks. When a user clicks the button, the browser sends a click event to the button. In this button's definition, the attribute says that whenever the button receives that event, it should invoke one of the window object's methods, `alert()`. The `alert()` method displays a simple alert dialog box whose content is whatever text is passed as a parameter to the method. Like most arguments to HTML attributes, the attribute setting to the right of the equal sign goes inside quotes. If additional quotes are necessary, as in the case of the text to be passed along with the event handler, those inner quotes can be single quotes. In actuality, JavaScript doesn't distinguish between single or double quotes but does require that each pair be of the same type. Therefore, you can write the attribute this way:

```
onclick='alert("Ouch!")'
```

## Exercises

- Which of the following applications are well suited to client-side JavaScript? Why or why not?
  - Music jukebox
  - Web-site visit counter
  - Chat room
  - Graphical Fahrenheit-to-Celsius temperature calculator
  - All of the above
  - None of the above
- Which of the following object names are valid in JavaScript? For each one that is invalid, explain why.
  - lastName
  - company\_name
  - 1stLineAddress
  - zip code
  - today's\_date
- Using the diagram from Figure 4-12 for reference, draw a diagram of the object model containment hierarchy that the browser would create in its memory for the following HTML. Write the script reference to the second paragraph element using W3C DOM syntax.

```
<html>
<head>
<title>Search Form</title>
</head>
<body>
<p id="logoPar"></p>
<p id="formPar">
<form name="searchForm" action="cgi-bin/search.pl" method="POST">
Search for: <input type="text" name="searchText" />
<input type="submit" value="Search" />
</form>
</p>
</body>
</html>
```
- Describe at least two characteristics that a text node and an element node have in common; describe at least two characteristics that distinguish a text node from an element node.
- Write the HTML tag for a button input element named "Hi," whose visible label reads "Howdy" and whose `onclick` event handler displays an alert dialog box that says "Hello to you, too!"

# Scripts and HTML Documents

---

In this chapter's tutorial, you begin to see how scripts are embedded within HTML documents and what comprises a script statement. You also see how script statements can run when the document loads or in response to user action. Finally, you find out where script error information is hiding.

## Where Scripts Go in Documents

Chapter 4 did not thoroughly cover what scripts look like or how you add them to an HTML document. That's where this lesson picks up the story.

### The `<script>` tag

To assist the browser in recognizing lines of code in an HTML document as belonging to a script, you surround lines of script code with a `<script>...</script>` tag set. This is common usage in HTML where start and end tags encapsulate content controlled by that tag, whether the tag set is for a form or a paragraph.

Depending on the browser, the `<script>` tag has a variety of attributes you can set that govern the script. One attribute, `type`, advises the browser to treat the code within the tag as JavaScript. Some other browsers accept additional languages (such as Microsoft's VBScript in Windows versions of Internet Explorer). The following setting is one that all scriptable browsers accept:

```
<script type="text/javascript">
```

Be sure to include the ending tag for the script. Lines of JavaScript code go between the two tags:

```
<script type="text/javascript">
    one or more lines of JavaScript code here
</script>
```

If you forget the closing script tag, the script may not run properly and the HTML elsewhere in the page may look strange.

Although you don't work with it in this tutorial, another attribute works with more recent browsers to blend the contents of an external script file into the current document. An `src` attribute (similar to

### In This Chapter

Where to place scripts in HTML documents

What a JavaScript statement is

What makes a script run

Viewing script errors

the `src` attribute of an `<img>` tag) points to the file containing the script code. Such files must end with a `.js` extension. The tag set looks like the following:

```
<script type="text/javascript" SRC="myscript.js"></script>
```

All script lines are in the external file, so no script lines are included between the start and end script tags in the document.

## Tag positions

Where do these tags go within a document? The answer is, anywhere they're needed in the document. Most of the time it makes sense to include the tags nested within the `<head>...</head>` tag set; other times it is essential that you drop the script into a very specific location in the `<body>...</body>` section.

In the following four listings, I demonstrate — with the help of a skeletal HTML document — some of the possibilities of `<script>` tag placement. Later in this lesson, you see why scripts may need to go in different places within a page depending on the scripting requirements.

Listing 5-1 shows the outline of what may be the most common position of a `<script>` tag set in a document: in the `<head>` tag section. Typically, the Head is a place for tags that influence noncontent settings for the page — so-called HTML “directive” elements, such as `<meta>` tags and the document title. It turns out that this is also a convenient place to plant scripts that are called on in response to user action.

### Listing 5-1: Scripts in the Head

```
<html>
<head>
<title>A Document</title>
<script type="text/javascript">
  //script statement(s) here
  ...
</script>
</head>
<body>
</body>
</html>
```

## The Old language Attribute

Another `<script>` tag attribute, `language`, used to be the way to specify the scripting language for the enclosed code. That attribute allowed scripters to specify the language version. For example, if the scripts included code that required JavaScript syntax available only in version 4 browsers (which implemented JavaScript version 1.2), the `<script>` tag used to be written as follows:

```
<script language="JavaScript1.2">...</script>
```

The `language` attribute was never part of the HTML 4.0 specification, and is now falling out of favor. If W3C validation is one of your development concerns, the attribute does not validate in strict versions of HTML 4.01 or XHTML 1.0. Older browsers that do not know the `type` attribute automatically default to JavaScript anyway. Use only the `type` attribute.

On the other hand, if you need a script to run as the page loads so that the script generates content in the page, the script goes in the `<body>` portion of the document, as shown in Listing 5-2. If you check the code listing for your first script in Chapter 3, you see that the script tags are in the Body because the script needs to fetch information about the browser and write the results to the page as the page loads.

### Listing 5-2: A Script in the Body

```
<html>
<head>
<title>A Document</title>
</head>
<body>
<script type="text/javascript">
  //script statement(s) here
  ...
</script>
</body>
</html>
```

It's also good to know that you can place an unlimited number of `<script>` tag sets in a document. For example, Listing 5-3 shows a script in both the Head and Body portions of a document. Perhaps this document needs the Body script to create some dynamic content as the page loads, but the document also contains a button that needs a script to run later. That script is stored in the Head portion.

### Listing 5-3: Scripts in the Head and Body

```
<html>
<head>
<title>A Document</title>
<script type="text/javascript">
  //script statement(s) here
  ...
</script>
</head>
<body>
<script type="text/javascript">
  //script statement(s) here
  ...
</script>
</body>
</html>
```

You also are not limited to one `<script>` tag set in either the Head or Body. You can include as many `<script>` tag sets in a document as are needed to complete your application. In Listing 5-4, for example, two `<script>` tag sets are located in the Body portion, with some other HTML between them.

**Listing 5-4: Two Scripts in the Body**

```
<html>
<head>
<title>A Document</title>
</head>
<body>
<script type="text/javascript">
  //script statement(s) here
  ...
</script>
<more html>
<script type="text/javascript">
  //script statement(s) here
  ...
</script>
</body>
</html>
```

## Handling non-JavaScript browsers

Only browsers that include JavaScript in them know to interpret the lines of code between the `<script>...</script>` tag pair as script statements and not HTML text for display in the browser. This means that a pre-JavaScript browser or a simplified browser in a cell phone not only ignores the tags, but it also treats the JavaScript code as page content. The results can be disastrous to a page.

You can reduce the risk of non-JavaScript browsers displaying the script lines by playing a trick. The trick is to enclose the script lines between HTML comment symbols, as shown in Listing 5-5. Most nonscriptable browsers completely ignore the content between the `<!--` and `-->` comment tags, whereas scriptable browsers ignore those comment symbols when they appear inside a `<script>` tag set.

**Listing 5-5: Hiding Scripts from Most Old Browsers**

```
<script type="text/javascript">
<!--
  //script statement(s) here
  ...
// -->
</script>
```

The odd construction right before the ending script tag needs a brief explanation. The two forward slashes are a JavaScript comment symbol. This symbol is necessary because JavaScript otherwise tries to interpret the components of the ending HTML symbol (`-->`). Therefore, the forward slashes tell JavaScript to skip the line entirely; a nonscriptable browser simply treats those slash characters as part of the entire HTML comment to be ignored.

Despite the fact that this technique is often called *hiding scripts*, it does not disguise the scripts entirely. All client-side JavaScript scripts are part of the HTML document and download to the browser just like all other HTML. Furthermore, you can view them as part of the document's source code. Do not be fooled into thinking that you can hide your scripts entirely from prying eyes.

## JavaScript Statements

Virtually every line of code that sits between a `<script>... </script>` tag pair is a JavaScript *statement*. To be compatible with habits of experienced programmers, JavaScript accepts a semicolon at the end of every statement (the computer equivalent of a period at the end of a sentence). Fortunately for newcomers, this semicolon is optional: The carriage return at the end of a statement suffices for JavaScript to know the statement has ended. It is possible that in the future the semicolon will be required, so it's a good idea to get into the semicolon habit now.

A statement must be in the script for a purpose. Therefore, every statement does “something” relevant to the script. The kinds of things that statements do are

- ♦ Define or initialize a variable
- ♦ Assign a value to a property or variable
- ♦ Change the value of a property or variable
- ♦ Invoke an object's method
- ♦ Invoke a function routine
- ♦ Make a decision

If you don't yet know what all of these mean, don't worry—you will by the end of this tutorial. The point I want to stress is that each statement contributes to the scripts you write. The only statement that doesn't perform any explicit action is the *comment*. A pair of forward slashes (no space between them) is the most common way to include a comment in a script. You add comments to a script for your benefit. They usually explain in plain language what a statement or group of statements does. The purpose of including comments is to remind you six months from now how your script works.

## When Script Statements Execute

Now that you know where scripts go in a document, it's time to look at when they run. Depending on what you need a script to do, you have four choices for determining when a script runs:

- ♦ While a document loads
- ♦ Immediately after a document loads
- ♦ In response to user action
- ♦ When called upon by other script statements

The determining factor is how the script statements are positioned in a document.

## While a document loads – immediate execution

Your first script in Chapter 3 (reproduced in Listing 5-6) runs while the document loads into the browser. For this application, it is essential that a script inspects some properties of the `navigator` object and includes those property values in the content being rendered for the page as it loads. It makes sense, therefore, to include the `<script>` tags and statements in the Body portion of the document. I call the kind of statements that run as the page loads *immediate statements*.

### Listing 5-6: HTML Page with Immediate Script Statements

```
<html>
<head>
<title>My First Script</title>
<style type="text/css">
.highlight {font-weight: bold}
</style>
</head>

<body>
<h1>Let's Script...</h1>
<hr>
<script type="text/javascript">
<!-- hide from old browsers
document.write("This browser is version " + navigator.appVersion);
document.write(" of <span class='highlight'>" + navigator.appName + "</span>.");
// end script hiding -->
</script>
</body>
</html>
```

## Deferred scripts

The other three ways that script statements run are grouped together as what I call *deferred scripts*. To demonstrate these deferred script situations, I must introduce you briefly to a concept covered in more depth in Chapter 7: the function. A *function* defines a block of script statements summoned to run some time after those statements load into the browser. Functions are clearly visible inside a `<script>` tag because each function definition begins with the word `function` followed by the function name (and parentheses). Once a function is loaded into the browser (commonly in the Head portion so it loads early), it stands ready to run whenever called upon.

One of the times a function is called upon to run is immediately after a page loads. The `window` object has an event handler called `onload`. Unlike most event handlers, which are triggered in response to user action (for example, clicking a button), the `onload` event handler fires the instant that all of the page's components (including images, Java applets, and embedded multimedia) are loaded into the browser. The `onload` event handler goes in the `<body>` tag, as shown in Listing 5-7. Recall from Chapter 4 (Listing 4-1) that an event handler can run a script statement directly. But if the event handler must run several script statements, it is usually more convenient to put those statements in a function definition and then have the event handler *invoke* that function. That's what happens in Listing 5-7: When the page completes loading, the `onload` event handler triggers the `done()` function. That function (simplified for this example) displays an alert dialog box.

**Listing 5-7: Running a Script from the onload Event Handler**

```
<html>
<head>
<title>An onload script</title>
<script type="text/javascript">
<!--
function done() {
    alert("The page has finished loading.");
}
// -->
</script>
</head>
<body onload="done()">
Here is some body text.
</body>
</html>
```

Don't worry about the curly braces or other oddities in Listing 5-7 that may cause you concern at this point. Focus instead on the structure of the document and the flow. The entire page loads without running any script statements, although the page loads the `done()` function in memory so that it is ready to run at a moment's notice. After the document loads, the browser fires the `onload` event handler, which causes the `done()` function to run. Then the user sees the alert dialog box.

Getting a script to execute in response to a user action is very similar to the preceding example for running a deferred script right after the document loads. Commonly, a script function is defined in the Head portion, and an event handler in, say, a form element calls upon that function to run. Listing 5-8 includes a script that runs when a user clicks a button.

**Listing 5-8: Running a Script from User Action**

```
<html>
<head>
<title>An onclick script</title>
<script type="text/javascript">
<!--
function alertUser() {
    alert("Ouch!");
}
// -->
</script>
</head>
<body>
Here is some body text.
<form>
    <input type="text" name="entry">
    <input type="button" name="oneButton" value="Press Me!"
onclick="alertUser()">
</form>
</body>
</html>
```

Not every object must have an event handler defined for it in the HTML, as shown in Listing 5-8—only the ones for which scripting is needed. No script statements execute in Listing 5-8 until the user clicks the button. The `alertUser()` function is defined as the page loads, and it waits to run as long as the page remains loaded in the browser. If it is never called upon to run, there's no harm done.

The last scenario for when script statements run also involves functions. In this case, a function is called upon to run by another script statement. Before you see how that works, it helps to read through the next lesson (Chapter 6). Therefore, I will hold off on this example until later in the tutorial.

## Viewing Script Errors

In the early days of JavaScript in browsers, script errors displayed themselves in very obvious dialog boxes. These boxes were certainly helpful for scripters who wanted to debug their scripts. However, if a bug got through to a page served up to a non-technical user, the error alert dialog boxes were not only disruptive, but also scary. To prevent such dialog boxes from disturbing unsuspecting users, the browser makers tried to diminish the visual impact of errors in the browser window. Unfortunately for scripters, it is often easy to overlook the fact that your script contains an error because the error is not so obvious. Recent browser versions have different ways of letting scripters see the errors.

In IE5+, you can set its preferences so that scripts do not generate error dialog boxes (go to Tools ⇨ Internet Options ⇨ Advanced ⇨ Browsing and find the check-box entry that says “Display a notification about every script error”). Even with error dialog boxes turned off, error indications are displayed subtly at the left edge of the browser window's status bar. An alert icon and message (“Error on page.”) appear in the status bar. If you double-click the icon, the error dialog box appears (see Figure 5-1). Be sure to expand the dialog box by clicking the Show Details button. Unless you turn on script error dialog boxes and keep them coming, you have to train yourself to monitor the status bar when a page loads and after each script runs.

**Figure 5-1:** The expanded IE error dialog box.

For Mozilla-based browsers, choose Tools ⇨ Web Development ⇨ JavaScript Console. The JavaScript console window (a separate window from the Java console) opens to reveal the error message details (see Figure 5-2). You can keep this window open all the time if you like. Unless you clear the window, subsequent error messages are appended to the bottom of the window.

**Figure 5-2:** The Mozilla 1.4 JavaScript console window.

Safari 1.0 records script errors, but it's not obvious how to read them. You must first enable Safari's Debug menu by typing the following command in the Terminal application:

```
defaults write com.apple.Safari IncludeDebugMenu 1
```

Then, each time you launch Safari, choose the Log JavaScript Exceptions item in the Debug menu. Open the MacOS X Console application window, where JavaScript error messages appear amid other Console logging messages. With luck, future versions will be more developer-friendly.

Understanding error messages and doing something about them is a very large subject, reserved for advanced discussion in Chapter 45 on the CD-ROM. During this tutorial, however, you can use the error messages to see if you have perhaps mistyped a script from a listing in the book.

## Scripting versus Programming

You may get the impression that scripting is easier than programming. “Scripting” simply sounds easier or more friendly than “programming.” In many respects, this is true. One of my favorite analogies is the difference between a hobbyist who builds model airplanes from scratch and a hobbyist who builds model airplanes from commercial kits. The “from scratch” hobbyist carefully cuts and shapes each piece of wood and metal according to very detailed plans before the model starts to take shape. The commercial kit builder starts with many prefabricated parts and assembles them into the finished product. When both builders are finished, you may not be able to tell which airplane was built from scratch and which one came out of a box of components. In the end, both builders used many of the same techniques to complete the assembly, and each can take pride in the result.

As you've seen with the Document Object Model, the browser gives scripters many prefabricated components with which to work. Without the browser, you'd have to be a pretty good programmer to develop from scratch your own application that served up content and

offered user interaction. In the end, both authors have working applications that look equally professional.

Beyond the DOM, however, “real programming” nibbles its way into the scripting world. That’s because scripts (and programs) work with more than just objects. When I said earlier in this lesson that each statement of a JavaScript script does something, that “something” involves *data* of some kind. Data is the information associated with objects or other pieces of information that a script pushes around from place to place with each statement.

Data takes many forms. In JavaScript, the common incarnations of data are numbers; text (called *strings*); objects (both from the object model and others you can create with scripts); and `true` and `false` (called *Boolean values*).

Each programming or scripting language determines numerous structures and limits for each kind of data. Fortunately for newcomers to JavaScript, the universe of knowledge necessary for working with data is smaller than in a language such as Java. At the same time, what you learn about data in JavaScript is immediately applicable to future learning you may undertake in any other programming language — don’t believe for an instant that your efforts in learning scripting will be wasted.

Because deep down scripting is programming, you need to have a basic knowledge of fundamental programming concepts to consider yourself a good JavaScript scripter. In the next two lessons, I set aside most discussion about the DOM and focus on the programming principles that will serve you well in JavaScript and future programming endeavors.

## Exercises

1. Write the complete script tag set for a script whose lone statement is

```
document.write("Hello, world.");
```
2. Build an HTML document and include the answer to the previous question such that the page executes the script as it loads. Open the document in your browser to test the results.
3. Add a comment to the script in the previous answer that explains what the script does.
4. Create an HTML document that displays an alert dialog box immediately after the page loads and displays a different alert dialog box when the user clicks a form button.
5. Carefully study the document in Listing 5-9. Without entering and loading the document, predict
  - a. What the page looks like
  - b. How users interact with the page
  - c. What the script does

Then type the listing into a text editor as shown (observe all capitalization and punctuation). **Do not type a carriage return after the “=” sign in the upperMe function statement; let the line word-wrap as it does in the following listing.** It’s okay to use a carriage return between attribute name/value pairs, as shown in the first `<input>` tag. Save the document as an HTML file, and load the file into your browser to see how well you did.

**Listing 5-9: How Does This Page Work?**

```
<html>
<head>
<title>Text Object Value</title>
<script type="text/javascript">
<!--
function upperMe() {
    document.getElementById("output").value =
document.getElementById("input").value.toUpperCase();
}
// -->
</script>
</head>

<body>
Enter lowercase letters for conversion to uppercase:<br>
<form name="converter">
    <input type="text" name="input" id="input"
        value="sample" onchange="upperMe()" /><br />
    <input type="text" name="output" id="output" value="" />
</form>
</body>
</html>
```

---

# Programming Fundamentals, Part I

---

**T**he tutorial breaks away from HTML and documents for a while as you begin to learn programming fundamentals that apply to practically every scripting and programming language you will encounter. Here, you start learning about variables, expressions, data types, and operators — things that might sound scary if you haven’t programmed before. Don’t worry. With a little practice, you will become quite comfortable with these terms and concepts.

## What Language Is This?

The language you’re studying is called JavaScript. But the language has some other names that you may have heard. JScript is Microsoft’s name for the language. By leaving out the “ava,” the company doesn’t have to license the “Java” name from its trademark owner: Sun Microsystems.

A standards body called ECMA (pronounced ECK-ma) now governs the specifications for the language (no matter what you call it). The document that provides all of the details about the language is known as *ECMA-262* (it’s the 262nd standard published by ECMA). Both JavaScript and JScript are ECMA-262 compatible. Some earlier browser versions exhibit very slight deviations from ECMA-262 (which came later than the earliest browsers). The most serious discrepancies are noted in the core language reference in Part IV of this book.

## Working with Information

With rare exception, every JavaScript statement you write does something with a hunk of information — *data*. Data may be text information displayed on the screen by a JavaScript statement or the on/off setting of a radio button in a form. Each single piece of information in programming is also called a *value*. Outside of programming, the term *value* usually connotes a number of some kind; in the programming world, however, the term is not as restrictive. A string

### In This Chapter

What variables are and how to use them

Why you must learn how to evaluate expressions

How to convert data from one type to another

How to use basic operators

of letters is a value. A number is a value. The setting of a checkbox (whether it is checked or not) is a value.

In JavaScript, a value can be one of several types. Table 6-1 lists JavaScript's formal data types, with examples of the values you will see displayed from time to time.

**Table 6-1: JavaScript Value (Data) Types**

<i>Type</i>	<i>Example</i>	<i>Description</i>
String	"Howdy"	A series of characters inside quote marks
Number	4.5	Any number not inside quote marks
Boolean	true	A logical true or false
Null	null	Completely devoid of any content, but a value just the same
Object		A software "thing" that is defined by its properties and methods (arrays are also objects)
Function		A function definition

A language that contains these few data types simplifies programming tasks, especially those involving what other languages consider to be incompatible types of numbers (integers versus real or floating-point values). In some definitions of syntax and parts of objects later in this book, I make specific reference to the type of value accepted in placeholders. When a string is required, any text inside a set of quotes suffices.

You will encounter situations, however, in which the value type may get in the way of a smooth script step. For example, if a user enters a number into a form's text input field, the browser stores that number as a string value type. If the script is to perform some arithmetic on that number, you must convert the string to a number before you can apply the value to any math operations. You see examples of this later in this lesson.

## Variables

Cooking up a dish according to a recipe in the kitchen has one advantage over cooking up some data in a program. In the kitchen, you follow recipe steps and work with real things: carrots, milk, or a salmon fillet. A computer, on the other hand, follows a list of instructions to work with data. Even if the data represents something that looks real, such as the text entered into a form's input field, once the value gets into the program, you can no longer reach out and touch it.

In truth, the data that a program works with is merely a collection of bits (on and off states) in your computer's memory. More specifically, data in a JavaScript-enhanced Web page occupies parts of the computer's memory set aside for exclusive use by the browser software. In the olden days, programmers had to know the numeric address in memory (RAM) where a value was stored to retrieve a copy of it for, say, some addition. Although the innards of a program have that level of complexity, programming languages such as JavaScript shield you from it.

The most convenient way to work with data in a script is to first assign the data to a *variable*. It's usually easier to think of a variable as a basket that holds information. How long the variable holds the information depends on a number of factors. But the instant a Web page clears the window (or frame), any variables it knows about are immediately discarded.

## Creating a variable

You have a couple of ways to create a variable in JavaScript, but one covers you properly in all cases. Use the `var` keyword, followed by the name you want to give that variable.

Therefore, to *declare* a new variable called `myAge`, the JavaScript statement is

```
var myAge;
```

That statement lets the browser know that you can use that variable later to hold information or to modify any of the data in that variable.

To assign a value to a variable, use one of the *assignment operators*. The most common one by far is the equal sign. If I want to assign a value to the `myAge` variable at the same time I declare it (a combined process known as *initializing the variable*), I use that operator in the same statement as the `var` keyword:

```
var myAge = 45;
```

On the other hand, if I declare a variable in one statement and later want to assign a value to it, the sequence of statements is

```
var myAge;  
myAge = 45;
```

Use the `var` keyword **only for declaration or initialization**—once for the life of any variable name in a document.

A JavaScript variable can hold any value type. Unlike many other languages, you don't have to tell JavaScript during variable declaration what type of value the variable will hold. In fact, the value type of a variable can change during the execution of a program. (This flexibility drives experienced programmers crazy because they're accustomed to assigning both a data type and a value to a variable.)

## Variable names

Choose the names you assign to variables with care. You'll often find scripts that use vague variable names, such as single letters. Other than a few specific times where using letters is a common practice (for example, using `i` as a counting variable in repeat loops in Chapter 7), I recommend using names that truly describe a variable's contents. This practice can help you follow the state of your data through a long series of statements or jumps, especially for complex scripts.

A number of restrictions help instill good practice in assigning names. First, you cannot use any reserved keyword as a variable name. That includes all keywords currently used by the language and all others held in reserve for future versions of JavaScript. The designers of JavaScript, however, cannot foresee every keyword that the language may need in the future. By using the kind of single words that currently appear in the list of reserved keywords (see Appendix B), you always run a risk of a future conflict.

To complicate matters, a variable name cannot contain space characters. Therefore, one-word variable names are fine. Should your description really benefit from more than one word, you can use one of two conventions to join multiple words as one. One convention is to place an underscore character between the words; the other is to start the combination word with a lowercase letter and capitalize the first letter of each subsequent word within the name—I refer to this as the *interCap format*. Both of the following examples are valid variable names:

```
my_age  
myAge
```

My preference is for the second version. I find it easier to type as I write JavaScript code and easier to read later. In fact, because of the potential conflict with future one-word keywords, using multiword combinations for variable names is a good idea. Multiword combinations are less likely to appear in the reserved word list.

Variable names have a couple of other important restrictions. Avoid all punctuation symbols except for the underscore character. Also, the first character of a variable name cannot be a numeral. If these restrictions sound familiar, it's because they're identical to those for HTML element identifiers described in Chapter 4.

## Expressions and Evaluation

Another concept closely related to the value and variable is *expression evaluation*—perhaps the most important concept of learning how to program a computer.

We use expressions in our everyday language. Remember the theme song of *The Beverly Hillbillies*?

*Then one day he was shootin' at some food*

*And up through the ground came a-bubblin' crude*

*Oil that is. Black gold. Texas tea.*

At the end of the song, you find four quite different references (“crude,” “oil,” “black gold,” and “Texas tea”). They all mean oil. They're all *expressions* for oil. Say any one of them and other people know what you mean. In our minds, we *evaluate* those expressions to mean one thing: oil.

In programming, a variable always evaluates to its contents, or value. For example, after assigning a value to a variable, such as

```
var myAge = 45;
```

any time the variable is used in a statement, its value (45) is automatically applied to whatever operation that statement calls. Therefore, if you're 15 years my junior, I can assign a value to a variable representing your age based on the evaluated value of myAge:

```
var yourAge = myAge - 15;
```

The variable, `yourAge`, evaluates to 30 the next time the script uses it. If the `myAge` value changes later in the script, the change has no link to the `yourAge` variable because `myAge` evaluated to 45 when it was used to assign a value to `yourAge`.

## Expressions in script1.htm

You probably didn't recognize it at the time, but you saw how expression evaluation came in handy in your first script of Chapter 3. Recall the second `document.write()` statement:

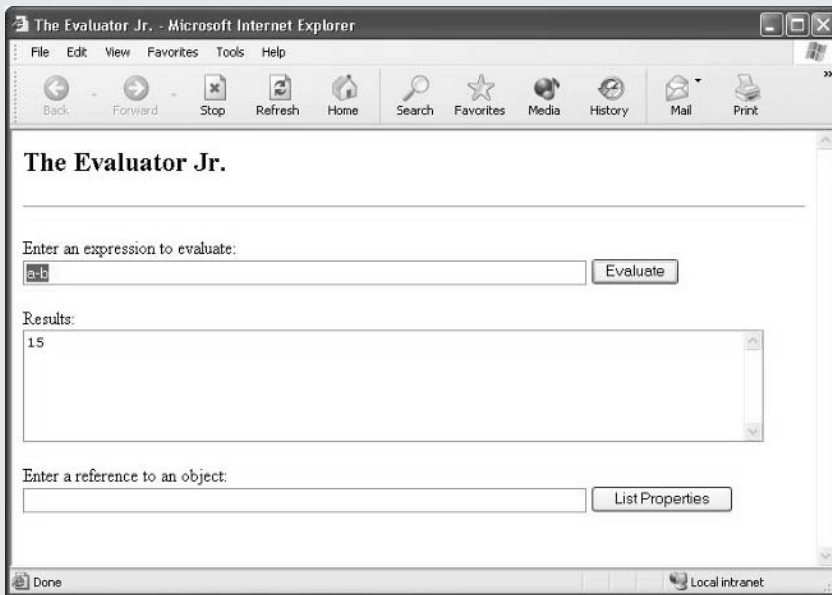

```
document.write(" of " + navigator.appName + ".");
```

The `document.write()` method (remember, JavaScript uses the term *method* to mean *command*) requires a parameter in the parentheses: the text string to be displayed on the Web page. The parameter here consists of one expression that joins three distinct strings:

```
" of "  
navigator.appName  
"."
```

## Testing JavaScript Evaluation

You can begin experimenting with the way JavaScript evaluates expressions with the help of The Evaluator Jr. (seen in the following figure), an HTML page you can find on the companion CD-ROM. (I introduce the Senior version in Chapter 13.) Enter any JavaScript expression into the top text box, and either press Enter/Return or click the Evaluate button.

The Evaluator Jr. for testing expression evaluation.

The Evaluator Jr. has 26 variables (lowercase a through z) predefined for you. Therefore, you can assign values to variables, test comparison operators, and even do math here. Using the `age` variable examples from earlier in this chapter, type each of the following statements into the upper text box and observe how each expression evaluates in the Results field. Be sure to observe case-sensitivity in your entries. The trailing semicolons are optional in The Evaluator.

```
a = 45;  
a;  
b = a - 15;  
b;  
a - b;  
a > b;
```

To start over, click the Reload button.

The plus symbol is one of JavaScript's ways of joining strings. Before JavaScript can display this line, it must perform some quick evaluations. The first evaluation is the value of the `navigator.appName` property. This property evaluates to a string of the name of your browser. With that expression safely evaluated to a string, JavaScript can finish the job of joining the three strings in the final evaluation. The evaluated string expression is what ultimately appears on the Web page.

## Expressions and variables

As one more demonstration of the flexibility that expression evaluation offers, this section shows you a slightly different route to the `document.write()` statement. Rather than join those strings as the direct parameter to the `document.write()` method, I can gather the strings in a variable and then apply the variable to the `document.write()` method. Here's how that sequence looks, as I simultaneously declare a new variable and assign it a value:

```
var textToWrite = " of " + navigator.appName + ".";
document.write(textToWrite);
```

This method works because the variable, `textToWrite`, evaluates to the combined string. The `document.write()` method accepts that string value and does its display job. As you read a script or try to work through a bug, pay special attention to how each expression (variable, statement, object property) evaluates. I guarantee that as you learn JavaScript (or any language), you will end up scratching your head from time to time because you haven't stopped to examine how expressions evaluate when a particular kind of value is required in a script.

## Data Type Conversions

I mentioned earlier that the type of data in an expression can trip up some script operations if the expected components of the operation are not of the right type. JavaScript tries its best to perform internal conversions to head off such problems, but JavaScript cannot read your mind. If your intentions differ from the way JavaScript treats the values, you won't get the results you expect.

A case in point is adding numbers that may be in the form of text strings. In a simple arithmetic statement that adds two numbers together, you get the expected result:

```
3 + 3           // result = 6
```

But if one of those numbers is a string, JavaScript leans toward converting the other value to a string—thus turning the plus sign's action from arithmetic addition to joining strings. Therefore, in the statement

```
3 + "3"        // result = "33"
```

the “string-ness” of the second value prevails over the entire operation. The first value is automatically converted to a string, and the result joins the two strings. Try this yourself in The Evaluator Jr.

If I take this progression one step further, look what happens when another number is added to the statement:

```
3 + 3 + "3"    // result = "63"
```

This might seem totally illogical, but there is logic behind this result. The expression is evaluated from left to right. The first plus operation works on two numbers, yielding a value of 6.

But as the 6 is about to be added to the “3,” JavaScript lets the “string-ness” of the “3” rule. The 6 is converted to a string, and two string values are joined to yield “63.”

Most of your concern about data types will focus on performing math operations like the ones here. However, some object methods also require one or more parameters of particular data types. While JavaScript provides numerous ways to convert data from one type to another, it is appropriate at this stage of the tutorial to introduce you to the two most common data conversions: string to number and number to string.

## Converting strings to numbers

As you saw in the last section, if a numeric value is stored as a string—as it is when entered into a form text field—your scripts may have difficulty applying that value to a math operation. The JavaScript language provides two built-in functions to convert string representations of numbers to true numbers: `parseInt()` and `parseFloat()`.

There is a difference between integers and floating-point numbers in JavaScript. *Integers* are always whole numbers, with no decimal point or numbers to the right of a decimal. *Floating-point numbers*, on the other hand, have fractional values to the right of the decimal. By and large, JavaScript math operations don’t differentiate between integers and floating-point numbers: A number is a number. The only time you need to be cognizant of the difference is when a method parameter requires an integer because it can’t handle fractional values. For example, parameters to the `scroll()` method of a window require integer values of the number of pixels vertically and horizontally you want to scroll the window. That’s because you can’t scroll a window a fraction of a pixel on the screen.

To use either of these conversion functions, insert the string value you wish to convert as a parameter to the function. For example, look at the results of two different string values when passed through the `parseInt()` function:

```
parseInt("42")           // result = 42
parseInt("42.33")       // result = 42
```

Even though the second expression passes the string version of a floating-point number to the function, the value returned by the function is an integer. No rounding of the value occurs here (although other math functions can help with that if necessary). The decimal and everything to its right are simply stripped off.

The `parseFloat()` function returns an integer if it can; otherwise, it returns a floating-point number as follows:

```
parseFloat("42")        // result = 42
parseFloat("42.33")     // result = 42.33
```

Because these two conversion functions evaluate to their results, you simply insert the entire function wherever you need a string value converted to a number. Therefore, modifying an earlier example in which one of three values was a string, the complete expression can evaluate to the desired result:

```
3 + 3 + parseInt("3")   // result = 9
```

## Converting numbers to strings

You’ll have less need for converting a number to its string equivalent than the other way around. As you saw in the previous section, JavaScript gravitates toward strings when faced

with an expression containing mixed data types. Even so, it is good practice to perform data type conversions explicitly in your code to prevent any potential ambiguity. The simplest way to convert a number to a string is to take advantage of JavaScript's string tendencies in addition operations. By adding an empty string to a number, you convert the number to its string equivalent:

```
("" + 2500)           // result = "2500"  
("" + 2500).length  // result = 4
```

In the second example, you can see the power of expression evaluation at work. The parentheses force the conversion of the number to a string. A *string* is a JavaScript object that has properties associated with it. One of those properties is the `length` property, which evaluates to the number of characters in the string. Therefore, the length of the string "2500" is 4. Note that the length value is a number, not a string.

## Operators

You will use lots of *operators* in expressions. Earlier, you used the equal sign (=) as an assignment operator to assign a value to a variable. In the preceding examples with strings, you used the plus symbol (+) to join two strings. An operator generally performs some kind of calculation (operation) or comparison with two values (the value on each side of an operator is called an *operand*) to reach a third value. In this lesson, I briefly describe two categories of operators—arithmetic and comparison. Chapter 32 covers many more operators, but once you understand the basics here, the others are easier to grasp.

### Arithmetic operators

It may seem odd to talk about text strings in the context of “arithmetic” operators, but you have already seen the special case of the plus (+) operator when one or more of the operands is a string. The plus operator instructs JavaScript to *concatenate* (pronounced kon-KAT-en-eight), or join, two strings together precisely where you place the operator. The string concatenation operator doesn't know about words and spaces, so the programmer must make sure that any two strings to be joined have the proper word spacing as part of the strings—even if that means adding a space:

```
firstName = "John";  
lastName = "Doe";  
fullName = firstName + " " + lastName;
```

JavaScript uses the same plus operator for arithmetic addition. When both operands are numbers, JavaScript knows to treat the expression as an arithmetic addition rather than a string concatenation. The standard math operators for addition, subtraction, multiplication, and division (+, -, \*, /) are built into JavaScript.

### Comparison operators

Another category of operator helps you compare values in scripts—whether two values are the same, for example. These kinds of comparisons return a value of the Boolean type—`true` or `false`. Table 6-2 lists the comparison operators. The operator that tests whether two items are equal consists of a pair of equal signs to distinguish it from the single equal sign assignment operator.

**Table 6-2: JavaScript Comparison Operators**

<i>Symbol</i>	<i>Description</i>
==	Equals
!=	Does not equal
>	Is greater than
>=	Is greater than or equal to
<	Is less than
<=	Is less than or equal to

Where comparison operators come into greatest play is in the construction of scripts that make decisions as they run. A cook does this in the kitchen all the time: If the sauce is too watery, add a bit of flour. You see comparison operators in action in the next chapter.

## Exercises

- Which of the following are valid variable declarations or initializations? Explain why each one is or is not valid. If an item is invalid, how do you fix it so that it is?
  - `my_name = "Cindy";`
  - `var how many = 25;`
  - `var zipCode = document.getElementById("zip").value`
  - `var laddress = document.("address1").value;`
- Assume that the following statements operate rapidly in sequence, where each statement relies on the result of the one before it. For each of the statements in the sequence, write down how the `someVal` expression evaluates after the statement executes in JavaScript.

```
var someVal = 2;
someVal = someVal + 2;
someVal = someVal * 10;
someVal = someVal + "20";
someVal = "Robert";
```
- Name the two JavaScript functions that convert strings to numbers. How do you give the function a string value to convert to a number?
- Type and load the HTML page and script shown in Listing 6-1. Enter a three-digit number into the top two fields and click the Add button. Examine the code and explain what is wrong with the script. How do you fix the script so the proper sum is displayed in the output field?

**Listing 6-1: What's Wrong with This Page?**

```
<html>
<head>
<title>Sum Maker</title>
<script type="text/javascript">
<!--
function addIt() {
  var value1 = document.getElementById("inputA").value;
  var value2 = document.getElementById("inputB").value;
  document.getElementById("output").value = value1 + value2;
}
// -->
</script>
</head>

<body>
<form name="adder">
<input type="text" name="inputA" id="inputA" value="0" size="4" /><br />
<input type="text" name="inputB" id="inputB" value="0" size="4" />
<input type="button" value="Add" onclick="addIt()">
<p>_____</p>
<input type="text" name="output" id="output" size="6" />
</form>
</body>
</html>
```

---

5. What does the term *concatenate* mean in the context of JavaScript programming?

# Programming Fundamentals, Part II

---

Your tour of programming fundamentals continues in this chapter with subjects that have more intriguing possibilities. For example, I show you how programs make decisions and why a program must sometimes repeat statements over and over. Before you're finished here, you will learn how to use one of the most powerful information holders in the JavaScript language: the array.

## Decisions and Loops

Every waking hour of every day you make decisions of some kind — most of the time you probably don't even realize it. Don't think so? Well, look at the number of decisions you make at the grocery store, from the moment you enter the store to the moment you clear the checkout aisle.

No sooner do you enter the store than you are faced with a decision. Based on the number and size of items you intend to buy, do you pick up a hand-carried basket or attempt to extricate a shopping cart from the metallic conga line near the front of the store? That key decision may have impact later when you see a special offer on an item that is too heavy to put into the hand basket.

Next, you head for the food aisles. Before entering an aisle, you compare the range of goods stocked in that aisle against items on your shopping list. If an item you need is likely to be found in this aisle, you turn into the aisle and start looking for the item; otherwise, you skip the aisle and move to the head of the next aisle.

Later, you reach the produce section in search of a juicy tomato. Standing in front of the bin of tomatoes, you begin inspecting them one by one — picking one up, feeling its firmness, checking the color, looking for blemishes or signs of pests. You discard one, pick up another, and continue this process until one matches the criteria you set in your mind for an acceptable morsel. Your last stop in the store is the checkout aisle. “Paper or plastic?” the clerk asks. One more decision to make. What you choose impacts how you get the groceries from the car to the kitchen as well as your recycling habits.

### In This Chapter

How control structures make decisions

How to define functions

Where to initialize variables efficiently

What those darned curly braces are all about

The basics of data arrays

In your trip to the store, you go through the same kinds of decisions and repetitions that your JavaScript programs also encounter. If you understand these frameworks in real life, you can now look into the JavaScript equivalents and the syntax required to make them work.

## Control Structures

In the vernacular of programming, the kinds of statements that make decisions and loop around to repeat themselves are called *control structures*. A control structure directs the execution flow through a sequence of script statements based on simple decisions and other factors.

An important part of a control structure is the *condition*. Just as you may travel different routes to work depending on certain conditions (for example, nice weather, nighttime, attending a soccer game), so, too, does a program sometimes have to branch to an execution route if a certain condition exists. Each condition is an expression that evaluates to `true` or `false`—one of those Boolean data types mentioned in Chapter 6. The kinds of expressions commonly used for conditions are expressions that include a comparison operator. You do the same in real life: If it is true that the outdoor temperature is less than freezing, you put on a coat before going outside. In programming, however, the comparisons are strictly comparisons of values.

JavaScript provides several kinds of control structures for different programming situations. Three of the most common control structures you'll use are `if` constructions, `if...else` constructions, and `for` loops.

Chapter 31 covers in great detail other common control structures you should know. For this tutorial, however, you need to learn about the three common ones just mentioned.

### if constructions

The simplest program decision is to follow a special branch or path of the program if a certain condition is true. Formal syntax for this construction follows. Items in italics get replaced in a real script with expressions and statements that fit the situation.

```
if (condition) {  
    statement[s] if true  
}
```

Don't worry about the curly braces yet. Instead, get a feel for the basic structure. The keyword, `if`, is a must. In the parentheses goes an expression that evaluates to a Boolean value. This is the condition being tested as the program runs past this point. If the condition evaluates to `true`, one or more statements inside the curly braces execute before continuing on with the next statement after the closing brace. If the condition evaluates to `false`, the statements inside the curly braces are ignored and processing continues with the next statement after the closing brace.

The following example assumes that a variable, `myAge`, has had its value set earlier in the script (exactly how is not important for this example). The condition expression compares the value `myAge` against a numeric value of 18.

```
if (myAge < 18) {  
    alert("Sorry, you cannot vote.");  
}
```

In this example, the data type of the value inside `myAge` must be a number so that the proper comparison (via the `<` comparison operator) does the right thing. For all instances of `myAge` less than 18, the nested statement inside the curly braces runs and displays the alert to the user. After the user closes the alert dialog box, the script continues with whatever statement follows the entire `if` construction.

## if . . . else constructions

Not all program decisions are as simple as the one shown for the `if` construction. Rather than specifying one detour for a given condition, you might want the program to follow either of two branches depending on that condition. It is a fine, but important, distinction. In the plain `if` construction, no special processing is performed when the condition evaluates to `false`. But if processing must follow one of two special paths, you need the `if . . . else` construction. The formal syntax definition for an `if . . . else` construction is as follows:

```
if (condition) {  
    statement[s] if true  
} else {  
    statement[s] if false  
}
```

Everything you know about the condition for an `if` construction applies here. The only difference is the `else` keyword, which provides an alternate path for execution to follow if the condition evaluates to `false`.

As an example, the following `if . . . else` construction determines how many days are in February for a given year. To simplify the demo, the condition simply tests whether the year divides evenly by 4. (True testing for this value includes special treatment of end-of-century dates, but I'm ignoring that for now.) The `%` operator symbol is called the *modulus operator* (covered in more detail in Chapter 32). The result of an operation with this operator yields the remainder of division of the two values. If the remainder is zero, the first value divides evenly by the second.

```
var febDays;  
var theYear = 2004;  
if (theYear % 4 == 0) {  
    febDays = 29;  
} else {  
    febDays = 28;  
}
```

The important point to see from this example is that by the end of the `if . . . else` construction, the `febDays` variable is set to either 28 or 29. No other value is possible. For years evenly divisible by 4, the first nested statement runs. For all other cases, the second statement runs. Processing then picks up with the next statement after the `if . . . else` construction.

## About Repeat Loops

Repeat loops in real life generally mean the repetition of a series of steps until some condition is met, thus enabling you to break out of that loop. Such was the case earlier in this chapter when you looked through a bushel of tomatoes for the one that came closest to your ideal tomato. The same can be said for driving around the block in a crowded neighborhood until a parking space opens up.

A *repeat loop* lets a script cycle through a sequence of statements until some condition is met. For example, a JavaScript data validation routine might inspect every character that you enter into a form text field to make sure that each one is a number. Or if you have a collection of data stored in a list, the loop can check whether an entered value is in that list. Once that condition is met, the script can then break out of the loop and continue with the next statement after the loop construction.

The most common repeat loop construction used in JavaScript is called the *for loop*. It gets its name from the keyword that begins the construction. A *for loop* is a powerful device because you can set it up to keep track of the number of times the loop repeats itself. The formal syntax of the *for loop* is as follows:

```
for ([initial expression]; [condition]; [update expression]) {  
    statement[s] inside loop  
}
```

The square brackets mean that the item is optional. However, until you get to know the *for loop* better, I recommend designing your loops to utilize all three items inside the parentheses. The *initial expression* portion usually sets the starting value of a counter variable. The *condition* — the same kind of condition you saw for *if* constructions — defines the condition that forces the loop to stop going around and around. Finally, the *update expression* is a statement that executes each time all of the statements nested inside the construction complete running.

A common implementation initializes a counting variable, *i*, increments the value of *i* by one each time through the loop, and repeats the loop until the value of *i* exceeds some maximum value, as in the following:

```
for (var i = startValue; i <= maxValue; i++) {  
    statement[s] inside loop  
}
```

Placeholders *startValue* and *maxValue* represent any numeric values, including explicit numbers or variables holding numbers. In the update expression is an operator you have not seen yet. The *++* operator adds 1 to the value of *i* each time the update expression runs at the end of the loop. If *startValue* is 1, the value of *i* is 1 the first time through the loop, 2 the second time through, and so on. Therefore, if *maxValue* is 10, the loop repeats itself 10 times (in other words, as long as *i* is less than or equal to 10). Generally speaking, the statements inside the loop use the value of the counting variable in their execution. Later in this lesson, I show how the variable can play a key role in the statements inside a loop. At the same time, you will see how to break out of a loop prematurely and why you may need to do this in a script.

## Functions

In Chapter 5, you saw a preview of the JavaScript function. A *function* is a definition of a set of deferred actions. Functions are invoked by event handlers or by statements elsewhere in the script. Whenever possible, good functions are designed for reuse in other documents. They can become building blocks you use over and over again.

If you have programmed before, you can see parallels between JavaScript functions and other languages' subroutines. But unlike some languages that distinguish between procedures (which carry out actions) and functions (which carry out actions and return values), only one

classification of routine exists for JavaScript. A function is capable of returning a value to the statement that invoked it, but this is not a requirement. However, when a function does return a value, the calling statement treats the function call like any expression — plugging in the returned value right where the function call is made. I will show some examples in a moment.

Formal syntax for a function is as follows:

```
function functionName ( [parameter1]...[,parameterN] ) {  
    statement[s]  
}
```

Names you assign to functions have the same restrictions as names you assign to HTML elements and variables. You should devise a name that succinctly describes what the function does. I tend to use multiword names with the interCap (internally capitalized) format that start with a verb because functions are action items, even if they do nothing more than get or set a value.

Another practice to keep in mind as you start to create functions is to keep the focus of each function as narrow as possible. It is possible to generate functions that are literally hundreds of lines long. Such functions are usually difficult to maintain and debug. Chances are that you can divide the long function into smaller, more tightly focused segments.

## Function parameters

In Chapter 5, you saw how an event handler invokes a function by calling the function by name. Any call to a function, including one that comes from another JavaScript statement, works the same way: a set of parentheses follows the function name.

You also can define functions so they receive parameter values from the calling statement. Listing 7-1 shows a simple document that has a button whose `onclick` event handler calls a function while passing text data to the function. The text string in the event handler call is in a *nested string* — a set of single quotes inside the double quotes required for the entire event handler attribute.

### Listing 7-1: Calling a Function from an Event Handler

```
<html>  
<head>  
<script type="text/javascript">  
function showMsg(msg) {  
    alert("The button sent: " + msg);  
}  
</script>  
</head>  
<body>  
<form>  
    <input type="button" value="Click Me"  
        onclick="showMsg('The button has been clicked!')">  
</form>  
</body>  
</html>
```

Parameters (also known as *arguments*) provide a mechanism for “handing off” a value from one statement to another by way of a function call. If no parameters occur in the function definition, both the function definition and call to the function have only empty sets of parentheses (as shown in Chapter 5, Listing 5-8).

When a function receives parameters, it assigns the incoming values to the variable names specified in the function definition’s parentheses. Consider the following script segment:

```
function sayHiToFirst(a, b, c) {  
    alert("Say hello, " + a);  
}  
sayHiToFirst("Gracie", "George", "Harry");  
sayHiToFirst("Larry", "Moe", "Curly");
```

After the function is defined in the script, the next statement calls that very function, passing three strings as parameters. The function definition automatically assigns the strings to variables *a*, *b*, and *c*. Therefore, before the `alert()` statement inside the function ever runs, *a* evaluates to “Gracie,” *b* evaluates to “George,” and *c* evaluates to “Harry.” In the `alert()` statement, only the *a* value is used and the alert reads

Say hello, Gracie

When the user closes the first alert, the next call to the function occurs. This time through, different values are passed to the function and assigned to *a*, *b*, and *c*. The alert dialog box reads

Say hello, Larry

Unlike other variables that you define in your script, function parameters do not use the `var` keyword to initialize them. They are automatically initialized whenever the function is called.

## Variable scope

Speaking of variables, it’s time to distinguish between variables that are defined outside and those defined inside of functions. Variables defined outside of functions are called *global variables*; those defined inside functions with the `var` keyword are called *local variables*.

A global variable has a slightly different connotation in JavaScript than it has in most other languages. For a JavaScript script, the “globe” of a global variable is the current document loaded in a browser window or frame. Therefore, when you initialize a variable as a global variable, it means that all script statements in the page (including those inside functions) have direct access to that variable value. Statements can retrieve and modify global variables from anywhere in the page. In programming terminology, this kind of variable is said to have *global scope* because everything on the page can “see” it.

It is important to remember that the instant a page unloads itself, all global variables defined in that page disappear from memory forever. If you need a value to persist from one page to another, you must use other techniques to store that value (for example, as a global variable in a framesetting document, as described in Chapter 16; or in a cookie, as described in Chapter 18). While the `var` keyword is usually optional for initializing global variables, I strongly recommend you use it for all variable initializations to guard against future changes to the JavaScript language.

In contrast to the global variable, a local variable is defined inside a function. You already saw how parameter variables are defined inside functions (without `var` keyword initializations). But you can also define other variables with the `var` keyword (absolutely required for local

variables or they become recognized as global variables). The scope of a local variable is only within the statements of the function. No other functions or statements outside of functions have access to a local variable.

*Local scope* allows for the reuse of variable names within a document. For most variables, I strongly discourage this practice because it leads to confusion and bugs that are difficult to track down. At the same time, it is convenient to reuse certain kinds of variable names, such as for loop counters. These are safe because they are always reinitialized with a starting value whenever a for loop starts. You cannot, however, nest one for loop inside another without specifying a different loop counting variable in the nested loop.

To demonstrate the structure and behavior of global and local variables — and show you why you shouldn't reuse most variable names inside a document — Listing 7-2 defines two global and two local variables. I intentionally use bad form by initializing a local variable that has the same name as a global variable.

### Listing 7-2: Global and Local Variable Scope Demonstration

```
<html>
<head>
<script type="text/javascript">
var aBoy = "Charlie Brown"; // global
var hisDog = "Snoopy";      // global
function demo() {
  // using improper design to demonstrate a point
  var hisDog = "Gromit";    // local version of hisDog
  var output = hisDog + " does not belong to " + aBoy + ".<br>";
  document.write(output);
}
</script>
</head>
<body>
<script type="text/javascript">
demo(); // runs as document loads
document.write(hisDog + " belongs to " + aBoy + ".");
</script>
</body>
</html>
```

When the page loads, the script in the Head portion initializes the two global variables (`aBoy` and `hisDog`) and defines the `demo()` function in memory. In the Body, another script begins by invoking the function. Inside the function, a local variable is initialized with the same name as one of the global variables — `hisDog`. In JavaScript, such a local initialization overrides the global variable for all statements inside the function. (But note that if the `var` keyword is left off of the local initialization, the statement reassigns the value of the global version to “Gromit.”)

Another local variable, `output`, is merely a repository for accumulating the text that is to be written to the screen. The accumulation begins by evaluating the local version of the `hisDog` variable. Then it concatenates some hard-wired text (note the extra spaces at the edges of the string segment). Next comes the evaluated value of the `aBoy` global variable — any global

not overridden by a local `is` available for use inside the function. The expression is accumulating HTML to be written to the page, so it ends with a period and a `<br>` tag. The final statement of the function writes the content to the page.

After the function completes its task, the next statement in the `Body` script writes another string to the page. Because this script statement is executing in global space (that is, not inside any function), it accesses only global variables—including those defined in another `<script>` tag set in the document. By the time the complete page finishes loading, it contains the following text lines:

```
Gromit does not belong to Charlie Brown.  
Snoopy belongs to Charlie Brown.
```

## About Curly Braces

Despite the fact that you probably rarely—if ever—use curly braces (`{ }`) in your writing, there is no mystery to their usage in JavaScript (and many other languages). Curly braces enclose blocks of statements that belong together. While they do assist humans who are reading scripts in knowing what's going on, curly braces also help the browser to know which statements belong together. You always must use curly braces in matched pairs.

You use curly braces most commonly in function definitions and control structures. In the function definition in Listing 7-2, curly braces enclose four statements that make up the function definition (including the comment line). The closing brace lets the browser know that whatever statement comes next is a statement outside of the function definition.

Physical placement of curly braces is not critical (nor is the indentation style you see in the code I provide). The following function definitions are treated identically by scriptable browsers:

```
function sayHiToFirst(a, b, c) {  
    alert("Say hello, " + a);  
}  
  
function sayHiToFirst(a, b, c)  
{  
    alert("Say hello, " + a);  
}  
  
function sayHiToFirst(a, b, c) {alert("Say hello, " + a);}
```

Throughout this book, I use the style shown in the first example because I find that it makes lengthy and complex scripts easier to read—especially scripts that have many levels of nested control structures.

## Arrays

The JavaScript array is one of the most useful data constructions you have available to you. You can visualize the structure of a basic array as if it were a single-column spreadsheet. Each row of the column holds a distinct piece of data, and each row is numbered. Numbers assigned to rows are in strict numerical sequence, starting with zero as the first row (programmers tend to start counting with zero). This row number is called an *index*. To access an

item in an array, you need to know the name of the array and the index for the row. Because index values start with zero, the total number of items of the array (as determined by the array's `length` property) is always one more than the highest index value of the array. More advanced array concepts enable you to create the equivalent of an array with multiple columns (described in Chapter 30). For this tutorial, I stay with the single-column basic array.

Data elements inside JavaScript arrays can be any data type, including objects. And, unlike a lot of other programming languages, different rows of the same JavaScript array can contain different data types.

## Creating an array

An array is stored in a variable, so when you create an array you assign the new array object to the variable. (Yes, arrays are objects, but they belong to the core JavaScript language rather than the document object model.) A special keyword — `new` — preceding a call to the JavaScript function that generates arrays creates space in memory for the array. An optional parameter to the `Array()` function enables you to specify at the time of creation how many elements (rows) of data eventually will occupy the array. JavaScript is very forgiving about this because you can change the size of an array at any time. Therefore, if you omit a parameter when generating a new array, your script incurs no penalty.

To demonstrate the array creation process, I create an array that holds the names of the 50 states plus the District of Columbia (a total of 51). The first task is to create that array and assign it to a variable of any name that helps me remember what this collection of data is about:

```
var USStates = new Array(51);
```

At this point, the `USStates` array is sitting in memory like a 51-row table with no data in it. To fill the rows, I must assign data to each row. Addressing each row of an array requires a special way of indicating the index value of the row: square brackets after the name of the array. The first row of the `USStates` array is addressed as

```
USStates[0]
```

To assign the string name of the first state of the alphabet to that row, I use a simple assignment operator:

```
USStates[0] = "Alabama";
```

To fill in the rest of the rows, I include a statement for each row:

```
USStates[1] = "Alaska";  
USStates[2] = "Arizona";  
USStates[3] = "Arkansas";  
...  
USStates[50] = "Wyoming";
```

Therefore, if you want to include a table of information in a document from which a script can look up information without accessing the server, you include the data in the document in the form of an array creation sequence. When the statements run as the document loads, by the time the document finishes loading into the browser, the data collection array is built and ready to go. Despite what appears to be the potential for a lot of statements in a document for such a data collection, the amount of data that must download for typical array

collections is small enough not to severely impact page loading—even for dial-up users at 28.8 Kbps. In Chapter 30, you also see some syntax shortcuts for creating arrays that reduce source code character counts.

## Accessing array data

The array index is the key to accessing an array element. The name of the array and an index in square brackets evaluates to the content of that array location. For example, after the `USStates` array is built, a script can display an alert with Alaska's name in it with the following statement:

```
alert("The largest state is " + USStates[1] + ".");
```

Just as you can retrieve data from an indexed array element, so can you change the element by reassigning a new value to any indexed element in the array.

## Parallel arrays

Now I show you why the numeric index methodology works well in JavaScript. To help with the demonstration, I generate another array that is parallel with the `USStates` array. This new array is also 51 elements long, and it contains the year in which the state in the corresponding row of `USStates` entered the Union. That array construction looks like the following:

```
var stateEntered = new Array(51);
stateEntered [0] = 1819;
stateEntered [1] = 1959;
stateEntered [2] = 1912;
stateEntered [3] = 1836;
...
stateEntered [50] = 1890;
```

In the browser's memory, then, are two data tables that you can visualize as looking like the model in Figure 7-1. I can build more arrays that are parallel to these for items such as the postal abbreviation and capital city. The important point is that the zeroth element in each of these tables applies to Alabama, the first state in the `USStates` array.

<b>USStates</b>		<b>stateEntered</b>
"Alabama"	[0]	1819
"Alaska"	[1]	1959
"Arizona"	[2]	1912
"Arkansas"	[3]	1836
⋮	⋮	⋮
"Wyoming"	[50]	1890

**Figure 7-1:** Visualization of two related parallel data tables.

If a Web page included these data tables and a way for a user to look up the entry date for a given state, the page would need a way to look through all of the `USStates` entries to find the index value of the one that matches the user's entry. Then, that index value could be applied to the `stateEntered` array to find the matching year.

For this demo, the page includes a text entry field in which the user types the name of the state to look up. In a real application, this methodology is fraught with peril unless the script performs some error checking in case the user makes a mistake. But for now, I assume that the user always types a valid state name. (Don't ever make this assumption in your Web site's pages.) An event handler from either the text field or a clickable button calls a function that looks up the state name, fetches the corresponding entry year, and displays an alert message with the information. The function is as follows:

```
function getStateDate() {
    var selectedState = document.getElementById("entry").value;
    for ( var i = 0; i < USStates.length; i++) {
        if (USStates[i] == selectedState) {
            break;
        }
    }
    alert("That state entered the Union in " + stateEntered[i] + ".");
}
```

In the first statement of the function, I grab the value of the text box and assign the value to a variable, `selectedState`. This is mostly for convenience because I can use the shorter variable name later in the script. In fact, the usage of that value is inside a `for` loop, so the script is marginally more efficient because the browser doesn't have to evaluate that long reference to the text field each time through the loop.

The key to this function is in the `for` loop. Here is where I combine the natural behavior of incrementing a loop counter with the index values assigned to the two arrays. Specifications for the loop indicate that the counter variable, `i`, is initialized with a value of zero. The loop is directed to continue as long as the value of `i` is less than the length of the `USStates` array. Remember that the length of an array is always one more than the index value of the last item. Therefore, the last time the loop runs is when `i` is 50, which is both less than the length of 51 and equal to the index value of the last element. Each time after the loop runs, the counter increments by one.

Nested inside the `for` loop is an `if` construction. The condition tests the value of an element of the array against the value typed in by the user. Each time through the loop, the condition tests a different row of the array starting with row zero. In other words, this `if` construction can be performed dozens of times before a match is found, but each time the value of `i` is one larger than the previous try.

The equality comparison operator (`==`) is strict when it comes to comparing string values. Such comparisons respect the case of each letter. In our example, the user must type the state name exactly as it is stored in the `USStates` array for the match to be found. In Chapter 10, you learn about some helper methods that eliminate case and sensitivity in string comparisons.

When a match is found, the statement nested inside the `if` construction runs. The `break` statement is designed to help control structures bail out if the program needs it. For this application, it is imperative that the `for` loop stop running when a match for the state name

is found. When the `for` loop breaks, the value of the `i` counter is fixed at the row of the `USStates` array containing the entered state. I need that index value to find the corresponding entry in the other array. Even though the counting variable, `i`, is initialized in the `for` loop, it is still “alive” and in the scope of the function for all statements after the initialization. That’s why I can use it to extract the value of the row of the `stateEntered` array in the final statement that displays the results in an alert message.

This application of a `for` loop and array indexes is a common one in JavaScript. Study the code carefully and be sure you understand how it works. This way of cycling through arrays plays a role not only in the kinds of arrays you create in your code, but also with the arrays that browsers generate for the document object model.

## Document objects in arrays

If you look at the `document` object portions of the Quick Reference in Appendix A, you can see that the properties of some objects are listed with square brackets after them. These are, indeed, the same kind of square brackets you just saw for array indexes. That’s because when a document loads, the browser creates arrays of like objects in the document. For example, if your page includes two `<form>` tag sets, then two forms appear in the document. The browser maintains an array of form objects for that document. References to those forms are

```
document.forms[0]
document.forms[1]
```

Index values for document objects are assigned according to the loading order of the objects. In the case of `form` objects, the order is dictated by the order of the `<form>` tags in the document. This indexed array syntax is another way to reference forms in an object reference. You can still use a form’s identifier if you prefer — and I heartily recommend using object names wherever possible because even if you change the physical order of the objects in your HTML, references that use names still work without modification. But if your page contains only one form, you can use the reference types interchangeably, as in the following examples of equivalent references to the `length` property of a form’s `elements` array (the `elements` array contains all the form controls in the form):

```
document.getElementById("entryForm").elements.length
document.forms[0].elements.length
```

In examples throughout this book, you can see that I often use the array type of reference to simple forms in simple documents. But in my production pages, I almost always use named references.

## Exercises

1. With your newly acquired knowledge of functions, event handlers, and control structures, use the script fragments from this chapter to complete the page that has the lookup table for all of the states and the years they entered into the Union. If you do not have a reference book for the dates, use different year numbers starting with 1800 for each entry. In the page, create a text entry field for the state and a button that triggers the lookup in the arrays.

2. Examine the following function definition. Can you spot any problems with the definition? If so, how can you fix the problems?

```
function format(ohmage) {
  var result;
  if ohmage >= 1e6 {
    ohmage = ohmage / 1e6;
    result = ohmage + " Mohms";
  } else {
    if (ohmage >= 1e3)
      ohmage = ohmage / 1e3;
    result = ohmage + " Kohms";
  } else
    result = ohmage + " ohms";
}
alert(result);
```

3. Devise your own syntax for the scenario of looking for a ripe tomato at the grocery store, and write a `for` loop using that object and property syntax.
4. Modify Listing 7-2 so it does not reuse the `hisDog` variable inside the function.
5. Given the following table of data about several planets of our solar system, create a Web page that enables users to enter a planet name and, at the click of a button, have the distance and diameter appear either in an alert box or (as extra credit) in separate fields of the page.

<i>Planet</i>	<i>Distance from the Sun</i>	<i>Diameter</i>
Mercury	36 million miles	3,100 miles
Venus	67 million miles	7,700 miles
Earth	93 million miles	7,920 miles
Mars	141 million miles	4,200 miles

# Window and Document Objects

---

**N**ow that you have exposure to programming fundamentals, it is easier to demonstrate how to script objects in documents. Starting with this lesson, the tutorial turns back to the document object model, diving more deeply into each of the objects you will place in many of your documents.

## Top-Level Objects

As a refresher, study the hierarchy of top-level objects in Figure 8-1. This chapter focuses on objects of this level that you'll frequently encounter in your scripting: `window`, `location`, `navigator`, and `document`. The goal is not only to equip you with the basics so you can script simple tasks, but also to prepare you for in-depth examinations of each object and its properties, methods, and event handlers in Part III of this book. I introduce only the basic properties, methods, and event handlers for objects in this tutorial — you can find far more in Part III. Examples in that part of the book assume you know the programming fundamentals covered in previous chapters.

# 8

C H A P T E R

## In This Chapter

What the `window` object does

How to access key `window` object properties and methods

How to trigger script actions after a document loads

The purposes of the `location` and `history` objects

How the `document` object is created

How to access key `document` object properties and methods

Figure 8-1: The top-level browser object model for all scriptable browsers.

## The window Object

At the very top of the object hierarchy is the `window` object. This object gains that exalted spot in the object food chain because it is the master container for all content you view in the Web browser. As long as a browser window is open—even if no document is loaded in the window—the `window` object is defined in the current model in memory.

In addition to the content part of the window where documents go, a window's sphere of influence includes the dimensions of the window and all of the “stuff” that surrounds the content area. The area where scrollbars, toolbars, the status bar, and (non-Macintosh) menu bar live is known as a window's *chrome*. Not every browser has full scripted control over the chrome of the main browser window, but you can easily script the creation of additional windows sized the way you want and that have only the chrome elements you wish to display in the subwindow.

Although the discussion about frames comes in Chapter 11, I can safely say now that each frame is also considered a `window` object. If you think about it, that makes sense because each frame can hold a different document. When a script runs in one of those documents, it regards the frame that holds the document as the `window` object in its view of the object hierarchy.

As you learn in this chapter, the `window` object is a convenient place for the document object model to attach methods that display modal dialog boxes and adjust the text that displays in the status bar at the bottom of the browser window. A `window` object method enables you to create a separate window that appears on the screen. When you look at all of the properties, methods, and event handlers defined for the `window` object (see Chapter 16), it should be clear why they are attached to window objects—visualize their scope and the scope of a browser window.

## Accessing window properties and methods

You can word script references to properties and methods of the `window` object in several ways, depending more on whim and style than on specific syntactical requirements. The most logical and common way to compose such references includes the `window` object in the reference:

```
window.propertyName  
window.methodName([parameters])
```

A `window` object also has a synonym when the script doing the referencing points to the window that houses the document. The synonym is `self`. Reference syntax then becomes

```
self.propertyName  
self.methodName([parameters])
```

You can use these initial reference object names interchangeably, but I tend to reserve the use of `self` for more complex scripts that involve multiple frames and windows. The `self` moniker more clearly denotes the current window holding the script's document. It makes the script more readable—by me and by others.

Back in Chapter 4, I indicated that because the `window` object is always “there” when a script runs, you could omit it from references to any objects inside that window. Therefore, the following syntax models assume properties and methods of the current window:

```
propertyName  
methodName([parameters])
```

In fact, as you will see in a few moments, some methods may be more understandable if you omit the `window` object reference. The methods run just fine either way.

## Creating a window

A script does not create the main browser window. A user does that by virtue of launching the browser or by opening a URL or file from the browser's menus (if the window is not already open). But a script can generate any number of subwindows once the main window is open (and that window contains a document whose script needs to open subwindows).

The method that generates a new window is `window.open()`. This method contains up to three parameters that define window characteristics, such as the URL of the document to load, its name for `target` attribute reference purposes in HTML tags, and physical appearance (size and chrome contingent). I don't go into the details of the parameters here (they're covered in great depth in Chapter 16), but I do want to expose you to an important concept involved with the `window.open()` method.

Consider the following statement that opens a new window to a specific size and with an HTML document from the same server directory that holds the current page:

```
var subWindow = window.open("define.html", "def", "height=200,width=300");
```

The important thing to note about this statement is that it is an assignment statement. Something gets assigned to that variable `subWindow`. What is it? It turns out that when the `window.open()` method runs, it not only opens up that new window according to specifications set as parameters, but it also evaluates to a reference to that new window. In programming parlance, the method is said to *return a value*—in this case, a genuine object reference. The value returned by the method is assigned to the variable.

Your script can now use that variable as a valid reference to the second window. If you need to access one of its properties or methods, you must use that reference as part of the complete reference. For example, to close the subwindow from a script in the main window, use this reference to the `close()` method for that subwindow:

```
subWindow.close();
```

If you issue `window.close()`, `self.close()`, or just `close()` in the main window's script, the method closes the main window (after confirming with the user) and not the subwindow. To address another window, then, you must include a reference to that window as part of the complete reference. This has an impact on your code because you probably want the variable holding the reference to the subwindow to be valid as long as the main document is loaded into the browser. For that to happen, the variable has to be initialized as a global variable, rather than inside a function (although you can set its value inside a function). That way, one function can open the window while another function closes it.

Listing 8-1 is a page that has a button for opening a blank, new window and closing that window from the main window. To view this demonstration, shrink your main browser window to less than full screen. Then when the new window is generated, reposition the windows so you can see the smaller, new window when the main window is in front. (If you “lose” a window behind another, use the browser's Window menu to choose the hidden window.) The key point of Listing 8-1 is that the `newWindow` variable is defined as a global variable so that both the `makeNewWindow()` and `closeNewWindow()` functions have access to it. When a variable is declared with no value assignment, its initial value is `null`. A `null` value is interpreted to be the same as `false` in a condition, while the presence of any non-zero value is the same as `true` in a condition. Therefore, in the `closeNewWindow()` function, the condition tests whether the window has been created before issuing the subwindow's `close()` method. Then, to clean up, the function sets the `newWindow` variable to `null` so that another click of the Close button doesn't try to close a nonexistent window.

### Listing 8-1: References to Window Objects

```
<html>
<head>
<title>Window Opener and Closer</title>
<script type="text/javascript">
var newWindow
function makeNewWindow() {
    newWindow = window.open("", "", "height=300,width=300");
}
function closeNewWindow() {
    if (newWindow) {
        newWindow.close();
        newWindow = null;
    }
}
</script>
</head>

<body>
<form>
<input type="button" value="Create New Window" onclick="makeNewWindow()">
<input type="button" value="Close New Window" onclick="closeNewWindow()">
</form>
</body>
</html>
```

## Window Properties and Methods

The one property and three methods for the `window` object described in this section have an immediate impact on user interaction. They work with all scriptable browsers. You can find extensive code examples in Part III for each property and method. You can also experiment with the one-statement script examples by entering them in the top text box of The Evaluator Jr. (from Chapter 6).

### `window.status` property

The status bar at the bottom of the browser window normally displays the URL of a link when you roll the mouse pointer atop it. Other messages also appear in that space during document loading, Java applet initialization, and the like. However, you can use JavaScript to display your own messages in the status bar at times that may be beneficial to your users. For example, rather than display the URL of a link, you can display a friendlier, plain-language description of the page at the other end of the link (or a combination of both to accommodate both newbies and geeks).

You can assign the `window.status` property some other text at any time. To change the status bar text of a link as the cursor hovers atop the link, you trigger the action with an `onmouseover` event handler of a link object.

Due to the simplicity of setting the `window.status` property, it is most common for the script statements to run as inline scripts in the event handler definition. This is handy for short scripts because you don't have to specify a separate function or add `<script>` tags to your page. You simply add the script statements to the `<a>` tag:

```
<a href="http://www.microsoft.com" onmouseover=  
"window.status='Visit the Microsoft Home page (microsoft.com)'"> Microsoft</a>
```

Look closely at the script statement assigned to the `onmouseover` event handler:

```
window.status='Visit the Microsoft Home page (microsoft.com)'
```

The entire statement is surrounded by double quotes ("..."). To nest the string being assigned to the `window.status` property inside the double-quoted script, you surround the string with single quotes ('...'). You get a big payoff for a little bit of script when you set the status bar. The downside is that scripting this property is how those awful status bar scrolling banners are created. Yech!

### `window.alert()` method

I have already used the `alert()` method many times so far in this tutorial. This window method generates a dialog box that displays whatever text you pass as a parameter (see Figure 8-2). A single OK button (whose label you cannot change) enables the user to dismiss the alert.

Figure 8-2: A JavaScript alert dialog box (old style).

The appearance of this and two other JavaScript dialog boxes (described next) has changed since the first scriptable browsers. In older browser versions (as shown in Figure 8-2), the browser inserted words clearly indicating that the dialog box was a “JavaScript Alert.” Different browsers display different title bars whose content cannot be altered by script. You can change only the other message content.

All three dialog box methods are good cases for using a `window` object’s methods without the reference to the window. Even though the `alert()` method is technically a `window` object method, no special relationship exists between the dialog box and the window that generates it. In production scripts, I usually use the shortcut reference:

```
alert("This is a JavaScript alert dialog.");
```

## window.confirm() method

The second style of dialog box presents two buttons (Cancel and OK in most versions on most platforms) and is called a confirm dialog box (see Figure 8-3). More importantly, this is one of those methods that returns a value: `true` if the user clicks OK, `false` if the user clicks Cancel. You can use this dialog box and its returned value as a way to have a user make a decision about how a script progresses.

**Figure 8-3:** A JavaScript confirm dialog box (IE6/WinXP style).

Because the method always returns a Boolean value, you can use the evaluated value of the entire method as a condition statement in an `if` or `if...else` construction. For example, in the following code fragment, the user is asked about starting the application over. Doing so causes the default page of the site to load into the browser.

```
if (confirm("Are you sure you want to start over?")) {  
    location.href = "index.html";  
}
```

## window.prompt() method

The final dialog box of the `window` object, the prompt dialog box (see Figure 8-4), displays a message that you set and provides a text field for the user to enter a response. Two buttons, Cancel and OK, enable the user to dismiss the dialog box with two opposite expectations: canceling the entire operation or accepting the input typed into the dialog box.

**Figure 8-4:** A JavaScript prompt dialog box (IE6/WinXP style).

The `window.prompt()` method has two parameters. The first is the message that acts as a prompt to the user. You can suggest a default answer in the text field by including a string as the second parameter. If you don't want any default answer to appear, include an empty string (two double quotes without any space between them).

This method returns one value when the user clicks either button. A click of the Cancel button returns a value of `null`, regardless of what the user types into the field. A click of the OK button returns a string value of the typed entry. Your scripts can use this information in conditions for `if` and `if...else` constructions. A value of `null` is treated as `false` in a condition. It turns out that an empty string is also treated as `false`. Therefore, a condition can easily test for the presence of real characters typed into the field to simplify a condition test, as shown in the following fragment:

```
var answer = prompt("What is your name?","");
if (answer) {
    alert("Hello, " + answer + "!");
}
```

The only time the `alert()` method is called is when the user enters something into the prompt dialog box and clicks the OK button.

## onload event handler

The `window` object reacts to several system and user events, but the one you will probably use most often is the event that fires as soon as everything in a page finishes loading. This event waits for images, Java applets, and data files for plug-ins to download fully to the browser. It can be dangerous to script access to elements of a document object while the page loads because if the object has not loaded yet (perhaps due to a slow network connection or server), a script error results. The advantage of using the `onload` event to invoke functions is that you are assured that all document objects are in the browser's document object model. Window event handlers are placed inside the `<body>` tag. Even though you will come to associate the `<body>` tag's attributes with the document object's properties, it is the `window` object's event handlers that go inside the tag.

## The location Object

Sometimes an object in the hierarchy represents something that doesn't seem to have the kind of physical presence that a window or a button does. That's the case with the `location` object. This object represents the URL loaded into the window. This differs from the `document` object (discussed later in this lesson) because the document is the real content; the `location` is simply the URL.

Unless you are truly Web-savvy, you may not realize a URL consists of many components that define the address and method of data transfer for a file. Pieces of a URL include the protocol (such as `http:`) and the hostname (such as `www.example.com`). You can access all of these items as properties of the `location` object. For the most part, though, your scripts will be interested in only one property: the `href` property, which defines the complete URL.

Setting the `location.href` property is the primary way your scripts navigate to other pages:

```
location.href = "http://www.dannyg.com";
```

You can generally navigate to a page in your own Web site by specifying a relative URL (that is, relative to the currently loaded page) rather than the complete URL with protocol and host information. For pages outside of the domain of the current page, you need to specify the complete URL.

If the page to be loaded is in another window or frame, the window reference must be part of the statement. For example, if your script opens a new window and assigns its reference to a variable named `newWindow`, the statement that loads a page into the subwindow is

```
newWindow.location.href = "http://www.dannyg.com";
```

## The navigator Object

Despite a name reminiscent of the Netscape Navigator branded browser, the `navigator` object is implemented in all scriptable browsers. All browsers also implement a handful of properties that reveal the same kind of information that browsers send to servers with each page request. Thus, the `navigator.userAgent` property returns a string text with numerous details about the browser and operating system. For example, a script running in Internet Explorer 6 in Windows XP receives the following value for the `navigator.userAgent` property:

```
Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1; Q312461)
```

The same script running in Mozilla 1.4 on a Macintosh reveals the following `userAgent` details:

```
Mozilla/5.0 (Macintosh; U; PPC Mac OS X Mach-O; en-US; rv:1.4) Gecko/20030624
```

You have already used two other navigator properties (`navigator.appVersion` and `navigator.appName`) in your first script of Chapter 3. See Chapter 38 on the CD-ROM for more details about this object and the meaning of the values returned by its properties. It was once used extensively to branch script execution according to various browser versions. Chapter 14 describes more modern ways to accomplish browser version detection.

## The document Object

The document object holds the real content of the page. Properties and methods of the document object generally affect the look and content of the document that occupies the window. All W3C DOM-compatible browsers (and IE4) allow script access to the text contents of a page once the document has loaded. However, as you saw in your first script of Chapter 3, the `document.write()` method lets a script dynamically create content as the page loads on any browser. Many document object properties are arrays of other objects in the document, which provide additional ways to reference these objects (over and above the `document.getElementById()` method).

Accessing a document object's properties and methods is straightforward, as shown in the following syntax examples:

```
[window.]document.propertyName  
[window.]document.methodName(parameters)
```

The window reference is optional when the script is accessing the document object that contains the script. If you want a preview of the long list of document object properties of the browser you're using, enter `document` into the bottom text box of The Evaluator Jr. and press Enter/Return. The object's properties and current values appear in the Results box. Following are some of the most commonly used properties and methods of the document object.

## document.forms[] property

It is convenient that the document object contains a property — `document.forms` — whose value is an array of all form element objects in the document. As you recall from the discussion of arrays in Chapter 7, an index number inside an array's square brackets points to one of the elements in the array. To find out how many form objects are in the current document, use

```
document.forms.length
```

To access the first form in a document, for example, the reference is

```
document.forms[0]
```

As a further convenience, all scriptable browsers let you reference a form more directly by its name (that is, the identifier assigned to the `name` attribute of the `<form>` tag) in one of two ways. The first way is via array syntax, applying the form's name as a string index value of the array:

```
document.forms["formName"]
```

You will see in future chapters that scripts sometimes have only the string name of the form to work with. To derive a valid reference to the form object indicated by that name, use this string index form with the array.

The second, even shorter way to reference a form object by name is to append the name as a property of the document object, as in

```
document.formName
```

Either methodology reaches the same object. You will see many instances of the shortcut approach in form-related example scripts throughout this book (including in the next chapter when working with form controls). Although this syntax dates back to the earliest scriptable browsers, it is still valid in the most modern versions.

## document.images[] property

Just as a document keeps track of forms in an array property, so does the document object maintain a collection (array) of images inserted into the document by way of `<img>` tags. Images referenced through the `document.images` array may be reached either by numeric or string index of the `img` element's name. Just like forms, the `name` attribute value is the identifier you use for a string index.

The presence of the `document.images` property indicates that the browser supports image swapping. You can therefore use the existence of the property as a controller to make sure the browser supports images as objects before attempting to perform any script action on an image. To do so, surround statements that deal with images with an `if` construction that verifies the property's existence, as follows:

```
if (document.images) {  
    // statements dealing with img objects  
}
```

Older browsers skip over the nested statements, preventing them from displaying error messages to their users.

## document.write() method

The `document.write()` method operates in both immediate scripts to create content in a page as it loads and in deferred scripts that create new content in the same or different window. The method requires one string parameter, which is the HTML content to write to the window or frame. Such string parameters can be variables or any other expressions that evaluate to a string. Very often, the written content includes HTML tags.

Bear in mind that after a page loads, the browser's *output stream* automatically closes. After that, any `document.write()` method issued to the current page opens a new stream that immediately erases the current page (along with any variables or other values in the original document). Therefore, if you wish to replace the current page with script-generated HTML, you need to accumulate that HTML in a variable and perform the writing with just one `document.write()` method. You don't have to explicitly clear a document and open a new data stream; one `document.write()` call does it all.

One last piece of housekeeping advice about the `document.write()` method involves its companion method, `document.close()`. Your script must close the output stream when it finishes writing its content to the window (either the same window or another). After the last `document.write()` method in a deferred script, be sure to include a `document.close()` method. Failure to do this may cause images and forms not to appear. Also, any `document.write()` method invoked later will only append to the page, rather than clear the existing content to write anew. To demonstrate the `document.write()` method, I show two versions of the same application. One writes to the same document that contains the script; the other writes to a separate window. Type in each document in a new text editor document, save it with an `.html` filename extension, and open it in your browser.

Listing 8-2 creates a button that assembles new HTML content for a document, including HTML tags for a new document title and color attribute for the `<BODY>` tag. An operator in the listing that may be unfamiliar to you is `+=`. It appends a string on its right side to whatever string is stored in the variable on its left side. This operator is a convenient way to accumulate a long string across several separate statements. With the content gathered in the `newContent` variable, one `document.write()` statement blasts the entire new content to the same document, obliterating all vestiges of the content of Listing 8-2. The `document.close()` statement, however, is required to close the output stream properly. When you load this document and click the button, notice that the document title in the browser's title bar changes accordingly. As you click back to the original and try the button again, notice that the dynamically written second page loads much faster than even a reload of the original document.

### Listing 8-2: Using `document.write()` on the Current Window

```
<html>
<head>
<title>Writing to Same Doc</title>
<script type="text/javascript">
function reWrite() {
    // assemble content for new window
    var newContent = "<html><head><title>A New Doc</title></head>";
    newContent += "<body bgcolor='aqua'><h1>This document is brand new.</h1>";
    newContent += "Click the Back button to see original document.";
    newContent += "</body></html>";
    // write HTML to new window document
    document.write(newContent);
    document.close(); // close layout stream
}
```

```

</script>
</head>
<body>
<form>
<input type="button" value="Replace Content" onclick="reWrite()">
</form>
</body>
</html>

```

In Listing 8-3, the situation is a bit more complex because the script generates a subwindow to which is written an entirely script-generated document. To keep the reference to the new window alive across both functions, the `newWindow` variable is declared as a global variable. As soon as the page loads, the `onload` event handler invokes the `makeNewWindow()` function. This function generates a blank subwindow. I added a property to the third parameter of the `window.open()` method that instructs the status bar of the subwindow to appear.

A button in the page invokes the `subWrite()` method. The first task it performs is to check the `closed` property of the subwindow. This property (which exists only in newer browser versions) returns `true` if the referenced window is closed. If that's the case (if the user manually closed the window), the function invokes the `makeNewWindow()` function again to reopen that window.

With the window open, new content is assembled as a string variable. As with Listing 8-2, the content is written in one blast (although that isn't necessary for a separate window), followed by a `close()` method. But notice an important difference: both the `write()` and `close()` methods explicitly specify the subwindow.

### Listing 8-3: Using `document.write()` on Another Window

```

<html>
<head>
<title>Writing to Subwindow</title>
<script type="text/javascript">
var newWindow;
function makeNewWindow() {
    newWindow = window.open("", "", "status,height=200,width=300");
}

function subWrite() {
    // make new window if someone has closed it
    if (newWindow.closed) {
        makeNewWindow();
    }
    // bring subwindow to front
    newWindow.focus();
    // assemble content for new window
    var newContent = "<html><head><title>A New Doc</title></head>";
    newContent += "<body bgcolor='coral'><h1>This document is brand new.</h1>";
    newContent += "</body></html>";
    // write HTML to new window document
    newWindow.document.write(newContent);
    newWindow.document.close(); // close layout stream

```

*Continued*

**Listing 8-3 (continued)**

```
</script>
</head>
<body onload="makeNewWindow()">
<form>
<input type="button" value="Write to Subwindow" onclick="subWrite()">
</form>
</body>
</html>
```

## **document.createElement() and document.createTextNode() methods**

The `document.write()` method works on a piece of a Web page only while the page is loading into the browser the first time. Any subsequent invocation of the method erases the page and writes a new page. But if you want to add to or modify a page that has already loaded, you need to call upon the Dynamic HTML capabilities of W3C DOM-compatible browsers. Your goal will be to add to, delete from, or replace sections of the node hierarchy of the document. Most element objects have methods to perform those actions (see more in-depth discussion in Chapter 14). But if you need to add content, you'll have to create new element or text nodes. The `document` object has the methods to do that.

The `document.createElement()` method lets you create in the browser's memory a brand new element object. To specify the precise element you wish to create, pass the tag name of the element as a string parameter of the method:

```
var newElem = document.createElement("p");
```

You may also wish to add some attribute values to the element, which you may do by assigning values to the newly created object's properties, even before the element becomes part of the document.

As you saw in Chapter 4's object hierarchy illustrations, an element object frequently needs text content between its start and end tags. The W3C DOM way to create that text is to generate a brand new text node via the `document.createTextNode()` method, and populate the node with the desired text. For example:

```
var newText = document.createTextNode("Greetings to all.");
```

The act of creating an element or text node does not, by itself, influence the document node tree. You must invoke one of the various insertion or replacement methods (see Chapter 14) to place the new text node into its element and place the element into the document. You learn how to do this in the last tutorial chapter (Chapter 12).

## **document.getElementById() method**

You met the `document.getElementById()` method in Chapter 4 when learning about the syntax for referencing element objects. This W3C DOM method is one you will use a lot. Get to know its finger-twisting name well. Be sure to honor the upper- and lowercase spelling of this all-important method.

The sole parameter of this method is a quoted string containing the ID of the element you wish to reference. The method returns a value, which you typically preserve in a variable for use by subsequent script statements:

```
var oneTable = document.getElementById("salesResults");
```

After the assignment statement, the variable represents the element object, allowing you to get and set its properties or invoke whatever methods belong to that type of object.

The next logical step past the document level in the object hierarchy is the form. That's where you will spend the next lesson.

## Exercises

1. Which of the following references are valid and which are not? Explain what is wrong with the invalid references.
  - a. `window.document.form[0]`
  - b. `self.entryForm.submit()`
  - c. `document.forms[2].name`
  - d. `document.getElementById("firstParagraph")`
  - e. `newWindow.document.write("Howdy")`
2. Write the JavaScript statement that displays a message in the status bar welcoming visitors to your Web page.
3. Write the JavaScript statement that executes while the page loads to display the same message from question 2 to the document as an `<h1>`-level headline on the page.
4. Create a page that prompts the user for his or her name as the page loads (via a dialog box) and then welcomes the user by name in the body of the page.
5. Create a page with any content you like, but one that automatically displays a dialog box after the page loads to show the user the URL of the current page.

# Forms and Form Elements

---

**M**ost interactivity between a Web page and the user takes place inside a form. That's where a lot of the interactive HTML stuff lives for every browser: text fields, buttons, checkboxes, option lists, and so on.

As described in earlier chapters, you may use the modern DOM `document.getElementById()` method to reference any element, including forms and form controls. But this chapter focuses on an older, yet equally valid way of referencing forms and controls. It's important to be familiar with this widely used syntax so that you can understand existing JavaScript source code written according to the original (and fully backward-compatible) form syntax—the so-called DOM Level 0 syntax.

## The form Object

Using the original DOM Level 0 syntax, you can reference a `form` object either by its position in the array of forms contained by a document or by name (if you assign an identifier to the `name` attribute inside the `<form>` tag). If only one form appears in the document, it is still a member of an array (a one-element array) and is referenced as follows:

```
document.forms[0]
```

Or use the string of the element's name as the array index:

```
document.forms[formName]
```

Notice that the array reference uses the plural version of the word, followed by a set of square brackets containing the index number (zero is always first) or name of the element. Alternatively, you can use the form's name (not as a quoted string) as if it were a property of the `document` object:

```
document.formName
```

### In This Chapter

What the `form` object represents

How to access key `form` object properties and methods

How `text`, `button`, and `select` objects work

How to submit forms from a script

How to pass information from form elements to functions

## Form as object and container

Unlike the modern DOM's ID reference model—which lets a script dive anywhere into a document to grab an element object reference—DOM Level 0 form syntax imposes a hierarchical approach. It treats the `form` object as a container whose contents consist of the form control element objects (`input`, `select`, and `textarea` elements). Figure 9-1 shows the structure of this hierarchy and its place relative to the document object. You'll see the effect this structure has on the way you reference form control elements in a moment. This structure echoes perfectly the HTML tag organization within the `<form>` and `</form>` tag “bookends.”

In addition to a large collection of properties and methods it has in common with all HTML element objects, the `form` object features a number of items that are unique to this object. Almost all of these unique properties are scripted representations of the `form` element's attributes. Scriptable browsers allow scripts to change these properties under script control, which gives your scripts potentially significant power to direct the behavior of a form submission in response to user selections on the page.

**Figure 9-1:** DOM Level 0 hierarchy for forms and controls.

## Accessing form properties

Forms are created entirely from standard HTML tags in the page. You can set attributes for name, target, action, method, and enctype. Each of these is a property of a `form` object, accessed by all lowercase versions of those words, as in

```
document.forms[0].action
document.formName.action
```

To change any of these properties, simply assign new values to them:

```
document.forms[0].action = "http://www.giantco.com/cgi/login.pl";
```

## form.elements[] property

In addition to keeping track of each type of element inside a form, the browser also maintains a list of all control elements within a form. This list is another array, with items listed according to the order in which their HTML tags appear in the source code. It is generally more efficient to create references to elements directly, using their names. However, sometimes a script needs to look through all of the elements in a form. This is especially true if the content of a form changes with each loading of the page because the number of text fields changes based on the user's browser type. (For example, a script on the page uses `document.write()` to add an extra text box for information required only from Windows users.)

The following code fragment shows the `form.elements[]` property at work in a `for` repeat loop that looks at every element in a form to set the contents of text fields to an empty string. The script cannot simply barge through the form and set every element's content to an empty string because some elements may be types (for example, a button) whose `value` properties have different purposes.

```
var form = window.document.forms[0];
for (var i = 0; i < form.elements.length; i++) {
    if (form.elements[i].type == "text") {
        form.elements[i].value = "";
    }
}
```

In the first statement, I create a variable—`form`—that holds a reference to the first form of the document. I do this so that when I make many references to form elements later in the script, the typical length of each reference is much shorter (and marginally faster). I can use the `form` variable as a shortcut to building references to items more deeply nested in the form.

Next, I start looping through the items in the `elements` array for the form. Each form element has a `type` property, which reveals what kind of form control it is: text, button, radio, checkbox, and so on. I'm interested in finding elements whose `type` is `text`. For each of those, I set the `value` property to an empty string.

I return to forms later in this chapter to show you how to submit a form without a Submit button and how client-side form validation works.

## Form Controls as Objects

Three kinds of HTML elements nested inside a `<form>` tag become scriptable objects in all browser document object models. Most of the objects owe their existence to the `<input>` tag in the page's source code. Only the value assigned to the `type` attribute of an `<input>` tag determines whether the element is a text box, password entry field, hidden field, button, checkbox, or radio button. The other two kinds of form controls, `textarea` and `select`, have their own tags.

To reference a particular form control as an object in DOM Level 0 syntax, you build the reference as a hierarchy starting with the `document`, through the form, and then to the control. You've already seen how many ways you can reference merely the form part — all of which are valid for building form control references. But if you were using only the identifiers assigned to the form and form control elements (that is, none of the associated arrays of elements), the syntax is as follows:

```
document.formName.controlName
```

For example, consider the following simple form:

```
<form name="searchForm" action="cgi-bin/search.pl">  
  <input type="text" name="entry">  
  <input type="submit" name="sender" value="Search">  
</form>
```

The following sample references to the text input control are all valid:

```
document.searchForm.entry  
document.searchForm.elements[0]  
document.forms["searchForm"].elements["entry"]  
document.forms["searchForm"].entry
```

While form controls have several properties in common, some properties are unique to a particular control type or related types. For example, only a `select` object offers a property that reveals which item in its list is currently selected. But checkboxes and radio buttons both have a property that indicates whether the control is currently set to “on.” Similarly, all text-oriented controls operate the same way for reading and modifying their content.

Having a good grasp of the scriptable features of form control objects is important to your success with JavaScript. In the next sections, you meet the most important form control objects and see how scripts interact with them.

## Text-related objects

Each of the four text-related HTML form elements — `input` elements of the text, password, and hidden types, plus the `textarea` element — is an element in the document object hierarchy. All but the hidden object display themselves in the page, enabling users to enter information. These objects also display text information that changes in the course of using a page (although browsers capable of modern Dynamic HTML also allow the scripted change of other body text in a document).

To make these form control objects scriptable in a page, you do nothing special to their normal HTML tags — with the possible exception of assigning a `name` attribute. I strongly recommend assigning unique names to every text-related form control element if your scripts will be getting or setting properties or invoking their methods. Besides, if the form is actually submitted to a server program, the `name` attributes must be assigned in order for the server to receive the element's data.

## Text Object Behavior

Many scripters look to JavaScript to solve what are perceived as shortcomings or behavioral anomalies with text-related objects in forms. I want to single these out early in your scripting experience so that they do not confuse you later.

First, only the most recent browsers let scripts reliably alter the font, font size, font style, and text alignment of a text object's content. You can access changes through the element's style-related properties (see Chapter 26).

Second, most browser forms practice a behavior that was recommended long ago as an informal standard by Web pioneers. When a form contains only one text `input` object, a press of the Enter/Return key while the text object has focus automatically submits the form. For two or more fields in browsers other than IE5/Mac and Safari, you need another way to submit the form (for example, a Submit button). This one-field submission scheme works well in many cases, such as the search page of most Web search sites. But if you are experimenting with simple forms containing only one field, you can submit the form with a press of the Enter/Return key. Submitting a form that has no other action or target specified means the page performs an unconditional reload—wiping out any information entered into the form. You can, however, cancel the submission through an `onsubmit` event handler in the form, as shown later in this chapter. Also, starting with version 4 browsers, you can script the press of the Enter/Return key in any text field to submit a form (see Chapter 25).

For the visible objects in this category, event handlers are triggered from many user actions, such as giving a field focus (getting the text insertion pointer in the field) and changing text (entering new text and leaving the field). Most of your text field actions are triggered by the change of text (the `onchange` event handler). In modern browsers, event handlers fire in response to individual keystrokes as well.

Without a doubt, the single most used property of a text-related element is the `value` property. This property represents the current contents of the text element. A script can retrieve and set its content at any time. Content of the `value` property is always a string. This may require conversion to numbers (see Chapter 6) if text fields are used to enter values for some math operations.

To demonstrate how a text field's `value` property can be read and written, Listing 9-1 provides a complete HTML page with a single-entry field. Its `onchange` event handler invokes the `upperMe()` function, which converts the text to uppercase. In the `upperMe()` function, the first statement assigns the text object reference to a more convenient variable: `field`. A lot goes on in the second statement of the function. The right side of the assignment statement performs a couple of key tasks. The reference to the `value` property of the object (`field.value`) evaluates to whatever content is in the text field at that instant. That string is then handed over to one of JavaScript's string functions, `toUpperCase()`, which converts the value to uppercase. The evaluated result of the right-side statement is then assigned to the second variable: `upperCaseVersion`. Nothing has changed yet in the text box. That comes in the third statement where the `value` property of the text box is assigned whatever the `upperCaseVersion` variable holds. The need for the second statement is more for learning purposes, so you can see the process more slowly. In practice, you can combine the actions of steps two and three into one power-packed statement:

```
field.value = field.value.toUpperCase();
```

**Listing 9-1: Getting and Setting a Text Object's value Property**

```
<html>
<head>
<title>Text Object value Property</title>
<script type="text/javascript">
function upperMe() {
    var field = document.forms[0].converter;
    var upperCaseVersion = field.value.toUpperCase();
    field.value = upperCaseVersion;
}
</script>
</head>
<body>
<form onsubmit="return false">
<input type="text" name="converter" value="sample" onchange="upperMe()">
</form>
</body>
</html>
```

Later in this chapter, I show you how to reduce even further the need for explicit references in functions such as `upperMe()` in Listing 9-1. In the meantime, notice for a moment the `onsubmit` event handler in the `<form>` tag. I delve more deeply into this event handler later in this chapter, but I want to point out the construction that prevents a single-field form from being submitted when you press the Enter key. If the event handler weren't there, a press of the Enter key would reload the page, returning the field to its original text. Try it!

## The Button Object

I have used the button-type `input` element in many examples up to this point in the tutorial. The button is one of the simplest objects to script. In the simplified object model of this tutorial, the button object has only a few properties that are rarely accessed or modified in day-to-day scripts. Like the text object, the visual aspects of the button are governed not by HTML or scripts, but by the operating system and browser that the page visitor uses. By far, the most useful event handler of the button object is the `onclick` event handler. It fires whenever the user clicks the button. Simple enough. No magic here.

## The Checkbox Object

A checkbox is also a simple element of the `form` object, but some of the properties may not be intuitive entirely. Unlike the `value` property of a plain button object (the text of the button label), the `value` property of a checkbox is any other text you want associated with the object. This text does not appear on the page in any fashion, but the property (initially set via the `value` attribute) might be important to a script that wants to know more about the purpose of the checkbox within the form.

The key property of a checkbox object is whether or not the box is checked. The `checked` property is a Boolean value: `true` if the box is checked, `false` if not. When you see that a property is a Boolean value, it's a clue that the value might be usable in an `if` or `if...else` condition expression. In Listing 9-2, the value of the `checked` property determines which alert box the user sees.

**Listing 9-2: The Checkbox Object's checked Property**

```
<html>
<head>
<title>Checkbox Inspector</title>
<script type="text/javascript">
function inspectBox() {
    if (document.forms[0].checkThis.checked) {
        alert("The box is checked.");
    } else {
        alert("The box is not checked at the moment.");
    }
}
</script>
</head>
<body>
<form>
<input type="checkbox" name="checkThis">Check here<br>
<input type="button" value="Inspect Box" onclick="inspectBox()">
</form>
</body>
</html>
```

Checkboxes are generally used as preferences setters, rather than as action inducers. While a checkbox object has an `onclick` event handler, a click of a checkbox should never do anything drastic, such as navigate to another page.

## The Radio Object

Setting up a group of radio objects for scripting requires a bit more work. To let the browser manage the highlighting and unhighlighting of a related group of buttons, you must assign the same name to each of the buttons in the group. You can have multiple groups within a form, but each member of the same group must share the same name.

Assigning the same name to a form element forces the browser to manage the elements differently than if they each had a unique name. Instead, the browser maintains an array list of objects with the same name. The name assigned to the group becomes the name of the array. Some properties apply to the group as a whole; other properties apply to individual buttons within the group and must be addressed via array index references. For example, you can find out how many buttons are in a group by reading the `length` property of the group:

```
document.forms[0].groupName.length
```

If you want to find out if a particular button is currently highlighted—via the same `checked` property used for the checkbox—you must access the button element individually:

```
document.forms[0].groupName[0].checked
```

Listing 9-3 demonstrates several aspects of the radio button object, including how to look through a group of buttons to find out which one is checked and how to use the `value` attribute and corresponding property for meaningful work.

The page includes three radio buttons and a plain button. Each radio button's `value` attribute contains the full name of one of the Three Stooges. When the user clicks the button,

the `onclick` event handler invokes the `fullName()` function. In that function, the first statement creates a shortcut reference to the form. Next, a `for` repeat loop looks through all of the buttons in the `stooges` radio button group. An `if` construction looks at the `checked` property of each button. When a button is highlighted, the `break` statement bails out of the `for` loop, leaving the value of the `i` loop counter at the number where the loop broke ranks. The `alert` dialog box then uses a reference to the `value` property of the `i`th button so that the full name can be displayed in the alert.

### Listing 9-3: Scripting a Group of Radio Objects

```
<html>
<head>
<title>Extracting Highlighted Radio Button</title>
<script type="text/javascript">
function fullName() {
    var form = document.forms[0];
    for (var i = 0; i < form.stooges.length; i++) {
        if (form.stooges[i].checked) {
            break;
        }
    }
    alert("You chose " + form.stooges[i].value + ".");
}
</script>
</head>

<body>
<form>
<p>Select your favorite Stooge:
<input type="radio" name="stooges" value="Moe Howard" checked>Moe
<input type="radio" name="stooges" value="Larry Fine">Larry
<input type="radio" name="stooges" value="Curly Howard">Curly<br>
<input type="button" name="Viewer" value="View Full Name..."
onclick="fullName()"></p>
</form>
</body>
</html>
```

## The select Object

The most complex form control to script is the `select` element object. As you can see from the DOM Level 0 form object hierarchy diagram (see Figure 9-1), the `select` object is really a compound object: an object that contains an array of `option` objects. Moreover, you can establish this object in HTML to display itself as either a pop-up list or a scrolling list—the latter configurable to accept multiple selections by users. For the sake of simplicity at this stage, this lesson focuses on deployment as a pop-up list that allows only single selections.

Some properties belong to the entire `select` object; others belong to individual options inside the `select` object. If your goal is to determine which item the user selects, and you want the code to work on the widest range of browsers, you must use properties of both the `select` and `option` objects.

The most important property of the `select` object itself is the `selectedIndex` property, accessed as follows:

```
document.form[0].selectName.selectedIndex
```

This value is the index number of the currently selected item. As with most index counting schemes in JavaScript, the first item (the one at the top of the list) has an index of zero. The `selectedIndex` value is critical for enabling you to access properties of the selected option. Two important properties of an option item are `text` and `value`, accessed as follows:

```
document.forms[0].selectName.options[n].text
document.forms[0].selectName.options[n].value
```

The `text` property is the string that appears onscreen in the `select` object. It is unusual for this information to be exposed as a form object property because in the HTML that generates a `select` object, the `text` is defined as an `<option>` tag's nested `text`. But inside the `<option>` tag, you can set a `value` attribute, which, like the radio buttons shown earlier, enables you to associate some hidden string information with each visible entry in the list.

To read the `value` or `text` property of a selected option most efficiently for all browsers, you can use the `select` object's `selectedIndex` property as an index value to the option. References for this kind of operation get pretty long, so take the time to understand what's happening here. In the following function, the first statement creates a shortcut reference to the `select` object. The `selectedIndex` property of the `select` object is then substituted for the index value of the `options` array of that same object:

```
function inspect() {
    var list = document.forms[0].choices;
    var chosenItemText = list.options[list.selectedIndex].value;
}
```

To bring a `select` object to life, use the `onchange` event handler. As soon as a user makes a new selection in the list, this event handler runs the script associated with that event handler. Listing 9-4 shows a common application for a `select` object. Its `text` entries describe places to go in and out of a Web site, while the `value` attributes hold the URLs for those locations. When a user makes a selection in the list, the `onchange` event handler triggers a script that extracts the `value` property of the selected option and assigns that value to the `location.href` object property to effect the navigation. Under JavaScript control, this kind of navigation doesn't need a separate Go button on the page.

#### Listing 9-4: Navigating with a select Object

```
<html>
<head>
<title>Select Navigation</title>
<script type="text/javascript">
function goThere() {
    var list = document.forms[0].urlList;
    location.href = list.options[list.selectedIndex].value;
}
</script>
</head>
```

*Continued*

## Listing 9-4 (continued)

```
<body>
<form>
Choose a place to go:
<select name="urlList" onchange="goThere()">
  <option selected value="index.html">Home Page
  <option value="store.html">Shop Our Store
  <option value="policies.html">Shipping Policies
  <option value="http://www.google.com">Search the Web
</select>
</form>
</body>
</html>
```

Note

Recent browsers also expose the `value` property of the selected option item by way of the `value` property of the `select` object. This is certainly a logical and convenient shortcut, and you can use it safely if your target browsers include IE, Mozilla-based browsers, and Safari.

There is much more to the `select` object, including the ability to change the contents of a list in newer browsers. Chapter 24 covers the `select` object in depth.

## Passing Form Data and Elements to Functions

In all of the examples so far in this lesson, when an event handler invokes a function that works with form elements, the form or form control is explicitly referenced in the function. But valuable shortcuts exist for transferring information about the form or form control directly to the function without dealing with those typically long references that start with the `window` or `document` object level.

JavaScript features a keyword — `this` — that always refers to whatever object contains the script in which the keyword is used. Thus, in an `onchange` event handler for a text field, you can pass a reference to the text object to the function by inserting the `this` keyword as a parameter to the function:

```
<input type="text" name="entry" onchange="upperMe(this)">
```

At the receiving end, the function defines a parameter variable that turns that reference into a variable that the rest of the function can use:

```
function upperMe(field) {
  statement[s]
}
```

The name you assign to the function's parameter variable is purely arbitrary, but it is helpful to give it a name that expresses what the reference is. Importantly, this reference is a "live" connection back to the object. Therefore, statements in the script can get and set property values of the object at will.

For other functions, you may wish to receive a reference to the entire form, rather than just the object calling the function. This is certainly true if the function needs to access other elements of the same form. Because every form control object contains a property that points to the containing form, you can use the `this` keyword to reference the current control, plus its form property as `this.form`, as in

```
<input type="button" value="Click Here" onclick="inspect(this.form)">
```

The function definition should then have a parameter variable ready to be assigned to the form object reference. Again, you decide the name of the variable. I tend to use the variable name `form` as a way to remind me exactly what kind of object is referenced.

```
function inspect(form) {
    statement[s]
}
```

Listing 9-5 demonstrates passing both an individual form element and the entire form in the performance of two separate acts. This page makes believe it is connected to a database of Beatles songs. When you click the Process Data button, it passes the `form` object, which the `processData()` function uses to access the group of radio buttons inside a `for` loop. Additional references using the passed `form` object extract the `value` properties of the selected radio button and the text field.

The text field has its own event handler, which passes just the text field to the `verifySong()` function. Notice how short the reference is to reach the `value` property of the song field inside the function.

### Listing 9-5: Passing a Form Object and Form Element to Functions

```
<html>
<head>
<title>Beatle Picker</title>
<script type="text/javascript">
function processData(form) {
    for (var i = 0; i < form.Beatles.length; i++) {
        if (form.Beatles[i].checked) {
            break
        }
    }
    // assign values to variables for convenience
    var beatle = form.Beatles[i].value
    var song = form.song.value
    alert("Checking whether " + song + " features " + beatle + "...")
}

function verifySong(entry) {
    var song = entry.value
    alert("Checking whether " + song + " is a Beatles tune...")
}
</script>
</head>
```

*Continued*

**Listing 9-5 (continued)**

```
<body>
<form onsubmit="return false">
<p>Choose your favorite Beatle:
<input type="radio" name="Beatles" value="John Lennon" checked>John
<input type="radio" name="Beatles" value="Paul McCartney">Paul
<input type="radio" name="Beatles" value="George Harrison">George
<input type="radio" name="Beatles" value="Ringo Starr">Ringo</p>

<p>Enter the name of your favorite Beatles song:<br>
<input type="text" name="song" value = "Eleanor Rigby"
onchange="verifySong(this)">
<input type="button" name="process" value="Process Request..."
onclick="processData(this.form)"</p>
</form>
</body>
</html>
```

Get to know the usage of the `this` keyword in passing form and form element objects to functions. The technique not only saves you typing in your code, but it also ensures accuracy in references to those objects.

## Submitting and Prevalidating Forms

The scripted equivalent of submitting a form is the form object's `submit()` method. All you need in the statement is a reference to the form and this method:

```
document.forms[0].submit();
```

Before you get ideas about having a script silently submit a form to a URL bearing the `mailto:` protocol, forget it. Because such a scheme could expose visitors' e-mail addresses without their knowledge, `mailto:` submissions are either blocked or revealed to users as a security precaution.

Before a form is submitted, you may wish to perform some last-second validation of data in the form or in other scripting (for example, changing the form's `action` property based on user choices). You can do this in a function invoked by the form's `onsubmit` event handler. Specific validation routines are beyond the scope of this tutorial (but are explained in substantial detail in Chapter 43 on the CD-ROM), but I want to show you how the `onsubmit` event handler works.

You can let the results of a validation function cancel a submission if the validation shows some incorrect data or empty fields. To control submission, the `onsubmit` event handler must evaluate to return `true` (to allow submission to continue) or return `false` (to cancel submission). This is a bit tricky at first because it involves more than just having the function called by the event handler return `true` or `false`. The `return` keyword must be part of the final evaluation.

Listing 9-6 shows a page with a simple validation routine that ensures all fields have something in them before allowing submission to continue. (The sample form has no `action` attribute, so this sample form doesn't get sent to the server.) Notice how the `onsubmit` event handler (which passes a reference to the `form` object as a parameter — in this case the `this` keyword points to the `form` object because its tag holds the event handler) includes the `return` keyword before the function name. When the function returns its `true` or `false` value, the event handler evaluates to the requisite `return true` or `return false`.

### Listing 9-6: Last-Minute Checking Before Form Submission

```
<html>
<head>
<title>Validator</title>
<script type="text/javascript">
function checkForm(form) {
    for (var i = 0; i < form.elements.length; i++) {
        if (form.elements[i].value == "") {
            alert("Fill out ALL fields.");
            return false;
        }
    }
    return true;
}
</script>
</head>

<body>
<form onsubmit="return checkForm(this)">
Please enter all requested information:<br>
First Name:<input type="text" name="firstName"><br>
Last Name:<input type="text" name="lastName"><br>
Rank:<input type="text" name="rank"><br>
Serial Number:<input type="text" name="serialNumber"><br>

<input type="submit">
</form>
</body>
</html>
```

One quirky bit of behavior involving the `submit()` method and `onsubmit` event handler needs explanation. While you might think (and logically so, in my opinion) that the `submit()` method would be the exact scripted equivalent of a click of a real Submit button, it's not. The `submit()` method does not cause the form's `onsubmit` event handler to fire at all. If you want to perform validation on a form submitted via the `submit()` method, invoke the validation in the script function that ultimately calls the `submit()` method.

So much for the basics of forms and form controls. In the next chapter, you step away from HTML for a moment to look at more advanced JavaScript core language items: strings, math, and dates.

## Exercises

1. Rework Listings 9-1, 9-2, 9-3, and 9-4 so that the script functions all receive the most efficient form or form element references directly from the invoking event handler.
2. For the following form (assume it's the only form on the page), write at least 10 ways to reference the text input field as an object in all modern scriptable browsers.

```
<form name="subscription" action="cgi-bin/maillist.pl" method="post">
  <input type="text" id="email" name="email">
  <input type="submit">
</form>
```

3. In the following HTML tag, what kind of information do you think is being passed with the event handler? Write a function that displays in an alert dialog box the information being passed.

```
<input type="text" name="phone" onchange="format(this.value)">
```

4. A document contains two forms named `specifications` and `accessories`. In the `accessories` form is a field named `acc1`. Write at least two different statements that set the contents of that field to `Leather Carrying Case`.
5. Create a page that includes a `select` object to change the background color of the current page. The property that you need to set is `document.bgColor`, and the three values you should offer as options are `red`, `yellow`, and `green`. In the `select` object, the colors should display as `Stop`, `Caution`, and `Go`.

# Strings, Math, and Dates

---

**F**or most of the lessons in the tutorial so far, the objects at the center of attention belong to the document object model. But as indicated in Chapter 2, a clear dividing line exists between the document object model and the JavaScript language. The language has some of its own objects that are independent of the document object model. These objects are defined such that if a vendor wished to implement JavaScript as the programming language for an entirely different kind of product, the language would still use these core facilities for handling text, advanced math (beyond simple arithmetic), and dates. You can find formal specifications of these objects in the ECMA-262 recommendation.

## Core Language Objects

It is often difficult for newcomers to programming—or even experienced programmers who have not worked in object-oriented worlds before—to think about objects, especially when attributed to “things” that don’t seem to have a physical presence. For example, it doesn’t require lengthy study to grasp the notion that a button on a page is an object. It has several physical properties that make perfect sense. But what about a string of characters? As you learn in this chapter, in an object-based environment such as JavaScript, everything that moves is treated as an object—each piece of data from a Boolean value to a date. Each such object probably has one or more properties that help define the content; such an object may also have methods associated with it to define what the object can do or what you can do to the object.

I call all objects that are not part of the document object model *core language objects*. You can see the full complement of them in the Quick Reference in Appendix A. In this chapter, I focus on the `String`, `Math`, and `Date` objects.

## String Objects

You have already used `String` objects many times in earlier lessons. A *string* is any text inside a quote pair. A quote pair consists of either double quotes or single quotes. This allows one string to nest inside

### In This Chapter

How to modify strings with common string methods

When and how to use the `Math` object

How to use the `Date` object

another, as often happens in event handlers. In the following example, the `alert()` method requires a quoted string as a parameter, but the entire method call also must be inside quotes:

```
onclick="alert('Hello, all!')"
```

JavaScript imposes no practical limit on the number of characters that a string can hold. However, most older browsers have a limit of 255 characters in length for a script statement. This limit is sometimes exceeded when a script includes a lengthy string that is to become scripted content in a page. You need to divide such lines into smaller chunks using techniques described in a moment.

You have two ways to assign a string value to a variable. The simplest is a basic assignment statement:

```
var myString = "Howdy";
```

This works perfectly well except in some exceedingly rare instances. Beginning with Navigator 3 and Internet Explorer 4, you can also create a string object using the more formal syntax that involves the `new` keyword and a constructor function (that is, it “constructs” a new object):

```
var myString = new String("Howdy");
```

Whichever way you use to initialize a variable with a string, the variable receiving the assignment can respond to all `String` object methods.

## Joining strings

Bringing two strings together as a single string is called *concatenating* strings, a term you learned in Chapter 6. String concatenation requires one of two JavaScript operators. Even in your first script in Chapter 3, you saw how the addition operator (+) linked multiple strings together to produce the text dynamically written to the loading Web page:

```
document.write(" of <span class='highlight'>" + navigator.appName + "</span>.");
```

As valuable as that operator is, another operator can be even more scripter friendly. This operator is helpful when you are assembling large strings in a single variable. The strings may be so long or cumbersome that you need to divide the building process into multiple statements. The pieces may be combinations of *string literals* (strings inside quotes) or variable values. The clumsy way to do it (perfectly doable in JavaScript) is to use the addition operator to append more text to the existing chunk:

```
var msg = "Four score";  
msg = msg + " and seven";  
msg = msg + " years ago,";
```

But another operator, called the *add-by-value operator*, offers a handy shortcut. The symbol for the operator is a plus and equal sign together (+=). This operator means “append the stuff on the right of me to the end of the stuff on the left of me.” Therefore, the preceding sequence is shortened as follows:

```
var msg = "Four score";  
msg += " and seven";  
msg += " years ago,";
```

You can also combine the operators if the need arises:

```
var msg = "Four score";  
msg += " and seven" + " years ago";
```

I use the add-by-value operator a lot when accumulating HTML text to be written to the current document or another window.

## String methods

Of all the core JavaScript objects, the `String` object has the most diverse collection of methods associated with it. Many methods are designed to help scripts extract segments of a string. Another group, rarely used and now obsolete in favor of CSS, wraps a string with one of several style-oriented tags (a scripted equivalent of tags for font size, style, and the like).

To use a string method, the string being acted upon becomes part of the reference followed by the method name. All methods return a value of some kind. Most of the time, the returned value is a converted version of the string object referred to in the method call—but the original string is still intact. To capture the modified version, you need to assign the results of the method to a variable:

```
var result = string.methodName();
```

The following sections introduce you to several important string methods available to all browser brands and versions.

### Changing string case

Two methods convert a string to all uppercase or lowercase letters:

```
var result = string.toUpperCase();  
var result = string.toLowerCase();
```

Not surprisingly, you must observe the case of each letter of the method names if you want them to work. These methods come in handy when your scripts need to compare strings that may not have the same case (for example, a string in a lookup table compared with a string typed by a user). Because the methods don't change the original strings attached to the expressions, you can simply compare the evaluated results of the methods:

```
var foundMatch = false;  
if (stringA.toUpperCase() == stringB.toUpperCase()) {  
    foundMatch = true;  
}
```

### String searches

You can use the `string.indexOf()` method to determine if one string is contained by another. Even within JavaScript's own object data, this can be useful information. For example, the `navigator.userAgent` property reveals a lot about the browser that loads the page. A script can investigate the value of that property for the existence of, say, "Win" to determine that the user has a Windows operating system. That short string might be buried somewhere inside a long string, and all the script needs to know is whether the short string is present in the longer one—wherever it might be.

The `string.indexOf()` method returns a number indicating the index value (zero based) of the character in the larger string where the smaller string begins. The key point about this method is that if no match occurs, the returned value is `-1`. To find out whether the smaller string is inside, all you need to test is whether the returned value is something other than `-1`.

Two strings are involved with this method: the shorter one and the longer one. The longer string is the one that appears in the reference to the left of the method name; the shorter string is inserted as a parameter to the `indexOf()` method. To demonstrate the method in action, the following fragment looks to see if the user is running Windows:

```
var isWindows = false;
if (navigator.userAgent.indexOf("Win") != -1) {
    isWindows = true;
}
```

The operator in the `if` construction's condition (`!=`) is the inequality operator. You can read it as meaning "is not equal to."

## Extracting copies of characters and substrings

To extract a single character at a known position within a string, use the `charAt()` method. The parameter of the method is an index number (zero based) of the character to extract. When I say *extract*, I don't mean delete, but rather grab a snapshot of the character. The original string is not modified in any way.

For example, consider a script in a main window that is capable of inspecting a variable, `stringA`, in another window that displays map images of different corporate buildings. When the window has a map of Building C in it, the `stringA` variable contains "Building C." The building letter is always at the tenth character position of the string (or number 9 in a zero-based counting world), so the script can examine that one character to identify the map currently in that other window:

```
var stringA = "Building C";
var bldgLetter = stringA.charAt(9);
// result: bldgLetter = "C"
```

Another method—`string.substring()`—enables you to extract a contiguous sequence of characters, provided you know the starting and ending positions of the substring of which you want to grab a copy. Importantly, the character at the ending position value is not part of the extraction: All applicable characters, up to but not including that character, are part of the extraction. The string from which the extraction is made appears to the left of the method name in the reference. Two parameters specify the starting and ending index values (zero based) for the start and end positions:

```
var stringA = "banana daiquiri";
var excerpt = stringA.substring(2,6);
// result: excerpt = "nana"
```

String manipulation in JavaScript is fairly cumbersome compared to some other scripting languages. Higher-level notions of words, sentences, or paragraphs are completely absent. Therefore, sometimes it takes a bit of scripting with string methods to accomplish what seems like a simple goal. And yet you can put your knowledge of expression evaluation to the test as you assemble expressions that utilize heavily nested constructions. For example, the following fragment needs to create a new string that consists of everything from the larger string except the first word. Assuming the first word of other strings can be of any length, the second statement utilizes the `string.indexOf()` method to look for the first space character and adds 1 to that value to serve as the starting index value for an outer

`string.substring()` method. For the second parameter, the `length` property of the string provides a basis for the ending character's index value (one more than the actual character needed).

```
var stringA = "The United States of America";
var excerpt = stringA.substring(stringA.indexOf(" ") + 1, stringA.length);
// result: excerpt = "United States of America"
```

Creating statements like this one is not something you are likely to enjoy over and over again, so in Chapter 27 I show you how to create your own library of string functions you can reuse in all of your scripts that need their string-handling facilities. More powerful string-matching facilities are built into today's browsers by way of regular expressions (see Chapter 27 and Chapter 42 on the CD-ROM).

## The Math Object

JavaScript provides ample facilities for math—far more than most scripters who don't have a background in computer science and math will use in a lifetime. But every genuine programming language needs these powers to accommodate clever programmers who can make windows fly in circles on the screen.

The `Math` object contains all of these powers. This object is unlike most of the other objects in JavaScript in that you don't generate copies of the object to use. Instead your scripts summon a single `Math` object's properties and methods. (One `Math` object actually occurs per window or frame, but this has no impact whatsoever on your scripts.) Programmers call this kind of fixed object a *static object*. That `Math` object (with an uppercase M) is part of the reference to the property or method. Properties of the `Math` object are constant values, such as pi and the square root of two:

```
var piValue = Math.PI;
var rootOfTwo = Math.SQRT2;
```

`Math` object methods cover a wide range of trigonometric functions and other math functions that work on numeric values already defined in your script. For example, you can find which of two numbers is the larger:

```
var larger = Math.max(value1, value2);
```

Or you can raise one number to a power of 10:

```
var result = Math.pow(value1, 10);
```

More common, perhaps, is the method that rounds a value to the nearest integer value:

```
var result = Math.round(value1);
```

Another common request of the `Math` object is a random number. The `Math.random()` method returns a floating-point number between 0 and 1. If you design a script to act like a card game, you need random integers between 1 and 52; for dice, the range is 1 to 6 per die. To generate a random integer between zero and any top value, use the following formula:

```
Math.floor(Math.random() * (n + 1))
```

where `n` is the top number. (`Math.floor` returns the integer part of any floating-point number.) To generate random numbers between 1 and any higher number, use this formula:

```
Math.floor(Math.random() * n) + 1
```

where `n` equals the top number of the range. For the dice game, the formula for each die is

```
newDieValue = Math.floor(Math.random() * 6) + 1;
```

To see this, enter the right-hand part of the preceding statement in the top text box of The Evaluator Jr. and repeatedly click the Evaluate button.

One bit of help JavaScript doesn't offer except in IE5.5+ and Mozilla-based browsers is a way to specify a number-formatting scheme. Floating-point math can display more than a dozen numbers to the right of the decimal. Moreover, results can be influenced by each operating system's platform-specific floating-point errors, especially in earlier versions of scriptable browsers. For other browsers you must perform any number formatting—for dollars and cents, for example—through your own scripts. Chapter 28 provides an example.

## The Date Object

Working with dates beyond simple tasks can be difficult business in JavaScript. A lot of the difficulty comes with the fact that dates and times are calculated internally according to *Greenwich Mean Time (GMT)*—provided the visitor's own internal PC clock and control panel are set accurately. As a result of this complexity, better left for Chapter 29, this section of the tutorial touches on only the basics of the JavaScript `Date` object.

A scriptable browser contains one global `Date` object (in truth, one `Date` object per window) that is always present, ready to be called upon at any moment. The `Date` object is another one of those static objects. When you wish to work with a date, such as displaying today's date, you need to invoke the `Date` object constructor function to obtain an instance of a `Date` object tied to a specific time and date. For example, when you invoke the constructor without any parameters, as in

```
var today = new Date();
```

the `Date` object takes a snapshot of the PC's internal clock and returns a date object for that instant. Notice the distinction between the static `Date` object and a `Date` object instance, which contains an actual date value. The variable, `today`, contains not a ticking clock, but a value that you can examine, tear apart, and reassemble as needed for your script.

Internally, the value of a `Date` object instance is the time, in milliseconds, from zero o'clock on January 1, 1970, in the Greenwich Mean Time zone—the world standard reference point for all time conversions. That's how a `Date` object contains both date and time information.

You can also grab a snapshot of the `Date` object for a particular date and time in the past or future by specifying that information as parameters to the `Date` object constructor function:

```
var someDate = new Date("Month dd, yyyy hh:mm:ss");
var someDate = new Date("Month dd, yyyy");
var someDate = new Date(yy,mm,dd,hh,mm,ss);
var someDate = new Date(yy,mm,dd);
var someDate = new Date(GMT milliseconds from 1/1/1970);
```

If you attempt to view the contents of a raw `Date` object, JavaScript converts the value to the local time zone string as indicated by your PC's control panel setting. To see this in action, use The Evaluator Jr.'s top text box to enter the following:

```
new Date();
```

Your PC's clock supplies the current date and time as the clock calculates them (even though JavaScript still stores the date object's millisecond count in the GMT zone). You can,

however, extract components of the `Date` object via a series of methods that you apply to a `Date` object instance. Table 10-1 shows an abbreviated listing of these properties and information about their values.

**Table 10-1: Some Date Object Methods**

<i>Method</i>	<i>Value Range</i>	<i>Description</i>
<code>dateObj.getTime()</code>	0-...	Milliseconds since 1/1/70 00:00:00 GMT
<code>dateObj.getYear()</code>	70-...	Specified year minus 1900; four-digit year for 2000+
<code>dateObj.getFullYear()</code>	1970-...	Four-digit year (Y2K-compliant); version 4+ browsers
<code>dateObj.getMonth()</code>	0-11	Month within the year (January = 0)
<code>dateObj.getDate()</code>	1-31	Date within the month
<code>dateObj.getDay()</code>	0-6	Day of week (Sunday = 0)
<code>dateObj.getHours()</code>	0-23	Hour of the day in 24-hour time
<code>dateObj.getMinutes()</code>	0-59	Minute of the specified hour
<code>dateObj.getSeconds()</code>	0-59	Second within the specified minute
<code>dateObj.setTime(val)</code>	0-...	Milliseconds since 1/1/70 00:00:00 GMT
<code>dateObj.setYear(val)</code>	70-...	Specified year minus 1900; four-digit year for 2000+
<code>dateObj.setMonth(val)</code>	0-11	Month within the year (January = 0)
<code>dateObj.setDate(val)</code>	1-31	Date within the month
<code>dateObj.setDay(val)</code>	0-6	Day of week (Sunday = 0)
<code>dateObj.setHours(val)</code>	0-23	Hour of the day in 24-hour time
<code>dateObj.setMinutes(val)</code>	0-59	Minute of the specified hour
<code>dateObj.setSeconds(val)</code>	0-59	Second within the specified minute

**Caution**

Be careful about values whose ranges start with zero, especially the months. The `getMonth()` and `setMonth()` method values are zero based, so the numbers are one less than the month numbers you are accustomed to working with (for example, January is 0, December is 11).

You may notice one difference about the methods that set values of a `Date` object. Rather than returning some new value, these methods actually modify the value of the `Date` object referenced in the call to the method.

## Date Calculations

Performing calculations with dates frequently requires working with the millisecond values of the `Date` objects. This is the surest way to compare date values. To demonstrate a few `Date` object machinations, Listing 10-1 displays the current date and time as the page loads. Another script shows one way to calculate the date and time seven days from the current date and time value.

**Listing 10-1: Date Object Calculations**

```
<html>
<head>
<title>Date Calculation</title>
<script type="text/javascript">
function nextWeek() {
    var todayInMS = today.getTime();
    var nextWeekInMS = todayInMS + (60 * 60 * 24 * 7 * 1000);
    return new Date(nextWeekInMS);
}
</script>
</head>

<body>
Today is:
<script type="text/javascript">
var today = new Date();
document.write(today);
</script>
<br>
Next week will be:
<script type="text/javascript">
document.write(nextWeek());
</script>
</body>
</html>
```

In the Body portion, the first script runs as the page loads, setting a global variable (`today`) to the current date and time. The string equivalent is written to the page. In the second Body script, the `document.write()` method invokes the `nextWeek()` function to get a value to display. That function utilizes the `today` global variable, copying its millisecond value to a new variable: `todayInMS`. To get a date seven days from now, the next statement adds the number of milliseconds in seven days (60 seconds times 60 minutes times 24 hours times seven days times 1000 milliseconds) to today's millisecond value. The script now needs a new `Date` object calculated from the total milliseconds. This requires invoking the `Date` object constructor with the milliseconds as a parameter. The returned value is a `Date` object, which is automatically converted to a string version for writing to the page.

To add or subtract time intervals from a `Date` object, you can use a shortcut that doesn't require the millisecond conversions. By combining the date object's `set` and `get` methods, you can let the `Date` object work out the details. For example, in Listing 10-1 you could eliminate the function entirely, and let the following two statements in the second Body script obtain the desired result:

```
today.setDate(today.getDate() + 7);
document.write(today);
```

Because JavaScript tracks the date and time internally as milliseconds, the accurate date appears in the end, even if the new date is into the next month. JavaScript automatically takes care of figuring out how many days there are in a month as well as in leap years.

Many other quirks and complicated behavior await you if you script dates in your page. As later chapters demonstrate, however, the results may be worth the effort.

## Exercises

1. Create a Web page that has one form field for entry of the user's e-mail address and a Submit button. Include a pre-submission validation routine that verifies that the text field has the @ symbol found in all e-mail addresses before you allow submission of the form.
2. Given the string "Internet Explorer", fill in the blanks of the string.substring() method parameters here that yield the results shown to the right of each method call:

```
var myString = "Internet Explorer";
myString.substring(__,__) // result = "Int"
myString.substring(__,__) // result = "plorer"
myString.substring(__,__) // result = "net Exp"
```

3. Fill in the rest of the function in the listing that follows so that it looks through every character of the entry field and counts how many times the letter "e" appears in the field. (Hint: All that is missing is a for repeat loop.)

```
<html>
<head>
<title>Wheel o' Fortuna</title>
<script type="text/javascript">
function countE(form) {
    var count = 0;
    var inputString = form.mainstring.value.toLowerCase();
    missing code
    var msg = "The string has " + count;
    msg += " instances of the letter e.";
    alert(msg);
}
</script>
</head>

<body>
<form>
Enter any string: <input type="text" name="mainstring" size="30"><br>
<input type="button" value="Count the Es"
onclick="countE(this.form)">
</form>
</body>
</html>
```

4. Create a page that has two fields and one button. The button should trigger a function that generates two random numbers between 1 and 6, placing each number in one of the fields. (Think of using this page as a substitute for rolling a pair of dice in a board game.)
5. Create a page that displays the number of days between today and next Christmas.

# Scripting Frames and Multiple Windows

---

One of the attractive aspects of JavaScript for some applications on the client is that it allows user actions in one frame or window to influence what happens in other frames and windows. In this section of the tutorial, you extend your existing knowledge of object references to the realm of multiple frames and windows.

## Frames: Parents and Children

You've seen in earlier top-level hierarchy illustrations (such as Figure 4-1) that the `window` object is at the very top of the chart. The `window` object also has several synonyms, which stand in for the `window` object in special cases. For instance, in Chapter 8, you learned that `self` is synonymous with `window` when the reference applies to the same window that contains the script's document. In this lesson, you learn the roles of three other references that point to objects behaving as windows — `frame`, `top`, and `parent`.

Loading an ordinary HTML document into the browser creates a model in the browser that starts out with one `window` object and the document it contains. (The document likely contains other elements, but I'm not concerned with that stuff yet.) The top rungs of the hierarchy model are as simple as can be, as shown in Figure 11-1. This is where references begin with `window` or `self` (or with `document` because the current window is assumed).

The instant a framesetting document loads into a browser, the browser starts building a slightly different hierarchy model. The precise structure of that model depends entirely on the structure of the frameset defined in that framesetting document. Consider the following skeletal frameset definition:

```
<html>
<frameset cols="50%,50%">
  <frame name="leftFrame" src="somedoc1.html">
  <frame name="rightFrame" src="somedoc2.html">
</frameset>
</html>
```

### In This Chapter

Relationships among frames in the browser window

How to access objects and values in other frames

How to control navigation of multiple frames

Communication skills between separate windows

**Figure 11-1:** Single-frame window and document hierarchy.

This HTML splits the browser window into two frames side by side, with a different document loaded into each frame. The model is concerned only with structure—it doesn't care about the relative sizes of the frames or whether they're set up in columns or rows.

Framesets establish relationships among the frames in the collection. Borrowing terminology from the object-oriented programming world, the framesetting document loads into a *parent window*. Each of the frames defined in that parent window document is a *child frame*. Figure 11-2 shows the hierarchical model of a two-frame environment. This illustration reveals a lot of subtleties about the relationships among framesets and their frames.

**Figure 11-2:** Two-frame window and document hierarchy.

It is often difficult at first to visualize the frameset as a window object in the hierarchy. After all, with the exception of the URL showing in the Location/Address field, you don't see anything about the frameset in the browser. But that window object exists in the object model. Notice, too, that in the diagram the framesetting parent window has no document object showing. This may also seem odd because the window obviously requires an HTML file containing the specifications for the frameset. In truth, the parent window has a `document` object associated with it, but it is omitted from the diagram to better portray the relationships among parent and child windows. A frameset parent's document cannot contain most of the typical HTML objects such as forms and controls, so references to the parent's document are rarely, if ever, used.

If you add a script to the framesetting document that needs to access a property or method of that window object, references are like any single-frame situation. Think about the point of view of a script located in that window. Its immediate universe is the very same window.

Things get more interesting when you start looking at the child frames. Each of these frames contains a `document` object whose content you see in the browser window. And the structure is such that each frame's document is entirely independent of the other. It is as if each document lived in its own browser window. Indeed, that's why each child frame is also a window type of object. A frame has the same kinds of properties and methods of the `window` object that occupies the entire browser.

From the point of view of either child window in Figure 11-2, its immediate container is the parent window. When a parent window is at the very top of the hierarchical model loaded in the browser, that window is also referred to as the `top` object.

## References among Family Members

Given the frame structure of Figure 11-2, it's time to look at how a script in any one of those windows can access objects, functions, or variables in the others. An important point to remember about this facility is that if a script has access to an object, function, or global variable in its own window, that same item can be reached by a script from another frame in the hierarchy (provided both documents come from the same Web server).

A script reference may need to take one of three possible routes in the two-generation hierarchy described so far: parent to child; child to parent; or child to child. Each of the paths between these windows requires a different reference style.

### Parent-to-child references

Probably the least common direction taken by references is when a script in the parent document needs to access some element of one of its frames. The parent contains two or more frames, which means the parent maintains an array of the child frame objects. You can address a frame by array syntax or by the name you assign to it with the `name` attribute inside the `<frame>` tag. In the following examples of reference syntax, I substitute a placeholder named *ObjFuncVarName* for whatever object, function, or global variable you intend to access in the distant window or frame. Remember that each visible frame contains a `document` object, which is generally the container of elements you script—be sure references to the elements include `document`. With that in mind, a reference from a parent to one of its child frames follows any of these models:

```
[window.]frames[n].ObjFuncVarName  
[window.]frames["frameName"].ObjFuncVarName  
[window.]frameName.ObjFuncVarName
```

Numeric index values for frames are based on the order in which their `<frame>` tags appear in the framesetting document. You will make your life easier, however, if you assign recognizable names to each frame and use the frame's name in the reference.

## Child-to-parent references

It is not uncommon to place scripts in the parent (in the Head portion) that multiple child frames or multiple documents in a frame use as a kind of script library. By loading in the frameset, these scripts load only once while the frameset is visible. If other documents from the same server load into the frames over time, they can take advantage of the parent's scripts without having to load their own copies into the browser.

From the child's point of view, the next level up the hierarchy is called the `parent`. Therefore, a reference from a child frame to items at the parent level is simply

```
parent.ObjFuncVarName
```

If the item accessed in the parent is a function that returns a value, the returned value transcends the parent/child borders down to the child without hesitation.

When the parent window is also at the very top of the object hierarchy currently loaded into the browser, you can optionally refer to it as the *top window*, as in

```
top.ObjFuncVarName
```

Using the `top` reference can be hazardous if for some reason your Web page gets displayed in some other Web site's frameset. What is your top window is not the master frameset's top window. Therefore, I recommend using the `parent` reference whenever possible (unless you want to blow away an unwanted framer of your Web site).

## Child-to-child references

The browser needs a bit more assistance when it comes to getting one child window to communicate with one of its siblings. One of the properties of any window or frame is its `parent` (whose value is `null` for a single window). A reference must use the `parent` property to work its way out of the current frame to a point that both child frames have in common — the parent in this case. Once the reference is at the parent level, the rest of the reference can carry on as if starting at the parent. Thus, from one child to one of its siblings, you can use any of the following reference formats:

```
parent.frames[n].ObjFuncVarName  
parent.frames["frameName"].ObjFuncVarName  
parent.frameName.ObjFuncVarName
```

A reference from the other sibling back to the first looks the same, but the `frames[]` array index or `frameName` part of the reference differs. Of course, much more complex frame hierarchies exist in HTML. Even so, the object model and referencing scheme provide a solution for the most deeply nested and gnarled frame arrangement you can think of — following the same precepts you just learned.

## Frame Scripting Tips

One of the first mistakes that frame scripting newcomers make is writing immediate script statements that call upon other frames while the pages load. The problem here is that you cannot rely on the document loading sequence to follow the frameset source code order. All you know for sure is that the parent document *begins* loading first. Regardless of the order of `<frame>` tags, child frames can begin loading at any time. Moreover, a frame's loading time depends on other elements in the document, such as images or Java applets.

Fortunately, you can use a certain technique to initiate a script once all of the documents in the frameset are completely loaded. Just as the `onload` event handler for a document fires when that document is fully loaded, a parent's `onload` event handler fires after the `onload` event handler in its child frames is fired. Therefore, you can specify an `onload` event handler in the `<frameset>` tag. That handler might invoke a function in the framesetting document that then has the freedom to tap the objects, functions, or variables of all frames throughout the object hierarchy.

Make special note that a reference to a frame as a type of window object is quite separate from a reference to the `frame` element object. An element object is one of those DOM element nodes in the document node tree (see Chapter 4). The properties and methods of this node differ from the properties and methods that accrue to a window-type object. It may be a difficult distinction to grasp, but it's an important one. The way you reference a frame—as a window object or element node—determines which set of properties and methods are available to your scripts. See Chapter 15 for a more detailed introduction to element node scripting.

If you start with a reference to the `frame` element object, you can still reach a reference to the document object loaded into that frame. But the syntax is different depending on the browser. IE4+ and Safari let you use the same `document` reference as for a window; Mozilla-based browsers follow the W3C DOM standard more closely, using the `contentDocument` property of the frame element. To accommodate both syntaxes you can build a reference as follows:

```
var docObj;
var frameObj = document.getElementById("myFrame");
if (frameObj.contentDocument) {
    docObj = frameObj.contentDocument;
} else {
    docObj = frameObj.document;
}
```

## About iframe Elements

The `iframe` element is supported as a scriptable object in IE4+, Mozilla-based browsers, and Safari (among other modern browsers). It is often used as a way to fetch and load HTML or XML from a server without disturbing the current HTML page. Therefore it's not uncommon for an `iframe` to be hidden from view, while scripts handle all of the processing between it and the main document.

An `iframe` element becomes another member of the current window's `frames` collection. But you may also reference the `iframe` as an element object through W3C DOM `document.getElementById()` terminology. As with the distinction between the traditional frame-as-window object and DOM element object, a script reference to the document object within an `iframe` element object needs special handling. See Chapter 16 for additional details.

## Controlling Multiple Frames – Navigation Bars

If you are enamored of frames as a way to help organize a complex Web page, you may find yourself wanting to control the navigation of one or more frames from a static navigation panel. Here, I demonstrate scripting concepts for such control using an application called Decision Helper (which you can find in Chapter 55 on the CD-ROM). The application consists of three frames (see Figure 11-3). The top-left frame is one image that has four graphical buttons in it. The goal is to turn that image into a client-side image map and script it so the pages change in the right-hand and bottom frames. In the upper-right frame, the script loads an entirely different document along the sequence of five different documents that go in there. In the bottom frame, the script navigates to one of five anchors to display the segment of instructions that applies to the document loaded in the upper-right frame.

Listing 11-1 shows a slightly modified version of the actual file for the Decision Helper application's navigation frame. The listing contains a couple of new objects and concepts not yet covered in this tutorial. But as you will see, they are extensions to what you already know about JavaScript and objects. To help simplify the discussion here, I remove the scripting and HTML for the top and bottom button of the area map. In addition, I cover only the two navigation arrows.

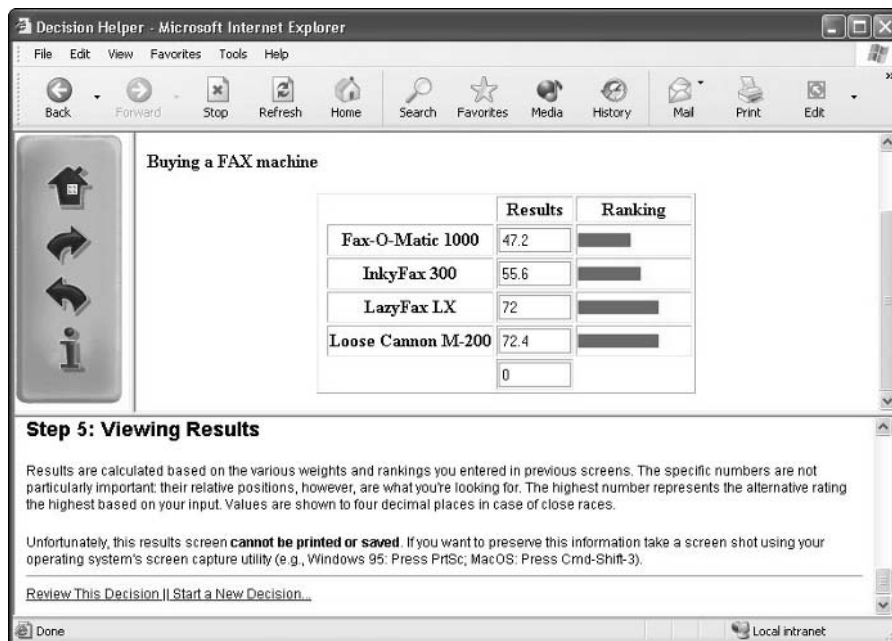

Figure 11-3: The Decision Helper screen.

**Listing 11-1: A Graphical Navigation Bar**

```
<html>
<head>
<title>Navigation Bar</title>
<script type="text/javascript">
<!-- start
function goNext() {
    var currOffset = parseInt(parent.currTitle);
    if (currOffset < 5) {
        currOffset += 1;
        parent.entryForms.location.href = "dh" + currOffset + ".htm";
        parent.instructions.location.hash = "help" + currOffset;
    } else {
        alert("This is the last form.");
    }
}
function goPrev() {
    var currOffset = parseInt(parent.currTitle);
    if (currOffset > 1) {
        currOffset -= 1;
        parent.entryForms.location.href = "dh" + currOffset + ".htm";
        parent.instructions.location.hash = "help" + currOffset;
    } else {
        alert("This is the first form.");
    }
}
// end -->
</script>
</head>
<body bgColor="white">
<map name="navigation">
<area shape="rect" coords="25,80,66,116" href="javascript:goNext()">
<area shape="rect" coords="24,125,67,161" href="javascript:goPrev()">
</map>

</body>
</html>
```

Look first at the HTML section for the Body portion. Almost everything there is standard stuff for defining client-side image maps. The coordinates define rectangles around each of the arrows in the larger image. The href attributes for the two areas point to JavaScript functions defined in the Head portion of the document (the javascript: pseudo-URL is covered in the next chapter).

In the frameset that defines the Decision Helper application, names are assigned to each frame. The upper-right frame is called entryForms; the bottom frame is called instructions.

Knowing that navigation from page to page in the upper-right frame requires knowledge of which page is currently loaded there, I build some other scripting into both the parent document and each of the documents that loads into that frame. A global variable called `currTitle` is defined in the parent document. Its value is an integer indicating which page of the sequence (1 through 5) is currently loaded. An `onload` event handler in each of the five documents (named `dh1.htm`, `dh2.htm`, `dh3.htm`, `dh4.htm`, and `dh5.htm`) assigns its page number to that parent global variable. This arrangement allows all frames in the frameset to share that value easily.

When a user clicks the right-facing arrow to move to the next page, the `goNext()` function is called. The first statement gets the `currTitle` value from the parent window and assigns it to a local variable: `currOffset`. An `if...else` construction tests whether the current page number is less than five. If so, the add-by-value operator adds one to the local variable so I can use that value in the next two statements.

In those next two statements, I adjust the content of the two right frames. Using the parent reference to gain access to both frames, I set the `location.href` property of the top-right frame to the name of the file next in line (by concatenating the number with the surrounding parts of the filename). The second statement sets the `location.hash` property (which controls the anchor being navigated to) to the corresponding anchor in the instructions frame (anchor names `help1`, `help2`, `help3`, `help4`, and `help5`).

A click of the left-facing arrow reverses the process, subtracting 1 from the current page number (using the subtract-by-value operator) and changing the same frames accordingly.

The example shown in Listing 11-1 is one of many ways to script a navigation frame in JavaScript. Whatever methodology you use, much interaction occurs among the frames in the frameset.

## References for Multiple Windows

In Chapter 8, you saw how to create a new window and communicate with it by way of the `window` object reference returned from the `window.open()` method. In this section, I show you how one of those subwindows can communicate with objects, functions, and variables in the window or frame that creates the subwindow.

Every `window` object has a property called `opener`. This property contains a reference to the window or frame that held the script whose `window.open()` statement generated the subwindow. For the main browser window and frames therein, this value is `null`. Because the `opener` property is a valid window reference, you can use it to begin the reference to items in the original window—just like a script in a child frame uses `parent` to access items in the parent document. The parent-child terminology doesn't apply to subwindows, however.

Listings 11-2 and 11-3 contain documents that work together in separate windows. Listing 11-2 displays a button that opens a smaller window and loads Listing 11-3 into it. The main window document also contains a text field that gets filled in when you enter text into a corresponding field in the subwindow.

In the main window document, the `newWindow()` function generates the new window. Because no other statements in the document require the reference to the new window just opened, the statement does not assign its returned value to any variable. This is an acceptable practice in JavaScript if you don't need the returned value of a function or method.

**Listing 11-2: A Main Window Document**

```
<html>
<head>
<title>Main Document</title>
<script type="text/javascript">
function newWindow() {
    window.open("subwind.htm","sub","height=200,width=200");
}
</script>
</head>

<body>
<form>
<input type="button" value="New Window" onclick="newWindow()">
<br>
Text incoming from subwindow:
<input type="text" name="entry">
</form>
</body>
</html>
```

---

All of the action in the subwindow document comes in the `onchange` event handler of the text field. It assigns the subwindow field's own value to the value of the field in the opener window's document. Remember that the contents of each window and frame belong to a document. So even after your reference targets a specific window or frame, the reference must continue helping the browser find the ultimate destination, which is generally some element of the document.

**Listing 11-3: A Subwindow Document**

```
<html>
<head>
<title>A SubDocument</title>
</head>
<body>
<form onsubmit="return false">
Enter text to be copied to the main window:
<input type="text"
onchange="opener.document.forms[0].entry.value = this.value">
</form>
</body>
</html>
```

---

Just one more lesson to go before I let you explore all the details elsewhere in the book. I use the final tutorial chapter to show you some fun things you can do with your Web pages, such as changing images when the user rolls the mouse atop a picture.

## Exercises

Before answering the first three questions, study the structure of the following frameset for a Web site that lists college courses:

```
<frameset rows="85%,15%">
  <frameset cols="20%,80%">
    <frame name="mechanics" src="history101M.html">
    <frame name="description" src="history101D.html">
  </frameset>
  <frameset cols="100%">
    <frame name="navigation" src="navigator.html">
  </frameset>
</frameset>
</html>
```

1. Each document that loads into the description frame has an `onload` event handler in its `<body>` tag that stores a course identifier in the framesetting document's global variable called `currCourse`. Write the `onload` event handler that sets this value to "history101".
2. Draw a block diagram that describes the hierarchy of the windows and frames represented in the frameset definition.
3. Write the JavaScript statements located in the navigation frame that loads the file "french201M.html" into the mechanics frame and the file "french201D.html" into the description frame.
4. While a frameset is still loading, a JavaScript error message suddenly appears saying that "window.document.navigation.form.selector is undefined." What do you think is happening in the application's scripts, and how can you solve the problem?
5. A script in a child frame of the main window uses `window.open()` to generate a second window. How can a script in the second window access the `location` object (URL) of the top (framesetting) window in the main browser window?

# Images and Dynamic HTML

---

The previous eight lessons have been intensive, covering a lot of ground for both programming concepts and JavaScript. Now it's time to apply those fundamentals to the learning of more advanced techniques. I cover two areas here. First, I show you how to implement the ever-popular *mouse rollover* in which images swap when the user rolls the cursor around the screen. Then I introduce you to techniques for modifying a page's content after the page has loaded.

## The Image Object

One of the objects contained by the document is the image object—supported in all scriptable browsers since the days of NN3 and IE4. Image object references for a document are stored in the object model as an array belonging to the `document` object. You can therefore reference an image by array index or image name. Moreover, the array index can be a string version of the image's name. Thus, all of the following are valid references to an image object:

```
document.images[n]  
document.images["imageName"]  
document.imageName
```

If your goal is to support scriptable images for browsers such as NN3 and NN4, you must be aware of image object limitations for those browsers. In particular, the range of scriptable properties is limited, although the all-important `src` property is accessible. Also, no mouse-related event handlers are affiliated with the image object (until you get to IE4+ and NN6+). If you want to make an image a clickable item in older browsers, surround it with a link (and set the image's border to zero) or attach a client-side image map to it. The combination of a link and image is how you make a backward-compatible clickable image button.

## Interchangeable images

The advantage of having a scriptable image object is that a script can change the image occupying the rectangular space already occupied by an image. In IE4+ and NN6+, the images can even change size, with surrounding content automatically reflowing around the resized image.

### In This Chapter

How to precache images

How to swap images for mouse rollovers

Assigning scripts as tag attribute URLs

Modifying Body content dynamically

The script behind this kind of image change is simple enough. All it entails is assigning a new URL to the image object's `src` property. The size of the image on the page is governed by the `height` and `width` attributes set in the `<img>` tag as the page loads. The most common image rollovers use the same size image for each of the rollover states.

## Precaching images

Images take extra time to download from a Web server until the images are stored in the browser's cache. If you design your page so that an image changes in response to user action, you usually want the same fast response that users are accustomed to in other programs. Making the user wait seconds for an image to change can severely detract from enjoyment of the page.

JavaScript comes to the rescue by enabling scripts to load images into the browser's memory cache without displaying the image, a technique called *precaching images*. The tactic that works best is to preload the image into the browser's image cache while the page initially loads. Users are less impatient for those few extra seconds as the main page loads than waiting for an image to download in response to some mouse action.

Precaching an image requires constructing an image object in memory. An image object created in memory differs in some respects from the document image object that you create with the `<img>` tag. Memory-only objects are created by script, and you don't see them on the page at all. But their presence in the document code forces the browser to load the images as the page loads. The object model provides an `Image` object constructor function to create the memory type of image object as follows:

```
var myImage = new Image(width, height);
```

Parameters to the constructor function are the pixel width and height of the image. These dimensions should match the `<img>` tag's `width` and `height` attributes. Once the image object exists in memory, you can then assign a filename or URL to the `src` property of that image object:

```
myImage.src = "someArt.gif";
```

When the browser encounters a statement assigning a URL to an image object's `src` property, the browser fetches and loads that image into the image cache. All the user sees is some extra loading information in the status bar, as if another image were in the page. By the time the entire page loads, all images generated in this way are tucked away in the image cache. You can then assign your cached image's `src` property or the actual image URL to the `src` property of the document image created with the `<img>` tag:

```
document.images[0].src = myImage.src;
```

The change to the image in the document is instantaneous.

Listing 12-1 is a simple listing for a page that has one `<img>` tag and a select list that enables you to replace the image in the document with any of four precached images (including the original image specified for the tag). If you type this listing — as I strongly recommend — you can obtain copies of the four image files from the companion CD-ROM in the Chapter 12 directory of listings (you must still type the HTML and code, however).

**Listing 12-1: Precaching Images**

```
<html>
<head>
<title>Image Object</title>
<script type="text/javascript">
// initialize empty array
var imageLibrary = new Array();
// pre-cache four images
imageLibrary["image1"] = new Image(120,90);
imageLibrary["image1"].src = "desk1.gif";
imageLibrary["image2"] = new Image(120,90);
imageLibrary["image2"].src = "desk2.gif";
imageLibrary["image3"] = new Image(120,90);
imageLibrary["image3"].src = "desk3.gif";
imageLibrary["image4"] = new Image(120,90);
imageLibrary["image4"].src = "desk4.gif";

// load an image chosen from select list
function loadCached(list) {
    var img = list.options[list.selectedIndex].value;
    document.thumbnail.src = imageLibrary[img].src;
}
</script>
</head>

<body >
<h2>Image Object</h2>

<form>
<select name="cached" onchange="loadCached(this)">
<option value="image1">Bands
<option value="image2">Clips
<option value="image3">Lamp
<option value="image4">Erasers
</select>
</form>
</body>
</html>
```

As the page loads, it executes several statements immediately. These statements create an empty array that is populated with four new memory image objects. Each image object has a filename assigned to its `src` property. These images are loaded into the image cache as the page loads. Down in the Body portion of the document, an `<img>` tag stakes its turf on the page and loads one of the images as a starting image.

A `select` element lists user-friendly names for the pictures while housing the names of image objects already precached in memory. When the user makes a selection from the list, the `loadCached()` function extracts the selected item's value—which is a string index of the image within the `imageLibrary` array. The `src` property of the chosen image object is assigned to the `src` property of the visible image object on the page, and the precached image appears instantaneously.

## Creating image rollovers

A favorite technique to add some pseudo-excitement to a page is to swap button images as the user rolls the cursor atop them. The degree of change to the image is largely a matter of taste. The effect can be subtle—a slight highlight or glow around the edge of the original image—or drastic—a radical change of color. Whatever your approach, the scripting is the same.

When several of these graphical buttons occur in a group, I tend to organize the memory image objects as arrays and create naming and numbering schemes that facilitate working with the arrays. Listing 12-2 shows such an arrangement for four buttons that control a jukebox. The code in the listing is confined to the image-swapping portion of the application. This is the most complex and lengthiest listing of the tutorial, so it requires a bit of explanation as it goes along.

### Listing 12-2: Image Rollovers

```
<html>
<head>
<title>Jukebox/Image Rollovers</title>
<script type="text/javascript">
```

Only browsers capable of handling image objects should execute statements that precache images. Therefore, the entire sequence is nested inside an `if` construction that tests for the presence of the `document.images` array. In older browsers, the condition evaluates to “undefined,” which an `if` condition treats as `false`.

```
if (document.images) {
```

Image precaching starts by building two arrays of image objects. One array stores information about the images depicting the graphical button’s “off” position; the other is for images depicting their “on” position. These arrays use strings (instead of integers) as index values. The string names correspond to the names given to the visible image objects whose tags come later in the source code. The code is clearer to read (for example, you know that the `offImgArray["play"]` entry has to do with the Play button image). Also, as you see later in this listing, rollover images don’t conflict with other visible images on the page (a possibility if you rely exclusively on numeric index values when referring to the visible images for the swapping).

After creating the array and assigning new blank image objects to the first four elements of the array, I go through the array again, this time assigning file pathnames to the `src` property of each object stored in the array. These lines of code execute as the page loads, forcing the images to load into the image cache along the way.

```
// precache all 'off' button images
var offImgArray = new Array();
offImgArray["play"] = new Image(75,33);
offImgArray["stop"] = new Image(75,33);
offImgArray["pause"] = new Image(75,33);
offImgArray["rewind"] = new Image(86,33);
```

```

// off image array -- set 'off' image path for each button
offImgArray["play"].src = "images/playoff.jpg";
offImgArray["stop"].src = "images/stopoff.jpg";
offImgArray["pause"].src = "images/pauseoff.jpg";
offImgArray["rewind"].src = "images/rewindoff.jpg";

// precache all 'on' button images
var onImgArray = new Array();
onImgArray["play"] = new Image(75,33);
onImgArray["stop"] = new Image(75,33);
onImgArray["pause"] = new Image(75,33);
onImgArray["rewind"] = new Image(86,33);

// on image array -- set 'on' image path for each button
onImgArray["play"].src = "images/playon.jpg";
onImgArray["stop"].src = "images/stopon.jpg";
onImgArray["pause"].src = "images/pauseon.jpg";
onImgArray["rewind"].src = "images/rewindon.jpg";
}

```

As you can see in the following HTML, when the user rolls the mouse atop any of the visible document image objects, the `onmouseover` event handler (from the link object surrounding the image in the document) invokes the `imageOn()` function, passing the name of the particular image. The `imageOn()` function uses that name to synchronize the `document.images` array entry (the visible image) with the entry of the in-memory array of “on” images from the `onImgArray` array. The `src` property of the array entry is assigned to the corresponding document image `src` property.

```

// functions that swap images & status bar
function imageOn(imgName) {
    if (document.images) {
        document.images[imgName].src = onImgArray[imgName].src;
    }
}

```

The same goes for the `onmouseout` event handler, which needs to turn the image off by invoking the `imageOff()` function with the same index value.

```

function imageOff(imgName) {
    if (document.images) {
        document.images[imgName].src = offImgArray[imgName].src;
    }
}

```

Both the `onmouseover` and `onmouseout` event handlers set the status bar to prevent the ugly `javascript: URL` (described later) from appearing there as the user rolls the mouse atop the image. The `onmouseout` event handler sets the status bar message to an empty string.

```

function setMsg(msg) {
    window.status = msg;
    return true;
}

```

For this demonstration, I disable the functions that control the jukebox. But I leave the empty function definitions here so they catch the calls made by the clicks of the links associated with the images.

```
// controller functions (disabled)
function playIt() {
}
function stopIt() {
}
function pauseIt(){
}
function rewindIt() {
}
</script>
</head>
```

```
<body>
<center>
<form>
Jukebox Controls<br>
```

I surround each image in the document with a link because the link object has the event handlers needed to respond to the mouse rolling over the area for compatibility back to NN3. Each link's `onmouseover` event handler calls the `imageOn()` function, passing the name of the image object to be swapped. Because both the `onmouseover` and `onmouseout` event handlers require a `return true` statement to work in older browsers, I combine the second function call (to `setMsg()`) with the `return true` requirement. The `setMsg()` function always returns `true` and is combined with the `return` keyword before the call to the `setMsg()` function. It's just a trick to reduce the amount of code in these event handlers.

**Note**

If you are typing this listing to try it out, be sure to keep each entire `<a>` tag and its attributes in one unbroken line; or insert a carriage return *before* any event handler name.

```
<a href="javascript:playIt()"
  onmouseover="imageOn('play'); return setMsg('Play the selected tune')"
  onmouseout="imageOff('play'); return setMsg('')">

</a>
<a href="javascript:stopIt()"
  onmouseover="imageOn('stop'); return setMsg('Stop the playing tune')"
  onmouseout="imageOff('stop'); return setMsg('')">

</a>
<a href="javascript:pauseIt()"
  onmouseover="imageOn('pause'); return setMsg('Pause the playing tune')"
  onmouseout="imageOff('pause'); return setMsg('')">

</a>
<a href="javascript:rewindIt()"
  onmouseover="imageOn('rewind'); return setMsg('Rewind back to the
beginning')"
  onmouseout="imageOff('rewind'); return setMsg('')">

</a>
</form>
</center>
</body>
</html>
```

You can see the results of this lengthy script in Figure 12-1. As the user rolls the mouse atop one of the images, it changes from a light to dark color by swapping the entire image. You can access the image files on the CD-ROM, and I encourage you to enter this lengthy listing and see the magic for yourself.

Figure 12-1: Typical mouse rollover image swapping.

## The javascript: Pseudo-URL

You have seen several instances in this and previous chapters of applying what is called the `javascript: pseudo-URL` to `href` attributes of `<a>` and `<area>` tags. This technique should be used sparingly at best, especially for public Web sites that may be accessed by users with non-scriptable browsers (for whom the links will be inactive).

The technique was implemented to supplement the `onclick` event handler of objects that act as hyperlinks. Especially in the early scripting days, when elements such as images had no event handlers of their own, hyperlinked elements surrounding those inactive elements allowed users to appear to interact directly with elements such as images. When the intended action was to invoke a script function (rather than navigate to another URL, as is usually the case with a hyperlink), the language designers invented the `javascript:` protocol for use in assignments to the `href` attributes of hyperlink elements (instead of leaving the required attribute empty).

When a scriptable browser encounters an `href` attribute pointing to a `javascript: pseudo-URL`, the browser executes the script content after the colon when the user clicks on the element. For example, near the end of Listing 12-2, all four `<a>` tags point to `javascript: pseudo-URLs` that invoke script functions on the page, such as

```
<a href="javascript:playIt()" ... >
```

Be aware that unless you override the status bar text with mouse event handlers (as shown in Listing 12-2), the pseudo-URL appears in the status bar for the user to see (and perhaps be frightened). More importantly, however, remember that this URL is to be used only for assignment to `href` attributes. Do not use it with event handlers.

## Popular Dynamic HTML Techniques

Because today's scriptable browsers uniformly permit scripts to access each element of the document and automatically reflow the page's content when anything changes, a much

higher degree of dynamism is possible in your applications. Dynamic HTML is a very deep subject, with lots of browser-specific peculiarities. In this final section of the tutorial, you will learn techniques that work in all W3C DOM-compatible browsers. I'll focus on two of the most common tasks for which DHTML is used: changing element styles and modifying Body content.

## Changing stylesheet settings

Each element that renders on the page (and even some that don't) has a property called `style`. This property provides script access to all Cascading Style Sheet (CSS) properties supported for that element by the current browser. Property values are the same as those used for CSS specifications—frequently a different syntax than similar settings that used to be made by HTML tag attributes. For example, if you wish to set the text color of a quote element whose ID is `FranklinQuote`, the syntax is

```
document.getElementById("FranklinQuote").style.color = "rgb(255, 255, 0)";
```

Because the CSS `color` property accepts other ways of specifying colors (such as the traditional hexadecimal triplet—`#ffff00`), you may use those as well.

Some CSS property names, however, do not conform to JavaScript naming conventions. Several CSS property names contain hyphens. When that occurs, the scripted equivalent of the property compresses the words together and capitalizes the start of each word. For example, the CSS property `font-weight` would be set in script as follows:

```
document.getElementById("highlight").style.fontWeight = "bold";
```

A related technique puts more of the design burden on the CSS code. For example, if you define CSS rules for two different classes, you can simply switch the class definition being applied to the element by way of the element object's `className` property. For example, let's say you define two CSS class definitions with different background colors:

```
.normal {background-color: #ffffff}
.highlighted {background-color: #ff0000}
```

In the HTML page, the element first receives its default class assignment as follows:

```
<p id="news" class="normal">...</p>
```

A script statement can then change the class of that element object so that the highlighted style applies to it:

```
document.getElementById("news").className = "highlighted";
```

Restoring the original class name also restores its look and feel. This approach is also a quick way to change multiple style properties of an element with a single statement.

## Dynamic content via W3C DOM nodes

In Chapter 8 you met the `document.createElement()` and `document.createTextNode()` methods. These methods create new DOM objects out of thin air, which you may then modify by setting properties (attributes) prior to plugging the new stuff into the document tree for all to see.

As an introduction to this technique, I'll demonstrate the steps you would go through to add an element and its text to a placeholder `span` element on the page. In this example, a

paragraph element belonging to a class called `centered` will be appended to a span whose ID is `placeholder`. Some of the text for the content of the paragraph comes from a text field in a form (the visitor's first name). Here is the complete sequence:

```
var newElem = document.createElement("p");
newElem.className = "centered";
var newText = document.createTextNode("Thanks for visiting, " +
    document.forms[0].firstName.value);
// insert text node into new paragraph
newElem.appendChild(newText);
// insert completed paragraph into placeholder
document.getElementById("placeholder").appendChild(newElem);
```

The W3C DOM approach takes a lot of tiny steps to create, assemble, and insert the pieces into their destinations. After creating the element and text nodes, the text node must be inserted into the element node. Because the new element node is empty when it is created, the DOM `appendChild()` method plugs the text node into the element (between its start and end tags, if you could see the tags). With the paragraph element assembled, it then gets inserted at the end of the initially empty span element. Additional W3C DOM methods (described in Chapters 15 and 16) provide more ways to insert, remove, and replace nodes.

## Dynamic content via the `innerHTML` property

Prior to the W3C DOM specification, Microsoft invented a property of all element objects: `innerHTML`. This property first appeared in IE4, and became popular due to its practicality. The property's value is a string containing HTML tags and other content, just as it would appear in an HTML document inside the current element's tags. Even though the W3C DOM working group did not implement this property for the published standard, the property proved to be too practical and popular for modern browser makers to ignore. You can find it implemented as a de facto standard in Mozilla-based browsers and Safari, among others.

To show you the difference in the approach, the following code example shows the same content creation and insertion as shown in the previous W3C DOM section, but this time with the `innerHTML` property:

```
// accumulate HTML as a string
var newHTML = "<p class='centered'>Thanks for visiting, ";
newHTML += document.forms[0].firstName.value;
newHTML += "</p>";
// blast into placeholder element's content
document.getElementById("placeholder").innerHTML = newHTML;
```

While the `innerHTML` version seems more straightforward—and it makes it easier for HTML coders to visualize what's being added—the more code-intensive DOM node approach is more efficient when the Body modification task entails lots of content. Extensive string concatenation operations can slow down browser script processing. Sometimes the shortest script is not necessarily the fastest.

And so ends the final lesson of the *JavaScript Bible, Fifth Edition* tutorial. If you have gone through every lesson and tried your hand at the exercises, you are now ready to dive into the rest of the book to learn the fine details and many more features of both the document object model and the JavaScript language. You can work sequentially through the chapters of Parts III and IV, but before too long, you should also take a peek at Chapter 45 on the CD-ROM to learn some debugging techniques that help the learning process.

## Exercises

1. Explain the difference between a document image object and the memory type of image object.
2. Write the JavaScript statements needed to precache an image file named `jane.jpg` that later will be used to replace the document image defined by the following HTML:

```

```

3. With the help of the code you wrote for question 2, write the JavaScript statement that replaces the document image with the memory image.
4. Backward-compatible document image objects do not have event handlers for mouse events. How do you trigger scripts needed to swap images for mouse rollovers?
5. Assume that a `table` element contains an empty table cell (`td`) element whose ID is `forwardLink`. Using W3C DOM node creation techniques, write the sequence of script statements that create and insert the following hyperlink into the table cell:

```
<a href="page4.html">Next Page</a>
```

# JavaScript Essentials

---

**W**henever JavaScript is discussed in the context of the Web browser environment, it is sometimes difficult to distinguish between JavaScript the scripting language and the objects that you use the language to control. Even so, it's important to separate the language from the object model just enough to help you make important design decisions when considering JavaScript-enhanced pages. You may come to appreciate the separation in the future if you use JavaScript for other object models, such as server-side programming. All the basics of the language are identical. Only the objects differ.

This chapter elaborates on many of the fundamental subjects about the core JavaScript language raised throughout the tutorial (Part II), particularly as they relate to deploying scripts in a world in which visitors to your pages may use a wide variety of browsers. Along the way, you receive additional insights into the language itself. You can find details about the JavaScript core language syntax in Part IV.

## JavaScript Versions

The JavaScript language has its own numbering system, which is completely independent of the version numbers assigned to browsers. The language's creator, Netscape, historically has had the most influence on the numbering system.

The first version, logically enough, was JavaScript 1.0. This was the version implemented in Navigator 2 and the first release of Internet Explorer 3. As the language evolved with succeeding browser versions, the JavaScript version number incremented in small steps. Internet Explorer 6 and Mozilla-based browsers support JavaScript 1.5.

Each successive generation of JavaScript employs additional language features. For example, in JavaScript 1.0, arrays were not developed fully, causing scripted arrays to not track the number of items in the array. JavaScript 1.1 filled that hole by providing a constructor function for generating arrays and an inherent `length` property for any generated array.

# 13

CHAPTER

## In This Chapter

How to separate the language from the document object model

Where scripts go in your documents

JavaScript language versions

Language highlights for experienced programmers

The JavaScript version implemented in a browser is not always a good predictor of core language features available for that browser. For example, while JavaScript 1.2 (as implemented by Netscape in NN4) included broad support for regular expressions, not all of those features appeared in Microsoft's corresponding JScript implementation in IE4. By the same token, Microsoft implemented `try-catch` error handling in its JScript in IE5, but Netscape didn't include that feature until the Mozilla-based NN6 implementation of JavaScript 1.5. Therefore, the language version number is far less important than the browser version in determining which language features are available for you to use.

## Core Language Standard – ECMAScript

Although Netscape first developed the JavaScript language, Microsoft incorporated the language in Internet Explorer 3. Microsoft did not want to license the “Java” name from its trademark owner (Sun Microsystems), which is why the language became known in the IE environment as JScript. Except for some very esoteric exceptions and the pace of newly introduced features, the two languages are essentially identical. The levels of compatibility between browser brands for a comparable generation are remarkably high for the core language (unlike the vast disparities in object model implementations discussed in Chapter 14).

As mentioned in Chapter 2, standards efforts have been under way to create industry-wide recommendations for browser makers to follow (to make developers' lives easier). The core language was among the first components to achieve standard status. Through the European standards body called ECMA, a formal standard for the language has been agreed to and published. The first specification for the language, dubbed ECMAScript by the standards group, was roughly the same as JavaScript 1.1 in Netscape Navigator 3. The standard defines how various data types are treated, how operators work, what a particular data-specific syntax looks like, and other language characteristics. A newer version (called version 3) adds many enhancements to the core language (version 2 was version 1 with errata fixed). You can view the current version of the ECMA-262 specification at <http://www.ecma-international.org/>. If you are a student of programming languages, you will find the document fascinating; if you simply want to script your pages, you will probably find the minutia mind-boggling.

Both Netscape and Microsoft have pledged to make their browsers compliant with the ECMA standard. The vast majority of the ECMAScript standard has appeared in Navigator since version 3 and Internet Explorer since version 4. And, as new features are added to the ECMA standard, they tend to find their way into newer browsers as well. The latest version of ECMAScript is version 3, which is supported in JavaScript 1.5 (Moz1) and JScript in IE6.

**Note**

Version 4 of ECMAScript is currently in the works, along with comparable implementations of JavaScript (2.0) and JScript by The Mozilla Foundation and Microsoft, respectively.

## Embedding Scripts in HTML Documents

Scriptable browsers offer several ways to include scripts or scripted elements in your HTML documents. Not all approaches are available in all versions of every browser, but you have sufficient flexibility starting with Navigator 3 and some versions of Internet Explorer 3. When you consider that the vast majority of computer users are now using at least version 4 browsers, it's safe to assume a core level of script support among Web users. Exceptions to this rule include users who have specifically turned off scripting in their browsers, some organizations that install browsers with scripting turned off, and users with physical disabilities who require specialized browsers.

## <script> tags

The simplest and most compatible way to include script statements in an HTML document is inside a `<script>...</script>` tag set that specifies the scripting language via the `type` attribute. You can have any number of such tag sets in your document. For example, you can define some functions in the Head section to be called by event handlers in HTML tags within the Body section. Another tag set can reside within the Body to write part of the content of the page as the page loads. Place only script statements and comments between the start and end tags of the tag set. Do not place any HTML tags inside unless they are part of a string parameter to a `document.write()` statement that creates content for the page.

Every opening `<script>` tag should specify the `type` attribute. Because the `<script>` tag is a generic tag indicating that the contained statements are to be interpreted as executable script and not renderable HTML, the tag is designed to accommodate any scripting language the browser knows.

### Specifying the language version

Browsers starting with IE5 and Moz1 support the `type` attribute of the `<script>` tag. This attribute accepts the type of a script as a MIME type. For example, the MIME type of JavaScript is specified as `type="text/javascript"`. So, a `<script>` block for JavaScript is coded as follows:

```
<script type="text/javascript">...</script>
```

The `type` attribute is required for the `<script>` tag as of HTML 4. Earlier versions of HTML, and therefore earlier browsers, recognize the `language="JavaScript"` attribute setting as opposed to `type`. The `language` attribute allows the scripter to write for a specific minimum version of JavaScript or, in the case of Internet Explorer, other languages such as VBScript. For example, the JavaScript interpreter built into Navigator 3 knows the JavaScript 1.1 version of the language; Navigator 4 and Internet Explorer 4 include the JavaScript 1.2 version. For versions beyond the original JavaScript, you may specify the language version by appending the version number after the language name without any spaces, as in

```
<script language="JavaScript1.1">...</script>
```

```
<script language="JavaScript1.2">...</script>
```

It's important to note that the `language` attribute was deprecated in HTML 4, with the `type` attribute being the recommended way of specifying the scripting language for `<script>` tags. However, only IE5+ and W3C DOM-compatible browsers recognize this attribute, and JavaScript versions are not taken into account with this methodology. To be both backward compatible and forward looking, you can specify both the `language` and `type` attributes in your `<script>` tags because older browsers ignore the `type` attribute. Following is an example of how you might do this:

```
<script type="text/javascript" language="JavaScript 1.2">...</script>
```

### <script for> tags

IE4+ browsers offer a variation on the `<script>` tag that binds a `<script>` tag's statements to a specific object and event generated by that object. In addition to the language specification, the tag's attributes must include `for` and `event` attributes (not part of the HTML 4.0 specification). The value assigned to the `for` attribute is a reference to the desired object. Most often, this is simply the identifier assigned to the object's `id` attribute (IE4+ enables you to reference an object by either `document.all.objectID` or just `objectID`). The `event` attribute is the event handler name that you wish the script to respond to. For example, if

you design a script to perform some action upon a `mousedown` event in a paragraph whose ID is `myParagraph`, the script statements are enclosed in the following tag set:

```
<script for="myParagraph" event="onmousedown" type="text/javascript">
...
</script>
```

Statements inside the tag set execute only upon the firing of the event. No function definitions are required.

This way of binding an object's event to a script means that there is no event handler defined in the element's tag. Therefore, it guarantees that only IE4 or later can carry out the script when the event occurs. But the tag and attributes contain a lot of source code overhead for each object's script, so this is not a technique that you should use for script statements that need to be called by multiple objects.

Also be aware that you cannot use this tag variation if non-IE or pre-IE4 browsers load the page. In such browsers, script statements execute as the page loads, which certainly causes script errors.

## Hiding script statements from older browsers

The number of people using old Web browsers that don't support scripting languages has diminished considerably in the past few years. However, new devices, such as mobile phones and pocket-sized computers, often employ compact browsers that don't have built-in JavaScript interpreters.

Nonscriptable browsers do not know about the `<script>` tag. Normally, browsers ignore tags they don't understand. That's fine when a tag is just one line of HTML, but a `<script>` tag sets off any number of script statement lines in a document. Old and compact browsers don't know to expect a closing `</script>` tag. Therefore, their natural inclination is to render any lines they encounter after the opening `<script>` tag. Unfortunately, this places script code squarely in the document — surely to confuse anyone who sees such gibberish on the page.

You can, however, exercise a technique that tricks most nonscriptable browsers into ignoring the script statements: surround the script statements — inside the `<script>` tag set — with HTML comment markers. An HTML comment begins with the sequence `<!--` and ends with `-->`. Therefore, you should embed these comment sequences in your scripts according to the following format:

```
<script type="text/javascript">
<!--
script statements here
//-->
</script>
```

JavaScript interpreters know to ignore a line that begins with the HTML beginning comment sequence, but they need a little help with the ending sequence. The close of the HTML comment starts with a JavaScript comment sequence (`//`). This tells JavaScript to ignore the line; but a nonscriptable browser sees the ending HTML symbols and begins rendering the page with the next HTML tag or other text in the document. An older browser doesn't know what the `</script>` tag is, so the tag is ignored and rendering begins after that.

If you design your pages for public access, it's still a good idea to include these HTML comment lines in all your `<script>` tag sets. Make sure they go inside the tags, not outside. Also note that most of the script examples in this book do not include these comments for the sake of saving space in the listings.

## Hiding scripts entirely?

It may be misleading to say that this HTML comment technique “hides” scripts from older browsers. In truth, the comments hide the scripts from being rendered by the browsers. The tags and script statements, however, are still downloaded to the browser and appear in the source code when viewed by the user.

A common wish among authors is to truly hide scripts from visitors to a page. Client-side JavaScript must be downloaded with the page and is, therefore, visible in the source view of pages. There are, of course, some tricks you can implement that may disguise client-side scripts from prying eyes. The most easily implemented technique is to let the downloaded page contain no visible elements, only scripts that assemble the page that the visitor sees. Source code for such a page is simply the HTML for the page. But that page is not interactive because no scripting is attached unless it is written as part of the page—defeating the goal of hiding scripts. Any scripted solution for disguising scripts is immediately defeatable by the user turning off scripting temporarily before downloading the page. All of your code is ready for source view.

If you are worried about other scripters “stealing” your scripts, your best protection is to include a copyright notification in your page’s source code. Not only are your scripts visible to the world, but so, too, are a thief’s scripts. This way you can easily see when someone lifts your scripts verbatim.

**Note**

One other option for minimizing other people “borrowing” your JavaScript code is to use a JavaScript obfuscator, which is a special application that scrambles your code and makes it much harder to read and understand. The code still works fine but it is very hard to modify in any way. You would use an obfuscator just before placing your code online, making sure to keep the original version for making changes. One JavaScript obfuscator that has been available for several years is a shareware program called *JavaScript Scrambler* (<http://www.quadhead.de/>).

## Script libraries (.js files)

If you do a lot of scripting or script a lot of pages for a complex Web application, you will certainly develop some functions and techniques that you can use for several pages. Rather than duplicate the code in all of those pages (and go through the nightmare of making changes to all copies for new features or bug fixes), you can create reusable script library files and link them to your pages.

Such an external script file contains nothing but JavaScript code—no `<script>` tags, no HTML. The script file you create must be a text-only file, but its filename must end with the two-character extension `.js`. To instruct the browser to load the external file at a particular point in your regular HTML file, you add an `src` attribute to the `<script>` tag as follows:

```
<script type="text/javascript" src="hotscript.js"></script>
```

This kind of tag should go at the top of the document so it loads before any other in-document `<script>` tags load. If you load more than one external library, include a series of these tag sets at the top of the document.

Take notice of two features about this external script tag construction. First, the `<script>` `</script>` tag pair is required, even though nothing appears between them. You can mix `<script>` tag sets that specify external libraries with in-document scripts in the same document. Second, avoid putting other script statements between the start and end tags when the start tag contains an `src` attribute.

How you reference the source file in the `src` attribute depends on its physical location and your HTML coding style. In the preceding example, the `.js` file is assumed to reside in the same directory as the HTML file containing the tag. But if you want to refer to an absolute URL, the protocol for the file is `http://` (just like with an HTML file):

```
<script type="text/javascript" src="http://www.cool.com/hotscript.js"></script>
```

A very important prerequisite for using script libraries with your documents is that your Web server software must know how to map files with the `.js` extension to a MIME type of `application/x-javascript`. If you plan to deploy JavaScript in this manner, be sure to test a sample on your Web server beforehand and arrange for any necessary server configuration adjustments.

When a user views the source of a page that links in an external script library, code from the `.js` file does not appear in the window even though the browser treats the loaded script as part of the current document. However, the name or URL of the `.js` file is plainly visible (displayed exactly as it appears in your source code). Anyone can then turn off JavaScript in the browser and open that file (using the `http://` protocol) to view the `.js` file's source code. In other words, an external JavaScript source file is no more hidden from view than JavaScript embedded directly in an HTML file.

## Browser Version Detection

Without question, the biggest challenge facing many client-side scripters is how to program an application that accommodates a wide variety of browser versions and brands, each one of which can bring its own quirks and bugs. Happy is the intranet developer who knows for a fact that the company has standardized its computers with a particular brand and version of browser. But that is a rarity, especially in light of the concept of the *extranet*—private corporate networks and applications that open up for access to the company's suppliers and customers.

Having dealt with this problem since the original scripted browser (NN2) had to work alongside a hoard of nonscriptable browsers, I have identified several paths that an application developer can follow. Unless you decide to be autocratic about browser requirements for using your site, you must make compromises in desired functionality or provide multiple paths in your Web site for two or more classes of browsers. In this section, I give you several ideas about how to approach development in a fragmented browser world.

**Note**

While JavaScript support has stabilized to some degree when it comes to desktop Web browsers, the popularity of mobile phone and handheld Web browsers has complicated the matter; few compact Web browsers support JavaScript as of yet.

## Is JavaScript on?

Very often, the first decision an application must make is whether the client accessing the site is JavaScript-enabled. Non-JavaScript-enabled browsers fall into two categories: a) JavaScript-capable browsers that have JavaScript turned off in the preferences; and b) browsers that have no built-in JavaScript interpreter.

## Using the `<noscript>` tag

Except for some of the earliest releases of NN2, all JavaScript-capable browsers have a preferences setting to turn off JavaScript (and a separate one for Java). You should know that even

though JavaScript is turned on by default in most browsers, many institutional deployments turn it off when the browser is installed on client machines. The reasons behind this MIS deployment decision vary from scares about Java security violations incorrectly associated with JavaScript, valid JavaScript security concerns on some browser versions, and the fact that some firewalls try to filter JavaScript lines from incoming HTML streams.

All JavaScript-capable browsers include a set of `<noscript> . . . </noscript>` tags to balance the `<script> . . . </script>` tag set. If one of these browsers has JavaScript turned off, the `<script>` tag is ignored but the `<noscript>` tag is observed. As with the `<noframes>` tag, you can use the body of a `<noscript>` tag set to display HTML that lets users know JavaScript is turned off, and therefore the full benefit of the page isn't available unless they turn on JavaScript. Listing 13-1 shows a skeletal HTML page that uses these tags.

### Listing 13-1: Employing the `<noscript>` Tag

```
<html>
<head>
  <title>Some Document</title>
  <script type="text/javascript">
    // script statements
  </script>
</head>

<body>
  <noscript><b>Your browser has JavaScript turned off.</b><br />
  You will experience a more enjoyable time at this Web site if you
  turn JavaScript on.
  <hr /></noscript>

  <h2>The body of your document.</h2>
</body>
</html>
```

You can display any standard HTML within the `<noscript>` tag set. An icon image is a colorful way to draw the user's attention to the special advice at the top of the page. If your document is designed to create content dynamically in one or more places in the document, you may have to include a `<noscript>` tag set after more than one `<script>` tag set to let users know what they're missing. Do not include the HTML comment tags that you use in hiding JavaScript statements from older browsers. Their presence inside the `<noscript>` tags prevents the HTML from rendering.

### Other nonscriptable browsers

At this juncture, I must point out that newcomers to scripting frequently want to know what script to write to detect whether JavaScript is turned on. Because scripters are so ready to write a script to work around all situations, it takes some thought to realize that a non-JavaScript browser cannot execute such a script: If no JavaScript interpreter exists in the browser (or it is turned off), the script is ignored. I suppose that the existence of a JavaScript-accessible method for Java detection—the `navigator.javaEnabled()` method—promises a parallel method for JavaScript. But logic fails to deliver on that unspoken promise.

Another desire is to have JavaScript substitute document content when the browser is JavaScript-enabled. Only in IE4+ and W3C DOM-compatible browsers can a script replace regular HTML with scripted content. If you develop content that must be backward compatible with older browsers, remember that all HTML in a document appears in the browser window, while scripted content can be additive only.

You can use this additive scripting to create unusual effects when displaying different links and (with a caveat) body text for scriptable and nonscriptable browsers. Listing 13-2 shows a short document that uses HTML comment symbols to trick nonscriptable browsers into displaying a link to Netscape's Web site and two lines of text. A scriptable browser takes advantage of a behavior that allows only the nearest `<a>` tag to be associated with a closing `</a>` tag. Therefore, the Microsoft link isn't rendered at all, but the link to my Web site is. For the body text, the script assigns the same text color to a segment of HTML body text as the document's background. While the colored text is camouflaged in a scriptable browser (and some other text written to the document), the "hidden" text remains invisible in the document. HTML fans frown upon this kind of element spoofing, which will likely run afoul of HTML validators. However, it can be fun to play with.

### Listing 13-2: Rendering Different Content for Scriptable and Nonscriptable Browsers

```
<html>
<head>
  <title></title>
</head>

<body bgcolor="#FFFFFF">
  <a href="http://www.microsoft.com">
    <script type="text/javascript">
      <!--
      document.writeln("<a href='http://www.dannyg.com'>")
      //-->
    </script> Where?</a>
  <hr />
  <script type="text/javascript">
    <!--
    document.write("Howdy from the script!<font color='#FFFFFF'>")
    //-->
  </script>If you can read this, JavaScript is not available.
  <script type="text/javascript">
    <!--
    document.write("<\font>")
    //-->
  </script><br />
  Here's some stuff afterward.
</body>
</html>
```

## Scripting for different browsers

A number of solutions exist for accommodating different client browsers because the specific compatibility need might be as simple as letting a link navigate to a scripted page for

script-enabled browsers, as involved as setting up distinct areas of your application for different browser classes, or any degree in between. The first step in planning for compatibility is determining what your goals are for various visitor classes.

## Establishing goals

Once you map out your application, you must then look at the implementation details to see which browser is required for the most advanced aspect of the application. For example, if the design calls for image swapping on mouse rollovers, that feature requires NN3+ and IE4+, which is a relatively safe assumption these days. In implementing Dynamic HTML features, you have potentially three different ways to implement tricks (such as movable elements or changeable content) because the document object models require different scripting (and sometimes HTML) for NN4, IE4+, and the W3C DOM implemented in Moz1+, IE5+, Safari, and other recent browsers.

In an ideal scenario, you have an appreciation for the kinds of browsers that your visitors use. For example, if you want to implement some DHTML features, but NN4 usage is only a small and decreasing percentage of hits, you can probably get by with designing for the IE4+ and W3C DOM. Or you may wish to forget the past and design your DHTML exclusively for W3C DOM-compatible browsers. If your Web hosting service maintains a log of visitor activity to your site, you can study the browsers listed among the hits to see which browsers your visitors use.

After you determine the lowest common denominator for the optimum experience, you then must decide how gracefully you want to degrade the application for visitors whose browsers do not meet the common denominator. For example, if you plan a page or site that requires a W3C DOM-compatible browser for all the bells and whistles, you can provide an escape path with content in a simple format that every browser from Lynx to IE4 and NN4 can view. You might even provide for users of handheld devices a third offering with limited or no scriptability that is designed specifically for a constrained user interface.

Creating an application or site that has multiple paths for viewing the same content may sound good at the outset, but don't forget that maintenance chores lie ahead as the site evolves. Will you have the time, budget, and inclination to keep all paths up to date? Despite whatever good intentions a designer of a new Web site may have, in my experience the likelihood that a site will be maintained properly diminishes rapidly with the complexity of the maintenance task.

## Implementing a branching index page

If you decide to offer two or more paths into your application or content, one place you can start visitors down their individual paths is at the default page for your site. Numerous techniques are available that can redirect visitors to the appropriate perceived starting point of the site.

One design to avoid is placing the decision about the navigation path in the hands of the visitor. Offering buttons or links that describe the browser requirements may work for users who are HTML and browser geeks, but average consumers surfing the Web these days likely don't have a clue about what level of HTML their browsers support or whether they are JavaScript-enabled. It is incumbent upon the index page designer to automate the navigation task as much as possible.

A *branching index page* has almost no content. It is not the "home page" per se of the site, but rather a gateway to the entire Web site. Its job is to redirect users to what appears to be the home page for the site. Listing 13-3 shows what such a branching index page looks like.

**Listing 13-3: A Branching Index Page**

```
<html>
<head>
  <title>GiantCo On The Web</title>
  <script type="text/javascript">
  <!--
    window.location = "home1.html"
  //-->
  </script>
  <meta http-equiv="REFRESH" content=
    "0; URL=http://www.giantco.com/home2.html">
</head>

<body>
  <center>
    <a href="home2.html"></a>
  </center>
</body>
</html>
```

Notice that the only visible content is an image surrounded by a standard link. The `<body>` tag contains no background color or art. A single script statement is located in the Head. A `<meta>` tag is also in the Head to automate navigation for some users. To see how a variety of browsers respond to this page, here are what three different classes of browser do with Listing 13-3:

- ♦ **A JavaScript-enabled browser.** Although the entire page may load momentarily (at most, flashing the company logo for a brief moment), the browser executes the script statement that loads `home1.html` into the window. In the meantime, the image is preloaded into the browser's memory cache. This image should be reused in `home1.html` so the download time isn't wasted on a one-time image. If your pages require a specific browser brand or minimum version number, this is the place to filter out browsers that don't meet the criteria (which may include the installation of a particular plug-in). Use the properties of the `navigator` object (Chapter 38 on the CD-ROM) to write a *browser sniffer script* that allows only those browsers meeting your design minimum to navigate to the scripted home page. All other browsers fall through to the next execution possibility.
- ♦ **A modern browser with JavaScript turned off or missing.** Several modern browsers recognize the special format of the `<meta>` tag as one that loads a URL into the current window after a stated number of seconds. In Listing 13-3, that interval is zero seconds. The `<meta>` tag is executed only if the browser ignores the `<script>` tag. Therefore, any scriptable browser that has JavaScript turned off or any browser that knows `<meta>` tags but no scripting follows the refresh command for the `<meta>` tag. If you utilize this tag, be very careful to observe the tricky formatting of the `content` attribute value. A semicolon and the subattribute `url` follow the number of seconds. A complete URL for your non-scriptable home page version is required for this subattribute. Importantly, the entire `content` attribute value is inside one set of quotes.
- ♦ **Older graphical browsers, compact PDA browsers, and Lynx.** The last category includes graphical browsers with limited capabilities, as well as intentionally stripped-down browsers. Lynx is designed to work in a text-only VT-100 terminal screen; mobile phones, personal digital assistants (PDAs), and handheld computers have browsers

optimized for usage through relatively slow network connections and viewing on small screens. Numerous other browsers are designed to provide Web accessibility for users with disabilities through technologies such as speech synthesis and touch screens (see <http://www.w3.org/WAI>). If such browsers do not understand the `<meta>` tag for refreshing content, they land at this page with no further automatic processing. But by creating an image that acts as a link, the user will likely click (or tap) on it to continue. The link then leads to the nonscriptable home page. Also note that the `alt` attribute for the image is supplied. This takes care of Lynx and compact browsers (with image loading off) because these browsers show the `alt` attribute text in lieu of the image. Users click or tap on the text to navigate to the URL referenced in the link tag.

I have a good reason to keep the background of the branching index page plain. For those whose browsers automatically lead them to a content-filled home page, the browser window flashes from a set background color to the browser's default background color before the new home page and its background color appear. By keeping the initial content to only the company logo, less screen flashing and obvious navigation are visible to the user.

## One link – alternate destinations

Another filtering technique is available directly from links. With the exceptions of NN2 and IE3, a link can navigate to one destination via a link's `onclick` event handler and to another via the `href` attribute if the browser is not scriptable.

The trick is to include an extra `return false` statement in the `onclick` event handler. This statement cancels the link action of the `href` attribute. For example, if a nonscriptable browser should go to one version of a page at the click of a link and the scriptable browser should go to another, the link tag is as follows:

```
<a href="nonJSCatalog.html" onclick="location.href='JSCatalog.html';return false">Product Catalog</a>
```

Only nonscriptable browsers, NN2, and IE3 go to the `nonJSCatalog.html` page; all others go to the `JSCatalog.html` page.

## Object detection

The final methodology for implementing browser version branching is known as *object detection*. The principle is simple: If an object type exists in the browser's object model, it is safe to execute script statements that work with that object.

Perhaps the best example of object detection is the way scripts can swap images on a page in newer browsers without tripping up on older browsers that don't implement images as objects. In a typical image swap, `onmouseover` and `onmouseout` event handlers (assigned to a link surrounding an image, to be backward compatible) invoke functions that change the `src` property of the desired image. Each of those functions is invoked for all scriptable browsers, but you want them to run their statements only when images can be treated as objects.

Object models that implement images always include an array of image objects belonging to the `document` object. The `document.images` array always exists, even with a length of zero when no images are on the page. Therefore, if you wrap the image swapping statements inside an `if` construction that lets browsers pass only if the `document.images` array exists, older browsers simply skip over the statements:

```
function imageSwap(imgName, url) {  
    if (document.images) {  
        document.images[imgName].src = url;  
    }  
}
```

Object detection works best when you know for sure how all browsers implement the object. In the case of `document.images`, the implementation across browsers is identical, so it is a very safe branching condition. That's not always the case, and you should use this feature with careful thought. For example, IE4 introduced a `document` object array called `document.all`, which is used very frequently in building references to HTML element objects. NN4, however, did not implement that array, but instead had a document-level array object called `layers`, which was not implemented in IE4. Unfortunately, many scripters used the existence of these array objects as determinants for browser version. They set global variables signifying a minimum version of IE4 if `document.all` existed and NN4 if `document.layers` existed. This is most dangerous because there is no way of knowing if a future version of a browser may adopt the object of the other browser brand or eliminate a language feature. For example, Opera in its native setting supports the `document.all` array. But if you expect that browser to support every detail of the IE4 browser, scripts will break left and right.

This is why I recommend object detection not for browser version sniffing but for object availability branching, as shown previously for images. Moreover, it is safest to implement object detection only when all major browser brands (and the W3C DOM recommendation) have adopted the object so that behavior is predictable wherever your page loads in the future.

Techniques for object detection include testing for the availability of an object's method. A reference to an object's method returns a value, so such a reference can be used in a conditional statement. For example, the following code fragment demonstrates how a function can receive an argument containing the string ID of an element and convert the string to a valid object reference for three different document object models:

```
function myFunc(elemID) {
    var obj;
    if (document.getElementById) {
        obj = document.getElementById(elemID);
    } else if (document.all) {
        obj = document.all(elemID);
    } else if (document.layers) {
        obj = document.layers[elemID];
    }
    if (obj) {
        // statements that work on the object
    }
}
```

With this object detection scheme, it no longer matters which browser brand, operating system, and version supports a particular way of changing an element ID to an object reference. Whichever of the three `document` object properties or method is supported by the browser (or the first one, if the browser supports more than one), that is the property or method used to accomplish the conversion. If the browser supports none of them, no further statements execute.

If your script wants to check for the existence of an object's property or method, you may also have to check for the existence of the object beforehand if that object is not part of all browsers' object models. An attempt to reference a property of a non-existent object in a conditional expression generates a script error. To avoid the error, you can cascade the conditional tests with the help of the `&&` operator. The following fragment tests for the existence of both the `document.body` object and the `document.body.style` property:

```
if (document.body && document.body.style) {
    // statements that work on the body's style property
}
```

If the test for `document.body` fails, JavaScript bypasses the second test.

One potential “gotcha” to using conditional expressions to test for the existence of an object’s property is that even if the property exists but its value is zero or an empty string, the conditional test reports that the property does not exist. To work around this potential problem, the conditional expression can examine the data type of the value to ensure that the property genuinely exists. A nonexistent property for an object reports a data type of `undefined`. Use the `typeof` operator (see Chapter 32) to test for a valid property:

```
if (document.body && typeof document.body.scroll != "undefined") {  
    // statements that work on the body's scroll property  
}
```

Object detection is the wave of the future, and I wholeheartedly recommend designing your scripts to take advantage of it in lieu of branching on particular browser name strings and version numbers. Scriptable features are gradually finding their way into browsers embedded in a wide range of non-traditional computing devices. These browsers may not go by the same names and numbering systems that we know today, yet such browsers may be able to interpret your scripts. By testing for browser functionality, your scripts will likely require less maintenance in the future. You can see more object detection at work in Chapters 47 and 56 on the CD-ROM.

## Designing for Compatibility

Each new major release of a browser brings compatibility problems for page authors. It’s not so much that old scripts break in the new versions (well-written scripts rarely break in new versions with the rare exception of the jump from NN4 to the new browser engine in Mozilla). No, the problems center on the new features that attract designers when the designers forget to accommodate visitors who have not yet advanced to the latest and greatest browser version or who don’t share your browser brand preference.

Catering only to the lowest common denominator can more than double your development time due to the expanded testing matrix necessary to ensure a good working page in all operating systems and on all versions. Decide how important the scripted functionality you employ in a page is for every user. If you want some functionality that works only in a later browser, you may have to be a bit autocratic in defining the minimum browser for scripted access to your page—any lesser browser gets shunted to a simpler presentation of your site’s data.

Another possibility is to make a portion of the site accessible to most, if not all, browsers, and restrict the scripting to only the occasional enhancement that nonscriptable browser users won’t miss. Once the application reaches a certain point in the navigation flow, the user needs a more capable browser to get to the really good stuff. This kind of design is a carefully planned strategy that lets the site welcome all users up to a point, but then enables the application to shine for users of, say, W3C DOM-compatible browsers.

The ideal page is one that displays useful content on any browser, but whose scripting enhances the experience of the page visitor—perhaps by offering more efficient site navigation or interactivity with the page’s content. That is certainly a worthy goal to aspire to. But even if you can achieve this ideal on only some pages, you will reduce the need for defining entirely separate, difficult-to-maintain paths for browsers of varying capabilities.

Regardless of your specific browser compatibility strategy, the good news is that time tends to minimize the problem. Web standards have solidified greatly in the past few years, and browser vendors are finally making a more serious effort to support those standards. Furthermore, as more of the Web community upgrades to modern browsers, the issue of supporting old browsers becomes less and less significant. Bottom line — there is light at the end of the tunnel.

## Dealing with beta browsers

If you have crafted a skillfully scripted Web page or site, you may be concerned when a pre-release (or *beta*) version of a browser available to the public causes script errors or other compatibility problems to appear on your page. Do yourself a favor — don't overreact to bugs and errors that occur in prerelease browser versions. If your code is well written, it should work with any new generation of browser. If the code doesn't work correctly, consider the browser to be buggy. Report the bug (preferably with a simplified test case script sample) to the browser maker.

The exception to the “it's a beta bug” rule arose in the transition from NN4 to the new Mozilla engine (first released as NN6). As you learn in Chapter 14, a conscious effort to eliminate a proprietary NN4 feature (the `<layer>` tag and corresponding scriptable object) caused many NN4 scripts to break on Moz1 betas (and final release). Had scripters gone to report the problem to the new browsers' developer (Mozilla), they would have learned of the policy change, and planned for the new implementation. It is extremely rare for a browser to eliminate a popular feature so quickly, but it can happen.

It is often difficult to prevent yourself from getting caught up in browser makers' enthusiasm for a new release. But remember that a prerelease version is not a shipping version. Users who visit your page with prerelease browsers should know that there may be bugs in the browser. That your code does not work with a prerelease version is not a sin, nor is it worth losing sleep over. Just be sure to connect with the browser's maker either to find out if the problem will continue in the final release or to report the bug so the problem doesn't make it into the release version.

## The Evaluator Sr.

In Chapter 6, you were introduced to a slimmed-down version of The Evaluator Jr., which provides an interactive workbench to experiment with expression evaluation and object inspection. At this point, you should meet The Evaluator Sr., a tool you will use in many succeeding chapters to help you learn both core JavaScript and DOM terminology.

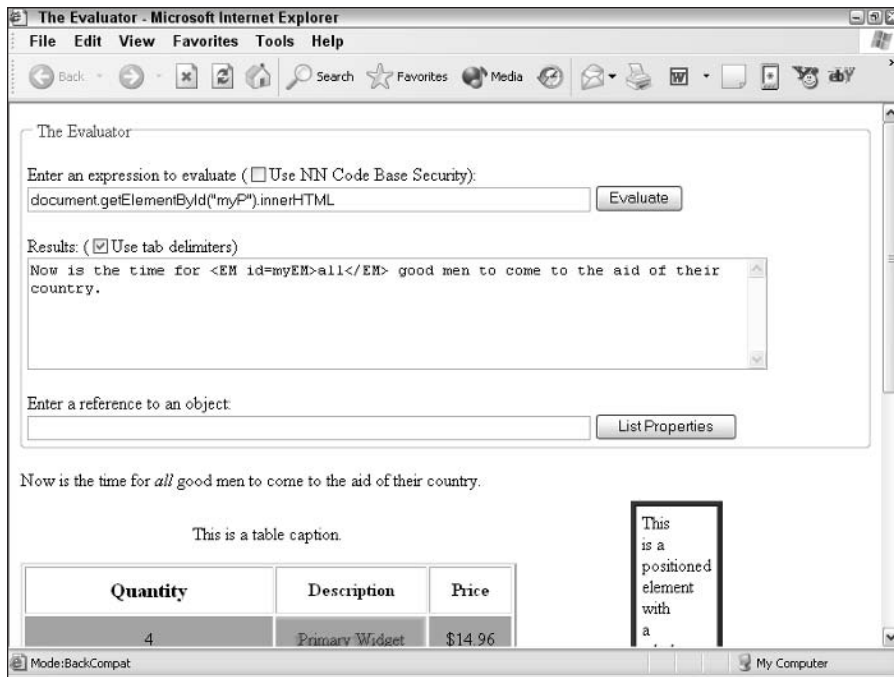

Figure 13-1 shows the top part of the page. Two important features differentiate this full version from the Jr. version in Chapter 6.

## IE Browser Version Headaches

As described more fully in the discussion of the `navigator` object in Chapter 38 on the CD-ROM, your scripts can easily determine which browser is the one running the script. However, the properties that reveal the version don't always tell the whole story about Internet Explorer.

As you can see in detail in Chapter 38 on the CD-ROM, the `navigator.appVersion` property for IE5, 5.5, and 6 for Windows reports version 4 (the same as IE4). You can still “sniff” for versions 5 and 6 (you can find the designation `MSIE 5` or `MSIE6` in the `navigator.userAgent` property), but the process is not as straightforward as it could be. The best advice is to be vigilant when new browsers come on the scene or adopt object detection techniques in your scripts.

**Figure 13-1:** The Evaluator Sr.

First, you can try some Netscape/Mozilla secure features if you have Code Base Principles turned on for your browser (Chapter 46 on the CD-ROM) and you check the Use Code Base Security checkbox (NN4+ only). Second, the page has several HTML elements preinstalled, which you can use to explore DOM properties and methods. As with the smaller version, a set of 26 one-letter global variables (a through z) are initialized and ready for you to assign values for extended evaluation sequences.

You should copy the file `evaluator.html` from the companion CD-ROM to a local hard disk and set a bookmark for it in all of your test browsers. Feel free to add your own elements to the bottom of the page to explore other objects. I describe a version of The Evaluator for embedding in your projects as a debugging tool in Chapter 45 on the CD-ROM, where you can learn more built-in functionality of The Evaluator.

## Compatibility ratings in reference chapters

With the proliferation of scriptable browser versions since Navigator 2, it is important to know up front whether a particular language or object model object, property, method, or event handler is supported in the lowest common denominator for which you are designing. Therefore, beginning with Chapter 15 of this reference part of the book, I include frequent compatibility ratings, such as the following example:

Compatibility: WinIE5+, MacIE5+, NN4+, Moz1.01+, Safari1+

A plus sign after a browser version number means that the language feature was first implemented in the numbered version and continues to be supported in succeeding versions. A minus sign means that the feature is not supported in that browser. The browsers tested for compatibility include Internet Explorer for Windows and Macintosh, Netscape Navigator, Mozilla (including all browsers based on the Mozilla engine), and Apple's Safari. I also recommend that you print the JavaScript and Browser Objects Quick Reference file shown in Appendix A. The file is on the companion CD-ROM in Adobe Acrobat format. This quick reference clearly shows each object's properties, methods, and event handlers, along with keys to the browser version in which each language item is supported. You should find the printout to be valuable as a day-to-day resource.

## Language Essentials for Experienced Programmers

In this section, experienced programmers can read the highlights about the core JavaScript language in terms that may not make complete sense to those with limited or no scripting experience. This section is especially for you if you found the tutorial of Part II rudimentary. Here, then, is the quick tour of the essential issues surrounding the core JavaScript language:

- ♦ **JavaScript is a scripting language.** The language is intended for use in an existing *host environment* (for example, a Web browser) that exposes objects whose properties and behaviors are controllable via statements written in the language. Scripts execute within the context of the host environment. The host environment controls what, if any, external environmental objects may be addressed by language statements running in the host environment. For security and privacy reasons, Web browsers generally afford little or no direct access via JavaScript to browser preferences, the operating system, or other programs beyond the scope of the browser. The exception to this rule is that modern browsers allow deeper client access (with the user's permission) through trust mechanisms such as signed scripts (Netscape) or trusted ActiveX controls (Microsoft).
- ♦ **JavaScript is object-based.** Although JavaScript exhibits many syntactic parallels with the Java language, JavaScript is not as pervasively object-oriented as Java. The core language includes several built-in static objects from which working objects are generated. Objects are created via a call to a constructor function for any of the built-in objects plus the `new` operator. For example, the following expression generates a `String` object and returns a reference to that object:

```
new String("Hello");
```

Table 13-1 lists the built-in objects with which scripters come in contact.

**Table 13-1: JavaScript Built-In Objects**

Array <sup>1</sup>	Boolean	Date	Error <sup>2</sup>
EvalError <sup>2</sup>	Function <sup>1</sup>	Math	Number <sup>1</sup>
Object <sup>1</sup>	RangeError <sup>2</sup>	ReferenceError <sup>2</sup>	RegExp <sup>3</sup>
String <sup>1</sup>	SyntaxError <sup>2</sup>	TypeError <sup>2</sup>	URIError <sup>2</sup>

<sup>1</sup>Although defined in ECMA Level 1, was first available in NN3 and IE3/J2.

<sup>2</sup>Defined in ECMA Level 3; implemented in Moz1.

<sup>3</sup>Defined in ECMA Level 3; implemented fully in NN4 and IE6.

- ♦ **JavaScript is loosely typed.** Variables, arrays, and function return values are not defined to be of any particular data type. In fact, an initialized variable can hold different data type values in subsequent script statements (obviously not good practice, but possible nonetheless). Similarly, an array may contain values of multiple types. The range of built-in data types is intentionally limited:
  - Boolean (true or false)
  - Null
  - Number (double-precision 64-bit format IEEE 754 value)
  - Object (encompassing the Array object)
  - String
  - Undefined
- ♦ **The host environment defines global scope.** Web browsers traditionally define a browser window or frame to be the global context for script statements. When a document unloads, all global variables defined by that document are destroyed.
- ♦ **JavaScript variables have either global or local scope.** A global variable in a Web browser is typically initialized in `var` statements that execute as the document loads. All statements in that document can read or write that global variable. A local variable is initialized inside a function (also with the `var` operator). Only statements inside that function may access that local variable.
- ♦ **Scripts sometimes access JavaScript static object properties and methods.** Some static objects encourage direct access to their properties or methods. For example, all properties of the `Math` object act as constant values (for example, `Math.PI`).
- ♦ **You can add properties or methods to working objects at will.** To add a property to an object, simply assign a value of any type to it. For example, to add an `author` property to a string object named `myText`, use:

```
myText.author = "Jane";
```

Assign a function reference to an object property to give that object a new method:

```
// function definition
function doSpecial(arg1) {
    // statements
}
// assign function reference to method name
myObj.handleSpecial = doSpecial;
...
// invoke method
myObj.handleSpecial(argValue);
```

Inside the function definition, the `this` keyword refers to the object that owns the method.

- ♦ **JavaScript objects employ prototype-based inheritance.** All object constructors create working objects whose properties and methods inherit the properties and methods defined for the *prototype* of that object. Starting with NN3 and late versions of IE3, scripts can add and delete custom properties and/or methods associated with the static object's prototype so that new working objects inherit the current state of the

prototype. Scripts can freely override prototype property values or assign different functions to prototype methods in a working object if desired without affecting the static object prototype. But if inherited properties or methods are not modified in the current working object, any changes to the static object's prototype are reflected in the working object. (The mechanism is that a reference to an object's property works its way up the prototype inheritance chain to find a match to the property name.)

- ♦ **JavaScript includes a large set of operators.** You can find most operators that you are accustomed to working with in other languages.
- ♦ **JavaScript provides typical control structures.** All versions of JavaScript offer `if`, `if-else`, `for`, and `while` constructions. JavaScript 1.2 (NN4+ and IE4+) added `do-while` and `switch` constructions. Iteration constructions provide `break` and `continue` statements to modify control structure execution.
- ♦ **JavaScript functions may or may not return a value.** There is only one kind of JavaScript function. A value is returned only if the function includes a `return` keyword followed by the value to be returned. Return values can be of any data type.
- ♦ **JavaScript functions cannot be overloaded.** A JavaScript function accepts zero or more arguments, regardless of the number of parameter variables defined for the function. All arguments are automatically assigned to the `arguments` array, which is a property of a function object. Parameter variable data types are not predefined.
- ♦ **Values are passed “by reference” and “by value.”** An object passed to a function is actually a reference to that object, offering full read/write access to properties and methods of that object. But other types of values (including object properties) are passed by value, with no reference chain to the original object. Thus, the following nonsense fragment empties the text box when the `onchange` event fires:

```
function emptyMe(arg1) {
    arg1.value = "";
}
...
<input type="text" value="Howdy" onchange="emptyMe(this)">
```

But in the following version, nothing happens to the text box:

```
function emptyMe(arg1) {
    arg1 = "";
}
...
<input type="text" value="Howdy" onchange="emptyMe(this.value)">
```

The local variable (`arg1`) simply changes from "Howdy" to an empty string.

- ♦ **Error trapping techniques depend on JavaScript version.** There is no error trapping in NN2 or IE3. Error trapping in NN3, NN4, and IE4 is event-driven in the Web browser object model. JavaScript, as implemented in IE5+ and Moz1+, Safari, and other recent browsers, supports `try-catch` and `throw` statements, as well as built-in error objects that are not dependent on the host environment.
- ♦ **Memory management is not under script control.** The host environment manages memory allocation, including garbage collection. Different browsers may handle memory in different ways.
- ♦ **White space (other than a line terminator) is insignificant.** Space and tab characters may separate lexical units (for example, keywords, identifiers, and so on).

- ♦ **A line terminator is usually treated as a statement delimiter.** Except in very rare constructions, JavaScript parsers automatically insert the semicolon statement delimiter whenever they encounter one or more line terminators (for example, carriage returns or line feeds). A semicolon delimiter is required between two statements on the same physical line of source code. Moreover, string literals may not have carriage returns in their source code (but an escaped newline character `(\n)` may be a part of the string).

## Onward to Object Models

The core language is only a small part of what you work with while scripting Web pages. The bulk of your job entails understanding the ins and outs of document object models as implemented in several generations of browsers. That's where the next chapter picks up the “essentials” story.

# Document Object Model Essentials

---

**W**ithout question, the biggest challenge facing client-side Web scripters is the sometimes-baffling array of document object models that have competed for our attention throughout the short history of scriptable browsers. Netscape got the ball rolling in Navigator 2 with the first object model. By the time the version 4 browsers came around, the original object model had gained not only some useful cross-browser features, but also a host of features that were unique to only Navigator or Internet Explorer. The object models were diverging, causing no end of headaches for page authors whose scripts had to run on as many browsers as possible. A ray of hope emerged from the standards process of the World Wide Web Consortium (W3C) in the form of a document object model (DOM) recommendation. The DOM brought forward much of the original object model, plus new ways of addressing every object in a document. The goal of this chapter is to put each of the object models into perspective and help you select the model(s) you intend to support in your Web applications. But before we get to those specifics, let's examine the role of the object model in designing scripted applications.

## The Object Model Hierarchy

In the tutorial chapters of Part II, you were introduced to the fundamental ideas behind a document object hierarchy in scriptable browsers. In other object-oriented environments, object hierarchy plays a much greater role than it does in JavaScript-able browsers. (In JavaScript, you don't have to worry about related terms, such as classes, inheritance, and instances.) Even so, you cannot ignore the hierarchy concept because much of your code relies on your ability to write references to objects that depend on their positions within the hierarchy.

Calling these objects "JavaScript objects" is not entirely correct. These are really browser document objects: you just happen to use the JavaScript language to bring them to life. Some scripters of Microsoft Internet Explorer use the VBScript language to script the very same document objects. Technically speaking, JavaScript objects apply to data types and other core language objects separate from the document. The more you can keep document and core language objects separate in your head, the more quickly you can deal with browser brand compatibility issues.

### In This Chapter

Object models versus browser versions

Proprietary model extensions

Structure of the W3C DOM

Mixing object models in a single document

## Hierarchy as road map

For the programmer, the primary role of the document object hierarchy is to provide scripts with a way to reference a particular object among all the objects that a browser window can contain. The hierarchy acts as a road map the script can use to know precisely which object to address.

Consider, for a moment, a scene in which you and your friend Tony are in a high school classroom. It's getting hot and stuffy as the afternoon sun pours in through the wall of windows on the west side of the room. You say to Tony, "Would you please open a window?" and motion your head toward a particular window in the room. In programming terms, you've issued a command to an object (whether or not Tony appreciates the comparison). This human interaction has many advantages over anything you can do in programming. First, by making eye contact with Tony before you speak, he knows that he is the intended recipient of the command. Second, your body language passes along some parameters with that command, pointing ever so subtly to a particular window on a particular wall.

If, instead, you are in the principal's office using the public address system, and you broadcast the same command, "Would you please open a window?," no one knows what you mean. Issuing a command without directing it to an object is a waste of time because every object thinks, "That can't be meant for me." To accomplish the same goal as your one-on-one command, the broadcast command has to be something like, "Would Tony Jeffries in Room 312 please open the middle window on the west wall?"

Let's convert this last command to JavaScript *dot syntax* form (see Chapter 4). Recall from the tutorial that a reference to an object starts with the most global point of view and narrows to the most specific point of view. From the point of view of the principal's office, the location hierarchy of the target object is

```
room312.Jeffries.Tony
```

You can also say that Tony's knowledge about how to open a window is one of Tony's methods. The complete reference to Tony and his method then becomes

```
room312.Jeffries.Tony.openWindow()
```

Your job isn't complete yet. The method requires a parameter detailing which window to open. In this case, the window you want is the middle window of the west wall of Room 312. Or, from the hierarchical point of view of the principal's office, it becomes

```
room312.westWall.middleWindow
```

This object road map is the parameter for Tony's `openWindow()` method. Therefore, the entire command that comes over the PA system is

```
room312.Jeffries.Tony.openWindow(room312.westWall.middleWindow)
```

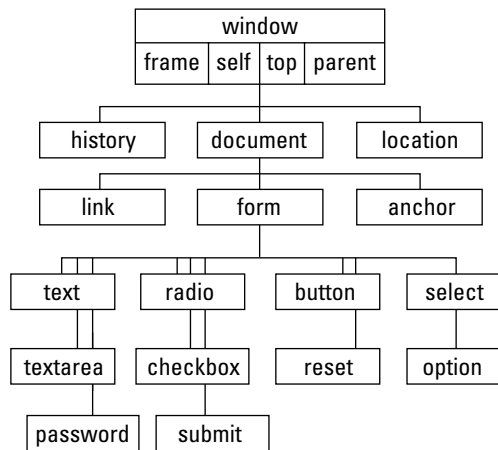

If, instead of barking out orders while sitting in the principal's office, you attempt the same task via radio from an orbiting space shuttle to all the inhabitants on Earth, imagine how laborious your object hierarchy is. The complete reference to Tony's `openWindow()` method and the window that you want opened has to be mighty long to distinguish the desired objects from the billions of objects within the space shuttle's view.

The point is that the smaller the scope of the object-oriented world you're programming, the more you can assume about the location of objects. For client-side JavaScript, the scope is no wider than the browser itself. In other words, every object that a JavaScript script can work

with resides within the browser application. With few exceptions, a script does not access anything about your computer hardware, operating system, other applications, desktop, or any other stuff beyond the browser program.

## The browser document object road map

Figure 14-1 shows the lowest common denominator document object hierarchy that is implemented in all scriptable browsers. Notice that the `window` object is the topmost object in the entire scheme. Everything you script in JavaScript is in the browser's window.

**Figure 14-1:** The lowest common denominator browser document object hierarchy.

Pay attention to the shading of the concentric rectangles. Every object in the same shaded area is at the same level relative to the `window` object. When a line from an object extends to the next darker shaded rectangle, that object contains all the objects in darker areas. There exists, at most, one of these lines between levels. The `window` object contains the `document` object; the `document` object contains a `form` object; a `form` object contains many different kinds of form control elements.

Study Figure 14-1 to establish a mental model for the basic scriptable elements of a Web page. Models of more recent browsers have more objects in their hierarchies, but the fundamental organization remains. After you script these objects several times, the object hierarchy will become second nature to you — even if you don't necessarily remember every detail (property, method, and event handler) of every object. At least you know where to look for information.

## How Document Objects Are Born

Most of the objects that a browser creates for you are established when an HTML document loads into the browser. The same kind of HTML code you use to create links, anchors, and input elements tells a JavaScript-enhanced browser to create those objects in memory. The objects are there whether or not your scripts call them into action.

The only visible differences to the HTML code for defining those objects are the one or more optional attributes specifically dedicated to JavaScript. By and large, these attributes specify the event you want the user interface element to react to and what JavaScript should do when the user takes that action. By relying on the document's HTML code to perform the object generation, you can spend more time figuring out how to do things with those objects or have them do things for you.

Bear in mind that objects are created in their load order. And if you create a multiframe environment, a script in one frame cannot communicate with another frame's objects until both frames load. This trips up a lot of scripters who create multiframe and multiwindow sites (more in Chapter 16).

## Object Properties

A property generally defines a particular current setting of an object. The setting may reflect a visible attribute of an object, such as the state of a checkbox (checked or not); it may also contain information that is not so obvious, such as the action and method of a submitted form.

Document objects have most of their initial properties assigned by the attribute settings of the HTML tags that generate the objects. Thus, a property may be a word (for example, a name) or a number (for example, a size). A property can also be an array, such as an array of images contained by a document. If the HTML does not include all attributes, the browser usually fills in a default value for both the attribute and the corresponding JavaScript property.

When used in script statements, property names are case-sensitive. Therefore, if you see a property name listed as `bgColor`, you must use it in a script statement with that exact combination of lowercase and uppercase letters. But when you set an initial value of a property by way of an HTML attribute, the attribute name (like all of HTML) is not case-sensitive. Thus, `<BODY BGCOLOR="white">` and `<body bgcolor="white">` both set the same `bgColor` property value. Although XHTML won't validate correctly if you use anything but lowercase letters for tag and attribute names, most browsers continue to be case-insensitive for markup, regardless of the HTML or XHTML version you specify for the page's `DOCTYPE`. The case for property names is not influenced by the case of the markup attribute name.

Each property determines its own read/write status. Some properties are read-only, whereas you can change others on the fly by assigning a new value to them. For example, to put some new text into a text box object, you assign a string to the object's `value` property:

```
document.forms[0].phone.value = "555-1212";
```

Once an object contained by the document exists (that is, its HTML is loaded into the document), you can also add one or more custom properties to that object. This can be helpful if you wish to associate some additional data with an object for later retrieval. To add such a property, simply specify it in the same statement that assigns a value to it:

```
document.forms[0].phone.delimiter = "-";
```

Any property you set survives as long as the document remains loaded in the window and scripts do not overwrite the object. Be aware, however, that reloading the page usually destroys custom properties.

## A Note to Experienced Object-Oriented Programmers

Although the basic object model hierarchy appears to have a class/subclass relationship, many of the traditional aspects of a true, object-oriented environment don't apply to the model. The original JavaScript document object hierarchy is a *containment hierarchy*, not an *inheritance hierarchy*. No object inherits properties or methods of an object higher up the chain. Nor is there any automatic message passing from object to object in any direction. Therefore, you cannot invoke a window's method by sending a message to it via the `document` or a form object. All object references must be explicit.

Predefined document objects are generated only when the HTML code containing their definitions loads into the browser. You cannot modify many properties, methods, and event handlers in early object models once you load the document into the browser. In Chapter 33, you learn how to create your own objects, but those objects do not present new visual elements on the page that go beyond what HTML, Java applets, and plug-ins can portray.

Inheritance *does* play a role, as you will see later in this chapter, in the object model defined by the W3C. The new hierarchy is of a more general nature to accommodate requirements of XML as well as HTML. But the containment hierarchy for HTML objects, as described in this section, is still valid in W3C DOM-compatible browsers.

## Object Methods

An object's method is a command that a script can give to that object. Some methods return values, but that is not a prerequisite for a method. Also, not every object has methods defined for it. In a majority of cases, invoking a method from a script causes some action to take place. The resulting action may be obvious (such as resizing a window) or something more subtle (such as sorting an array in memory).

All methods have parentheses after them, and they always appear at the end of an object's reference. When a method accepts or requires parameters, the parameter values go inside the parentheses (with multiple parameters separated by commas).

While an object has its methods predefined by the object model, you can also assign one or more additional methods to an object that already exists (that is, after its HTML is loaded into the document). To do this, a script in the document (or in another window or frame accessible by the document) must define a JavaScript function and then assign that function to a new property name of the object. In the following example written to take advantage of version 4 or later browser features, the `fullScreen()` function invokes one `window` object method and adjusts two `window` object properties. By assigning the function reference to the new `window.maximize` property, I define a `maximize()` method for the `window` object. Thus, a button's event handler can call that method directly.

```
// define the function
function fullScreen() {
    this.moveTo(0,0);
    this.outerWidth = screen.availWidth;
    this.outerHeight = screen.availHeight;
}
// assign the function to a custom property
window.maximize = fullScreen;
...
<!-- invoke the custom method -->
<input type="button" value="Maximize Window" onclick="window.maximize()" />
```

## Object Event Handlers

An *event handler* specifies how an object reacts to an event that is triggered by a user action (for example, a button click) or a browser action (for example, the completion of a document load). Going back to the earliest JavaScript-enabled browser, event handlers were defined inside HTML tags as extra attributes. They included the name of the attribute, followed by an equal sign (working as an assignment operator) and a string containing the script statement(s) or function(s) to execute when the event occurs (see Chapter 5). Event handlers also have other forms. In NN3+ and IE4+, event handlers have corresponding methods for their objects and every event handler is a property of its object.

### Event handlers as methods

Consider a button object whose sole event handler is `onclick`. This means whenever the button receives a click event, the button triggers the JavaScript expression or function call assigned to that event handler in the button's HTML definition:

```
<input type="button" name="clicker" value="Click Me" onclick="doIt()" />
```

Normally, that click event is the result of a user physically clicking the button in the page. In NN3+ and IE4+, you can also trigger the event handler with a script by calling the event handler as if it were a method of the object:

```
document.formName.clicker.onclick();
```

Invoking an event handler this way is different from using a method to simulate the physical action denoted by the event. For example, imagine a page containing three simple text fields. One of those fields has an `onfocus` event handler defined for it. Physically tabbing to or clicking in that field brings focus to the field and thereby triggers its `onfocus` event handler. If the field does not have focus, a button can invoke that field's `onfocus` event handler by referencing it as a method:

```
document.formName.fieldName.onfocus();
```

This scripted action does not bring physical focus to the field. The field's own `focus()` method, however, does that under script control.

A byproduct of an event handler's capability to act like a method is that you can define the action of an event handler by defining a function with the event handler's name. For example, instead of specifying an `onload` event handler in a document's `<body>` tag, you can define a function like this:

```
function onload() {  
    statements  
}
```

This capability is particularly helpful if you want event handler actions confined to a script running in NN3, IE4, or later. Your scripts don't require special traps for Navigator 2 or Internet Explorer 3.

### Event handlers as properties

Although event handlers are commonly defined in an object's HTML tag, you also have the power in NN3+ and IE4+ to assign or change an event handler just like you assign or change the property of an object. The value of an event handler property looks like a function definition. For example, given this HTML definition:

```
<input type="text" name="entry" onfocus="doIt()" />
```

the value of the object's `onfocus` (all lowercase) property is

```
function onfocus() {  
    doIt();  
}
```

You can, however, assign an entirely different function to an event handler by assigning a function reference to the property. Such references don't include the parentheses that are part of the function's definition. (You see this again much later in Chapter 33 when you assign functions to object properties.)

Using the same text field definition you just looked at, you can assign a different function to the event handler because based on user input elsewhere in the document you want the field to behave differently when it receives the focus. If you define a function like this:

```
function doSomethingElse() {  
    statements  
}
```

you can then assign the function to the field with this assignment statement:

```
document.formName.entry.onfocus = doSomethingElse;
```

Because the new function reference is written in JavaScript, you must observe case for the function name. Although NN4 accepts interCap versions of the event handler names, you are best served across all browsers by sticking with all lowercase event handler names as properties.

**Caution**

Be aware, however, that as with several settable object properties that don't manifest themselves visually, any change you make to an event handler property disappears with a document reload. Therefore, I advise you not to make such changes except as part of a script that also invokes the event handler like a method: Any gap in time leaves room for users to reload the page accidentally or intentionally.

If your scripts create new element objects dynamically, you can assign event handlers to these objects by way of event handler properties. For example, the following code uses W3C DOM syntax to create a new button input element and assign an `onclick` event handler that invokes a function defined elsewhere in the script:

```
var newElem = document.createElement("input");  
newElem.type = "button";  
newElem.value = "Click Here";  
newElem.onclick = doIt;  
document.forms[0].appendChild(newElem);
```

Because every event handler operates as both property and method, I don't list these properties and methods as part of each object's definition in the next chapters. You can be assured this feature works for every JavaScript object that has an event handler starting with Navigator 3 and Internet Explorer 4.

## Object Model Smorgasbord

A survey of the entire evolution of scriptable browsers from NN2 and IE3 through IE6 and Moz1 reveals six (yes, six!) distinct document object model families. Even if your job entails developing content for just one current browser version, you may be surprised that family members from more than one document object model inhabit your authoring space.

Studying the evolution of the object model is extremely valuable for newcomers to scripting. It is too easy to learn the latest object model gadgets in your current browser, only to discover that your heroic scripting efforts are lost on earlier browsers accessing your pages. Therefore, take a look at the six major object model types and how they came into being. Table 14-1 lists the object model families (in chronological order of their release) and the browser versions that support them. Later in this chapter are some guidelines you can follow to help you choose the object model(s) that best suit your users' "appetites."

**Table 14-1: Object Model Families**

<i>Model</i>	<i>Browser Support</i>
Basic Object Model	NN2, NN3, IE3/J1, IE3/J2, NN4, IE4, IE5, IE5.5, IE6, Moz1, Safari1
Basic Plus Images	NN3, IE3.01 (Mac only), NN4, IE4, IE5, IE5.5, IE6, Moz1, Safari1
NN4 Extensions	NN4
IE4 Extensions	IE4, IE5, IE5.5, IE6 (some features in all versions require Win32 OS)
IE5 Extensions	IE5, IE5.5, IE6 (some features in all versions require Win32 OS)
W3C DOM (I and II)	IE5 (partial), IE5.5 (partial), IE6 (partial), Moz1 (most), Safari 1 (partial)

## Basic Object Model

The first scriptable browser, Netscape Navigator 2, implemented a very basic document object model. Figure 14-1 provides a visual guide to the objects that were exposed to scripting. The hierarchical structure starts with the window and drills inward toward the document, forms, and form control elements. A document is a largely immutable page on the screen. Only elements that are by nature interactive — links and form elements such as text fields, buttons, and so on — are treated as objects with properties, methods, and event handlers.

The heavy emphasis on form controls opened up numerous possibilities that were radical ideas at the time. Because a script could inspect the values of form controls, forms could be pre-validated on the client. If the page included a script that performed some calculations, data entry and calculated results were displayed via editable text fields.

Additional objects that exist outside of the document — `window`, `history`, and `location` objects — provide scriptable access to simple yet practical properties of the browser that loads the page. The most global view of the environment is the `navigator` object, which includes properties about the browser brand and version.

When Internet Explorer 3 arrived on the scene, the short life of Navigator 2 was nearing its end. Even though NN3 was already widely available in prerelease form, IE3 implemented the basic object model from NN2 (plus one `window` object property from NN3). Therefore, despite the browser version number discrepancy, NN2 and IE3 are essentially the same with respect to their document object models. For a brief moment in Internet Time, there was nearly complete harmony between Microsoft and Netscape document object models — albeit at a very simple level.

## Basic Object Model Plus Images

A very short time after IE3 was released, Netscape released Navigator 3 with an object model that built upon the original version. A handful of existing objects — especially the `window` object — gained new properties, methods, and/or event handlers. Scripts could also communicate with Java applets as objects. But the biggest new object on the scene was the `Image` object and the array of image objects exposed to the `document` object.

Most of the properties for an NN3 image object gave read-only access to values typically assigned to attributes in the `<img>` tag. But you could modify one property — the `src` property — after the page loaded. Scripts could swap out images within the fixed image rectangle. Although these new image objects didn't have mouse-related event handlers, nesting an image inside a link (which had `onmouseover` and `onmouseout` event handlers) let scripts implement “image rollovers” to liven up a page.

As more new scripters investigated the possibilities of adding JavaScript to their pages, frustration ensued when the image swapping they implemented for NN3 failed to work in IE3. Although you could easily script around the lack of an image object to prevent script errors in IE3 (see Chapter 12), the lack of this “cool” page feature disappointed many. Had they also taken into account the installed base of NN2 in the world, they would have been disappointed there, too. To confuse matters even more, the Macintosh version of IE 3.01 (the second release of the IE3/Mac browser) implemented scriptable image objects.

Despite these rumblings of compatibility problems to come, the object model implemented in Navigator 3 eventually became the baseline reference for future document object models. With few exceptions, code written for this object model runs on all browsers from NN3 and IE4 through the latest versions of both brands. Exceptions primarily involve Java applet object support in non-Windows versions of IE4+.

## Navigator 4–Only Extensions

The next browser released to the world was Netscape Navigator 4. Numerous additions to the existing objects put more power into the hands of scripters. You could move and resize browser windows within the context of script-detectable `screen` object properties (for example, how big the user's monitor screen was). Two concepts that represented new thinking about the object model were an enhanced event model and the layer object.

### Event capture model

Navigator 4 added many new events to the repertoire. Keyboard events and more mouse events (`onmousedown` and `onmouseup`) allowed scripts to react to more user actions on form control elements and links. All of these events worked as they did in previous object models in which event handlers were typically assigned as attributes to an element's tag (although you could also assign event handlers as properties in script statements). To facilitate some of the Dynamic HTML potential in the rest of the Navigator 4 object model, the event model was substantially enhanced.

At the root of the system is the idea that when a user performs some physical action on an event-aware object (for example, clicking a form button), the event reaches that button from top down through the document object hierarchy. If you have multiple objects that share the

same event handler, it may be more convenient to capture that event in just one place—the `window` or `document` object level—rather than assigning the same event handler to all the elements. The default behavior of Navigator 4 allowed the event to reach the target object, just as it had in earlier browsers. But you could also turn on *event capture* in the `window`, `document`, or `layer` object. Once captured, the event could be handled at the upper level, preprocessed before being passed onto its original target, or redirected to another object altogether.

Whether or not you capture events, the Navigator 4 event model produces an event object (lowercase “e” to distinguish from the static `Event` object) for each event. That object contains properties that reveal more information about the specific event, such as the keyboard character pressed for a keyboard event or the position of a click event on the page. Any event handler can inspect event object properties to learn more about the event and process the event accordingly.

## Layers

Perhaps the most radical addition to the NN4 object model was a new object that reflected an entirely new HTML element, the `layer` element. A *layer* is a container that is capable of holding its own HTML document, yet it exists in a plane in front of the main document. You can move, size, and hide a layer under script control. This new element allowed, for the first time, overlapping elements in an HTML page.

To accommodate the layer object in the document object hierarchy, Netscape defined a nesting hierarchy such that a layer was contained by a document. As the result, the `document` object acquired a property (`document.layers`) that was an array of layer objects in the document. This array exposed only the first level of layer(s) in the current `document` object. References to a layer in the main document started with any one of the following:

```
document.layerName
document.layers[n]
document.layers[layerName]
```

Each layer had its own `document` object because each layer could load an external HTML document if desired. Thus, if a script needed access to, say, a form control element inside a layer, the reference would begin:

```
document.layerName.document.forms[0]...
```

If a layer contained yet another layer, the reference grew even longer:

```
document.outerLayerName.document.innerLayerName.document.forms[0]...
```

As a positionable element, a layer object had numerous properties and methods that allowed scripts to move, hide, show, and change its stacking order.

Unfortunately for Netscape, the W3C did not agree to make the `<layer>` tag a part of the HTML 4.0 specification. As such, it is an orphan element that exists only in Navigator 4 (not implemented in Moz1 or later). The same goes for the scripting of the layer object and its nested references. Navigator 4 does, however, implement a little bit of the HTML 4.0 and CSS specifications for positionable elements because you can assign Cascading Style Sheets (with the position and related attributes) to `div` and `span` elements in NN4. Navigator treats positioned `div` or `span` elements as near equivalents of layer objects for scripting purposes. This means, however, that even if you can get the HTML to work the same across browsers (not always guaranteed due to occasionally different rendering characteristics of positioned `div`

elements in NN4 and IE4), the scripting for NN4 must adhere to the layer syntax, which differs from the IE4 CSS syntax.

## Internet Explorer 4+ Extensions

Microsoft broke important new ground with the release of IE4, which came several months after the release of NN4. The main improvements were in the exposure of all HTML elements, scripted support of CSS, and a new event model. Some other additions were available only on Windows 32-bit operating system platforms.

### HTML element objects

The biggest change to the object model world was that every HTML element became a scriptable object, while still supporting the original object model. Microsoft invented the `document.all` array (also called a *collection*). This array contains references to every element in the document, regardless of element nesting. If you assign an identifier (name) to the `id` attribute of an element, you can reference the element by the following syntax:

```
document.all.elementID
```

In most cases, you can also drop the `document.all.` part of the reference and begin with only the element ID.

Every element object has an entirely new set of properties and methods that give scripters a level of control over document content unlike anything seen before. Table 14-2 shows the properties and methods that all HTML element objects have in common in IE4 (properties followed by brackets are arrays).

**Table 14-2: IE4 HTML Element Features in Common**

<i>Properties</i>	<i>Methods</i>
<code>all[]</code>	<code>click()</code>
<code>children[]</code>	<code>contains()</code>
<code>className</code>	<code>getAttribute()</code>
<code>document</code>	<code>insertAdjacentHTML()</code>
<code>filters[]</code>	<code>insertAdjacentText()</code>
<code>id</code>	<code>removeAttribute()</code>
<code>innerHTML</code>	<code>scrollIntoView()</code>
<code>innerText</code>	<code>setAttribute()</code>
<code>isTextEdit</code>	
<code>lang</code>	
<code>language</code>	
<code>offsetHeight</code>	
<code>offsetLeft</code>	
<code>offsetParent</code>	

*Continued*

**Table 14-2** (continued)

<i>Properties</i>	<i>Methods</i>
offsetTop	
offsetWidth	
outerHTML	
outerText	
parentElement	
parentTextEdit	
sourceIndex	
style	
tagName	
title	

You can find details for all of the items listed in Table 14-2 in Chapter 15. But several groups of properties deserve special mention here.

Four properties (`innerHTML`, `innerText`, `outerHTML`, and `outerText`) provide read/write access to the actual content within the body of a document. This means that you no longer must use text boxes to display calculated output from scripts. You can modify content inside paragraphs, table cells, or anywhere on the fly. The browser's rendering engine immediately reflows a document when the dimensions of an element's content change. That feature puts the "Dynamic" in "Dynamic HTML." To those of us who scripted the static pages of earlier browsers, this feature — now taken for granted — was nothing short of a revelation.

The series of "offset" properties are related to the position of an element on the page. These properties are distinct from the kind of positioning performed by CSS. Therefore, you can get the dimensions and location of any element on the page, making it easier to move positionable content atop elements that are part of the document and may appear in various locations due to the browser window's current size.

Finally, the `style` property is the gateway to CSS specifications defined for the element. Importantly, the script can modify the numerous properties of the `style` object. Therefore, you can modify font specifications, colors, borders, and the positioning properties after the page loads. The dynamic reflow of the page takes care of any layout changes that the alteration requires (for example, adjusting to a bigger font size).

## Element containment hierarchy

While IE4 still recognizes the element hierarchy of the original object model (see Figure 14-1), the document object model for IE4 does not extend this kind of hierarchy fully into other elements. If it did, it would mean that `td` elements inside a table might have to be addressed via its next outer `tr` or `table` element (just as a form control element must be addressed via its containing `form` element). Look at Figure 14-2 to see how all HTML elements are grouped together under the document object. The `document.all` array flattens the containment hierarchy as far as referencing object goes. A reference to the most deeply nested TD element is still `document.all.cellID`. The highlighted pathway from the `window` object is the predominant reference path used when working with the IE4 document object hierarchy.

**Figure 14-2:** The IE4 document object hierarchy.

Element containment in IE4, however, is important for other reasons. Because an element can inherit some stylesheet attributes from an element that contains it, you should devise a document's HTML by embedding every piece of content inside a container. Paragraph elements are text containers (with start and end tags), not tall line breaks between text chunks. IE4 introduced the notion of a parent-child relationship between a container and elements nested within it. Also, the position of an element may be calculated relative to the position of its next outermost positioning context.

The bottom line here is that element containment doesn't have anything to do with object references (like the original object model). It has everything to do with the *context* of an element relative to the rest of the page's content.

## Cascading Style Sheets

By arriving a bit later to market with its version 4 browser than Netscape, Microsoft benefited from having the CSS Level 1 specification more fully developed before the browser's release. Therefore, the implementation is far more complete than that of NN4 (but it is not 100 percent compatible with the standard).

I should point out that the scriptability of stylesheet properties is a bit at odds with the first-generation CSS specification, which seemed to ignore the potential of scripting styles with JavaScript. Many CSS attribute names are hyphenated words (for example, `text-align`, `z-index`). But hyphens are not allowed in identifier names in JavaScript. This necessitated conversion of the multiword CSS attribute names to interCap JavaScript property names. Therefore, `text-align` becomes `textAlign` and `z-index` becomes `zIndex`. You can access all of these properties through an element's `style` property:

```
document.all.elementID.style.stylePropertyName
```

One byproduct of the scriptability of stylesheets in IE4 and later is what some might call the *phantom page syndrome*. This occurs when the layout of a page is handled after the primary HTML for the page has downloaded to the browser. As the page loads, not all content may be visible, or it may be in a visual jumble. An `onload` event handler in the page then triggers scripts to set styles and/or content for the page. Elements jump around to get to their final resting places. This may be disconcerting to some users who at first see a link to click; but by

the time the cursor reaches the click location, the page has reflowed, thereby moving the link to somewhere else on the page.

**Note**

For Internet Explorer users with 32-bit Windows operating systems, IE4 includes some extra features in the object model that can enhance presentations. *Filters* are stylesheet additives that offer a variety of visual effects on body text. For example, you can add a drop shadow or a glowing effect to text by simply applying filter styles to the text, or you can create the equivalent of a slide presentation by placing the content of each slide in a positioned `div` element. Although filters follow the CSS syntax, they are not a part of the W3C specification.

## Event bubbling

Just as Netscape invented an event model for NN4, so, too, did Microsoft invent one for IE4. Unfortunately for cross-browser scripters, the two event models are quite different. Instead of events trickling down the hierarchy to the target element, an IE event starts at the target element and, unless instructed otherwise, “bubbles up” through the element containment hierarchy to eventually reach the `window` object. At any object along the way, an event handler can perform additional processing on that event if desired. Therefore, if you want a single event handler to process all click events for the page, assign the event handler to the `body` or `window` object so the events reach those objects (provided the event bubbling isn’t cancelled by some other object along the containment hierarchy).

IE also has an `event` object (a property of the `window` object) that contains details about the event, such as the keyboard key pressed for a keyboard event and the location of a mouse event. Names for these properties are entirely different from the event object properties of NN4.

Despite what seems like incompatible, if not completely opposite, event models in NN4 and IE4, you can make a single set of scripts handle events in both browsers (see Chapter 25 and Chapter 56 on the CD-ROM for examples). In fact, the two event models are made to work together in the W3C DOM Level 2 specification, described later in this chapter.

## Event binding of scripts

IE4 introduced an additional way of binding events to objects via a `<script>` tag that has two additional, non-W3C attributes: `for` and `event` (see a syntax example in Chapter 13 in the section titled “`<script for>` tags”). The value assigned to the `for` attribute is the ID of an element object for which the script is intended; the value of the `event` attribute is the name of the event handler (for example, `onclick`) by which the script statements within the tag are to be triggered.

Inside the tags are straight script statements, but when the browser sees the special attributes, execution is deferred until the event fires for the designated object. The instant the event fires for the object, the script statements inside the tag execute. This special form of script tag takes the place of a function definition assigned to the event handler by other means. This technique appears to have been a “dry run” for what eventually became DHTML behaviors in IE5/Windows (see the following section).

You can use this binding method only if you run the page inside IE4+. All other browsers, including IE3, ignore the special attributes and treat the statements inside the tags as statements to execute as the page loads.

## Internet Explorer 5+ Extensions

With the release of IE5, Microsoft built more onto the proprietary object model it launched in IE4. Although the range of objects remained pretty much the same, the number of properties, methods, and event handlers for the objects increased dramatically. Some of those additions were added to meet some of the specifications of the W3C DOM (discussed in the next section), occasionally causing a bit of incompatibility with IE4. But Microsoft also pushed ahead with efforts for Windows users only that may not necessarily become industry standards: DHTML behaviors and HTML applications.

A *DHTML behavior* is a chunk of script — saved as an external file — that defines some action (usually a change of one or more style properties) that you can apply to any kind of element. The goal is to create a reusable component that you can load into any document whose elements require that behavior. The behavior file is known as an *HTML component*, and the file has an `.htc` extension. Components are XML documents whose XML tags specify events and event-handling routines for whatever element is assigned that behavior. Script statements in `.htc` documents are written inside `<script>` tag sets just as in regular, scriptable HTML documents. As an example of a DHTML behavior, you can define a behavior that turns an element's text to red whenever the cursor rolls atop it and reverts to black when the cursor rolls out. When you assign the behavior to an element in the document (via CSS-like rule syntax), the element picks up that behavior and responds to the user accordingly. You can apply that same behavior to any element(s) you like in the document. (Microsoft has submitted behaviors to the W3C for possible inclusion into CSS Level 3.) You can see an example of a DHTML behavior in Chapter 15's description of the `addBehavior()` method and read an extended discussion in Chapter 47 on the CD-ROM.

*HTML applications* (HTAs in Microsoft parlance) are HTML files that include an XML element known as the `hta:application` element. You can download an HTA to IE5+ from the server as if it were a Web page (although its file extension is `.hta` rather than `.htm` or `.html`). A user can also install an HTA on a client machine so it behaves very much like an application with a Desktop icon and significant control over the look of the window. HTAs are granted greater security privileges on the client so that this “application” can behave more like a regular program. In fact, you can elect to turn off the system menu bar and use DHTML techniques to build your own menu bar for the application. Implementation details of HTAs are beyond the scope of this book, but you should be aware of their existence. More information is available at <http://msdn.microsoft.com>.

## The W3C DOM

Conflicting browser object models from Netscape and Microsoft made life difficult for developers. Scripters craved a standard that would serve as a common denominator much like HTML and CSS standards did for content and styles. The W3C took up the challenge of creating a document object model standard, the W3C DOM.

The charter of the W3C DOM working group was to create a document object model that could be applied to both HTML and XML documents. Because an XML document can have tags of virtually any name (as defined by the Document Type Definition), it has no intrinsic structure or fixed vocabulary of elements like an HTML document does. As a result, the DOM specification had to accommodate the known structure of HTML (as defined in the HTML 4.0 specification) as well as the unknown structure of an XML document.

To make this work effectively, the working group divided the DOM specification into two sections. The first, called the *Core DOM*, defines specifications for the basic document structure that both HTML and XML documents share. This includes notions of a document containing elements that have tag names and attributes; an element is capable of containing zero or more other elements. The second part of the DOM specification addresses the elements and other characteristics that apply only to HTML. The HTML portion “inherits” all the features of the Core DOM, while providing a measure of backward compatibility to object models already implemented in legacy browsers and providing a framework for new features.

It is important for veteran scripters to recognize that the W3C DOM does not specify all features from existing browser object models. Many features of the IE4 (and later) object model are not part of the W3C DOM specification. This means that if you are comfortable in the IE environment and wish to shift your focus to writing for the W3C DOM spec, you have to change some practices as highlighted in this chapter. Navigator 4 page authors lose the `<layer>` tag (which is not part of HTML 4.0 and likely will never see the light of day in a standard) as well as the `layer` object. In many respects, especially with regard to Dynamic HTML applications, the W3C DOM is an entirely new DOM with new concepts that you must grasp before you can successfully script in the environment.

By the same token, you should be aware that whereas Mozilla-based browsers go to great lengths to implement all of DOM Level 1 and most of Level 2, Microsoft (for whatever reason) features only a partial implementation of the W3C DOM through IE5.5. Although IE6 implements more W3C DOM features, some important parts, notably W3C DOM events, are missing. Other modern browsers, such as Safari, provide basic W3C DOM support, but have not yet caught up with Mozilla levels of DOM support.

## DOM levels

Like most W3C specifications, one version is rarely enough. The job of the DOM working group was too large to be swallowed whole in one sitting. Therefore, the DOM is a continually evolving specification. The timeline of specification releases rarely coincides with browser releases. Therefore, it is very common for any given browser release to include only some of the most recent W3C version.

The first formal specification, DOM Level 1, was released well after NN4 and IE4 shipped. The HTML portion of Level 1 includes DOM Level 0. This is essentially the object model as implemented in Navigator 3 (and for the most part in Internet Explorer 3 plus image objects). Perhaps the most significant omission from Level 1 is an event model (it ignores even the simple event model implemented in NN2 and IE3).

DOM Level 2 builds on the work of Level 1. In addition to several enhancements of both the Core and HTML portions of Level 1, Level 2 adds significant new sections (published as separate modules) on the event model, ways of inspecting a document’s hierarchy, XML namespaces, text ranges, stylesheets, and style properties. Work on Level 3 is under way, but very little of it has yet reached browsers.

## What stays the same

By adopting DOM Level 0 as the starting point of the HTML portion of the DOM, the W3C provided a way for a lot of existing script code to work even in a W3C DOM-compatible browser. Every object you see in the original object model starting with the `document` object (see Figure 14-1) plus the image object are in DOM Level 0. Almost all of the same object properties and methods are also available.

More importantly, when you consider the changes to referencing other elements in the W3C DOM (discussed in the next section), we're lucky that the old ways of referencing objects such as forms, form control elements, and images still work. Had the working group been planning from a clean slate, it is unlikely that the `document` object would have been given properties consisting of arrays of forms, links, and images.

The only potential problems you could encounter with your existing code have to do with a handful of properties that used to belong to the `document` object. In the new DOM, four style-related properties of the `document` object (`alinkColor`, `bgColor`, `linkColor`, and `vlinkColor`) become properties of the `body` object (referenced as `document.body`). In addition, the three link color properties pick up new names in the process (`aLink`, `link`, `vLink`). It appears, however, that for now, IE6 and Moz1 maintain backward compatibility with the older `document` object color properties.

Also, note that the DOM specification concerns itself only with the `document` and its content. Objects such as `window`, `navigator`, and `screen` are not part of the DOM specification through Level 2. Scripters are still at the mercy of browser makers for compatibility in these areas, but the `window` object (or its equivalent) likely will be added to the W3C DOM Level 3.

## What isn't available

As mentioned earlier, the W3C DOM is not simply a restatement of existing browser specifications. Many convenience features of the IE and NN object models do not appear in the W3C DOM. If you develop Dynamic HTML content in IE4+ or NN4, you have to learn how to get along without some of these conveniences.

Navigator 4's experiment with the `<layer>` tag was not successful in the W3C process. As a result, both the tag and the scripting conventions surrounding it do not exist in the W3C DOM. To some scripters' relief, the `document.layerName` referencing scenario (even more complex with nested layers) disappears from the object model entirely. A positioned element is treated as just another element that has some special stylesheet attributes that enable you to move it anywhere on the page, stack it amid other positioned elements, and hide it from view.

Among popular IE4+ features missing from the W3C DOM are the `document.all` collection of HTML elements and four element properties that facilitate dynamic content: `innerHTML`, `innerText`, `outerHTML`, and `outerText`. A new W3C way provides for acquiring an array of all elements in a document, but generating HTML content to replace existing content or be inserted in a document requires a tedious sequence of statements (see the section "New DOM concepts" later in this chapter). Mozilla, however, has implemented the `innerHTML` property for HTML element objects in Mozilla-based browsers (Moz1+).

## "New" HTML practices

Exploitation of Dynamic HTML possibilities in both IE4+ and the W3C DOM relies on some HTML practices that may be new to long-time HTML authors. At the core of these practices (espoused by the HTML 4.0 specification) is making sure that all content is within an HTML container of some kind. Therefore, instead of using the `<p>` tag as a separator between blocks of running text, surround each paragraph of the running text with a `<p>...</p>` tag set. If you don't do it, the browser treats each `<p>` tag as the beginning of a paragraph and ends the paragraph element just before the next `<p>` tag or other block-level element.

While recent browsers continue to accept the omission of certain end tags (for `td`, `tr`, and `li` elements, for instance), it is best to get in the habit of supplying these end tags. If for no other reason, they help you visualize where an element's sphere of influence truly begins and ends.

Any element that you intend to script — whether to change its content or its style — should have an identifier assigned to the element's `id` attribute. Form control elements still require `name` attributes if you submit the form content to a server. But you can freely assign a different identifier to a control's `id` attribute. Scripts can use either the `id` or the `document.formReference.elementName` reference to reach a control object. Identifiers are essentially the same as the values you assign to the `name` attributes of form and form input elements. Following the same rules for the `name` attribute value, an `id` identifier must be a single word (no white space), it cannot begin with a numeral (to avoid conflicts in JavaScript), and it should avoid punctuation symbols except for the underscore. While an element can be accessed by numeric index within the context of some surrounding element (such as the `body`), this is a risky practice when content is under construction. Unique identifiers make it much easier for scripts to reference objects and are not affected by changes in content order.

## New DOM concepts

With the W3C DOM come several concepts that may be entirely new to you unless you have worked extensively with the terminology of tree hierarchies. Concepts that have the most impact on your scripting are new ways of referencing elements and nodes.

### Element referencing

Script references to objects in the DOM Level 0 are observed in the W3C DOM for backward compatibility. Therefore, a form input element whose `name` attribute is assigned the value `userName` is addressed just like it always is:

```
document.forms[0].userName
```

or

```
document.formName.userName
```

But because all elements of a document are exposed to the `document` object, you can use the new `document` object method to access any element whose ID is assigned. The method is `document.getElementById()`, and the sole parameter is a string version of the identifier of the object whose reference you wish to get. To help put this in context with what you may have used with the IE4 object model, consider the following HTML paragraph tag:

```
<p id="myParagraph">...</p>
```

In IE4+, you can reference this element with

```
var elem = document.all.myParagraph;
```

Although the `document.all` collection is not implemented in the W3C DOM, use the new `document` object method (available in IE5+, Moz1+, Safari, and others) that enables you to access any element by its ID:

```
var elem = document.getElementById("myParagraph");
```

Unfortunately for scripters, this method is difficult to type since it is case-sensitive, so watch out for that ending lowercase "d".

### A hierarchy of nodes

The issue surrounding containers (described earlier) comes into play for the underlying architecture of the W3C DOM. Every element or freestanding chunk of text in an HTML (or XML) document is an object that is contained by its next outermost container. Let's look at a

simple HTML document to see how this system works. Listing 14-1 is formatted to show the containment hierarchy of elements and string chunks.

### Listing 14-1: A Simple HTML Document

```
<html>
  <head>
    <title>
      A Simple Page
    </title>
  </head>

  <body>
    <p id="paragraph1">
      This is the
      <em id="emphasis1">
        one and only
      </em>
      paragraph on the page.
    </p>
  </body>
</html>
```

What you don't see in the listing is a representation of the `document` object. The `document` object exists automatically when this page loads into a browser. Importantly, the `document` object encompasses everything you see in Listing 14-1. Therefore, the `document` object has a single nested element: the `html` element. The `html` element, in turn, has two nested elements: `head` and `body`. The `head` element contains the `title` element, while the `title` element contains a chunk of text. Down in the `body` element, the `p` element contains three pieces: a string chunk, the `em` element, and another string chunk.

According to W3C DOM terminology, each container, standalone element (such as a `br` element), or text chunk is known as a *node*—a fundamental building block of the W3C DOM. Nodes have parent-child relationships when one container holds another. As in real life, parent-child relationships extend only between adjacent generations, so a node can have zero or more children. However, the number of third-generation nodes further nested within the family tree does not influence the number of children associated with a parent. Therefore, in Listing 14-1, the `html` node has two child nodes, `head` and `body`, which are *siblings* that share the same parent. The `body` element has one child (`p`) even though that child contains three children (two text nodes and an `em` element node).

If you draw a hierarchical tree diagram of the document in Listing 14-1, it should look like the illustration in Figure 14-3.

#### Note

If the document's source code contains a Document Type Definition (in a `DOCTYPE` element) above the `<html>` tag, the browser treats that `DOCTYPE` node as a sibling of the HTML element node. In that case, the root `document` node contains two child nodes.

The W3C DOM (through Level 2) defines 12 different types of nodes, 7 of which have direct application in HTML documents. These seven types of nodes appear in Table 14-3 (the rest apply to XML). Of the 12 types, the three most common are the document, element, and text types. All W3C DOM browsers (including IE5+, Moz1, Safari, and others) implement the three common node types, while Moz1 implements all of them.

```

document
+--<html>
  +--<head>
    | +--<title>
    |   +--"A Simple Page"
  +--<body>
    +--<p ID="paragraph1">
      +--"This is the "
      +--<em ID="emphasis1">
        | +--"one and only"
      +--" paragraph on the page."

```

**Figure 14-3:** Tree diagram of nodes for the document in Listing 14-1.

**Table 14-3: W3C DOM HTML-Related Node Types**

<i>Type</i>	<i>Number</i>	<i>nodeName</i>	<i>nodeValue</i>	<i>Description</i>	<i>IE5+</i>	<i>Moz1</i>	<i>Safari1</i>
Element	1	<i>tag name</i>	null	Any HTML or XML tagged element	Yes	Yes	Yes
Attribute	2	<i>attribute name</i>	<i>attribute value</i>	A name-value attribute pair in an element	No <sup>1</sup>	Yes	Yes
Text	3	<i>#text</i>	<i>text content</i>	A text fragment contained by an element	Yes	Yes	Yes
Comment	8	<i>#comment</i>	<i>comment text</i>	HTML comment	No <sup>1</sup>	Yes	No
Document	9	<i>#document</i>	null	Root document object	No <sup>1</sup>	Yes	Yes
DocumentType	10	DOCTYPE	null	DTD specification	No	Yes	No
Fragment	11	<i>#document-fragment</i>	null	Series of one or more nodes outside of the document	No <sup>1</sup>	Yes	Yes

<sup>1</sup>Implemented in IE6.

Applying the node types of Table 14-3 to the node diagram in Figure 14-3, you can see that the simple page consists of one document node, six element nodes, and four text nodes.

## Node properties

A node has many properties, most of which are references to other nodes related to the current node. Table 14-4 lists all properties shared by all node types in DOM Level 2.

**Table 14-4: Node Object Properties (W3C DOM Level 2)**

<i>Property</i>	<i>Value</i>	<i>Description</i>	<i>IE5Win+</i>	<i>IE5Mac+</i>	<i>Moz1</i>	<i>Safari1</i>
nodeName	String	Varies with node type (see Table 14-3)	Yes	Yes	Yes	Yes
nodeValue	String	Varies with node type (see Table 14-3)	Yes	Yes	Yes	Yes
nodeType	Integer	Constant representing each type	Some	Yes	Yes	Yes
parentNode	Object	Reference to next outermost container	Yes	Yes	Yes	Yes
childNodes	Array	All child nodes in source order	Yes	Yes	Yes	Yes
firstChild	Object	Reference to first child node	Yes	Yes	Yes	Yes
lastChild	Object	Reference to last child node	Yes	Yes	Yes	Yes
previousSibling	Object	Reference to sibling node up in source order	Yes	Yes	Yes	Yes
nextSibling	Object	Reference to sibling node next in source order	Yes	Yes	Yes	Yes
attributes	NodeMap	Array of attribute nodes	No	Yes	Yes	Yes
ownerDocument	Object	Containing document object	No	Yes	Yes	Yes
namespaceURI	String	URI to namespace definition (element and attribute nodes only)	No	No	Yes	Yes
prefix	String	Namespace prefix (element and attribute nodes only)	No	No	Yes	Yes
localName	String	Applicable to namespace-affected nodes	No	No	Yes	Yes

**Note**

You can find all of the properties shown in Table 14-4 that also show themselves to be implemented in IE5+ or Moz1 in Chapter 15's listing of properties that all HTML element objects have in common. That's because an HTML element, as a type of node, inherits all of the properties of the prototypical node.

To help you see the meanings of the key node properties, Table 14-5 shows the property values of several nodes in the simple page shown in Listing 14-1. For each node column, find the node in Figure 14-3 and then follow the list of property values for that node, comparing the values against the actual node structure in Figure 14-3.

**Table 14-5: Properties of Selected Nodes for a Simple HTML Document**

<i>Properties</i>	<i>Nodes</i>			
	document	html	p	"one and only"
nodeType	9	1	1	3
nodeName	#document	html	p	#text
nodeValue	null	null	null	"one and only"
parentNode	null	document	body	em
previousSibling	null	null	null	null
nextSibling	null	null	null	null
childNodes	html	head body	"This is the " em " paragraph on the page."	(none)
firstChild	html	head	"This is the "	null
lastChild	html	body	" paragraph on the page."	null

The `nodeType` property is an integer that is helpful in scripts that iterate through an unknown collection of nodes. Most content in an HTML document is of type 1 (an HTML element) or 3 (a text node), with the outermost container, the document, of type 9. A node's `nodeName` property is either the name of the node's tag (for an HTML element) or a constant value (preceded by a # [hash mark] as shown in Table 14-3). And, what may surprise some, the `nodeValue` property is `null` except for the text node type, in which case the value is the actual string of text of the node. In other words, for HTML elements, the W3C DOM does not expose a container's HTML as a string.

It is doubtful that you will use all of the relationship-oriented properties of a node, primarily because there is some overlap in how you can reach a particular node from any other. The `parentNode` property is important because it is a reference to the current node's immediate container. While the `firstChild` and `lastChild` properties point directly to the first and last children inside a container, most scripts generally use the `childNodes` property with array notation inside a `for` loop to iterate through child nodes. If there are no child nodes, the `childNodes` array has a length of zero.

## Node methods

Actions that modify the HTML content of a node in the W3C DOM world primarily involve the methods defined for the prototype `Node`. Table 14-6 shows the methods and their support in the W3C DOM-capable browsers.

## The Object-Oriented W3C DOM

If you are familiar with concepts of object-oriented (OO) programming, you will appreciate the OO tendencies in the way the W3C defines the DOM. The `Node` object includes sets of properties (see Table 14-4) and methods (see Table 14-6) that are inherited by every object based on the `Node`. Most of the objects that inherit the `Node`'s behavior have their own properties and/or methods that define their specific behaviors. The following figure shows (in W3C DOM terminology) the inheritance tree from the `Node` root object. Most items are defined in the Core DOM, while items shown in boldface are from the HTML DOM portion.

```

Node
+--Document
| +--HTMLDocument
+--CharacterData
| +--Text
| | +--CDATASection
| +--Comment
+--Attr
+--Element
| +--HTMLElement
|   +-- (Each specific HTML element)
+--DocumentType
+--DocumentFragment
+--Notation
+--Entity
+--Entity Reference
+--ProcessingInstruction
  
```

W3C DOM Node object inheritance tree.

You can see from the preceding figure that individual HTML elements inherit properties and methods from the generic HTML element, which inherits from the Core `Element` object, which, in turn, inherits from the basic `Node`.

It isn't important to know the `Node` object inheritance to script the DOM. But it does help explain the ECMA Script Language Binding appendix of the W3C DOM recommendation, as well as explain how a simple element object winds up with so many properties and methods associated with it.

**Table 14-6: Node Object Methods (W3C DOM Level 2)**

<i>Method</i>	<i>Description</i>	<i>IE5+</i>	<i>Moz1</i>	<i>Safari1</i>
<code>appendChild(newChild)</code>	Adds child node to end of current node	Yes	Yes	Yes
<code>cloneNode(deep)</code>	Grabs a copy of the current node (optionally with children)	Yes	Yes	Yes

*Continued*

Table 14-6 (continued)

<i>Method</i>	<i>Description</i>	<i>IE5+</i>	<i>Moz1</i>	<i>Safari1</i>
<code>hasChildNodes()</code>	Determines whether current node has children (Boolean)	Yes	Yes	Yes
<code>insertBefore(new, ref)</code>	Inserts new child in front of another child	Yes	Yes	Yes
<code>removeChild(old)</code>	Deletes one child	Yes	Yes	Yes
<code>replaceChild(new, old)</code>	Replaces an old child with a new one	Yes	Yes	Yes
<code>isSupported(feature, version)</code>	Determines whether the node supports a particular feature	No	Yes	Yes

The important methods for modifying content are `appendChild()`, `insertBefore()`, `removeChild()`, and `replaceChild()`. Notice, however, that all of these methods assume that the point of view for the action is from the parent of the nodes being affected by the methods. For example, to delete an element (using `removeChild()`), you don't invoke that method on the element being removed, but rather on its parent element. This leaves open the possibility for creating a library of utility functions that obviate having to know too much about the precise containment hierarchy of an element. A simple function that lets a script appear to delete an element actually does so from its parent:

```
function removeElement(elemID) {
    var elem = document.getElementById(elemID);
    elem.parentNode.removeChild(elem);
}
```

If this seems like a long way to go to accomplish the same result as setting the `outerHTML` property of an IE4+ object to empty, you are right. While some of this convolution makes sense for XML, unfortunately the W3C working group doesn't seem to have HTML scripters' best interests in mind. All is not lost, however, as you see later in this chapter.

## Generating new node content

The final point about the node structure of the W3C DOM focuses on the similarly gnarled way scripters must go about generating content they want to add or replace on a page. For text-only changes (for example, the text inside a table cell), there is both an easy and a hard way to perform the task. For HTML changes, there is only the hard way (plus a handy workaround discussed later). Let's look at the hard way first and then pick up the easy way for text changes.

To generate a new node in the DOM, you look to the variety of methods that are defined for the Core DOM's `document` object (and are therefore inherited by the HTML `document` object). A node creation method is defined for nearly every node type in the DOM. The two important ones for HTML documents are `createElement()` and `createTextNode()`. The first generates an element with whatever tag name (string) you pass as a parameter; the second generates a text node with whatever text you pass.

When you first create a new element, it exists only in the browser's memory and not as part of the document containment hierarchy. Moreover, the result of the `createElement()` method is a reference to an empty element except for the name of the tag. For example, to create a new `p` element, use

```
var newElem = document.createElement("p");
```

The new element has no ID, attributes, or any content. To assign some attributes to that element, you can use the `setAttribute()` method (a method of every element object) or assign a value to the object's corresponding property. For example, to assign an identifier to the new element, use either

```
newElem.setAttribute("id", "newP");
```

or

```
newElem.id = "newP";
```

Both ways are perfectly legal. Even though the element has an ID at this point, it is not yet part of the document so you cannot retrieve it via the `document.getElementById()` method.

To add some content to the paragraph, you next generate a text node as a separate object:

```
var newText = document.createTextNode("This is the second paragraph.");
```

Again, this node is just sitting around in memory waiting for you to apply it as a child of some other node. To make this text the content of the new paragraph, you can append the node as a child of the paragraph element that is still in memory:

```
newElem.appendChild(newText);
```

If you were able to inspect the HTML that represents the new paragraph element, it would look like the following:

```
<p id="newP">This is the second paragraph.</p>
```

The new paragraph element is ready for insertion into a document. Using the document shown in Listing 14-1, you can append it as a child of the `body` element:

```
document.body.appendChild(newElem);
```

At last, the new element is part of the document containment hierarchy. You can now reference it just like any other element in the document.

## Replacing node content

The addition of the paragraph shown in the last section requires a change to a portion of the text in the original paragraph (the first paragraph is no longer the “one and only” paragraph on the page). As mentioned earlier, you can perform text changes either via the `replaceChild()` method or by assigning new text to a text node's `nodeValue` property. Let's see how each approach works to change the text of the first paragraph's `em` element from “one and only” to “first.”

To use `replaceChild()`, a script must first generate a valid text node with the new text:

```
var newText = document.createTextNode("first");
```

The next step is to use the `replaceChild()` method. But recall that the point of view for this method is the parent of the child being replaced. The child here is the text node inside the `em` element, so you must invoke the `replaceChild()` method on the `em` element. Also, the `replaceChild()` method requires two parameters: the first is the new node; the second is a reference to the node to be replaced. Because the script statements get pretty long with the `getElementById()` method, an intermediate step grabs a reference to the text node inside the `em` element:

```
var oldChild = document.getElementById("emphasis1").childNodes[0];
```

Now the script is ready to invoke the `replaceChild()` method on the `em` element, swapping the old text node with the new:

```
document.getElementById("emphasis1").replaceChild(newText, oldChild);
```

If you want to capture the old node before it disappears entirely, be aware that the `replaceChild()` method returns a reference to the replaced node (which is only in memory at this point, and not part of the document node hierarchy). You can assign the method statement to a variable and use that old node somewhere else, if needed.

This may seem like a long way to go; it is, especially if the HTML you are generating is complex. Fortunately, you can take a simpler approach for replacing text nodes. All it requires is a reference to the text node being replaced. You can assign that node's `nodeValue` property its new string value:

```
document.getElementById("emphasis1").childNodes[0].nodeValue = "first";
```

When an element's content is entirely text (for example, a table cell that already has a text node in it), this is the most streamlined way to swap text on the fly using W3C DOM syntax. This doesn't work for the creation of the second paragraph text earlier in this chapter because the text node did not exist yet. The `createTextNode()` method had to explicitly create it.

Also remember that a text node does not have any inherent style associated with it. The style of the containing HTML element governs the style of the text. If you want to change not only the text node's text but also how it looks, you have to modify the `style` property of the text node's parent element. Browsers that perform these kinds of content swaps and style changes automatically reflow the page to accommodate changes in the size of the content.

To summarize, Listing 14-2 is a live version of the modifications made to the original document shown in Listing 14-1. The new version includes a button and script that makes the changes described throughout this discussion of nodes. Reload the page to start over.

### Listing 14-2: Adding/Replacing DOM Content

```
<html>
<head>
  <title>A Simple Page</title>
  <script type="text/javascript">
    function modify() {
      var newElem = document.createElement("p");
      newElem.id = "newP";
      var newText = document.createTextNode("This is the second paragraph.");
      newElem.appendChild(newText);
      document.body.appendChild(newElem);
      document.getElementById("emphasis1").childNodes[0].nodeValue = "first";
    }
  </script>
</head>
<body>
  <button onclick="modify()">Add/Replace Text</button>

  <p id="paragraph1">This is the <em id="emphasis1">one and
    only</em> paragraph on the page.</p>
</body>
</html>
```

Chapter 15 details node properties and methods that are inherited by all HTML elements. Most are implemented in both IE5+ and W3C DOM browsers. Also look to the reference material for the `document` object in Chapter 18 for other valuable W3C DOM methods.

## A de facto standard: innerHTML

Microsoft was the first to implement the `innerHTML` property of all element objects starting with IE4. While the W3C DOM has not supported this property, scripters frequently find it more convenient to modify content dynamically by way of a string containing HTML markup, rather than creating and assembling element and text nodes. As a result, most modern W3C DOM browsers, including Moz1 and Safari1, support the read/write `innerHTML` property of all element objects as a de facto standard.

When you assign a string containing HTML markup to the `innerHTML` of an existing element, the browser automatically inserts the newly rendered elements into the document node tree. You may also use `innerHTML` with unmarked text to perform the equivalent of the IE-only `innerText` property.

Despite the apparent convenience of the `innerHTML` property compared to the step-by-step process of manipulating element and text node objects, browsers operate on nodes much more efficiently than on assembly of long strings. This is one case where less JavaScript code does not necessarily translate to greater efficiency.

## Static W3C DOM HTML objects

The Moz1 DOM (but unfortunately not IE5+) adheres to the core JavaScript notion of prototype inheritance with respect to the object model. When a page loads into Moz1, the browser creates HTML objects based on the prototypes of each object defined by the W3C DOM. For example, if you use The Evaluator Sr. (Chapter 13) to see what kind of object the `myP` paragraph object is (enter `document.getElementById("myP")` into the top text box and click the Evaluate button), it reports that the object is based on the `HTMLParagraphElement` object of the DOM. Every “instance” of a `p` element object in the page inherits its default properties and methods from `HTMLParagraphElement` (which, in turn, inherits from `HTMLDivElement`, `Element`, and `Node` objects—all detailed in the JavaScript binding appendix of the W3C DOM specification).

You can use scripting to add properties to the prototypes of some of these static objects. To do so, you must use new features added to Moz1. Two new methods—`__defineGetter__()` and `__defineSetter__()`—enable you to assign functions to a custom property of an object.

### Note

These methods are Mozilla-specific. To prevent their possible collision with standardized implementations of these features in future implementations of ECMAScript, the underscore characters on either side of the method name are pairs of underscore characters.

The functions execute whenever the property is read (the function assigned via the `__defineGetter__()` method) or modified (the function assigned via the `__defineSetter__()` method). The common way to define these functions is in the form of an anonymous function (see Chapter 33). The formats for the two statements that assign these behaviors to an object prototype are as follows:

```
object.prototype.__defineGetter__("propName", function([param1[,...[,paramN]]])
{
    // statements
    return returnValue;
})
```

```
object.prototype.__defineSetter__("propName", function([param1[,...[,paramN]]])
{
    // statements
    return returnValue;
})
```

The example in Listing 14-3 demonstrates how to add a read-only property to every HTML element object in the current document. The property, called `childNodesDetail`, returns an object; the object has two properties, one for the number of element child nodes and one for the number of text child nodes. Note that the `this` keyword in the function definition is a reference to the object for which the property is calculated. And because the function runs each time a script statement reads the property, any scripted changes to the content after the page loads are reflected in the returned property value.

### Listing 14-3: Adding a Read-Only Prototype Property to All HTML Element Objects

```
<script type="text/javascript">
if (HTMLElement) {
    HTMLElement.prototype.__defineGetter__("childNodesDetail", function() {
        var result = {elementNodes:0, textNodes:0 }
        for (var i = 0; i < this.childNodes.length; i++) {
            switch (this.childNodes[i].nodeType) {
                case 1:
                    result.elementNodes++;
                    break;
                case 3:
                    result.textNodes++;
                    break;
            }
        }
        return result;
    })
}
</script>
```

To access the property, use it like any other property of the object. For example:

```
var BodyNodeDetail = document.body.childNodesDetail;
```

The returned value in this example is an object, so you use regular JavaScript syntax to access one of the property values:

```
var BodyElemNodesCount = document.body.childNodesDetail.elementNodes;
```

## Bidirectional event model

Despite the seemingly conflicting event models of NN4 (trickle down) and IE4 (bubble up), the W3C DOM event model (defined in Level 2) manages to employ both event propagation models. This gives the scripter the choice of where along an event's propagation path the event gets processed. To prevent conflicts with existing event model terminology, the W3C model invents many new terms for properties and methods for events. Some coding probably requires W3C DOM-specific handling in a page aimed at multiple object models.

The W3C event model also introduces a new concept called the *event listener*. An event listener is essentially a mechanism that instructs an object to respond to a particular kind of event — very much like the way the event handler attributes of HTML tags respond to events. But the DOM recommendation points out that it prefers use of a more script-oriented way of assigning event listeners: the `addEventListener()` method available for every node in the document hierarchy. Through this method, you advise the browser whether to force an event to bubble up the hierarchy (the default behavior that is also in effect if you use the HTML attribute type of event handler) or to be captured at a higher level.

Functions invoked by the event listener receive a single parameter consisting of the event object whose properties contain contextual details about the event (details such as the position of a mouse click, character code of a keyboard key, or a reference to the target object). For example, if a form includes a button whose job is to invoke a calculation function, the W3C DOM prefers the following way of assigning the event handler:

```
document.getElementById("calcButton").addEventListener("click", doCalc, false);
```

The `addEventListener()` method takes three parameters. The first parameter is a string of the event to listen for; the second is a reference to the function to be invoked when that event fires; and the third parameter is a Boolean value. When you set this Boolean value to `true`, it turns on event capture whenever this event is directed to this target. The function then takes its cue from the event object passed as the parameter:

```
function doCalc(evt) {
    // get shortcut reference to input button's form
    var form = evt.target.form;
    var results = 0;
    // other statements to do the calculation //
    form.result.value = results;
}
```

To modify an event listener, you use the `removeEventListener()` method to get rid of the old listener and then employ `addEventListener()` with different parameters to assign the new one.

Preventing an event from performing its default action is also a different procedure in the W3C event model than in IE. In IE4 (as well as NN3 and NN4), you can cancel the default action by allowing the event handler to evaluate to return `false`. While this still works in IE5+, Microsoft includes another property of the `window.event` object, called `returnValue`. Setting that property to `false` anywhere in the function invoked by the event handler also kills the event before it does its normal job. But the W3C event model uses a method of the event object, `preventDefault()`, to keep the event from its normal task. You can invoke this method anywhere in the function that executes when the event fires.

Detailed information about an event is contained in an event object that must be passed to an event handler function where details may be read. If you assign event handlers via the W3C DOM `addEventListener()` method or an event handler property, the event object is passed automatically as the sole parameter to the event handler function. Include a parameter variable to “catch” the incoming parameter:

```
function swap(evt) {
    // statements here to work with W3C DOM event object
}
```

But if you assign events via a tag attribute, then you must explicitly pass the event object in the call to the function:

```
<a href="http://www.example.com" onmouseover="swap(event)">
```

Unfortunately, neither IE5 through IE6 on Windows nor IE5 for Macintosh implements the W3C DOM event model. You can, however, make the two event models work together if you assign event handlers by way of object properties or tag attributes, and throw in a little object detection described later in this chapter and in more detail in Chapter 25.

## Mixing Object Models

The more browsers that your audience uses, the more likely you will want to make your pages work on as many browsers as possible. You've seen in this chapter that scripts written for older browsers, such as Navigator 2 and Internet Explorer 3, tend to work in even the latest browsers without modification. But aiming at that compatibility target doesn't let you take advantage of more advanced features, in particular Dynamic HTML. You must balance the effort required to support as many as four classifications of browsers (non-DHTML, NN4, IE4/5, and W3C DOM common denominator in IE6 and Moz1) against the requirements of your audience. Moreover, those requirements can easily change over time. For example, the share of the audience using non-DHTML and NN4 browsers will diminish over time, while the installed base of browsers capable of using the Microsoft IE DOM (for IE4+) and the W3C DOM (IE6+ and Moz1+) will increase. If the percentage of visitors using NN4 is not significant at this point, you may well decide to not worry about implementing DHTML features for that browser and lump NN4 together with the rest of the non-DHTML browsers.

For any given application or Web site, it is important to develop a strategy to apply to the deployment of scripted features. But be aware that one strategy simply cannot fit all situations. The primary considerations are the breadth of browser versions reaching your site (many for public sites; perhaps only one for a tightly controlled intranet) and the amount of DHTML you intend to implement.

In the rest of this section, you see three scenarios and strategies employed to meet the developer's requirements. Although they are labeled as three different levels of aggressiveness, it is likely that you can apply individual techniques from each of the levels in establishing a strategy of your own.

### The conservative approach

In the first scenario, the content requires a modest level of data entry interaction with a user via a form as well as image rollovers. Supported browsers encompass the entire range of non-scriptable and scriptable browsers, with one version of each page to serve all visitors.

If the form gathers information from the user for submission to a server CGI that stores the data in a database or performs a search based on user-supplied criteria, the obvious mode of entry is through traditional form control elements. Scriptable browsers can perform pre-submission validations to hasten the correction of any improperly formatted fields. Event handlers attached to the text fields (`onchange` event handlers) and an `onsubmit` event handler for the form itself can do the validation on the client. Nonscriptable browsers ignore the event handlers, and the form is submitted as usual, relying on server-side validation of input data (and the slow back-and-forth processing that this entails when there is an error or missing field data).

For image rollovers, links surround the image elements. The `onmouseover` and `onmouseout` event handlers for the links trigger functions that swap images. By wrapping the statements in the event handler functions in `if` constructions that test for the presence of the `document.images` array, first-generation scriptable browsers that don't implement images as objects perform no action:

```
function imageOn(imgName) {
  if (document.images) {
    document.images[imgName].src = onImages[imgName].src;
  }
}
```

The same goes for script statements in the Head that precache the swappable images as the page loads:

```
if (document.images) {
  var onImages = new Array();
  onImages["home"] = new Image(50,30);
  onImages["home"].src = "images/homeOn.gif";
  ...
}
```

This scenario can also provide added content on the page for scriptable browser users by embedding scripts within the body that use `document.write()` to generate content as the page loads. For example, the page can begin with a time-sensitive greeting (“Good Morning,” “Good Afternoon,” and so on), while nonscriptable browser users see a standard greeting inside the `<noscript>` tag pair.

## Middle ground

The second scenario includes pages that employ stylesheets. The goal again is to support all browser users with the same HTML pages, but also provide users of modern browsers with an enhanced experience. Where supported by the browser, styles of objects change in response to user action (for example, links highlight with a special font color and background during rollover). One of the design elements on the page is a form within a table. As users enter values into some text boxes, calculated results appear at the bottom of the table, preferably as regular content within a table cell (otherwise in another text box).

This scenario requires browser version branching in several places to allow for variations in browser treatment of the features and to avoid problems with older scriptable browsers and nonscriptable browsers alike. You can (and should) perform some (if not all) of the branching via object detection, as you will see in a moment. Table 14-7 highlights the major feature requirements for this scenario and describes the browser support for each.

---

**Table 14-7: Features and Support for a Typical “Middle Ground” Scenario**

---

<i>Feature</i>	<i>Support and Approach</i>
Dynamic Styles	IE4+ and W3C DOM browsers through the <code>style</code> property of any HTML element object.
Form Calculations	Unless requiring regular expression parsing of input, should work with all scriptable browsers without any branching required.
Dynamic Content	IE4+ and W3C DOM browsers support Dynamic HTML content within a cell, but MS and W3C object models require different ways of changing a table cell's content. (Or you can use the nonstandard, but convenient, <code>innerHTML</code> property of the cell.) For older scriptable browsers, the cell should contain a text box to display the results; for nonscriptable browsers, the cell should contain a button that submits the form to a server CGI to process the calculation and return a new page with the results.

---

## Dynamic styles

For dynamic styles, both the IE4+ and W3C object models provide access to stylesheet settings via the `style` property of any HTML element. This simplifies matters because you can wrap modifications to `style` properties inside `if` clauses that check for the existence of the `style` property for the specified object:

```
function hilite(elem) {
    if (elem.style) {
        elem.style.fontWeight = "bold";
    }
}
```

If the event handler that triggers the change can be localized to the affected element (for example, an `onmouseover` event handler for a `span` element surrounding some text), the event doesn't fire in browsers that don't also support the `style` property. (By good fortune, browsers that implement the `style` property also expose all elements to the object model.) To compensate for the differences in object references between the IE4+ and W3C models, you can pass the object as a parameter to event handler functions:

```
<span onmouseover="hilite(this)" onmouseout="revert(this)"
onclick="go('...')>...</span>
```

This technique obviates the need to use browser version detection because the functions invoked by the event handlers do not have to build DOM-specific references to the objects to adjust the style.

## Branching variables

If, for now, you continue to be more comfortable with browser version detection than object detection, you can apply version detection for this “middle ground” scenario by establishing branches for the IE4+ and W3C object models. Global variables that act as flags elsewhere in your page's scripts are still the primary mechanism. For this scenario, you can initialize two global variables as follows:

```
function getIEVersion() {
    var ua = navigator.userAgent;
    var IEOffset = ua.indexOf("MSIE ");
    return parseFloat(ua.substring(IEOffset+5, ua.indexOf(";", IEOffset)));
}
```

```
var isIE4 = ((navigator.appName.indexOf("Microsoft") == 0 &&
    parseInt(getIEVersion()) >= 4));
var isW3C = (document.documentElement) ? true : false;
```

Notice how the `getIEVersion()` function digs out the precise IE version from deep within the `navigator.userAgent` property. Both global variables are Boolean values. While each variable conveys valuable information on its own, the combination of the two reveals even more about the browser environment if necessary. Figure 14-4 shows the truth table for using the AND (&&) operator in a conditional clause with both values. For example, if you need a branch that works only in IE4, the `if` clause is

```
if (isIE4 && !isW3C) {...}
```

The overlap between MS and the W3C object models in IE5+ means that you need to determine for each branch which model to use when the script is running. This governs the order of nested `if` conditions when they arise. If you trap for the W3C version first, IE5+ runs the branch containing the W3C DOM syntax.

isIE4	isW3C	isIE4 && isW3C
true	true	IE5+
true	false	IE4 Only
false	true	Non-IE W3C Only
false	false	Older browser

**Figure 14-4:** Truth table for two browser version variables with the AND operator.

## Dynamic content

Once you have the branching variables in place, your scripts can use them for executing functions invoked by event handlers as well as for scripts that run while the page loads. The importance of the second type comes when you want a page to display one kind of HTML for one class of browsers and other HTML for other classes (or all of the rest). The design for the current scenario calls for a table cell to display the results of a form's calculation in HTML where capable. In lesser scriptable browsers, the results should appear in a text box in the table. Nonscriptable browsers should display a button to submit the form.

In the Body of the page, a script should take over and use `document.write()` for the `td` element that is to show the results. Buggy behavior in early versions of Navigator require that at least the entire `td` element be written dynamically, instead of just the cell's content. The structure of such a form and table is as follows:

```

...
<form name="calculator" action="http://xxx/cgi-bin/calculate.pl"
onsubmit="return false">
<table>
...
<tr>
  <td>...</td>
  <script type="text/javascript">
    if (isIE4 || isW3C) {
      document.write("<td id='result'>0</td>");
    } else {
      document.write("<td>");
      document.write("<input type='text' name='result' size='10' value='0' />");
      document.write("</td>");
    }
  </script>
  <noscript>
    <td>Click 'Submit' for Results</td>
  </noscript>
</tr>
</table>
<noscript>
  <input type="submit" />
</noscript>
</form>
...

```

The preceding code assumes that other table cells contain text boxes whose `onchange` event handlers trigger a calculation script. That calculation script must also branch for the two classes of scriptable browser so that results are displayed to fit the browser's object model:

```
function calculate(form) {
    var results;
    ...
    // statements here that perform math and stuff answer into 'results' variable
    ...
    if (isIE4) {
        document.all.result.innerText = results;
    } else if (isW3C) {
        document.getElementById("result").childNodes[0].nodeValue = results;
    } else {
        document.calculator.result.value = results;
    }
}
```

Adding dynamic content for NN4 requires a little more planning. The technique usually involves nesting an absolute-positioned `div` inside a relative-positioned `span`. Scripts can then use `document.write()` to create new content for the deeply nested `div` element. Pulling this off successfully entails pretty complex references through multiple layers and their documents. But no matter what lengths you go to in an effort to employ dynamic content in NN4, the new content does not automatically resize the table or cell to accommodate larger or smaller chunks of text. Without automatic reflow of the page, as is found in IE4+ and most W3C DOM browsers, writing to an NN4 positioned layer does not force other page content to move.

## A radical approach

By “radical,” I mean that the page content is designed to employ extensive DHTML features, including positioned (if not flying) elements on the page. Perhaps some clicking and dragging of elements can add some fun to the page while you're at it.

Employing these kinds of features requires some extensive forethought about your audience and the browsers they use. While some aspects of DHTML, such as CSS, degrade gracefully in older browsers (the content is still presented, although not in optimum font display perhaps), positioned elements do not degrade well at all. The problem is that older browsers ignore the CSS attributes that control positioning, stacking order, and visibility. Therefore, when the page loads in a pre-version 4 browser, all content is rendered in source code order. Elements that are supposed to be positioned, hidden, or overlapped are drawn on the page in “old-fashioned” rendering.

To use element positioning for the greatest effect, your Web site should preexamine the browser at some earlier page in the navigation sequence to reach the DHTML-equipped page. Only browsers capable of your fancy features should be allowed to pass onto the “cool” pages. All other browsers get diverted to another page or pathway through your application so they can at least get the information they came for, if not in the most lavish presentation. Techniques detailed in Chapter 13 demonstrate how to make a branching index page.

By filtering out non-DHTML-capable browsers, some of your job is easier — but not all. On the plus side, you can ignore a lot of weirdness that accrues to scripting bugs in earlier browsers. But you must still decide which of the three element positioning models to follow: IE4+, NN4, or W3C. Chances are that you will want to support at least two of the three unless you are in the luxurious position of designing for a single browser platform (or have taken a stand that you will support only one DOM, probably the newer W3C).

Of the three models, NN4's DOM is the trickiest one to deal with at the HTML level. While it may be possible that your content design will look the same using positioned `div` and `span` elements in all DHTML-capable browsers, often the appearance in NN4 is unacceptable. At that point, you will probably have to use scripts in your Body to dynamically generate HTML, specifying the `<layer>` tag for NN4 and positioned `<div>` elements for the rest.

**Note**

Although IE4+ can use the same basic Microsoft object model, not all DHTML code renders the same on both generations of browsers. Microsoft made some changes here and there to the way some style attributes are rendered so that IE5.x comes into better compliance with the CSS recommendation, while IE6 is in full compliance with CSS Level 1 when you specify a complete DOCTYPE element pointing to URLs of the DTDs for HTML 4.0 or later and XHTML.

## Using script libraries

As long as you plan to use scripts to dynamically generate HTML for the page, you might consider creating separate, external `.js` libraries for each of the object models you want to support for the page. Scripts in each library contain code for both the HTML accumulation (for use with `document.write()` in the main page) and for processing user interaction. Assuming that only DHTML-capable browsers reach the page, branching is required only at the beginning of the document where an object model-specific library is loaded:

```
var isIE4 = ((navigator.appName.indexOf("Microsoft") == 0 &&
    parseInt(navigator.appVersion) == 4));
var isW3C = (document.documentElement) ? true : false;
if (isW3C) {
    // give priority to W3C model for IE5+
    document.write("<script type='text/javascript' src='page3_W3C.js'><" +
        "\\script>");
} else if (isIE4) {
    document.write("<script type='text/javascript' src='page3_IE4.js'><" +
        "\\script>");
} else {
    document.write("<script type='text/javascript' src='page3_generic.js'><" +
        "\\script>");
}
```

Each of the statements that writes the `<script>` tag includes a workaround that is required on some browsers (NN4 especially) to facilitate using `document.write()` to write script tags to the page.

Once these libraries are specified for the page, script statements anywhere later in the page can invoke functions defined in each library to generate a particular element or set of elements in the object model HTML optimized for the current browser. Of course, it's not necessary to have one library devoted to each object model. You might find it more convenient for authoring and maintenance to keep all the code in one library that has numerous internal branchings for browser versions. Branches in a library can use the version-sniffing global variables defined in the main HTML page's scripts. Better still, a library can be entirely self-contained by using object detection.

## Handling events

Thanks to the W3C DOM's event model implementing a similar event bubbling scheme as IE4+, you can apply that event propagation model to IE4+ and W3C DOM browsers. There are differences in the details, however. IE's approach does not pass the event object as a parameter to a function invoked by an event handler. Instead, the IE event object is a property of the

window object. Therefore, your functions have to look for the passed parameter and substitute the `window.event` object in its place for IE:

```
function calculate(evt) {
    evt = (evt) ? evt : window.event;
    // more statements to handle the event //
}
```

Additional branching is necessary to inspect many details of the event. For example, IE calls the object receiving the event the `srcElement`, while the W3C DOM calls it the `target`. Canceling the default behavior of the event (for example, preventing a form's submission if it fails client-side validation) is also different for the models (although the “old-fashioned” way of letting HTML-type event handlers evaluate to `return false` still works). You can find more event object details in Chapter 25.

## Standards Compatibility Modes (DOCTYPE Switching)

Both Microsoft and Netscape/Mozilla discovered that they had, over time, implemented CSS features in ways that ultimately differed from the published standards that came later (usually after much wrangling among working group members). To compensate for these differences and make a clean break to be compatible with the standards, the major browser makers decided to let the page author's choice of `<!DOCTYPE>` header element details determine whether the document was designed to follow the old way (sometimes called “quirks mode”) or the standards-compatible way. The tactic, known informally as DOCTYPE switching, is implemented in WinIE6, MacIE5, and all Mozilla-based browsers.

While most of the differences between the two modes are small, there are some significant differences between the two modes in WinIE6, particularly when styles or Dynamic HTML scripts rely on elements designed with borders, margins, and padding. Microsoft's original “box model” measured the dimensions of elements in a way that differed from the eventual CSS standard.

To place the affected browsers into CSS standards-compatible mode, you should include a `<!DOCTYPE>` element at the top of every document that specifies any of the following details:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.0 Transitional//EN"
    "http://www.w3.org/TR/REC-html40/loose.dtd">

<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.0 Frameset//EN"
    "http://www.w3.org/TR/REC-html40/frameset.dtd">

<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.0//EN"
    "http://www.w3.org/TR/REC-html40/strict.dtd">

<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
    "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">

<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Frameset//EN"
    "http://www.w3.org/TR/xhtml1/DTD/xhtml1-frameset.dtd">

<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN"
    "http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd">

<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1//EN"
    "http://www.w3.org/TR/xhtml11/DTD/xhtml11.dtd">
```

Be aware, however, that older versions of WinIE, such as WinIE5 or WinIE5.5, are ignorant of the standards-compatible mode, and will use the old Microsoft quirks mode, regardless of `<!DOCTYPE>` setting. But using the standards-compatible mode DOCTYPE is more likely to force your content and stylesheets to render more similarly across the latest browsers.

## Where to Go from Here

These past two chapters provided an overview of the core language and object model issues that anyone designing pages that use JavaScript must confront. The goal here is to stimulate your own thinking about how to embrace or discard levels of compatibility with your pages as you balance your desire to generate “cool” pages and serve your audience. From here on, the difficult choices are up to you.

To help you choose the objects, properties, methods, and event handlers that best suit your requirements, the rest of the chapters in Part III and all of Part IV provide in-depth references to the document object model and core JavaScript language features. Observe the compatibility ratings for each language term very carefully to help you determine which features best suit your audience’s browsers. Most example listings are complete HTML pages that you can load in various browsers to see how they work. Many others invite you to explore how things work via The Evaluator Sr. (see Chapter 13). Play around with the files, making modifications to build your own applications or expanding your working knowledge of JavaScript in the browser environment.

The language and object models have grown in the handful of years they have been in existence. The amount of language vocabulary has increased astronomically. It takes time to drink it all in and feel comfortable that you are aware of the powers available to you. Don’t worry about memorizing the vocabulary. It’s more important to acquaint yourself with the features, and then come back later when you need the implementation details.

Be patient. Be persistent. The reward will come.

# Generic HTML Element Objects

---

The object model specifications implemented in Internet Explorer 4+ and Mozilla-based browsers (including Netscape 6 and 7) feature a large set of scriptable objects that represent what we often call “generic” HTML elements. Generic elements can be divided into two groups. One group, such as the `b` and `strike` elements, define font styles to be applied to enclosed sequences of text. The need for these elements (and the objects that represent them) is receding as more page designers use stylesheets. The second group of elements assigns context to content within their start and end tags. Examples of contextual elements include `h1`, `blockquote`, and the ubiquitous `p` element. While browsers sometimes have consistent visual ways of rendering contextual elements by default (for example, the large, bold font of an `<h1>` tag), the specific rendering is not the intended purpose of the tags. No formal standard dictates that text within an `em` element must be italicized: the style simply has become the custom since the very early days of browsers.

All of these generic elements share a large number of scriptable properties, methods, and event handlers. The sharing extends not only among generic elements, but also among virtually every renderable element — even if it has additional, element-specific properties, methods, and/or event handlers that I cover in depth in other chapters of this reference. Rather than repeat the details of these shared properties, methods, and event handlers for each object throughout this reference, I describe them in detail only in this chapter (unless there is a special behavior, bug, or trick associated with the item in some object described elsewhere). In succeeding reference chapters, each object description includes a list of the object’s properties, methods, and event handlers, but I do not list shared items over and over (making it hard to find items that are unique to a particular element). Instead, you see a pointer back to this chapter for the items in common with generic HTML element objects.

## Generic Objects

Table 15-1 lists all of the objects that I treat in this reference as “generic” objects. All of these objects share the properties, methods, and event handlers described in succeeding sections and have no special items that require additional coverage elsewhere in this book.

### In This Chapter

Working with HTML element objects

Common properties and methods

Event handlers of all element objects

scrollTop		
scrollWidth		
sourceIndex		
style		
tabIndex		
tagName		
tagUrn		
title		
uniqueID		

## Syntax

To access element properties or methods, use this:

```
(IE4+)      [document.all.]objectID.property | method([parameters])
(IE5+/W3C) document.getElementById(objectID).property | method([parameters])
```

## About these objects

All objects listed in Table 15-1 are DOM representations of HTML elements that influence either the font style or the context of some HTML content. The large set of properties, methods, and event handlers associated with these objects also applies to virtually every other DOM object that represents an HTML element. Discussions about object details in this chapter apply to dozens of other objects described in succeeding chapters of this reference section.

## Properties

### accessKey

**Value:** One-character string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

For many elements, you can specify a keyboard character (letter, numeral, or punctuation symbol) that, when typed as an Alt+key combination (on the Win32 OS platform) or Ctrl+key combination (on the MacOS), brings focus to that element. An element that has focus is the one that is set to respond to keyboard activity. If the newly focused element is out of view in the document's current scroll position, the document is scrolled to bring that focused element into view (also see the `scrollIntoView()` method). The character you specify can be an uppercase or lowercase value, but these values are not case-sensitive. If you assign the same letter to more than one element, the user can cycle through all elements associated with that `accessKey` value.

Internet Explorer gives some added powers to the `accessKey` property in some cases. For example, if you assign an `accessKey` value to a `label` element object, the focus is handed to the form element associated with that label. Also, when elements such as buttons have focus, pressing the spacebar acts the same as clicking the element with a mouse.

Although W3C DOM browsers, such as Mozilla and Safari, expose this property for some element types (notably `a`, `area`, `button`, `input`, `label`, `legend`, and `textarea`), these browsers do not respond to scripted changes of the property.

Exercise some judgment in selecting characters for `accessKey` values. If you assign a letter that is normally used to access one of the Windows version browser's built-in menus (for example, `Alt+F` for the File menu), that `accessKey` setting overrides the browser's normal behavior. To users who rely on keyboard access to menus, your control over that key combination can be disconcerting.

## Example

Listing 15-1 shows an example of how to use the `accessKey` property to manipulate the keyboard interface for navigating a Web page. When you load the script in Listing 15-1, adjust the height of the browser window so that you can see nothing below the second dividing rule. Enter any character into the Settings portion of the page and press Enter. (The Enter key may cause your computer to beep.) Then hold down the Alt (Windows) or Ctrl (Mac) key while pressing the same keyboard key. The element from below the second divider should come into view.

### Listing 15-1: Controlling the `accessKey` Property

```
<html>
  <head>
    <title>accessKey Property</title>
    <script type="text/javascript">
      function assignKey(type, elem) {
        if (window.event.keyCode == 13) {
          switch (type) {
            case "button":
              document.forms["output"].access1.accessKey = elem.value;
              break;
            case "text":
              document.forms["output"].access2.accessKey = elem.value;
              break;
            case "table":
              document.getElementById("myTable").accessKey = elem.value;
          }
          return false;
        }
      }
    </script>
  </head>
  <body>
    <h1>accessKey Property Lab</h1>
    <hr />
    Settings:<br />
    <form name="input">
      Assign an accessKey value to the Button below and press Return: <input
      type="text" size="2" maxlength="1"
      onkeypress="return assignKey('button', this)" /><br />
      Assign an accessKey value to the Text Box below and press Return:
      <input type="text" size="2" maxlength="1"
      onkeypress="return assignKey('text', this)" /><br />
      Assign an accessKey value to the Table below (IE5.5+ only) and press
```

*Continued*

**elementObject.accessKey****Listing 15-1 (continued)**

```

        Return: <input type="text" size="2" maxlength="1"
                onkeypress="return assignKey('table', this)" />
    </form>
    <br />
    Then press Alt (Windows) or Control (Mac) + the key.<br />
    <em>Size the browser window to view nothing lower than this line.</em>
    <hr />
    <form name="output" onsubmit="return false">
        <input type="button" name="access1" value="Standard Button" /> <input
            type="text" name="access2" />
    </form>
    <table id="myTable" cellpadding="10" border="2">
        <tr>
            <th>Quantity</th>
            <th>Description</th>
            <th>Price</th>
        </tr>
        <tbody bgcolor="red">
            <tr>
                <td width="100">4</td>
                <td>Primary Widget</td>
                <td>$14.96</td>
            </tr>
            <tr>
                <td>10</td>
                <td>Secondary Widget</td>
                <td>$114.96</td>
            </tr>
        </tbody>
    </table>
</body>
</html>

```

**Related Item:** `scrollIntoView()` method.

**all[]**

**Value:** Array of nested element objects.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `all` property is a collection (array) of every HTML element and (in IE5+) XML tag within the scope of the current object. Items in this array appear in source-code order, and the array is oblivious to element containment among the items. For HTML element containers, the source-code order is dependent on the position of the start tag for the element—end tags are not counted. But for XML tags, end tags appear as separate entries in the array.

Every `document.all` collection contains objects for the `html`, `head`, `title`, and `body` element objects even if the actual HTML source code omits the tags. The object model creates these objects for every document that is loaded into a window or frame. While the `document.all` reference may be the most common usage, the `all` property is available for any container element. For example, `document.forms[0].all` exposes all elements defined within the first form of a page.

*elementObject.attributes*

You can access any element that has an identifier assigned to its `id` attribute by that identifier in string form (as well as by index integer). Rather than use the performance-costly `eval()` function to convert a string to an object reference, use the string value of the name as an array index value:

```
var paragraph = document.all["myP"];
```

Internet Explorer enables you to use either square brackets or parentheses for single collection index values. Thus, the following two examples evaluate identically:

```
var paragraph = document.all["myP"];
var paragraph = document.all("myP");
```

In the rare case that more than one element within the `all` collection has the same ID, the syntax for the string index value returns a collection of just those identically named elements. But you can use a second argument (in parentheses) to signify the integer of the initial collection and thus single out a specific instance of that named element:

```
var secondRadio = document.all("group0",1);
```

As a more readable alternative, you can use the `item()` method (described later in this chapter) to access the same kinds of items within a collection:

```
var secondRadio = document.all.item("group0",1);
```

Also see the `tags()` method (later in this chapter) as a way to extract a set of elements from an `all` collection that matches a specific tag name.

Although a few non-IE browsers support the `all` collection, a better choice for future compatibility is the `document.getElementById()` method described in Chapter 18.

## Example

Use The Evaluator (Chapter 13) to experiment with the `all` collection. Enter the following statements one at a time into the lower text box, and review the results in the text area for each.

```
document.all
myTable.all
myP.all
```

If you encounter a numbered element within a collection, you can explore that element to see which tag is associated with it. For example, if one of the results for the `document.all` collection says `document.all.8=[object]`, enter the following statement into the topmost text box:

```
document.all[8].tagName
```

**Related Items:** `item()`, `tags()`, `document.getElementById()` methods.

## attributes[]

**Value:** Array of attribute object references.

Read-Only

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `attributes` property consists of an array of attributes specified for an element. In IE5+, the `attributes` array contains an entry for every possible property that the browser has defined for its elements—even if the attribute is not set explicitly in the HTML tag. Also, any attributes that you add later via script facilities such as the `setAttribute()` method are not reflected in the `attributes` array. In other words, the IE5+ `attributes` array is fixed, using default values for all properties except those that you explicitly set as attributes in the HTML tag.

***elementObject.attributes***

Mozilla browsers' `attributes` property returns an array that is a named node map (in W3C DOM terminology)—an object that has its own properties and methods to read and write attribute values. For example, you can use the `getNamedItem(attrName)` and `item(index)` methods on the array returned from the `attributes` property to access individual attribute objects via W3C DOM syntax.

IE5+ and Moz1+ have different ideas about what an attribute object should be. Table 15-2 shows the variety of properties of an attribute object as defined by the two object models. The larger set of properties in Moz1+ reveals its dependence on the W3C DOM node inheritance model discussed in Chapter 14.

---

**Table 15-2: Attribute Object Properties**

---

<i>Property</i>	<i>IE5+</i>	<i>Moz1+</i>	<i>Description</i>
<code>attributes</code>	No	Yes	Array of nested attribute objects (null)
<code>childNodes</code>	No	Yes	Child node array
<code>firstChild</code>	No	Yes	First child node
<code>lastChild</code>	No	Yes	Last child node
<code>localName</code>	No	Yes	Name within current namespace
<code>name</code>	No	Yes	Attribute name
<code>namespaceURI</code>	No	Yes	XML namespace URI
<code>nextSibling</code>	No	Yes	Next sibling node
<code>nodeName</code>	Yes	Yes	Attribute name
<code>nodeType</code>	No	Yes	Node type (2)
<code>nodeValue</code>	Yes	Yes	Value assigned to attribute
<code>ownerDocument</code>	No	Yes	document object reference
<code>ownerElement</code>	No	Yes	Element node reference
<code>parentNode</code>	No	Yes	Parent node reference
<code>prefix</code>	No	Yes	XML namespace prefix
<code>previousSibling</code>	No	Yes	Previous sibling node
<code>specified</code>	Yes	Yes	Whether attribute is explicitly specified (Boolean)
<code>value</code>	No	Yes	Value assigned to attribute

---

The most helpful property of an attribute object is the Boolean `specified` property. In IE, this lets you know whether the attribute is explicitly specified in the element's tag. Because Moz1 returns only explicitly specified attributes in the `attributes` array, the value in Moz1 is always true. Most of the time, however, you'll probably use an element object's `getAttribute()` and `setAttribute()` methods to read and write attribute values.

### Example

Use The Evaluator (Chapter 13) to examine the values of the `attributes` array for some of the elements in that document. Enter each of the following expressions into the lower text field, and see the array contents in the Results text area for each:

```
document.body.attributes
document.getElementById("myP").attributes
document.getElementById("myTable").attributes
```

***elementObject.canHaveChildren***

If you have both IE5+ and a W3C DOM-compatible browser, compare the results you get for each of these expressions. To view the properties of a single attribute in WinIE5+, enter the following statement into the bottom text field:

```
document.getElementById("myP").attributes["class"]
```

For W3C browsers and MacIE5, use the W3C DOM syntax:

```
document.getElementById("myP").attributes.getNamedItem("class")
```

**Related Items:** `getAttribute()`, `mergeAttributes()`, `removeAttribute()`, `setAttribute()` methods.

**behaviorUrns[]**

**Value:** Array of behavior URN strings.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `behaviorUrns` property is designed to provide a list of addresses, in the form of *URNs* (*Uniform Resource Names*), of all behaviors assigned to the current object. If there are no behaviors, the array has a length of zero. In practice, however, IE5+ always returns an array of empty strings. Perhaps the potential exposure of URNs by script was deemed to be a privacy risk.

**Example**

The following function is embedded within a more complete example of WinIE HTML behaviors (Listing 15-19 in this chapter). It reports the length of the `behaviorUrns` array and shows — if the values are returned — the URL of the attached behavior.

```
function showBehaviors() {
    var num = document.getElementById("myP").behaviorUrns.length;
    var msg = "The myP element has " + num + " behavior(s). ";
    if (num > 0) {
        msg += "Name(s): \r\n";
        for (var i = 0; i < num; i++) {
            msg += document.getElementById("myP").behaviorUrns[i] + "\r\n";
        }
    }
    alert(msg);
}
```

**Related Item:** `urns()` method.

**canHaveChildren**

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

Useful in some dynamic content situations, the `canHaveChildren` property reveals whether a particular element is capable of containing a child (nested) element. Most elements that have start and end tags (particularly the generic elements covered in this chapter) can contain nested elements. A nested element is referred to as a *child* of its parent container.

**Example**

Listing 15-2 shows an example of how to use the `canHaveChildren` property to visually identify elements on a page that can have nested elements. This example uses color to demonstrate the difference between an element that can have children and one that cannot. The first button sets the `color` style property of every visible element on the page to red.

***elementObject.canHaveChildren***

Thus, elements (including the normally non-childbearing ones such as `hr` and `input`) are affected by the color change. But if you reset the page and click the largest button, only those elements that can contain nested elements receive the color change.

**Listing 15-2: Reading the `canHaveChildren` Property**

```

<html>
  <head>
    <title>canHaveChildren Property</title>
    <script type="text/javascript">
      function colorAll() {
        var elems = document.getElementsByTagName("*");
        for (var i = 0; i < elems.length; i++) {
          elems[i].style.color = "red";
        }
      }

      function colorChildBearing() {
        var elems = document.getElementsByTagName("*");
        for (var i = 0; i < elems.length; i++) {
          if (elems[i].canHaveChildren) {
            elems[i].style.color = "red";
          }
        }
      }
    </script>
  </head>
  <body>
    <h1>canHaveChildren Property Lab</h1>
    <hr />
    <form name="input">
      <input type="button" value="Color All Elements"
        onclick="colorAll()" /><br />
      <input type="button" value="Reset" onclick="history.go(0)" /><br />
      <input type="button"
        value="Color Only Elements That Can Have Children"
        onclick="colorChildBearing()" />
    </form>
    <br />
    <hr />
    <form name="output">
      <input type="checkbox" checked="checked" />Your basic checkbox <input
        type="text" name="access2" value="Some textbox text." />
    </form>
    <table id="myTable" cellpadding="10" border="2">
      <tr>
        <th>Quantity</th>
        <th>Description</th>
        <th>Price</th>
      </tr>
      <tbody>
        <tr>
          <td width="100">4</td>
          <td>Primary Widget</td>
          <td>$14.96</td>
        </tr>
      </tbody>
    </table>
  </body>
</html>

```

```

        </tr>
        <tr>
            <td>10</td>
            <td>Secondary Widget</td>
            <td>$114.96</td>
        </tr>
    </tbody>
</table>
</body>
</html>

```

**Related Items:** `childNodes`, `firstChild`, `lastChild`, `parentElement`, `parentNode` properties; `appendChild()`, `hasChildNodes()`, `removeChild()` methods.

## canHaveHTML

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

While most HTML elements are containers of HTML content, not all are. The `canHaveHTML` property lets scripts find out whether a particular object can accept HTML content, such as for insertion or replacement by object methods. The value for a `p` element, for example, is `true`. The value for a `br` element is `false`.

## Example

Use The Evaluator (Chapter 13) to experiment with the `canHaveHTML` property. Enter the following statements into the top text field and observe the results:

```

document.getElementById("input").canHaveHTML
document.getElementById("myP").canHaveHTML

```

The first statement returns `false` because an `input` element (the top text field in this case) cannot have nested HTML. But the `myP` element is a `p` element that gladly accepts HTML content.

**Related Items:** `appendChild()`, `insertAdjacentHTML()`, `insertBefore()` methods.

## childNodes[]

**Value:** Array of node objects.

Read-Only

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `childNodes` property consists of an array of node objects contained by the current object. Note that child nodes consist of both element objects and text nodes. Therefore, depending on the content of the current object, the number of `childNodes` and `children` collections may differ.

If you use the `childNodes` array in a `for` loop that iterates through a sequence of HTML (or XML) elements, watch out for the possibility that the browser treats source code whitespace (blank lines between elements and even simple carriage returns between elements) as text nodes. This potential problem affects MacIE5 and Moz1. If present, these extra text nodes occur primarily surrounding block elements.

Most looping activity through the `childNodes` array aims to examine, count, or modify element nodes within the collection. If that is your script's goal, then test each node returned by

***elementObject.childNodes***

the `childNodes` array, and verify that the `nodeType` property is 1 (element) before processing that node. Otherwise, skip over the node. The skeletal structure of such a loop follows:

```
for (var i = 0; i < myElem.childNodes.length; i++) {
    if (myElem.childNodes[i].nodeType == 1) {
        statements to work on element node i
    }
}
```

The presence of these “phantom” text nodes also impacts the nodes referenced by the `firstChild` and `lastChild` properties, described later in this chapter.

**Example**

Listing 15-3 contains an example of how you might code a function that “walks” the child nodes of a given node. The `walkChildNodes()` function shown in the listing accumulates and returns a hierarchical list of child nodes from the point of view of the document’s HTML element (the default) or any element whose ID you pass as a string parameter. This function is embedded in `The Evaluator` so that you can inspect the child node hierarchy of that page or (when using `evaluator.js` for debugging as described in Chapter 45 on the CD-ROM) the node hierarchy within any page you have under construction. Try it out in `The Evaluator` by entering the following statements into the top text field:

```
walkChildNodes()
walkChildNodes(getElementById("myP"))
```

The results of this function show the nesting relationships among all child nodes within the scope of the initial object. It also shows the act of drilling down to further `childNodes` collections until all child nodes are exposed and catalogued. Text nodes are labeled accordingly. The first 15 characters of the actual text are placed in the results to help you identify the nodes when you compare the results against your HTML source code.

**Listing 15-3: Collecting Child Nodes**

```
function walkChildNodes(objRef, n) {
    var obj;
    if (objRef) {
        if (typeof objRef == "string") {
            obj = document.getElementById(objRef);
        } else {
            obj = objRef;
        }
    } else {
        obj = (document.body.parentElement) ?
            document.body.parentElement : document.body.parentNode;
    }
    var output = "";
    var indent = "";
    var i, group, txt;
    if (n) {
        for (i = 0; i < n; i++) {
            indent += "+---";
        }
    } else {
        n = 0;
        output += "Child Nodes of <" + obj.tagName;
```

```

    output += ">\n=====\\n";
}
group = obj.childNodes;
for (i = 0; i < group.length; i++) {
    output += indent;
    switch (group[i].nodeType) {
        case 1:
            output += "<" + group[i].tagName;
            output += (group[i].id) ? " ID=" + group[i].id : "";
            output += (group[i].name) ? " NAME=" + group[i].name : "";
            output += ">\n";
            break;
        case 3:
            txt = group[i].nodeValue.substr(0,15);
            output += "[Text:\\n" + txt.replace(/[\r\n]/g,"<br>");
            if (group[i].nodeValue.length > 15) {
                output += "...";
            }
            output += "\\n";
            break;
        case 8:
            output += "[!COMMENT!]\n";
            break;
        default:
            output += "[Node Type = " + group[i].nodeType + "]\n";
    }
    if (group[i].childNodes.length > 0) {
        output += walkChildNodes(group[i], n+1);
    }
}
return output;
}

```

## children

**Value:** Array of element objects.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `children` property consists of an array of element objects contained by the current object. Unlike the `childNodes` property, `children` does not take into account text nodes but rather focuses strictly on the HTML (and XML) element containment hierarchy from the point of view of the current object. Children exposed to the current object are immediate children only. If you want to get all element objects nested within the current object (regardless of how deeply nested they are), use the `all` collection instead.

## Example

Listing 15-4 shows how you can use the `children` property to “walk” the child nodes of a given node. This function accumulates and returns a hierarchical list of child elements from the point of view of the document’s HTML element (the default) or any element whose ID you pass as a string parameter. This function is embedded in `The Evaluator` so that you can inspect the parent–child hierarchy of that page or (when using `evaluator.js` for debugging as described in Chapter 45 on the CD-ROM) the element hierarchy within any page you have

***elementObject.children***

under construction. Try it out in The Evaluator in IE5+ by entering the following statements into the top text field:

```
walkChildren()  
walkChildren("myP")
```

The results of this function show the nesting relationships among all parent and child elements within the scope of the initial object. It also shows the act of drilling down to further children collections until all child elements are exposed and catalogued. The element tags also display their id and/or name attribute values if any are assigned to the elements in the HTML source code.

**Listing 15-4: Collecting Child Elements**

```
function walkChildren(objRef, n) {  
  var obj;  
  if (objRef) {  
    if (typeof objRef == "string") {  
      obj = document.getElementById(objRef);  
    } else {  
      obj = objRef;  
    }  
  } else {  
    obj = document.body.parentElement;  
  }  
  var output = "";  
  var indent = "";  
  var i, group;  
  if (n) {  
    for (i = 0; i < n; i++) {  
      indent += "+---";  
    }  
  } else {  
    n = 0;  
    output += "Children of <" + obj.tagName;  
    output += ">\n=====\\n";  
  }  
  group = obj.children;  
  for (i = 0; i < group.length; i++) {  
    output += indent + "<" + group[i].tagName;  
    output += (group[i].id) ? " ID=" + group[i].id : "";  
    output += (group[i].name) ? " NAME=" + group[i].name : "";  
    output += ">\n";  
    if (group[i].children.length > 0) {  
      output += walkChildren(group[i], n+1);  
    }  
  }  
  return output;  
}
```

---

## className

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

A *class name* is an identifier that is assigned to the `class` attribute of an element. To associate a CSS rule with several elements in a document, assign the same identifier to the `class` attributes of those elements, and use that identifier (preceded by a period) as the CSS rule's selector. An element's `className` property enables the application of different CSS rules to that element under script control. Listing 15-5 shows an example of such a script.

### Example

The style of an element toggles between “on” and “off” in Listing 15-5 by virtue of setting the element's `className` property alternatively to an existing stylesheet class selector name and an empty string. When you set the `className` to an empty string, the default behavior of the `h1` element governs the display of the first header. A click of the button forces the stylesheet rule to override the default behavior in the first `h1` element.

#### Listing 15-5: Working with the `className` Property

```

<html>
  <head>
    <title>className Property</title>
    <style type="text/css">
      .special {font-size:16pt; color:red}
    </style>
    <script type="text/javascript">
      function toggleSpecialStyle(elemID) {
        var elem = (document.all) ? document.all(elemID) :
          document.getElementById(elemID);
        if (elem.className == "") {
          elem.className = "special";
        } else {
          elem.className = "";
        }
      }
    </script>
  </head>
  <body>
    <h1>className Property Lab</h1>
    <hr />
    <form name="input">
      <input type="button" value="Toggle Class Name"
        onclick="toggleSpecialStyle('head1')" />
    </form>
    <br />

    <h1 id="head1">ARTICLE I</h1>
    <p>Congress shall make no law respecting an establishment of religion, or
      prohibiting the free exercise thereof; or abridging the freedom of
      speech, or of the press; or the right of the people peaceably to
      assemble, and to petition the government for a redress of
      grievances.</p>
    <h1>ARTICLE II</h1>

```

*Continued*

*elementObject.className***Listing 15-5 (continued)**

```

    <p>A well regulated militia, being necessary to the security of a free
      state, the right of the people to keep and bear arms, shall not be
      infringed.</p>
  </body>
</html>

```

You can also create multiple versions of a style rule with different class selector identifiers and apply them at will to a given element.

**Related Items:** `rule`, `stylesheet` objects (Chapter 26); `id` property.

`clientHeight``clientWidth`**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN7, Moz1+, Safari1+

These two properties by and large reveal the pixel height and width of the content within an element whose stylesheet rule includes height and width settings. In theory, these measures do not take into account any margins, borders, or padding that you add to an element by way of stylesheets. In practice, however, different combinations of borders, margins, and padding influence these values in unexpected ways. One of the more reliable applications of the `clientHeight` property enables you to discover, for example, where the text of an overflowing element ends. To read the rendered dimensions of an element, you are better served across browsers with the `offsetHeight` and `offsetWidth` properties.

For the `document.body` object, the `clientHeight` and `clientWidth` properties return the inside height and width of the window or frame (plus or minus a couple of pixels). These take the place of desirable, but nonexistent, window properties in IE.

Internet Explorer 5+ expands the number of objects that employ these properties to include virtually all objects that represent HTML elements. For IE4, these properties apply only to the following objects: `body`, `button`, `caption`, `div`, `embed`, `fieldset`, `legend`, `marquee`, `table`, `td`, `textarea`, `th`, and `tr`.

Values for these properties in Mozilla-based browsers are zero, except for `document.body`, which measures the browser's current content area.

**Example**

Listing 15-6 for IE includes an example of how to dynamically size content on a page based upon the client area width and height. This example calls upon the `clientHeight` and `clientWidth` properties of a `div` element that contains a paragraph element. Only the width of the `div` element is specified in its stylesheet rule, which means that the paragraph's text wraps inside that width and extends as deeply as necessary to show the entire paragraph. The `clientHeight` property describes that depth. The `clientHeight` property then calculates where a logo image should be positioned immediately after `div`, regardless of the length of the text. As a bonus, the `clientWidth` property helps the script center the image horizontally with respect to the paragraph's text.

## Listing 15-6: Using clientHeight and clientWidth Properties

```

<html>
  <head>
    <title>clientHeight and clientWidth Properties</title>
    <script type="text/javascript">
      function showLogo() {
        var paragraphW = document.getElementById("myDIV").clientWidth;
        var paragraphH = document.getElementById("myDIV").clientHeight;
        // correct for Windows/Mac discrepancies
        var paragraphTop = (document.getElementById("myDIV").clientTop) ?
          document.getElementById("myDIV").clientTop :
          document.getElementById("myDIV").offsetTop;
        var logoW = document.getElementById("logo").style.pixelWidth;
        // center logo horizontally against paragraph
        document.getElementById("logo").style.pixelLeft =
          (paragraphW-logoW) / 2;
        // position image immediately below end of paragraph
        document.getElementById("logo").style.pixelTop =
          paragraphTop + paragraphH;
        document.getElementById("logo").style.visibility = "visible";
      }
    </script>
  </head>
  <body>
    <button onclick="showLogo()">Position and Show Logo Art</button>
    <div id="logo" style="position:absolute; width:120px; visibility:hidden">
      
    </div>
    <div id="myDIV" style="width:200px">
      <p>Lorem ipsum dolor sit amet, consetetur adipisicing elit, sed do
        eiusmod tempor incididunt ut labore et dolore magna aliqua. Ut enim
        adminim veniam, quis nostrud exercitation ullamco laboris nisi ut
        aliquip ex ea commodo consequat. Duis aute irure dolor in
        reprehenderit involuptate velit esse cillum dolore eu fugiat nulla
        pariatur. Excepteur sint occaecat cupidatat non proident.</p>
    </div>
  </body>
</html>

```

To assist in the vertical positioning of the logo, the `offsetTop` property of the `div` object provides the position of the start of the `div` with respect to its outer container (the `body`). Unfortunately, MacIE uses the `clientTop` property to obtain the desired dimension. That measure (assigned to the `paragraphTop` variable), plus the `clientHeight` of the `div`, provides the top coordinate of the image.

**Related Items:** `offsetHeight`, `offsetWidth` properties.

`clientLeft`

`clientTop`

**Value:** Integer.

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

Read-Only

***elementObject.clientLeft***

The purpose and names of the `clientLeft` and `clientTop` properties are confusing at best. Unlike the `clientHeight` and `clientWidth` properties, which apply to the content of an element, the `clientLeft` and `clientTop` properties return essentially no more information than the thickness of a border around an element — provided the element is positioned. If you do not specify a border or do not position the element, the values are zero (although the `document.body` object can show a couple of pixels in each direction without explicit settings). If you are trying to read the left and top coordinate positions of an element, the `offsetLeft` and `offsetTop` properties are more valuable in WinIE; as shown in Listing 15-6, however, the `clientTop` property returns a suitable value in MacIE. Virtually all elements have the `clientLeft` and `clientTop` properties in IE5+; in IE4, the properties apply only to the `body`, `button`, `caption`, `embed`, `fieldset`, `legend`, `marquee`, and `textarea` objects.

**Related Items:** `offsetLeft`, `offsetTop` properties.

**contentEditable**

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

IE5.5 introduced the concept of editable HTML content on a page. Element tags can include a `contentEditable` attribute, whose value is echoed via the `contentEditable` property of the element. The default value for this property is `inherit`, which means that the property inherits whatever setting this property has in the hierarchy of HTML containers outward to the `body`. If you set the `contentEditable` property to `true`, that element and all nested elements set to `inherit` the value become editable; conversely, a setting of `false` turns off the option to edit the content.

**Example**

Listing 15-7 demonstrates how to use the `contentEditable` property to allow a piece of text to be edited. When you click the button of a freshly loaded page, the `toggleEdit()` function captures the opposite of the current editable state via the `isContentEditable` property of the `div` that is subject to edit. You switch on editing for that element in the next statement by assigning the new value to the `contentEditable` property of the `div`. For added impact, turn the text of the `div` to red to provide additional user feedback about what is editable on the page. You can also switch the button label to one that indicates the action invoked by the next click on it.

**Listing 15-7: Using the contentEditable Property**

```
<html>
  <head>
    <style type="text/css">
      .normal {color: black}
      .editing {color: red}
    </style>
    <script type="text/javascript">
      function toggleEdit() {
        var newState = !editableText.isContentEditable;
        editableText.contentEditable = newState;
        editableText.className = (newState) ? "editing" : "normal";
        editBtn.innerHTML = (newState) ? "Disable Editing" : "Enable Editing";
      }
    </script>
  <title>
  </title>
```

```

</head>
<body>
  <h1>Editing Contents</h1>
  <hr />
  <p>Turn on editing to modify the following text:</p>
  <div id="editableText">
    Edit this text on the fly...
  </div>
  <p><button id="editBtn" onclick="toggleEdit()"
    onfocus="this.blur()">Enable Editing</button></p>
</body>
</html>

```

**Related Item:** `isContentEditable` property.

## currentStyle

**Value:** `style` object.

Read-Only

**Compatibility:** WinIE5+, MacIE5+, NN-, Moz-, Safari-

Every element has style attributes applied to it, even if those attributes are the browser's default settings. Because an element's `style` object reflects only those properties whose corresponding attributes are explicitly set via CSS statements, you cannot use the `style` property of an element object to view default style settings applied to an element. That's where the `currentStyle` property comes in.

This property returns a read-only `style` object that contains values for every possible `style` property applicable to the element. If a `style` property is explicitly set via CSS statement or script adjustment, the current reading for that property is also available here. Thus, a script can inquire about any property to determine if it should change to meet some scripted design goal. For example, if you surround some text with an `<em>` tag, the browser by default turns that text into an italic font style. This setting is not reflected in the element's `style` object (`fontStyle` property) because the italic setting was not set via CSS; in contrast, the element object's `currentStyle.fontStyle` property reveals the true, current `fontStyle` property of the element as italic.

## Example

To change a `style` property setting, access it via the element's `style` object. Use The Evaluator (Chapter 13) to compare the properties of the `currentStyle` and `style` objects of an element. For example, an unmodified copy of The Evaluator contains an `em` element whose ID is "myEM". Enter `document.getElementById("myEM").style` into the bottom property listing text box and press Enter. Notice how most of the property values are empty. Now enter `document.getElementById("myEM").currentStyle` into the property listing text box and press Enter. Every property has a value associated with it.

**Related Items:** `runtimeStyle`, `style` objects (Chapter 26); `window.getComputedStyle()` for W3C DOM browsers (Chapter 16).

## dataFld

## dataFormatAs

## dataSrc

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE5, NN-, Moz-, Safari-

**elementObject.dataFld**

The `dataFld`, `dataFormatAs`, and `dataSrc` properties (along with more element-specific properties such as `dataPageSize` and `recordNumber`) are part of the Internet Explorer data-binding facilities based on ActiveX controls. The Win32 versions of IE4 and later have several ActiveX objects built into the browsers that facilitate the direct communication between a Web page and a data source. Data sources include text files, XML data, HTML data, and external databases (MacIE supports text files only). Data binding is a very large topic, much of which extends more to discussions about Microsoft Data Source Objects (DSOs), ODBC, and JDBC — subjects well beyond the scope of this book. But data binding is a powerful tool and can be of use even if you are not a database guru. Therefore, this discussion of the three primary properties — `dataFld`, `dataFormatAs`, and `dataSrc` — briefly covers data binding through Microsoft's *Tabular Data Control DSO*. This allows any page to access, sort, display, and filter (but not update) data downloaded into a Web page from an external text file (commonly comma- or tab-delimited data).

You can load data from an external text file into a document with the help of the Tabular Data Control (TDC). You retrieve the data by specifying the TDC object within an `<object>` tag set and specifying additional parameters such as the URL of the text file and field delimiter characters. The `object` element can go anywhere within the body of your document. (I tend to put it at the bottom of the code so that all normal page rendering happens before the control loads.) Retrieving the data simply brings it into the browser and does not, on its own, render the data on the page.

If you haven't worked with embedded objects in IE, the `classid` attribute value might seem a bit strange. The most perplexing part to some is the long value of numeric data signifying the Globally Unique Identifier (GUID) for the object. You must enter this value exactly as shown in the following example for the proper ActiveX TDC to run. The HTML syntax for this object is as follows:

```
<object id="objName" classid="clsid:333C7BC4-460F-11D0-BC04-0080C7055A83">
  <param name="DataURL" value="URL">
    [additional optional parameters]
</object>
```

Table 15-3 lists the parameters available for the TDC. Only the `DataURL` parameter is required; others — such as `FieldDelim`, `UseHeader`, `RowDelim`, and `EscapeChar` — may be helpful depending on the nature of the data source.

---

**Table 15-3: Tabular Data Control Parameters**

---

<i>Parameter</i>	<i>Description</i>
<code>CharSet</code>	Character set of the data source file. Default is <code>latin1</code> .
<code>DataURL</code>	URL of data source file (relative or absolute).
<code>EscapeChar</code>	Character used to “escape” delimiter characters that are part of the data. Default is empty. A common value is <code>"\"</code> .
<code>FieldDelim</code>	Delimiter character between fields within a record. Default is comma ( <code>,</code> ). For a Tab character, use a value of <code>&amp;#09;</code> .
<code>Language</code>	ISO language code of source data. Default is <code>en-us</code> .
<code>TextQualifier</code>	Optional character surrounding a field's data. Default is empty.
<code>RowDelim</code>	Delimiter character between records. Default is newline ( <code>NL</code> ).
<code>UseHeader</code>	Set to <code>true</code> if the first row of data in the file contains field names. Default is <code>false</code> .

---

The value you assign to the `object` element's `id` attribute is the identifier that your scripts use to communicate with the data after the page and data completely load. You can therefore have as many uniquely named TDCs loaded in your page as there are data source files you want to access at once.

The initial binding of the data to HTML elements usually comes when you assign values to the `datasrc` and `datafld` attributes of the elements. The `datasrc` attribute points to the `dso` identifier (matching the `id` attribute of the `object` element, preceded with a hash symbol), while the `datafld` attribute points to the name of the field whose data should be extracted. When you use data binding with an interactive element such as a table, multiple records are displayed in consecutive rows of the table (more about this in a moment).

Adjust the `dataSrc` and `dataFld` properties if you want the same HTML element (other than a table) to change the data that it displays. These properties apply to a subset of HTML elements that can be associated with external data: `a`, `applet`, `body`, `button`, `div`, `frame`, `iframe`, `img`, `input` (most types), `label`, `marquee`, `object`, `param`, `select`, `span`, and `textarea` objects.

In some cases, your data source may store chunks of HTML-formatted text for rendering inside an element. Unless directed otherwise, the browser renders a data source field as plain text—even if the content contains HTML formatting tags. But if you want the HTML to be observed during rendering, you can set the `dataFormatAs` property (or, more likely, the `dataformatas` attribute of the tag) to `HTML`. The default value is `text`.

## Example

Listing 15-8 is a simple document that has two TDC objects associated with it. The external files are different formats of the U.S. Bill of Rights document. One file is a traditional, tab-delimited data file consisting of only two records. The first record is a tab-delimited sequence of field names (named "Article1", "Article2", and so on); the second record is a tab-delimited sequence of article content defined in HTML:

```
<h1>ARTICLE I</h1><p>Congress shall make...</p>
```

The second file is a raw text file consisting of the full Bill of Rights with no HTML formatting attached.

When you load Listing 15-8, only the first article of the Bill of Rights appears in a blue-bordered box. Buttons enable you to navigate to the previous and next articles in the series. Because the data source is a traditional, tab-delimited file, the `nextField()` and `prevField()` functions calculate the name of the next source field and assign the new value to the `dataFld` property. All of the data is already in the browser after the page loads, so cycling through the records is as fast as the browser can reflow the page to accommodate the new content.

### Listing 15-8: Binding Data to a Page

```
<html>
  <head>
    <title>Data Binding</title>
    <style type="text/css">
      #display {width:500px; border:10px ridge blue; padding:20px}
      .hiddenControl {display:none}
    </style>
    <script type="text/javascript">
      function nextField() {
```

*Continued*

**elementObject.dataFld****Listing 15-8 (continued)**

```

    var elem = document.getElementById("display");
    var fieldName = elem.dataFld;
    var currFieldNum = parseInt(fieldName.substring(7,
        fieldName.length),10);
    currFieldNum = (currFieldNum == 10) ? 1 : ++currFieldNum;
    elem.dataFld = "Article" + currFieldNum;
}
function prevField() {
    var elem = document.getElementById("display");
    var fieldName = elem.dataFld;
    var currFieldNum = parseInt(fieldName.substring(7,
        fieldName.length),10);
    currFieldNum = (currFieldNum == 1) ? 10 : --currFieldNum;
    elem.dataFld = "Article" + currFieldNum;
}

function toggleComplete() {
    if (document.getElementById("buttonWrapper").className == "") {
        document.getElementById("display").dataSrc = "#rights_raw";
        document.getElementById("display").dataFld = "column1";
        document.getElementById("display").dataFormatAs = "text";
        document.getElementById("buttonWrapper").className =
            "hiddenControl";
    } else {
        document.getElementById("display").dataSrc = "#rights_html";
        document.getElementById("display").dataFld = "Article1";
        document.getElementById("display").dataFormatAs = "HTML";
        document.getElementById("buttonWrapper").className = "";
    }
}
</script>
</head>
<body>
    <h1>U.S. Bill of Rights</h1>
    <form>
        <input type="button" value="Toggle Complete/Individual"
            onclick="toggleComplete()" /> <span id="buttonWrapper" class=""><input
            type="button" value="Prev" onclick="prevField()" /> <input
            type="button" value="Next" onclick="nextField()" /></span>
    </form>
    <div id="display" datasrc="#rights_html" datafld="Article1"
        dataformatas="HTML">
    </div>
    <object id="rights_html"
        classid="clsid:333C7BC4-460F-11D0-BC04-0080C7055A83">
        <param name="DataURL" value="Bill of Rights.txt" />
        <param name="UseHeader" value="True" />
        <param name="FieldDelim" value="&#09;" />
    </object> <object id="rights_raw"
        classid="clsid:333C7BC4-460F-11D0-BC04-0080C7055A83">
        <param name="DataURL" value="Bill of Rights (no format).txt" />
        <param name="FieldDelim" value="\ " />
        <param name="RowDelim" value="\ " />
    </object>
</body>
</html>

```

Another button on the page enables you to switch between the initial piecemeal version of the document and the unformatted version in its entirety. To load the entire document as a single record, the `FieldDelim` and `RowDelim` parameters of the second `object` element eliminate their default values by replacing them with characters that don't appear in the document at all. And because the external file does not have a field name in the file, the default value (`column1` for the lone column in this document) is the data field. Thus, in the `toggleComplete()` function, the `dataSrc` property is changed to the desired `object` element ID, the `dataFld` property is set to the correct value for the data source, and the `dataFormatAs` property is changed to reflect the different intention of the source content (to be rendered as HTML or as plain text). When the display shows the entire document, you can hide the two radio buttons by assigning a `className` value to the `span` element that surrounds the buttons. The `className` value is the identifier of the class selector in the document's stylesheet. When the `toggleComplete()` function resets the `className` property to empty, the default properties (normal inline display style) take hold.

One further example demonstrates the kind of power available to the TDC under script control. Listing 15-9 displays table data from a tab-delimited file of Academy Award information. The data file has eight columns of data, and each column heading is treated as a field name: Year, Best Picture, Best Director, Best Director Film, Best Actress, Best Actress Film, Best Actor, and Best Actor Film. For the design of the page, only five fields from each record appear: Year, Film, Director, Actress, and Actor. Notice in the listing how the HTML for the table and its content is bound to the data source object and the fields within the data.

The "dynamic" part of this example is apparent in how you can sort and filter the data, once loaded into the browser, without further access to the original source data. The TDC object features `Sort` and `Filter` properties that enable you to act on the data currently loaded in the browser. The simplest kind of sorting indicates on which field (or fields via a semicolon-delimited list of field names) the entire data set should be sorted. Leading the name of the sort field is either a plus (to indicate ascending) or minus (descending) symbol. After setting the data object's `Sort` property, invoke its `Reset()` method to tell the object to apply the new property. The data in the bound table is immediately redrawn to reflect any changes.

Similarly, you can tell a data collection to display records that meet specific criteria. In Listing 15-9, two select lists and a pair of radio buttons provide the interface to the `Filter` property's settings. For example, you can filter the output to display only those records in which the Best Picture was the same picture of the winning Best Actress's performance. Simple filter expressions are based on field names:

```
dataObj.Filter = "Best Picture" = "Best Actress Film";
```

### Listing 15-9: Sorting Bound Data

    </object>
</body>
</html>

```

**Related Items:** `recordNumber`, `table.dataPageSize` properties.

## dir

**Value:** "ltr" | "rtl" Read/Write  
**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `dir` property (based on the `dir` attribute of virtually every text-oriented HTML element) controls whether an element's text is rendered left-to-right (the default) or right-to-left. By and large, this property (and HTML attribute) is necessary only when you need to override the default directionality of a language's character set as defined by the Unicode standard.

### Example

Changing this property value in a standard U.S. version of a browser only makes the right margin the starting point for each new line of text (in other words, the characters are not rendered in reverse order). You can experiment with this in The Evaluator by entering the following statements into the expression evaluation field:

```
document.getElementById("myP").dir = "rtl"
```

**Related Item:** `lang` property.

## disabled

**Value:** Boolean. Read/Write  
**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

While some elements have a `disabled` property in IE4 and IE5, this property is associated with every HTML element in IE5.5+. W3C DOM browsers apply the property only to form control and `style` element objects. Disabling an HTML element (like form elements) usually gives the element a "dimmed" look, indicating that it is not active. A disabled element does not receive any events. It also cannot receive focus, either manually or by script (although disabled text fields in MacIE4 errantly manage to receive focus). But a user can still select and copy a disabled body text element.

### Note

If you disable a form control element, the element's data is not submitted to the server with the rest of the form elements. If you need to keep a form control "locked down," but still submit it to the server, use the form element's `onsubmit` event handler to enable the form control right before the form is submitted.

### Example

Use The Evaluator (Chapter 13) to experiment with the `disabled` property on both form elements (IE4+ and W3C) and regular HTML elements (WinIE5.5+). For IE4+ and W3C browsers, see what happens when you disable the output text area by entering the following statement into the top text box:

```
document.forms[0].output.disabled = true
```

The text area is disabled for user entry, although you can still set the field's `value` property via script (which is how the `true` returned value got there).

If you have WinIE5.5+, disable the `myP` element by entering the following statement into the top text box:

```
document.getElementById("myP").disabled = true
```

***elementObject.disabled***

The sample paragraph's text turns gray.

**Related Item:** `isDisabled` property.

**document**

**Value:** document object.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

In the context of HTML element objects as exposed in IE4+, the `document` property is a reference to the document that contains the object. While it is unlikely that you will need to use this property, `document` may come in handy for complex scripts and script libraries that handle objects in a generic fashion and do not know the reference path to the document containing a particular object. You might need a reference to the document to inspect it for related objects. The W3C version of this property is `ownerDocument`.

**Example**

The following simplified function accepts a parameter that can be any object in a document hierarchy. The script finds out the reference of the object's containing document for further reference to other objects:

```
function getCompanionFormCount(obj) {
    var ownerDoc = obj.document;
    return ownerDoc.forms.length;
}
```

Because the `ownerDoc` variable contains a valid reference to a document object, the `return` statement uses that reference to return a typical property of the document object hierarchy.

**Related Item:** `ownerDocument` property.

**filters[]**

**Value:** Array.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

*Filters* are IE-specific stylesheet add-ons that offer a greater variety of font rendering (such as drop shadows) and transitions between hidden and visible elements. Each filter specification is a *filter* object. The `filters` property contains an array of *filter* objects defined for the current element. You can apply filters to the following set of elements: `body`, `button`, `img`, `input`, `li`, `marquee`, `ol`, `table`, `td`, `textarea`, `th`, `ul`, and positioned `div` and `span` elements. See Chapter 26 for details about stylesheet filters.

**Related Item:** *filter* object.

**firstChild****lastChild**

**Value:** Node object reference.

Read-Only

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

W3C DOM-based document object models are built around an architecture known as a *node map*. Each object defined by HTML is a node in the map. A node has relationships with other nodes in the document — relationships described in family terms of parents, siblings, and children.

A *child node* is an element that is contained by another element. The container is the parent of such a child. Just as an HTML element can contain any number of child elements, so can a parent object have zero or more children. A list of those children (returned as an array) can be read from an object by way of its `childNodes` property:

```
var nodeArray = document.getElementById("elementID").childNodes;
```

While you can use this array (and its `length` property) to get a reference to the first or last child node, the `firstChild` and `lastChild` properties offer shortcuts to those positions. These are helpful when you wish to insert a new child before or after all of the others and you need a reference point for the IE `insertAdjacentElement()` method or other method that adds elements to the document's node list.

## Example

Listing 15-10 contains an example of how to use the `firstChild` and `lastChild` properties to access child nodes. These two properties come in handy in this example, which adds and replaces `li` elements to an existing `ol` element. You can enter any text you want to appear at the beginning or end of the list. Using the `firstChild` and `lastChild` properties simplifies access to the ends of the list. For the functions that replace child nodes, the example uses the `replaceChild()` method. Alternatively for IE4+, you can modify the `innerText` property of the objects returned by the `firstChild` or `lastChild` property. This example is especially interesting to watch when you add items to the list: The browser automatically rennumbers items to fit the current state of the list.

**Caution**

See the discussion of the `childNodes` property earlier in this chapter about the presence of “phantom” nodes in some browser versions. The problem may influence your use of the `firstChild` and `lastChild` properties.

### Listing 15-10: Using `firstChild` and `lastChild` Properties

```
<html>
  <head>
    <title>firstChild and lastChild Properties</title>
    <script type="text/javascript">
      // helper function for prepend() and append()
      function makeNewLI(txt) {
        var newItem = document.createElement("li");
        newItem.innerHTML = txt;
        return newItem;
      }
      function prepend(form) {
        var newItem = makeNewLI(form.input.value);
        var firstLI = document.getElementById("myList").firstChild;
        document.getElementById("myList").insertBefore(newItem, firstLI);
      }
      function append(form) {
        var newItem = makeNewLI(form.input.value);
        var lastLI = document.getElementById("myList").lastChild;
        document.getElementById("myList").appendChild(newItem);
      }
      function replaceFirst(form) {
        var newItem = makeNewLI(form.input.value);
        var firstLI = document.getElementById("myList").firstChild;
```

*Continued*

**elementObject.firstChild****Listing 15-10 (continued)**

```

        document.getElementById("myList").replaceChild(newItem, firstLI);
    }
    function replaceLast(form) {
        var newItem = makeNewLI(form.input.value);
        var lastLI = document.getElementById("myList").lastChild;
        document.getElementById("myList").replaceChild(newItem, lastLI);
    }
</script>
</head>
<body>
<h1>firstChild and lastChild Property Lab</h1>
<hr />
<form>
    <label>Enter some text to add to or replace in the OL
    element:</label><br />

    <li>Initial Item 2</li>
    <li>Initial Item 3</li>
    <li>Initial Item 4</li>
</ol>
</body>
</html>

```

**Related Items:** `nextSibling`, `parentElement`, `parentNode`, `previousSibling` **properties**; `appendChild()`, `hasChildNodes()`, `removeChild()`, `removeNode()`, `replaceChild()`, `replaceNode()` **methods**.

**height****width**

**Value:** Integer or percentage string.

Read/Write and Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `height` and `width` properties described here are not the identically named properties that belong to an element's `style`. Rather, these properties reflect the values normally assigned to `height` and `width` attributes of elements such as `img`, `applet`, `table`, and so on. As such, these properties are accessed directly from the object (for example, `document.getElementById("myTable").width` in IE4+) rather than through the `style` object (for example, `document.getElementById("myDIV").style.width`). Only elements for which the HTML 4.x standard provides `height` and `width` attributes have the corresponding properties.

***elementObject.hideFocus***

Values for these properties are either integer pixel values (numbers or strings) or percentage values (strings only). If you need to perform some math on an existing percentage value, use the `parseInt()` function to extract the numeric value for use with math calculations. If an element's `height` and `width` attributes are set as percentage values, you can use the `offsetHeight` and `offsetWidth` properties in many modern browsers to get the rendered pixel dimensions.

Property values are read/write for the `image` object in most recent browser versions because you can resize an `image` object in IE4+ and Moz1+ after the page loads. Properties are read/write for some other objects (such as the `table` object)—but not necessarily all others that support these properties.

In general, you cannot set the value of these properties to something less than is required to render the element. This is particularly true of a table. If you attempt to set the `height` value to less than the amount of pixels required to display the table as defined by its style settings, your changes have no effect (even though the property value retains its artificially low value). For other objects, however, you can set the size to anything you like and the browser scales the content accordingly (images, for example). If you want to see only a segment of an element (in other words, to crop the element), use a stylesheet to set the element's clipping region.

### Example

The following example demonstrates how to use the `width` property by increasing the width of a table by 10 percent.

```
var tableW = parseInt(document.getElementById("myTable").width);
document.getElementById("myTable").width = (tableW * 1.1) + "%";
```

Because the initial setting for the `width` attribute of the `table` element is set as a percentage value, the script calculation extracts the number from the percentage width string value. In the second statement, the old number is increased by 10 percent and turned into a percentage string by appending the percentage symbol to the value. The resulting string value is assigned to the `width` property of the table.

**Related Items:** `clientHeight`, `clientWidth` properties; `style.height`, `style.width` properties.

## hideFocus

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

In IE for Windows, button types of form controls and links display a dotted rectangle around some part of the element whenever that element has focus. If you set the `tabindex` attribute or `tabIndex` property of any other kinds of elements in IE5+, they, too, display that dotted line when given focus. You can still let an element receive focus, but hide that dotted line by setting the `hideFocus` property of the element object to `true` (default value is `false`).

Hiding focus does not disable the element. In fact, if the element about to receive focus is scrolled out of view, the page scrolls to bring the element into view. Form controls that respond to keyboard action (for example, pressing the spacebar to check or uncheck a checkbox control) also continue to work as normal. For some designers, the focus rectangle harms the design goals of the page. The `hideFocus` property gives them more control over the appearance while maintaining consistency of operation with other pages. There is no corresponding HTML attribute for a tag, so you can use an `onload` event handler in the page to set the `hideFocus` property of desired objects after the page loads.

***elementObject.hideFocus*****Example**

Use The Evaluator (Chapter 13) to experiment with the `hideFocus` property in WinIE5.5+. Enter the following statement into the top text field to assign a `tabIndex` value to the `myP` element so that, by default, the element receives focus and the dotted rectangle:

```
document.getElementById("myP").tabIndex = 1
```

Press the Tab key several times until the paragraph receives focus. Now, disable the focus rectangle:

```
document.getElementById("myP").hideFocus = true
```

If you now press the Tab key several times, the dotted rectangle does not appear around the paragraph. To prove that the element still receives focus, scroll the page down to the bottom so that the paragraph is not visible (you may have to resize the window). Click one of the focusable elements at the bottom of the page, and then press the Tab key slowly until the Address field toolbar has focus. Press the Tab key once. The page scrolls to bring the paragraph into view, but there is no focus rectangle around the element.

**Related Items:** `tabIndex` property; `scrollIntoView()` method.

**id**

**Value:** String.

(See text)

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `id` property returns the identifier assigned to an element's `id` attribute in the HTML code. A script cannot modify the ID of an existing element nor assign an ID to an element that lacks one. But if a script creates a new element object, an identifier may be assigned to it by way of the `id` property.

**Example**

Rarely do you need to access this property in a script — unless you write an authoring tool that iterates through all elements of a page to extract the IDs assigned by the author. You can retrieve an object reference once you know the object's `id` property (via the `document.getElementById(elemID)` method). But if for some reason your script doesn't know the ID of, say, the second paragraph of a document, you can extract that ID as follows:

```
var elemID = document.getElementsByTagName("p")[1].id;
```

**Related Item:** `className` property.

**innerHTML****innerText**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

One way that Internet Explorer exposes the contents of an element is through the `innerHTML` and `innerText` properties. (Moz1+/NN6+ offer only the `innerHTML` property.) All content defined by these “inner” properties consists of document data that is contained by an element's start and end tags, but not including the tags themselves (see `outerText` and `outerHTML` properties). Setting these inner properties is a common way to modify a portion of a page's content after the page loads.

The `innerHTML` property contains not only the text content for an element as seen on the page, but also every bit of HTML tagging that is associated with that content. (If there are no

tags in the content, the text is rendered as is.) For example, consider the following bit of HTML source code:

```
<p id="paragraph1">"How <em>are</em> you?" he asked.</p>
```

The value of the paragraph object's `innerHTML` property (`document.getElementById("paragraph1").innerHTML`) is:

```
"How <em>are</em> you?" he asked.
```

The browser interprets any HTML tags that you include in a string you assign to an element's `innerHTML` property as tags. This also means that you can introduce entirely new nested elements (or child nodes in the modern terminology) by assigning a slew of HTML content to an element's `innerHTML` property. The document's object model adjusts itself to the newly inserted content.

In contrast, the `innerText` property knows only about the text content of an element container. In the example you just saw, the value of the paragraph's `innerText` property (`document.getElementById("paragraph1").innerText`) is:

```
"How are you?" he asked.
```

It's important to remember that if you assign a string to the `innerText` property of an element and that string contains HTML tags, the tags and their angle brackets appear in the rendered page and are not interpreted as live tags.

Do not modify the `innerHTML` property to adjust the HTML for `frameset`, `html`, `head`, or `title` objects. You may modify table constructions through either `innerHTML` or the various table-related methods that create or delete rows, columns, and cells (see Chapter 37 on the CD-ROM). It is also safe to modify the contents of a cell by setting its `innerHTML` or `innerText` properties.

When the HTML you insert includes a `<script>` tag, be sure to include the `defer` attribute to the opening tag. This even goes for scripts that contain function definitions, which you might consider to be deferred automatically.

## Example

Listing 15-11 contains an example of how to use the `innerHTML` and `innerText` properties to dynamically alter the content within a page. The page generated in the listing contains an `h1` element label and a paragraph of text. The purpose is to demonstrate how the `innerHTML` and `innerText` properties differ in their intent. Two text boxes contain the same combination of text and HTML tags that replaces the inner content of the paragraph's label.

If you apply the default content of the first text box to the `innerHTML` property of the `label1` object, the italic style is rendered as such for the first word. In addition, the text in parentheses is rendered with the help of the small stylesheet rule assigned by virtue of the surrounding `<span>` tags. But if you apply that same content to the `innerText` property of the `label1` object, the tags are rendered as is.

Use this as a laboratory to experiment with some other content in both text boxes. See what happens when you insert a `<br>` tag within some text of both text boxes.

### Listing 15-11: Using `innerHTML` and `innerText` Properties

```
<html>
  <head>
    <title>innerHTML and innerText Properties</title>
```

*Continued*

**elementObject.innerHTML****Listing 15-11 (continued)**

    assemble, and to petition the government for a redress of
    grievances.</p>
</body>
</html>

```

**Related Items:** outerHTML, outerText properties; replaceNode() method.

**isContentEditable**

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The isContentEditable property returns a Boolean value indicating whether a particular element object is set to be editable (see the preceding discussion of the contentEditable property). This property is helpful because if a parent element's contentEditable property

***elementObject.isDisabled***

is set to true, a nested element's `contentEditable` property likely is set to its default value `inherit`. But because its parent is editable, the `isContentEditable` property of the nested element returns true.

**Example**

Use The Evaluator (Chapter 13) to experiment with both the `contentEditable` and `isContentEditable` properties on the `myP` and nested `myEM` elements (reload the page to start with a known version). Check the current setting for the `myEM` element by typing the following statement into the top text field:

```
myEM.isContentEditable
```

This value is `false` because no element upward in the element containment hierarchy is set to be editable yet. Next, turn on editing for the surrounding `myP` element:

```
myP.contentEditable = true
```

At this point, the entire `myP` element is editable because its child element is set, by default, to inherit the edit state of its parent. Prove it by entering the following statement into the top text box:

```
myEM.isContentEditable
```

While the `myEM` element is shown to be editable, no change has accrued to its `contentEditable` property:

```
myEM.contentEditable
```

This property value remains the default `inherit`.

You can see an additional example of these two properties in use in Listing 15-7.

**Related Item:** `contentEditable` property.

**isDisabled**

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `isDisabled` property returns a Boolean value that indicates whether a particular element object is set to be disabled (see the preceding discussion of the `disabled` property). This property is helpful; if a parent element's `disabled` property is set to true, then a nested element's `disabled` property likely is set to its default value of `false`. But because its parent is disabled, the `isDisabled` property of the nested element returns true. In other words, the `isDisabled` property returns the actual disabled status of an element regardless of its `disabled` property.

**Example**

Use The Evaluator (Chapter 13) to experiment with both the `disabled` and `isDisabled` properties on the `myP` and nested `myEM` elements (reload the page to start with a known version). Check the current setting for the `myEM` element by typing the following statement into the top text field:

```
myEM.isDisabled
```

This value is `false` because no element upward in the element containment hierarchy is set for disabling yet. Next, disable the surrounding `myP` element:

```
myP.disabled = true
```

***elementObject.isDisabled***

At this point, the entire `myP` element (including its children) is disabled. Prove it by entering the following statement into the top text box:

```
myEM.isDisabled
```

While the `myEM` element is shown as disabled, no change has accrued to its `disabled` property:

```
myEM.disabled
```

This property value remains the default `false`.

**Related Item:** `disabled` property.

**isMultiLine**

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `isMultiLine` property returns a Boolean value that reveals whether the element object is capable of occupying or displaying more than one line of text. Importantly, this value does not reveal whether the element actually occupies multiple lines; rather, it indicates the potential of doing so. For example, a text `input` element cannot wrap to multiple lines, so its `isMultiLine` property is `false`. However, a `button` element can display multiple lines of text for its label, so it reports `true` for the `isMultiLine` property.

**Example**

Use The Evaluator (Chapter 13) to read the `isMultiLine` property for elements on that page. Try the following statements in the top text box:

```
document.body.isMultiLine
document.forms[0].input.isMultiLine
myP.isMultiLine
myEM.isMultiLine
```

All but the text field form control report that they are capable of occupying multiple lines.

**isTextEdit**

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `isTextEdit` property reveals whether an object can have a WinIE `TextRange` object created with its content. (See the `TextRange` object in Chapter 35.) You can create `TextRange` objects only from a limited selection of objects in IE4+ for Windows: `body`, `button`, `text type input`, and `textarea`. This property always returns `false` in MacIE.

**Example**

Good coding practice dictates that your script check for this property before invoking the `createTextRange()` method on any object. A typical implementation is as follows:

```
if (document.getElementById("myObject").isTextEdit) {
    var myRange = document.getElementById("myObject").createTextRange();
    [more statements that act on myRange]
}
```

**Related Items:** `createRange()` method; `TextRange` object (Chapter 35).

## lang

**Value:** ISO language code string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `lang` property governs the written language system used to render an element's text content when overriding the default browser's language system. The default value for this property is an empty string unless the corresponding `lang` attribute is assigned a value in the element's tag. Modifying the property value by script control does not appear to have any effect in the current browser implementations.

### Example

Values for the `lang` property consist of strings containing valid ISO language codes. Such codes have, at the minimum, a primary language code (for example, "fr" for French) plus an optional region specifier (for example, "fr-ch" for Swiss French). The code to assign a Swiss German value to an element looks like the following:

```
document.getElementById("specialSpan").lang = "de-ch";
```

## language

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

IE4+'s architecture allows for multiple scripting engines to work with the browser. Two engines are included with the basic Windows version browser: JScript (compatible with JavaScript) and Visual Basic Scripting Edition (VBScript). The default scripting engine is JScript. But if you wish to use VBScript or some other scripting language in statements that are embedded within event handler attributes of a tag, you can specifically direct the browser to apply the desired scripting engine to those script statements by way of the `language` attribute of the tag. The `language` property provides scripted access to that property. Unless you intend to modify the event handler HTML code and replace it with a statement in VBScript (or any other non-JScript-compatible language installed with your browser), you do not need to modify this property (or read it, for that matter).

Valid values include `JScript`, `javascript`, `vbscript`, and `vbs`. Third-party scripting engines have their own identifier for use with this value. Because the `language` attribute was also used in the `<script>` tag, Internet Explorer 5 observes `language="xml"` as well.

**Related Item:** `script` element object.

## lastChild

(See `firstChild`)

## length

**Value:** Integer.

Read-Only and Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `length` property returns the number of items in an array or collection of objects. Its most common application is as a boundary condition in a `for` loop. While arrays and collections commonly use integer values as index values (always starting with zero), the `length` value is the actual number of items in the group. Therefore, to iterate through all items of the group, the condition expression should include a less-than (`<`) symbol rather than a less-than-or-equal (`<=`) symbol, as in the following:

```
for (var i = 0; i < someArray.length; i++) {...}
```

***elementObjectCollection.length***

For decrementing through an array (in other words, starting from the last item in the array and working toward the first), the initial expression must initialize the counting variable as the length minus one:

```
for (var i = someArray.length - 1; i >= 0; i--) {...}
```

For most arrays and collections, the `length` property is read-only and governed solely by the number of items in the group. But in more recent versions of the browsers, you can assign values to some object arrays (areas, options, and the `select` object) to create placeholders for data assignments. See discussions of the `area`, `select`, and `option` element objects for details. A plain JavaScript array can also have its `length` property value modified by script to either trim items from the end of the array or reserve space for additional assignments. See Chapter 30 for more about the Array object.

**Example**

You can try the following sequence of statements in the top text box of The Evaluator to see how the `length` property returns values (and sets them for some objects). Note that some statements work in only some browser versions.

```
(All browsers) document.forms.length
(All browsers) document.forms[0].elements.length
(NN3+, IE4+) document.images.length
(NN4+) document.layers.length
(IE4+) document.all.length
(IE5+, W3C) document.getElementById("myTable").childNodes.length
```

**Related Items:** `area`, `select`, `option`, and Array objects.

## localName

## namespaceURI

## prefix

**Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The three properties, `localName`, `namespaceURI`, and `prefix`, apply to any node in an XML document that associates a namespace URI with an XML tag. Although NN6 exposes all three properties for all element (and node) objects, the properties do not return the desired values. However, Mozilla-based browsers remedy the situation. To better understand what values these three properties represent, consider the following XML content:

```
<x xmlns:bk='http://bigbooks.org/schema'>
  <bk:title>To Kill a Mockingbird</bk:title>
</x>
```

The element whose tag is `<bk:title>` is associated with the Namespace URI defined for the block, and the element's `namespaceURI` property would return the string `http://bigbooks.org/schema`. The tag name consists of a prefix (before the colon) and the local name (after the colon). In the above example, the `prefix` property for the element defined by the `<bk:title>` tag would be `bk`, while the `localName` property would return `title`. The `localName` property of any node returns the same value as its `nodeName` property value, such as `#text` for a text node.

For more information about XML Namespaces, visit <http://www.w3.org/TR/REC-xml-names>.

**Related Items:** `scopeName`, `tagUrn` properties.

*elementObject.nodeName*

nextSibling

previousSibling

**Value:** Object reference.

Read-Only

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

A *sibling node* is one that is at the same nested level as another node in the hierarchy of an HTML document. For example, the following `p` element has two child nodes (the `em` and `span` elements). Those two child nodes are siblings of each other.

```
<p>MegaCorp is <em>the</em> source of the <span class="hot">hottest</span>
gizmos.</p>
```

Sibling order is determined solely by the source code order of the nodes. Therefore, in the previous example, the `em` node has no `previousSibling` property. Meanwhile, the `span` node has no `nextSibling` property (meaning that these properties return `null`). These properties provide another way to iterate through all nodes at the same level.

### Example

The following function assigns the same class name to all child nodes of an element:

```
function setAllChildClasses(parentElem, className) {
    var childElem = parentElem.firstChild;
    while (childElem.nextSibling) {
        childElem.className = className;
        childElem = childElem.nextSibling;
    }
}
```

This example is certainly not the only way to achieve the same results. Using a `for` loop to iterate through the `childNodes` collection of the parent element is an equally valid approach.

**Related Items:** `firstChild`, `lastChild`, `childNodes` properties; `hasChildNodes()`, `insertAdjacentElement()` methods.

nodeName

**Value:** String.

Read-Only

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

For HTML and XML elements, the name of a node is the same as the tag name. The `nodeName` property is provided for the sake of consistency with the node architecture specified by the formal W3C DOM standard. The value, just like the `tagName` property, is an all-uppercase string of the tag name (even if the HTML source code is written with lowercase tags).

Some nodes, such as the text content of an element, do not have a tag. The `nodeName` property for such a node is a special value: `#text`. Another kind of node is an attribute of an element. For an attribute, the `nodeName` is the name of the attribute. See Chapter 14 for more about Node object properties.

### Example

The following function demonstrates one (not very efficient) way to assign a new class name to every `p` element in an IE5+ document:

```
function setAllPClasses(className) {
    for (var i = 0; i < document.all.length; i++) {
        if (document.all[i].nodeName == "P") {
            document.all[i].className = className;
        }
    }
}
```

***elementObject.nodeName***

```

    }
  }
}

```

A more efficient approach uses the `getElementsByTagName()` method to retrieve a collection of all `p` elements and then iterate through them directly.

**Related Item:** `tagName` property.

**nodeType**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The W3C DOM specification identifies a series of constant values that denote categories of nodes. Every node has a value that identifies its type, but not all browsers support the `nodeType` property on all node types as objects. Table 15-4 lists the `nodeType` values implemented in recent browsers; all of the values are considered part of the W3C DOM Level 2 specification.

**Table 15-4: nodeType Property Values**

<i>Value</i>	<i>Description</i>	<i>WinIE</i>	<i>MacIE</i>	<i>NN/Moz</i>	<i>Safari</i>
1	Element node	5	5	NN6	1
2	Attribute node	6	5	NN6	1
3	Text ( <code>#text</code> ) node	5	5	NN6	1
4	CDATA section node	-	-	-	-
5	Entity reference node	-	-	-	-
6	Entity node	-	-	-	-
7	Processing instruction node	-	-	-	-
8	Comment node	6	5	NN6	-
9	Document node	5	5	NN6	1
10	Document type node	-	-	NN6	1
11	Document fragment node	6	5	NN6	1
12	Notation node	-	-	-	-

The `nodeType` value is automatically assigned to a node, whether the node exists in the document's HTML source code or it is generated on the fly via a script. For example, if you create a new element node through any of the ways available by script (for example, by assigning a string enclosed in HTML tags to the `innerHTML` property or by explicitly invoking the `document.createElement()` method), the new element assumes a `nodeType` of 1.

Mozilla-based browsers and Safari go one step further in supporting the W3C DOM specification by implementing a set of Node object property constants for each of the `nodeType` values.

Table 15-5 lists the entire set as defined in the DOM Level 2 specification. Substituting these constants for `nodeType` integers can improve readability of a script. For example, instead of

```
if (myElem.nodeType == 1) {...}
```

it is much easier to see what's going on with

```
if (myElem.nodeType == Node.ELEMENT_NODE) {...}
```

**Table 15-5: W3C DOM nodeType Constants**

<i>Reference</i>	<i>nodeType Value</i>
Node.ELEMENT_NODE	1
Node.ATTRIBUTE_NODE	2
Node.TEXT_NODE	3
Node.CDATA_SECTION_NODE	4
Node.ENTITY_REFERENCE_NODE	5
Node.ENTITY_NODE	6
Node.PROCESSING_INSTRUCTION_NODE	7
Node.COMMENT_NODE	8
Node.DOCUMENT_NODE	9
Node.DOCUMENT_TYPE_NODE	10
Node.DOCUMENT_FRAGMENT_NODE	11
Node.NOTATION_NODE	12

### Example

You can experiment with viewing `nodeType` property values in The Evaluator. The `p` element whose ID is `myP` is a good place to start. The `p` element itself is a `nodeType` of 1:

```
document.getElementById("myP").nodeType
```

This element has three child nodes: a string of text (`nodeName #text`); an `em` element (`nodeName em`); and the rest of the text of the element content (`nodeName #text`). If you view the `nodeType` of either of the text portions, the value comes back as 3:

```
document.getElementById("myP").childNodes[0].nodeType
```

**Related Item:** `nodeName` property.

## nodeValue

**Value:** Number, string, or null.

Read/Write

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

For a text node, the `nodeValue` property consists of the actual text for that node. Such a node cannot contain any further nested elements, so the `nodeValue` property offers another way of reading and modifying what Internet Explorer implements as an element's `innerText` property (but in the W3C DOM you must reference the child text node of an element to get or set its node value).

Of the node types implemented in the W3C DOM-capable browsers, only the text and attribute types have readable values. An element's node value returns a `null` value. For an attribute node, the `nodeValue` property consists of the value assigned to that attribute. According to the W3C DOM standard, attribute values should be reflected as strings. WinIE5, however, returns values of type `Number` when the value is all numeric characters. Even if you assign a string version of a number to such a `nodeValue` property, it is converted to a `Number` type internally. NN6 and MacIE5 return `nodeValue` values as strings in all cases (and convert numeric assignments to strings).

**elementObject.nodeValue****Example**

You can use the `nodeValue` property to carry out practical tasks. As an example, `nodeValue` can be used to increase the width of a `textarea` object by 10 percent. The `nodeValue` is converted to an integer before performing the math and reassignment:

```
function widenCols(textareaElem) {
    var colWidth = parseInt(textareaElem.attributes["cols"].nodeValue, 10);
    textareaElem.attributes["cols"].nodeValue = (colWidth * 1.1);
}
```

As another example, you can replace the text of an element, assuming that the element contains no further nested elements:

```
function replaceText(elem, newText) {
    if (elem.childNodes.length == 1 && elem.firstChild.nodeType == 3) {
        elem.firstChild.nodeValue = newText;
    }
}
```

The function builds in one final verification that the element contains just one child node and that it is a text type. An alternative version of the assignment statement of the second example uses the `innerText` property in IE with identical results:

```
elem.innerText = newText;
```

**Related Items:** `attributes`, `innerText`, `nodeType` properties.

**offsetHeight****offsetWidth**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

These properties, which ostensibly report the height and width of any element, have had a checkered history due to conflicts between interpretations of the CSS “box model” by Microsoft and the W3C. Both properties were invented by Microsoft for IE4. Although they are not part of any W3C standard, other modern browsers, including Mozilla-based browsers and Safari, implement the properties because they’re so valuable to scripters.

When IE6 is set to standards-compatible mode (by DOCTYPE switching described in Chapter 14), the properties measure the pixel dimensions of the element’s content, regardless of borders, margins, or padding. This is the W3C box model, which agrees with other W3C-compatible browsers. But in IE6 quirks mode and all older versions of WinIE, the measures incorrectly include border and padding thicknesses.

Be aware that for a normal block-level element whose height and width are not specified, the `offsetHeight` is determined by the actual height of the content after all text flows. But the `offsetWidth` always extends the full width of the containing element. Therefore, the `offsetWidth` property does not reveal the rendered width of text content that is narrower than the full parent element width. For example, a `p` element consisting of only a few words may report an `offsetWidth` of many hundreds of pixels because the paragraph’s block extends the full width of the `body` element that represents the containing parent of the `p` element. To find out the actual width of text within a full-width, block-level element, wrap the text within an inline element (such as a `span`) and inspect the `offsetWidth` property of the `span`.

## Example

With IE4+, you can substitute the `offsetHeight` and `offsetWidth` properties for `clientHeight` and `clientWidth` in Listing 15-6. The reason is that the two elements in question have their widths hard-wired in stylesheets. Thus, the `offsetWidth` property follows that lead rather than observing the default width of the parent (BODY) element.

With IE5+ and W3C browsers, you can use The Evaluator to inspect the `offsetHeight` and `offsetWidth` property values of various objects on the page. Enter the following statements into the top text box:

```
document.getElementById("myP").offsetWidth
document.getElementById("myEM").offsetWidth
document.getElementById("myP").offsetHeight
document.getElementById("myTable").offsetWidth
```

**Related Items:** `clientHeight`, `clientWidth` properties.

## offsetLeft

## offsetTop

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `offsetLeft` and `offsetTop` properties can suffer from the same version vagaries that afflict `offsetHeight` and `offsetWidth` properties when borders, margins, and padding are associated with an element and DOCTYPE switching is a factor. However, the `offsetLeft` and `offsetTop` properties are valuable in providing pixel coordinates of an element within the positioning context of the parent element—even when the elements are not positioned explicitly.

### Note

The `offsetLeft` and `offsetTop` properties for positioned elements in MacIE do not return the same values as the `style.left` and `style.top` properties of the same element. See Listing 39-17 on the CD-ROM for an example of how to correct these discrepancies without having to hard-wire the precise pixel differences in your code.

The element used as a coordinate context for these properties is whatever element the `offsetParent` property returns. This means that to determine the precise position of any element, you may have to add some code that iterates through the `offsetParent` hierarchy until that property returns `null`.

Although the `offsetLeft` and `offsetTop` properties are not part of the W3C DOM specification, they are supported across most browsers because they are convenient for some scriptable Dynamic HTML tasks. Through these two properties, a script can read the pixel coordinates of any block-level or inline element. Measurements are made relative to the body element, but this may change in the future. See the discussion later in this chapter about the `offsetParent` property.

## Example

The following IE script statements utilize all four “offset” dimensional properties to size and position a `div` element so that it completely covers a `span` element located within a `p` element. This can be for a fill-in-the-blank quiz that provides text entry fields elsewhere on the page. As the user gets an answer correct, the blocking `div` element is hidden to reveal the correct answer.

```
document.all.blocker.style.pixelLeft = document.all.span2.offsetLeft
document.all.blocker.style.pixelTop = document.all.span2.offsetTop
```

***elementObject.offsetLeft***

```
document.all.blockImg.height = document.all.span2.offsetHeight
document.all.blockImg.width = document.all.span2.offsetWidth
```

Because the `offsetParent` property for the `span` element is the `body` element, the positioned `div` element can use the same positioning context (it's the default context, anyway) for setting the `pixelLeft` and `pixelTop` style properties. (Remember that positioning properties belong to an element's style object.) The `offsetHeight` and `offsetWidth` properties can read the dimensions of the `span` element (the example has no borders, margins, or padding to worry about) and assign them to the dimensions of the image contained by the blocker `div` element.

This example is also a bit hazardous in some implementations. If the text of `span2` wraps to a new line, the new `offsetHeight` value has enough pixels to accommodate both lines. But the `blockImg` and `blocker` `div` elements are block-level elements that render as a simple rectangle. In other words, the `blocker` element doesn't turn into two separate strips to cover the pieces of `span2` that spread across two lines.

**Related Items:** `clientLeft`, `clientTop`, `offsetParent` properties.

**offsetParent**

**Value:** Object reference.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `offsetParent` property returns a reference to the object that acts as a positioning context for the current element. Values for the `offsetLeft` and `offsetTop` properties are measured relative to the top-left corner of the `offsetParent` object.

The returned object is usually, but not always, the next outermost block-level container. For most document elements, the `offsetParent` object is the `document.body` object (with exceptions for some elements in some browsers).

Table cells, for example, have different `offsetParent` elements in different browsers:

<i>Browser</i>	<i>td offsetParent</i>
WinIE4	tr
WinIE5+/NN7+/Moz1+	table
MacIE	table
NN6	body

The property behaves predictably for positioned elements in most browsers. For example, a first-level positioned element's `offsetParent` element is the `body`; the `offsetParent` of a nested positioned element (for example, one absolute-positioned `div` inside another) is the next outer container (in other words, the positioning context of the inner element).

**Example**

You can use the `offsetParent` property to help you locate the position of a nested element on the page. Listing 15-12 demonstrates how a script can “walk” up the hierarchy of `offsetParent` objects in IE for Windows to assemble the location of a nested element on a page. The goal of the exercise in Listing 15-12 is to position an image at the upper-left corner of the second table cell. The entire table is centered on the page.

The `onload` event handler invokes the `setImagePosition()` function. The function first sets a Boolean flag that determines whether the calculations should be based on the client or offset

sets of properties. WinIE4 and MacIE5 rely on client properties, while WinIE5+ works with the offset properties. The discrepancies even out, however, with the `while` loop. This loop traverses the `offsetParent` hierarchy starting with the `offsetParent` of the cell out to, but not including, the `document.body` object. The `body` object is not included because that is the positioning context for the image. In IE5, the `while` loop executes only once because just the `table` element exists between the cell and the body; in IE4, the loop executes twice to account for the `tr` and `table` elements up the hierarchy. Finally, the cumulative values of `left` and `top` measures are applied to the positioning properties of the `div` object's style and the image is made visible.

### Listing 15-12: Using the `offsetParent` Property

```
<html>
  <head>
    <title>offsetParent Property</title>
    <script type="text/javascript">
      function setImagePosition(){
        var x = 0;
        var y = 0;
        var offsetPointer = document.getElementById("myCell"); // cElement;
        while (offsetPointer) {
          x += offsetPointer.offsetLeft;
          y += offsetPointer.offsetTop;
          offsetPointer = offsetPointer.offsetParent;
        }
        // correct for MacIE body margin factors
        if (navigator.userAgent.indexOf("Mac") != -1 &&
            typeof document.body.leftMargin != "undefined") {
          x += document.body.leftMargin;
          y += document.body.topMargin;
        }
        document.getElementById("myDIV").style.left = x + "px";
        document.getElementById("myDIV").style.top = y + "px";
        document.getElementById("myDIV").style.visibility = "visible";
      }
    </script>
  </head>
  <body onload="setImagePosition()">
    <h1>The offsetParent Property</h1>
    <hr />
    <p>After the document loads, the script positions a small image in the
      upper left corner of the second table cell.</p>
    <table border="1" align="center">
      <tr>
        <td>This is the first cell</td>
        <td id="myCell">This is the second cell.</td>
      </tr>
    </table>
    
  </body>
</html>
```

**Related Items:** `offsetLeft`, `offsetTop`, `offsetHeight`, `offsetWidth` properties.

***elementObject.outerHTML***

outerHTML

outerText

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

One way that Internet Explorer exposes an entire element to scripting is by way of the `outerHTML` and `outerText` properties. The primary distinction between these two properties is that `outerHTML` includes the element's start and end tags whereas `outerText` includes only rendered text that belongs to the element (including text from any nested elements).

The `outerHTML` property contains not only the text content for an element as seen on the page, but also every bit of HTML tagging associated with that content. For example, consider the following bit of HTML source code:

```
<p id="paragraph1">"How <em>are</em> you?" he asked.</p>
```

The value of the `p` object's `outerHTML` property (`document.all.paragraph1.outerHTML`) is exactly the same as that of the source code.

The browser interprets any HTML tags in a string that you assign to an element's `outerHTML` property. This means that you can delete (set the property to an empty string) or replace an entire tag with this property. The document's object model adjusts itself to whatever adjustments you make to the HTML in this manner.

In contrast, the `outerText` property knows only about the text content of an element container. In the preceding example, the value of the paragraph's `outerText` property (`document.all.paragraph1.innerText`) is:

```
"How are you?" he asked.
```

If this looks familiar, it's because in most cases the `innerText` and `outerText` properties of an existing element return the exact same strings.

## Example

Listing 15-13 demonstrates how to use the `outerHTML` and `outerText` properties in IE to access and modify Web page content dynamically. The page generated by Listing 15-13 (WinIE4+ only) contains an `h1` element label and a paragraph of text. The purpose is to demonstrate how the `outerHTML` and `outerText` properties differ in their intent. Two text boxes contain the same combination of text and HTML tags that replaces the element that creates the paragraph's label.

If you apply the default content of the first text box to the `outerHTML` property of the `label1` object, the `h1` element is replaced by a `span` element whose `class` attribute acquires a different stylesheet rule defined earlier in the document. Notice that the ID of the new `span` element is the same as the original `h1` element. This allows the script attached to the second button to address the object. But this second script replaces the element with the raw text (including tags). The element is now gone, and any attempt to change the `outerHTML` or `outerText` properties of the `label1` object causes an error because there is no longer a `label1` object in the document.

Use this laboratory to experiment with some other content in both text boxes.

### Listing 15-13: Using `outerHTML` and `outerText` Properties

```
<html>  
  <head>
```

*elementObject.ownerDocument*

```

<title>outerHTML and outerText Properties</title>
<style type="text/css">
h1 {font-size:18pt; font-weight:bold; font-family:"Comic Sans MS", Arial,
  sans-serif}
.heading {font-size:20pt; font-weight:bold; font-family:"Arial Black",
  Arial, sans-serif}
</style>
<script type="text/javascript">
function setGroupLabelAsText(form) {
  var content = form.textInput.value;
  if (content) {
    document.getElementById("label1").outerText = content;
  }
}
function setGroupLabelAsHTML(form) {
  var content = form.HTMLInput.value;
  if (content) {
    document.getElementById("label1").outerHTML = content;
  }
}
</script>
</head>
<body>
<form>
  <p><input type="text" name="HTMLInput"
    value="&lt;SPAN ID='label1' CLASS='heading'&gt;Article the
    First&lt;/SPAN&gt;"
    size="55" /> <input type="button" value="Change Heading HTML"
    onclick="setGroupLabelAsHTML(this.form)" /></p>
  <p><input type="text" name="textInput"
    value="&lt;SPAN ID='label1' CLASS='heading'&gt;Article the
    First&lt;/SPAN&gt;"
    size="55" /> <input type="button" value="Change Heading Text"
    onclick="setGroupLabelAsText(this.form)" /></p>

```

---

**Related Items:** innerHTML, innerText properties; replaceNode() method.

## ownerDocument

**Value:** Document object reference.

Read-Only

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `ownerDocument` property belongs to any element or node in the W3C DOM. The property's value is a reference to the document node that ultimately contains the element or node. If a script encounters a reference to an element or node (perhaps it has been passed as a parameter to a function), the object's `ownerDocument` property provides a way to build references to other objects in the same document or to access properties and methods of the document objects. IE's proprietary version of this property is simply `document`.

***elementObject.ownerDocument*****Example**

Use The Evaluator (Chapter 13) to explore the `ownerDocument` property. Enter the following statement into the top text box:

```
document.body.childNodes[5].ownerDocument
```

The result is a reference to the `document` object. You can use that to inspect a property of the document, as shown in the following statement you should enter into the top text box:

```
document.body.childNodes[5].ownerDocument.URL
```

This returns the `document.URL` property for the document that owns the child node.

**Related Item:** `document` object.

**parentElement**

**Value:** Element object reference or `null`.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `parentElement` property returns a reference to the next outermost HTML element from the current element. This parent-child relationship of elements is often, but not always, the same as a parent-child node relationship (see `parentNode` property later in this chapter). The difference is that the `parentElement` property deals only with HTML elements as reflected as document objects, whereas a node is not necessarily an HTML element (for example, an attribute or text chunk).

There is also a distinction between `parentElement` and `offsetParent` properties. The latter returns an element that may be many generations removed from a given element but is the immediate parent with regard to positioning context. For example, a `td` element's `parentElement` property is most likely its enclosing `tr` element, but a `td` element's `offsetParent` property is its `table` element.

A script can “walk” the element hierarchy outward from an element with the help of the `parentElement` property. The top of the parent chain is the `html` element. Its `parentElement` property returns `null`.

**Example**

You can experiment with the `parentElement` property in The Evaluator. The document contains a `p` element named `myP`. Type each of the following statements from the left column into the upper expression evaluation text box and press Enter to see the results.

<i>Expression</i>	<i>Result</i>
<code>document.getElementById("myP").tagName</code>	<code>p</code>
<code>document.getElementById("myP").parentElement</code>	<code>[object]</code>
<code>document.getElementById("myP").parentElement.tagName</code>	<code>body</code>
<code>document.getElementById("myP").parentElement.parentElement</code>	<code>[object]</code>
<code>document.getElementById("myP").parentElement.parentElement.tagName</code>	<code>html</code>
<code>document.getElementById("myP").parentElement.parentElement.parentElement</code>	<code>null</code>

**Related Items:** `offsetParent`, `parentNode` properties.

## parentNode

**Value:** Node object reference or null.

Read-Only

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `parentNode` property returns a reference to the next outermost node that is reflected as an object belonging to the document. For a standard element object, the `parentNode` property is the same as IE's `parentElement` because both objects happen to have a direct parent-child node relationship as well as a parent-child element relationship.

Other kinds of content, however, can be nodes. This includes text fragments within an element. A text fragment's `parentNode` property is the next outermost node or element that encompasses that fragment. A text node object in IE does not have a `parentElement` property.

### Example

Use The Evaluator to examine the `parentNode` property values of both an element and a non-element node. Begin with the following two statements and watch the results of each:

```
document.getElementById("myP").parentNode.tagName  
document.getElementById("myP").parentElement.tagName (IE only)
```

Now examine the properties from the point of view of the first text fragment node of the `myP` paragraph element:

```
document.getElementById("myP").childNodes[0].nodeValue  
document.getElementById("myP").childNodes[0].parentNode.tagName  
document.getElementById("myP").childNodes[0].parentElement (IE only)
```

Notice (in IE) that the text node does not have a `parentElement` property.

**Related Items:** `childNodes`, `nodeName`, `nodeType`, `nodeValue`, `parentElement` properties.

## parentTextEdit

**Value:** Element object reference or null.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

Only a handful of objects in IE's object model are capable of creating text ranges (see the `TextRange` object in Chapter 35). To find an object's next outermost container capable of generating a text range, use the `parentTextEdit` property. If an element is in the hierarchy, that element's object reference is returned. Otherwise (for example, `document.body.parentTextEdit`), the value is null. MacIE always returns a value of null because the browser doesn't support the `TextRange` object.

### Example

Listing 15-14 contains an example that demonstrates how to use the `parentTextEdit` property to create a text range. The page resulting from Listing 15-14 contains a paragraph of Latin text and three radio buttons that select the size of a paragraph chunk: one character, one word, or one sentence. If you click anywhere within the large paragraph, the `onclick` event handler invokes the `selectChunk()` function. The function first examines which of the radio buttons is selected to determine how much of the paragraph to highlight (select) around the point at which the user clicks.

After the script employs the `parentTextEdit` property to test whether the clicked element has a valid parent capable of creating a text range, it calls upon the property again to help create the text range. From there, `TextRange` object methods shrink the range to a single insertion point, move that point to the spot nearest the cursor location at click time, expand the selection to encompass the desired chunk, and select that bit of text.

**elementObject.parentTextEdit**

Notice one workaround for the `TextRange` object's `expand()` method anomaly: If you specify a sentence, IE doesn't treat the beginning of a `p` element as the starting end of a sentence automatically. A camouflaged (white text color) period is appended to the end of the previous element to force the `TextRange` object to expand only to the beginning of the first sentence of the targeted `p` element.

**Listing 15-14: Using the parentTextEdit Property**

```

<html>
  <head>
    <title>parentTextEdit Property</title>
    <style type="text/css">
      p {cursor:hand}
    </style>
    <script type="text/javascript">
      function selectChunk() {
        var chunk, range;
        for (var i = 0; i < document.forms[0].chunk.length; i++) {
          if (document.forms[0].chunk[i].checked) {
            chunk = document.forms[0].chunk[i].value;
            break;
          }
        }
        var x = window.event.clientX;
        var y = window.event.clientY;
        if (window.event.srcElement.parentTextEdit) {
          range = window.event.srcElement.parentTextEdit.createTextRange();
          range.collapse();
          range.moveToPoint(x, y);
          range.expand(chunk);
          range.select();
        }
      }
    </script>
  </head>
  <body bgcolor="white">
    <form>
      <p>Choose how much of the paragraph is to be selected when you click
        anywhere in it:<br />
        <input type="radio" name="chunk" value="character"
          checked="checked" />Character <input type="radio" name="chunk"
          value="word" />Word <input type="radio" name="chunk"
          value="sentence" />Sentence <font color="white">.</font></p>
    </form>
    <p onclick="selectChunk()">Lorem ipsum dolor sit amet, consectetur
      adipiscing
      elit, sed do eiusmod tempor incididunt ut labore et dolore magna
      aliqua. Ut
      enim adminim veniam, quis nostrud exercitation ullamco laboris nisi ut
      aliquip ex ea commodo consequat. Duis aute irure dolor in

      pariatur. Excepteur sint occaecat cupidatat non proident, sunt in
      culpa qui officia deserunt mollit anim id est laborum.</p>
  </body>
</html>

```

**Related Items:** `isTextEdit` property; `TextRange` object (Chapter 35).

## previousSibling

(See `nextSibling`)

## readyState

**Value:** String (integer for OBJECT object).

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

A script can query an element in IE to find out if it has loaded all ancillary data (for example, external image files or other media files) before other statements act on that object or its data. The `readyState` property lets you know the loading status of an element.

Table 15-6 lists the possible values and their meanings.

**Table 15-6: readyState Property Values**

<i>HTML Value</i>	<i>OBJECT Value</i>	<i>Description</i>
complete	4	Element and data fully loaded
interactive	3	Data may not be loaded fully, but user can interact with element
loaded	2	Data is loaded, but object may be starting up
loading	1	Data is loading
uninitialized	0	Object has not started loading data yet

For most HTML elements, this property always returns `complete`. Most of the other states are used by elements such as `img`, `embed`, and `object`, which load external data and even start other processes (such as ActiveX controls) to work.

One word of caution: Do not expect the `readyState` property to reveal if an object exists yet in the document (for example, `uninitialized`). If the object does not exist, it cannot have a `readyState` property — the result is a script error for an undefined object. If you want to run a script only after every element and its data are fully loaded, trigger the function by way of the `onload` event handler for the body element or the `onreadystatechange` event handler for the object (and check that the `readyState` property is `complete`).

## Example

To witness a `readyState` property other than `complete` for standard HTML, you can try examining the property in a script that immediately follows an `<img>` tag:

```
...

<script type="text/javascript">
alert(document.getElementById("myImg").readyState);
</script>
...
```

Putting this fragment into a document that is accessible across a slow network helps. If the image is not in the browser's cache, you might get the `uninitialized` or `loading` result. The former means that the `img` object exists, but it has not started receiving the image data

***elementObject.readyState***

from the server yet. If you reload the page, chances are that the image will load instantaneously from the cache and the `readyState` property will report `complete`.

**Related Items:** `onreadystatechange` event handler.

**recordNumber**

**Value:** Integer or `null`.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

Virtually every object has a `recordNumber` property, but it applies only to elements used in Internet Explorer data binding to represent repeated data. For example, if you display 30 records from an external data store in a table, the `tr` element in the table is represented only once in the HTML. However, the browser repeats the table row (and its component cells) to accommodate all 30 rows of data. If you click a row, you can use the `recordNumber` property of the `tr` object to see which record was clicked. A common application of this facility is in data binding situations that allow for updating records. For example, script a table so that clicking on an uneditable row of data displays that record's data in editable text boxes elsewhere on the page. If an object is not bound to a data source, or it is a non-repeating object bound to a data source, the `recordNumber` property is `null`.

**Example**

Listing 15-15 shows how to use the `recordNumber` property to navigate to a specific record in a sequence of data. The data source is a small, tab-delimited file consisting of 20 records of Academy Award data. Thus, the table that displays a subset of the fields is bound to the data source object. Also bound to the data source object are three `span` objects embedded within a paragraph near the top of the page. As the user clicks a row of data, three fields from that clicked record are placed into the bound `span` objects.

The script part of this page is a mere single statement. When the user triggers the `onclick` event handler of the repeated `tr` object, the function receives as a parameter a reference to the `tr` object. The data store object maintains an internal copy of the data in a `recordset` object. One of the properties of this `recordset` object is the `AbsolutePosition` property, which is the integer value of the current record that the data object points to (it can point to only one row at a time, and the default row is the first row). The statement sets the `AbsolutePosition` property of the `recordset` object to the `recordNumber` property for the row that the user clicks. Because the three `span` elements are bound to the same data source, they are immediately updated to reflect the change to the data object's internal pointer to the current record. Notice, too, that the third `span` object is bound to one of the data source fields not shown in the table. You can reach any field of a record because the Data Source Object holds the entire data source content.

**Listing 15-15: Using the Data Binding `recordNumber` Property**

```
<html>
  <head>
    <title>Data Binding (recordNumber)</title>
    <style type="text/css">
      .filmTitle {font-style:italic}
    </style>
    <script type="text/javascript">
      // set recordset pointer to the record clicked on in the table.
      function setRecNum(row) {
```

**elementObject.runtimeStyle**

```

        document.oscars.recordset.AbsolutePosition = row.recordNumber;
    }
</script>
</head>
<body>
<p><b>Academy Awards 1978-1997</b> (Click on a table row to extract data
from one record.)</p>
<p>The award for Best Actor of <span datasrc="#oscars"
datafld="Year"></span>

  <param name="FieldDelim" value="&#09;" />
</object>
</body>
</html>

```

---

**Related Items:** dataFld, dataSrc properties; table, tr objects (Chapter 37 on the CD-ROM).

## runtimeStyle

**Value:** style object.

Read-Only

**Compatibility:** WinIE5+, MacIE5+, NN-, Moz-, Safari-

You can determine the browser default settings for stylesheet attributes with the help of the `runtimeStyle` property. The `style` object that this property returns contains all style attributes and the default settings at the time the page loads. This property does not reflect values assigned to elements by stylesheets in the document or by scripts. The default values returned by this property differ from the values returned by the `currentStyle` property. The latter includes data about values that are not assigned explicitly by stylesheets, yet are influenced by the default behavior of the browser's rendering engine. In contrast, the `runtimeStyle` property shows unassigned style values as empty or zero.

***elementObject.runtimeStyle*****Example**

To change a style property setting, access it via the element's `style` object. Use The Evaluator (Chapter 13) to compare the properties of the `runtimeStyle` and `style` objects of an element. For example, an unmodified copy of The Evaluator contains an `em` element whose ID is "myEM". Enter both

```
document.getElementById("myEM").style.color
```

and

```
document.getElementById("myEM").runtimeStyle.color
```

into the top text field in turn. Initially, both values are empty. Now assign a color to the `style` property via the upper text box:

```
document.getElementById("myEM").style.color = "red"
```

If you now type the two earlier statements into the upper box, you can see that the `style` object reflects the change, while the `runtimeStyle` object still holds onto its original (empty) value.

**Related Items:** `currentStyle` property; `style` object (Chapter 26).

**scopeName**

**Value:** String.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `scopeName` property is associated primarily with XML that is embedded within a document. When you include XML, you can specify one or more XML Namespaces that define the "owner" of a custom tag name, thus aiming toward preventing conflicts of identical custom tags from different sources in a document. (See Chapter 41 on the CD-ROM for more about XML objects.)

The XML Namespace is assigned as an attribute of the `<html>` tag that surrounds the entire document:

```
<html xmlns:fred='http://www.someURL.com'>
```

After that, the Namespace value precedes all custom tags linked to that Namespace:

```
<fred:FIRST_Name id="fredFirstName"/>
```

To find out the Namespace "owner" of an element, you can read the `scopeName` property of that element. For the preceding example, the `scopeName` returns `fred`. For regular HTML elements, the returned value is always `HTML`. The `scopeName` property is available only in Win32 and UNIX flavors of IE5+. The comparable property in the W3C DOM is `localName`.

**Example**

If you have a sample document that contains XML and a namespace spec, you can use `document.write()` or `alert()` methods to view the value of the `scopeName` property. The syntax is

```
document.getElementById("elementID").scopeName
```

**Related Item:** `tagUrn` property.

**scrollHeight****scrollWidth**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN7+, Moz1+, Safari1+

***elementObject.runtimeStyle***

The `scrollHeight` and `scrollWidth` properties contain the pixel measures of an object, regardless of how much of the object is visible on the page. Therefore, if the browser window displays a vertical scrollbar, and the body extends below the bottom of the viewable space in the window, the `scrollHeight` takes into account the entire height of the body as if you were to scroll downward and see the entire element. For most elements that don't have their own scrollbars, the `scrollHeight` and `scrollWidth` properties have the same values as the `clientHeight` and `clientWidth` properties.

**Example**

Use The Evaluator (Chapter 13) to experiment with these two properties of the `textarea` object, which displays the output of evaluations and property listings. To begin, enter the following into the bottom one-line text field to list the properties of the `body` object:

```
document.body
```

This displays a long list of properties for the `body` object. Now enter the following property expression in the top one-line text field to see the `scrollHeight` property of the output `textarea` when it holds the dozens of lines of property listings:

```
document.getElementById("output").scrollHeight
```

The result, some number probably in the hundreds, is now displayed in the output `textarea`. This means that you can scroll the content of the `output` element vertically to reveal that number of pixels. Click the Evaluate button once more. The result, 13 or 14, is a measure of the `scrollHeight` property of the `textarea` that had only the previous result in it. The scrollable height of that content was only 13 or 14 pixels, the height of the font in the `textarea`. The `scrollWidth` property of the output `textarea` is fixed by the width assigned to the element's `cols` attribute (as calculated by the browser to determine how wide to make the text area on the page).

**Related Items:** `clientHeight`, `clientWidth` properties; `window.scroll()` method.

**scrollLeft****scrollTop**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN7+, Moz1+, Safari1+

If an element is scrollable (in other words, it has its own scrollbars), you can find out how far the element is scrolled in the horizontal and vertical direction via the `scrollLeft` and `scrollTop` properties. These values are pixels. For non-scrollable elements, these values are always zero — even if they are contained by elements that are scrollable. For example, if you scroll a browser window (or frame in a multiframe environment) vertically, the `scrollTop` property of the `body` object is whatever the pixel distance is between the top of the object (now out of view) and the first visible row of pixels of the element. But the `scrollTop` value of a table that is in the document remains at zero.

Netscape browsers prior to version 7 (Moz1) treat scrolling of a `body` element from the point of view of the window. If you want to find out the scrolled offset of the current page in these browsers, use `window.scrollX` and `window.scrollY`.

Scripts that involve tracking mouse events in IE need to take into account the `scrollLeft` and `scrollTop` properties of the `body` to compensate for scrolling of the page. See the Event object in Chapter 25.

**elementObject.scrollTop****Example**

Use The Evaluator (Chapter 13) to experiment with these two properties of the `textarea` object, which displays the output of evaluations and property listings. To begin, enter the following into the bottom one-line text field to list the properties of the `body` object:

```
document.body
```

This displays a long list of properties for the `body` object. Use the `textarea`'s scrollbar to page down a couple of times. Now enter the following property expression in the top one-line text field to see the `scrollTop` property of the output `textarea` after you scroll:

```
document.getElementById("output").scrollTop
```

The result, some number, is now displayed in the output `textarea`. This means that the content of the `output` element was scrolled vertically. Click the Evaluate button once more. The result, 0, is a measure of the `scrollTop` property of the `textarea` that had only the previous result in it. There wasn't enough content in the `textarea` to scroll, so the content was not scrolled at all. The `scrollTop` property, therefore, is zero. The `scrollLeft` property of the output is always zero because the `textarea` element is set to wrap any text that overflows the width of the element. No horizontal scrollbar appears in this case, and the `scrollLeft` property never changes.

**Related Items:** `clientLeft`, `clientTop` properties; `window.scroll()` method.

**sourceIndex**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `sourceIndex` property returns the numeric index (zero-based) of the object within the entire document, which is the group of all elements in the document.

**Example**

While the operation of this property is straightforward, the sequence of elements exposed by the `document.all` property may not be. To that end, you can use The Evaluator (Chapter 13) to experiment in IE4+ with the values that the `sourceIndex` property returns to see how the index values of the `document.all` collection follow the source code.

To begin, reload The Evaluator. Enter the following statement in the top text box to set a preinitialized global variable:

```
a = 0
```

When you evaluate this expression, a zero should appear in the Results box. Next, enter the following statement into the top text box:

```
document.all[a].tagName + " [" + a++ + "]"
```

There are a lot of plus signs in this statement, so be sure you enter it correctly. As you successively evaluate this statement (repeatedly click the Evaluate button), the global variable (`a`) is incremented, thus enabling you to "walk through" the elements in source code order. The `sourceIndex` value for each HTML tag appears in square brackets in the Results box. You generally begin with the following sequence:

```
html [0]
head [1]
title [2]
```

You can continue until there are no more elements, at which point an error message appears because the value of `a` exceeds the number of elements in the `document.all` array. Compare your findings against the HTML source code view of The Evaluator.

**Related Item:** `item()` method.

## style

**Value:** `style` object reference.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `style` property is the gateway to an element's stylesheet settings. The property's value is a `style` object whose properties enable you to read and write the stylesheet settings for the element. While scripts do not usually manipulate the `style` object as a whole, it is quite common in a Dynamic HTML page for scripts to get or set multiple properties of the `style` object to effect animation, visibility, and all appearance parameters of the element. Note that style properties returned through this object are only those that are explicitly set by the element's `style` attribute or by script.

You can find significant differences in the breadth of properties of the `style` object in different versions of IE and NN. See Chapter 26 for more details on the `style` object.

### Example

Most of the action with the `style` property has to do with the `style` object's properties, so you can use The Evaluator here to simply explore the lists of `style` object properties available on as many DHTML-compatible browsers as you have running. To begin, enter the following statement into the lower, one-line text box to inspect the `style` property for the `document.body` object:

```
document.body.style
```

Now inspect the `style` property of the table element that is part of the original version of The Evaluator. Enter the following statement into the lower text box:

```
document.getElementById("myTable").style
```

In both cases, the values assigned to the `style` object's properties are quite limited by default.

**Related Items:** `currentStyle`, `runtimeStyle` properties; `style` object (Chapter 26).

## tabIndex

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `tabIndex` property controls where in the tabbing sequence the current object receives focus. This property obviously applies only to elements that can receive focus. IE5+ permits giving focus to more elements than most other browsers; but for all browsers compatible with this property, the primary elements for which you may want to control focus (namely form input elements) are covered.

In general, browsers treat form elements as focusable elements by default. Nonform elements usually don't receive focus unless you specifically set their `tabIndex` properties (or `tabindex` tag attributes). If you set the `tabIndex` property of one form element to 1, that element is first in the tabbing order. Meanwhile, the rest fall into source code tabbing order on successive presses of the Tab key. If you set two elements to, say, 1, the tabbing proceeds in source code order for those two elements and then onto the rest of the elements in source code order starting with the top of the page.

***elementObject.tabIndex***

In Internet Explorer, you can remove an element from tabbing order entirely by setting its `tabIndex` property to `-1`. Users can still click those elements to make changes to form element settings, but tabbing bypasses the element.

**Example**

Listing 15-16 contains a sample script that demonstrates how to control the tab order of a form via the `tabIndex` property. This example not only demonstrates the way you can modify the tabbing behavior of a form on the fly but also how to force form elements out of the tabbing sequence entirely in IE. In this page, the upper form (named `lab`) contains four elements. Scripts invoked by buttons in the lower form control the tabbing sequence. Notice that the `tabindex` attributes of all lower form elements are set to `-1`, which means that these control buttons are not part of the tabbing sequence in IE.

When you load the page, the default tabbing order for the `lab` form control elements (default setting of zero) takes charge. If you start pressing the Tab key, the precise results at first depend on the browser you use. In IE, the Address field is first selected; next the Tab sequence gives focus to the window (or frame, if this page were in a frameset); finally the tabbing reaches the `lab` form. Continue pressing the Tab key and watch how the browser assigns focus to each of the element types. In NN6+, however, you must click anywhere on the content to get the Tab key to start working on form controls.

The sample script inverts the tabbing sequence with the help of a `for` loop that initializes two variables that work in opposite directions as the looping progresses. This gives the last element the lowest `tabIndex` value. The `skip2()` function simply sets the `tabIndex` property of the second text box to `-1`, removing it from the tabbing entirely (IE only). Notice, however, that you can click in the field and still enter text. (See the `disabled` property earlier in this chapter to see how to prevent field editing.) NN6+ does not provide a `tabIndex` property setting that forces the browser to skip over a form control. You should disable the control instead.

**Listing 15-16: Controlling the `tabIndex` Property**

```
<html>
  <head>
    <title>tabIndex Property</title>
    <script type="text/javascript">
      function invert() {
        var form = document.lab;
        for (var i = 0, j = form.elements.length; i < form.elements.length;
             i++, j--) {
          form.elements[i].tabIndex = j;
        }
      }

      function skip2() {
        if (navigator.userAgent.indexOf("MSIE") != -1) {
          document.lab.text2.tabIndex = -1;
        } else {
          alert("Not available.");
        }
      }

      function resetTab() {
        var form = document.lab;
        for (var i = 0; i < form.elements.length; i++) {
```

*elementObject.tagName*

```

        form.elements[i].tabIndex = 0;
    }
}
</script>
</head>
<body>
  <h1>tabIndex Property Lab</h1>
  <hr />
  <form name="lab">
    Text box no. 1: <input type="text" name="text1" /><br />
    Text box no. 2: <input type="text" name="text2" /><br />
    <input type="button" value="A Button" /><br />
    <input type="checkbox" />And a checkbox
  </form>
  <hr />
  <form name="control">
    <input type="button" value="Invert Tabbing Order" tabindex="-1"
    onclick="invert()" /><br />
    <input type="button" value="Skip Text box no. 2 (IE Only)"
    tabindex="-1" onclick="skip2()" /><br />
    <input type="button" value="Reset to Normal Order" tabindex="-1"
    onclick="resetTab()" />
  </form>
</body>
</html>

```

---

The final function, `resetTab()`, sets the `tabIndex` property value to zero for all `lab` form elements; this restores the default order.

**Related Items:** `blur()`, `focus()` methods.

## tagName

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `tagName` property returns a string of the HTML or XML tag name belonging to the object. All `tagName` values are returned in all uppercase characters, even if the source code is written in all lowercase or a mixture. This consistency makes it easier to perform string comparisons. For example, you can create a generic function that contains a `switch` statement to execute actions for some tags and not others. The skeleton of such a function looks like the following:

```

function processObj(objRef) {
  switch (objRef.tagName) {
    case "TR":
      [statements to deal with table row object]
      break;
    case "TD":
      [statements to deal with table cell object]
      break;
    case "COLGROUP":
      [statements to deal with column group object]
      break;
    default:
      [statements to deal with all other object types]
  }
}

```

***elementObject.tagName*****Example**

You can also see the `tagName` property in action in the example associated with the `sourceIndex` property discussed earlier. In that example, the `tagName` property is read from a sequence of objects in source code order.

**Related Items:** `nodeName` property; `getElementsByTagName()` method.

**tagUrn**

(See `scopeName`)

**title**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The W3C standard states that you should use the `title` property (and `title` attribute) in an “advisory” role. Most browsers (although not Safari 1.0) interpret this role as text assigned to tooltips that pop up momentarily while the cursor rests atop an element. The advantage of having this property available for writing is that your scripts can modify an element’s tooltip text in response to other user interaction on the page. A tooltip can provide brief help about the behavior of icons or links on the page. It can also convey a summary of key facts from the destination of a link, thus enabling a visitor to see vital information without having to navigate to the other page.

As with setting the status bar, I don’t recommend using tooltips for conveying mission-critical information to the user. Not all users are patient enough to let the pointer pause for the tooltip to appear. On the other hand, a user may be more likely to notice a tooltip once it appears rather than a status bar message (even though the latter appears instantaneously).

**Example**

Listing 15-17 provides a glimpse at how you can use the `title` property to establish tooltips for a page. A simple paragraph element has its `title` attribute set to “First Time!”, which is what the tooltip displays if you roll the pointer atop the paragraph and pause after the page loads. But an `onmouseover` event handler for that element increments a global variable counter in the script, and the `title` property of the paragraph object is modified with each mouseover action. The `count` value is made part of a string assigned to the `title` property. Notice that there is not a live connection between the `title` property and the variable; instead, the new value explicitly sets the `title` property.

**Listing 15-17: Controlling the title Property**

```
<html>
  <head>
    <title>title Property</title>
    <script type="text/javascript">
      // global counting variable
      var count = 0;

      function setToolTip(elem) {
        elem.title = "You have previously rolled atop this paragraph " +
          count + " time(s).";
      }

      function incrementCount(elem) {
```

*elementObject.uniqueID*

```

        count++;
        setToolTip(elem);
    }
</script>
</head>
<body>
  <h1>title Property Lab</h1>
  <hr />
  <p id="myP" title="First Time!" onmouseover="incrementCount(this)">Roll
    the mouse over this paragraph a few times.<br />
    Then pause atop it to view the tooltip.</p>
</body>
</html>

```

**Related Item:** `window.status` property.

## uniqueID

**Value:** String.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

You can let the WinIE5+ browser generate an identifier (`id` property) for a dynamically generated element on the page with the aid of the `uniqueID` property. You should use this feature with care because the ID it generates at any given time may differ from the ID generated the next time the element is created in the page. Therefore, you should use the `uniqueID` property when your scripts require an unknown element to have an `id` property but the algorithms are not expecting any specific identifier.

To guarantee that an element gets only one ID assigned to it while the object exists in memory, assign the value via the `uniqueID` property of that same object—not some other object. Once you retrieve the `uniqueID` property of an object, the property's value stays the same no matter how often you access the property again. In general, you assign the value returned by the `uniqueID` property to the object's `id` property for other kinds of processing. (For example, the parameter of a `getElementById()` method requires the value assigned to the `id` property of an object.)

## Example

Listing 15-18 demonstrates the recommended syntax for obtaining and applying a browser-generated identifier for an object. After you enter some text into the text box and click the button, the `addRow()` function appends a row to the table. The left column displays the identifier generated via the table row object's `uniqueID` property. IE5+ generates identifiers in the format "ms\_\_id*n*", where *n* is an integer starting with zero for the current browser session. Because the `addRow()` function assigns `uniqueID` values to the row and the cells in each row, the integer for each row is three greater than the previous one. There is no guarantee that future generations of the browser will follow this format, so do not rely on the format or sequence in your scripts.

### Listing 15-18: Using the `uniqueID` Property

```

<html>
  <head>
    <title>Inserting an WinIE5+ Table Row</title>
    <script type="text/javascript">

```

*Continued*

**elementObject.uniqueID****Listing 15-18 (continued)**

```

function addRow(item1) {
  if (item1) {
    // assign long reference to shorter var name
    var theTable = document.getElementById("myTable");
    // append new row to the end of the table
    var newRow = theTable.insertRow(theTable.rows.length);
    // give the row its own ID
    newRow.id = newRow.uniqueID;

    // declare cell variable
    var newCell;

    // an inserted row has no cells, so insert the cells
    newCell = newRow.insertCell(0);
    // give this cell its own id
    newCell.id = newCell.uniqueID;
    // display the row's id as the cell text
    newCell.innerHTML = newRow.id;
    newCell.bgColor = "yellow"
    // re-use cell var for second cell insertion
    newCell = newRow.insertCell(1);
    newCell.id = newCell.uniqueID;
    newCell.innerHTML = item1;
  }
}
</script>
</head>
<body>
  <table id="myTable" border="1">
    <tr>
      <th>Row ID</th>
      <th>Data</th>
    </tr>
    <tr id="firstDataRow">
      <td>firstDataRow</td>
      <td>Fred</td>
    </tr>
    <tr id="secondDataRow">
      <td>secondDataRow</td>
      <td>Jane</td>
    </tr>
  </table>
  <hr />
  <form>
    Enter text to be added to the table:<br />
    <input type="text" name="input" size="25" /><br />
    <input type='button' value='Insert Row'
      onclick='addRow(this.form.input.value)' />
  </form>
</body>
</html>

```

---

**Related Items:** id property; getElementById() method.

## Methods

`addBehavior("URL")`

**Returns:** Integer ID.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `addBehavior()` method imports an external Internet Explorer behavior and attaches it to the current object, thereby extending the properties and/or methods of that object. See Chapter 48 on the CD-ROM for details on IE behaviors. The sole parameter of the `addBehavior()` method is a URL pointer to the behavior component's code. This component may be in an external file (with an `.htc` extension), in which case the parameter can be a relative or absolute URL. IE also includes a library of built-in (default) behaviors, whose URLs are in the following format:

```
#default#behaviorName
```

Here, *behaviorName* is one of the default behaviors (see Chapter 48 on the CD-ROM). If the behavior is imported into the document via the `object` tag, the `addBehavior()` method parameter is the ID of that element in the following format:

```
#objectID
```

When you add a behavior, the loading of the external code occurs asynchronously. This means that even though the method returns a value instantly, the behavior is not necessarily ready to work. Only when the behavior is fully loaded can it respond to events or allow access to its properties and methods. Behaviors loaded from external files observe domain security rules.

## Example

Listing 15-19a shows what a behavior file looks like. It is the file used to demonstrate the `addBehavior()` method in Listing 15-19b. The behavior component and the HTML page that loads it must come from the same server and domain; they also must load via the same protocol (for example, `http://`, `https://`, and `file://` are mutually exclusive, mismatched protocols).

### Listing 15-19a: The `makeHot.htc` Behavior Component

```
<PUBLIC:ATTACH EVENT="onmousedown" ONEVENT="makeHot()" />
<PUBLIC:ATTACH EVENT="onmouseup" ONEVENT="makeNormal()" />
<PUBLIC:PROPERTY NAME="hotColor" />
<PUBLIC:METHOD NAME="setHotColor" />
<SCRIPT LANGUAGE="JScript">
var oldColor;
var hotColor = "red";

function setHotColor(color) {
    hotColor = color;
}

function makeHot() {
    if (event.srcElement == element) {
        oldColor = style.color;
        runtimeStyle.color = hotColor;
    }
}
```

*Continued*

***elementObject.addBehavior()*****Listing 15-19a (continued)**

```
function makeNormal() {
    if (event.srcElement == element) {
        runtimeStyle.color = oldColor ;
    }
}
</SCRIPT>
```

The object to which the component is attached is a simple paragraph object, shown in Listing 15-19b. When the page loads, the behavior is not attached so clicking the paragraph text has no effect.

When you turn on the behavior by invoking the `turnOn()` function, the `addBehavior()` method attaches the code of the `makeHot.htc` component to the `myP` object. At this point, the `myP` object has one more property, one more method, and two more event handlers that are written to be made public by the component's code. If you want the behavior to apply to more than one paragraph in the document, you have to invoke the `addBehavior()` method for each paragraph object.

After the behavior file is instructed to start loading, the `setInitialColor()` function is called to set the new color property of the paragraph to the user's choice from the `select` list. But this can happen only if the component is fully loaded. Therefore, the function checks the `readyState` property of `myP` for completeness before invoking the component's function. If IE is still loading the component, the function is invoked again in 500 milliseconds.

As long as the behavior is loaded, you can change the color used to turn the paragraph "hot." The function first ensures that the component is loaded by checking that the object has the new color property. If it does, then (as a demonstration of how to expose and invoke a component method) the method of the component is invoked. You can also simply set the property value.

**Listing 15-19b: Using `addBehavior()` and `removeBehavior()`**

```
<html>
  <head>
    <title>addBehavior() and removeBehavior() Methods</title>
    <script type="text/javascript">
      var myPBehaviorID;

      function turnOn() {
        myPBehaviorID =
          document.getElementById("myP").addBehavior("makeHot.htc");
        setInitialColor();
      }

      function setInitialColor() {
        if (document.getElementById("myP").readyState == "complete") {
          var select = document.forms[0].colorChoice;
          var color = select.options[select.selectedIndex].value;
          document.getElementById("myP").setHotColor(color);
        } else {
          setTimeout("setInitialColor()", 500);
        }
      }
    </script>
  </head>
  <body>
    <div id="myP">
      <select id="colorChoice">
        <option value="red">Red</option>
        <option value="green">Green</option>
        <option value="blue">Blue</option>
      </select>
    </div>
  </body>
</html>
```

*elementObject.addBehavior()*

```

    }
  }

function turnOff() {
  document.getElementById("myP").removeBehavior(myPBehaviorID);
}

function setColor(select, color) {
  if (document.getElementById("myP").hotColor) {
    document.getElementById("myP").setHotColor(color);
  } else {
    alert("This feature is not available. Turn on the Behavior
    first.");
    select.selectedIndex = 0;
  }
}

function showBehaviorCount() {
  var num = document.getElementById("myP").behaviorUrns.length;
  var msg = "The myP element has " + num + " behavior(s). ";
  if (num > 0) {
    msg += "Name(s): \r\n";
    for (var i = 0; i < num; i++) {
      msg += document.getElementById("myP").behaviorUrns[i] + "\r\n";
    }
  }
  alert(msg);
}
</script>
</head>
<body>
<h1>addBehavior() and removeBehavior() Method Lab</h1>
<hr />
<p id="myP">This is a sample paragraph. After turning on the behavior, it
will turn your selected color when you mouse down anywhere in this
paragraph.</p>
<form>
  <input type="button" value="Switch On Behavior" onclick="turnOn()" />
  Choose a 'hot' color: <select name="colorChoice"
  onchange="setColor(this, this.value)">
    <option value="red">red</option>
    <option value="blue">blue</option>
    <option value="cyan">cyan</option>
  </select>
  <br />
  <input type="button" value="Switch Off Behavior"
  onclick="turnOff()" />
  <p><input type="button" value="Count the URNs"
  onclick="showBehaviorCount()" /></p>
</form>
</body>
</html>

```

To turn off the behavior, the `removeBehavior()` method is invoked. Notice that the `removeBehavior()` method is associated with the `myP` object, and the parameter is the ID of the behavior added earlier. If you associate multiple behaviors with an object, you can remove one without disturbing the others because each has its own unique ID.

***elementObject.addEventListener()***

**Related Items:** `readyState` property; `removeBehavior()` method; behaviors (Chapter 48 on the CD-ROM).

```
addEventListener("eventType", listenerFunc, useCapture)
removeEventListener("eventType", listenerFunc, useCapture)
```

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari+

The W3C DOM's event mechanism accommodates both event bubbling and trickling (see Chapter 25). While the new mechanism supports the long-standing notion of binding an event to an element by way of HTML attributes (for example, the old `onclick` event handler), it encourages binding events by registering an event listener with an element. (In browsers that support the W3C event model, other ways of binding events — such as event handler attributes — are internally converted to registered events.)

To tell the DOM that an element should “listen” for a particular kind of event, use the `addEventListener()` method on the element object. The method requires three parameters. The first is a string version of the event type for which the element should listen. Event type strings do not include the well-used “on” prefix of event handlers. Instead, the names consist only of the event and are usually in all lowercase (except for some special system-wide events preceded by DOM). Table 15-7 shows all the events recognized by the W3C DOM specification (including some new DOM ones that are not yet implemented in browsers).

---

**Table 15-7: W3C DOM Event Listener Types**

---

<code>abort</code>	<code>error</code>
<code>blur</code>	<code>focus</code>
<code>change</code>	<code>load</code>
<code>click</code>	<code>mousedown</code>
<code>DOMActivate</code>	<code>mousemove</code>
<code>DOMAttrModified</code>	<code>mouseout</code>
<code>DOMCharacterDataModified</code>	<code>mouseover</code>
<code>DOMFocusIn</code>	<code>mouseup</code>
<code>DOMFocusOut</code>	<code>reset</code>
<code>DOMNodeInserted</code>	<code>resize</code>
<code>DOMNodeInsertedIntoDocument</code>	<code>scroll</code>
<code>DOMNodeRemoved</code>	<code>select</code>
<code>DOMNodeRemovedFromDocument</code>	<code>submit</code>
<code>DOMSubtreeModified</code>	<code>unload</code>

---

Note that the event types specified in the DOM Level 2 are more limited than the wide range of events defined in IE4+. Also, the W3C temporarily tabled the issue of keyboard events until DOM Level 3. Fortunately, most W3C-compatible browsers implement keyboard events in a fashion that likely will appear as part of the W3C DOM Level 3.

The second parameter of the `addEventListener()` method is a reference to the JavaScript function to be invoked. This is the same form used to assign a function to an event property of an object (for example, `objReference.onclick = someFunction`), and it should *not* be a quoted string. This approach also means that you cannot specify parameters in the function

*elementObject.addEventListener()*

call. Therefore, functions that need to reference forms or form control elements must build their own references (with the help of the event object's property that says which object is the event's target).

By default, the W3C DOM event model has events bubble upward through the element container hierarchy starting with the target object of the event (for example, the button being clicked). However, if you specify `true` for the third parameter of the `addEventListener()` method, event capture is enabled for this particular event type whenever the current object is the event target. This means that any other event type targeted at the current object bubbles upward unless it, too, has an event listener associated with the object and the third parameter is set to `true`.

Using the `addEventListener()` method requires that the object to which it is attached already exists. Therefore, you most likely will use the method inside an initialization function triggered by the `onload` event handler for the page. (The `document` object can use `addEventListener()` for the load event immediately because the `document` object exists early in the loading process.)

A script can also eliminate an event listener that was previously added by script. The `removeEventListener()` method takes the same parameters as `addEventListener()`, which means that you can turn off one listener without disturbing others. In fact, because you can add two listeners for the same event and listener function (one set to capture and one not—a rare occurrence, indeed), the three parameters of the `removeEventListener()` enable you to specify precisely which listener to remove from an object.

Unlike the event capture mechanism of NN4, the W3C DOM event model does not have a “global” capture mechanism for an event type regardless of target. And with respect to Internet Explorer, the `addEventListener()` method is closely analogous to the IE5+ `attachEvent()` method. Also, event capture in IE5+ is enabled via the separate `setCapture()` method. Both the W3C and IE event models use their own syntaxes to bind objects to event handling functions, so the actual functions may be capable of serving both models with browser version branching required only for event binding. See Chapter 25 for more about event handling with these two event models.

## Example

Listing 15-20 provides a compact workbench to explore and experiment with the basic W3C DOM event model. When the page loads, no event listeners are registered with the browser (except for the control buttons, of course). But you can add an event listener for a `click` event in bubble and/or capture mode to the `body` element or the `p` element that surrounds the `span` holding the line of text. If you add an event listener and click the text, you see a readout of the element processing the event and information indicating whether the event phase is bubbling (3) or capture (1). With all event listeners engaged, notice the sequence of events being processed. Remove listeners one at a time to see the effect on event processing.

    </tr>
</table>
</form>
</body>
</html>

```

**Related Items:** `attachEvent()`, `detachEvent()`, `dispatchEvent()`, `fireEvent()`, `removeEventListener()` **methods.**

**appendChild(*elementObject*)**

**Returns:** Node object reference.

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `appendChild()` method inserts an element or text node (defined by other code that comes before it) as the new, last child of the current element. Aside from the more obvious application of adding a new child element to the end of a sequence of child nodes, the `appendChild()` method is also practical for building element objects and their content before appending, replacing, or inserting the element into an existing document. The `document.createElement()` method generates a reference to an element of whatever tag name you assign as that method's parameter.

The `appendChild()` method returns a reference to the appended node object. This reference differs from the object that is passed as the method's parameter because the returned value represents the object as part of the document rather than as a freestanding object in memory.

**Example**

Listing 15-21 contains an example that shows how to use the `appendChild()` method in concert with `removeChild()` and `replaceChild()` to modify child elements in a document. Because many W3C DOM browsers treat source code carriage returns as text nodes (and thus child nodes of their parent), the HTML for the affected elements in Listing 15-21 is shown without carriage returns between elements.

The `append()` function creates a new `li` element and then uses the `appendChild()` method to attach the text box text as the displayed text for the item. The nested expression, `document.createTextNode(form.input.value)`, evaluates to a legitimate node that is appended to the new `li` item. All of this occurs before the new `li` item is added to the document. In the final statement of the function, `appendChild()` is invoked from the vantage point of the `ul` element—thus adding the `li` element as a child node of the `ul` element.

***elementObject.appendChild()***

Invoking the `replaceChild()` method in the `replace()` function utilizes some of the same code. The main difference is that the `replaceChild()` method requires a second parameter: a reference to the child element to be replaced. This demonstration replaces the final child node of the `ul` list, so the function takes advantage of the `lastChild` property of all elements to get a reference to that final nested child. That reference becomes the second parameter to `replaceChild()`.

**Listing 15-21: Various Child Methods**

```

<html>
  <head>
    <title>appendChild(), removeChild(), and replaceChild() Methods</title>
    <script type="text/javascript">
      function append(form) {
        if (form.input.value) {
          var newItem = document.createElement("LI");
          newItem.appendChild(document.createTextNode(form.input.value));
          document.getElementById("myUL").appendChild(newItem);
        }
      }

      function replace(form) {
        if (form.input.value) {
          var newItem = document.createElement("LI");
          var lastChild = document.getElementById("myUL").lastChild;
          newItem.appendChild(document.createTextNode(form.input.value));
          document.getElementById("myUL").replaceChild(newItem, lastChild);
        }
      }

      function restore() {
        var oneChild;
        var mainObj = document.getElementById("myUL");
        while (mainObj.childNodes.length > 2) {
          oneChild = mainObj.lastChild;
          mainObj.removeChild(oneChild);
        }
      }
    </script>
  </head>
  <body>
    <h1>Child Methods</h1>
    <hr />
    Here is a list of items:
    <ul id="myUL"><li>First Item</li><li>Second Item</li></ul>
    <form>
      Enter some text to add/replace in the list: <input type="text"
      name="input" size="30" /><br />
      <input type="button" value="Append to List"
      onclick="append(this.form)" /> <input type="button"
      value="Replace Final Item" onclick="replace(this.form)" /> <input
      type="button" value="Restore List" onclick="restore()" />
    </form>
  </body>
</html>

```

*elementObject.applyElement()*

The final part of the demonstration uses the `removeChild()` method to peel away all children of the `ul` element until just the two original items are left standing. Again, the `lastChild` property comes in handy as the `restore()` function keeps removing the last child until only two remain.

**Related Items:** `removeChild()`, `replaceChild()` methods; nodes and children (Chapter 14).

`applyElement(elementObject[, type])`

**Returns:** Nothing.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `applyElement()` method enables you to insert a new element as the parent or child of the current object. An important feature of this method is that the new object is wrapped around the current object (if the new element is to become the parent) or the current object's content (if the new element is to become a child). When the new element becomes a child, all previous children are nested further by one generation to become immediate children of the new element. You can imagine how the resulting action of this method affects the containment hierarchy of the current element, so you must be careful in how you use the `applyElement()` method.

One parameter, a reference to the object to be applied, is required. This object may be generated from constructions such as `document.createElement()` or from one of the child or node methods that returns an object. The second parameter is optional, and it must be one of the following values:

<i>Parameter Value</i>	<i>Description</i>
Outside	New element becomes the parent of the current object
Inside	New element becomes the immediate child of the current object

If you omit the second parameter, the default value (`outside`) is assumed. Listing 15-22 shows how the `applyElement()` method is used both with and without default values.

### Example

To help you visualize the impact of the `applyElement()` method with its different parameter settings, Listing 15-22 enables you to apply a new element (an `em` element) to a `span` element inside a paragraph. At any time, you can view the HTML of the entire `p` element to see where the `em` element is applied as well as its impact on the element containment hierarchy for the paragraph.

After you load the page, inspect the HTML for the paragraph before doing anything else. Notice the `span` element and its nested `font` element, both of which surround the one-word content. If you apply the `em` element inside the `span` element (click the middle button), the `span` element's first (and only) child element becomes the `em` element; the `font` element is now a child of the new `em` element.

#### Listing 15-22: Using the `applyElement()` Method

```
<html>
  <head>
    <title>applyElement() Method</title>
```

*Continued*

**elementObject.applyElement()****Listing 15-22 (continued)**

```

<script type="text/javascript">
function applyOutside() {
    var newItem = document.createElement("EM");
    newItem.id = newItem.uniqueID;
    document.getElementById("mySpan").applyElement(newItem);
}

function applyInside() {
    var newItem = document.createElement("EM");
    newItem.id = newItem.uniqueID;
    document.getElementById("mySpan").applyElement(newItem, "inside");
}

function showHTML() {
    alert(document.getElementById("myP").outerHTML);
}
</script>
</head>
<body>
<h1>applyElement() Method</h1>
<hr />
<p id="myP">A simple paragraph with a <span id="mySpan"><font
    size="+1">special</font></span> word in it.</p>
<form>
    <input type="button" value="Apply &lt;EM&gt; Outside"
    onclick="applyOutside()" /> <input type="button"
    value="Apply &lt;EM&gt; Inside" onclick="applyInside()" /> <input
    type="button" value="Show &lt;P&gt; HTML..."
    onclick="showHTML()" /><br />
    <input type="button" value="Restore Paragraph"
    onclick="location.reload()" />
</form>
</body>
</html>

```

The visible results of applying the `em` element inside and outside the `span` element in this case are the same. But you can see from the HTML results that each element impacts the element hierarchy quite differently.

**Related Items:** `insertBefore()`, `appendChild()`, `insertAdjacentElement()` methods.

**attachEvent("eventName", functionRef)**

**detachEvent("eventName", functionRef)**

**Returns:** Boolean.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `attachEvent()` method is used primarily within code that specifies IE behaviors (see Chapter 48 on the CD-ROM). But you can also use it in regular scripting as yet another way to bind an event handler to an object. The following example characterizes the more typical approach to assigning an event handler:

```
myObject.onmousedown = setHilite;
```

*elementObject.blur()*

The version with `attachEvent()` is as follows:

```
myObject.attachEvent("onmousedown", setHilite);
```

Both parameters are required. The first parameter is a string version (case-insensitive) of the event name. The second is a reference to the function to be invoked when the event fires for this object. A *function reference* is an unquoted, case-sensitive identifier for the function without any parentheses (which also means that you cannot pass parameters in this function call).

There is a subtle benefit to using `attachEvent()` over the event property binding approach. When you use `attachEvent()`, the method returns a Boolean value of `true` if the event binding succeeds. IE triggers a script error if the function reference fails, so don't rely on a returned value of `false` to catch these kinds of errors. Also, there is no validation that the object recognizes the event name.

If you have used `attachEvent()` to bind an event handler to an object's event, you can disconnect that binding with the `detachEvent()` method. The parameters are the same as for `attachEvent()`. The `detachEvent()` method cannot unbind events whose associations are established via tag attributes or event property settings.

The W3C DOM event model provides functionality similar to these IE-only methods:

`addEventListener()` and `removeEventListener()`.

## Example

Use The Evaluator (Chapter 13) to create an anonymous function that is called in response to an `onmousedown` event of the first paragraph on the page. Begin by assigning the anonymous function to global variable `a` (already initialized in The Evaluator) in the upper text box:

```
a = new Function("alert('Function created at " + (new Date()) + "')")
```

The quote marks and parentheses can get jumbled easily, so enter this expression carefully. When you enter the expression successfully, the Results box shows the function's text. Now assign this function to the `onmousedown` event of the `myP` element by entering the following statement into the upper text box:

```
document.getElementById("myP").attachEvent("onmousedown", a)
```

The Results box displays `true` when successful. If you mouse down on the first paragraph, an alert box displays the date and time that the anonymous function was created (when the `new Date()` expression was evaluated).

Now, disconnect the event relationship from the object by entering the following statement into the upper text box:

```
document.getElementById("myP").detachEvent("onmousedown", a)
```

**Related Items:** `addEventListener()`, `detachEvent()`, `dispatchEvent()`, `fireEvent()`, `removeEventListener()` methods; Event binding (Chapter 14).

`blur()`

`focus()`

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `blur()` method removes focus from an element, while the `focus()` method gives focus to an element. Even though the `blur()` and `focus()` methods have been around since the earliest scriptable browsers, not every focusable object has enjoyed these methods since the

***elementObject.blur()***

beginning. Browsers prior to IE4 and NN6 limited these methods primarily to the `window` object and form control elements.

**Windows**

For window objects, the `blur()` method (NN3+, IE4+) pushes the referenced window to the back of all other open windows. If other browser suite windows (such as e-mail or news reader windows) are open, the window receiving the `blur()` method is placed behind these windows as well.

**Caution**

The `window.blur()` method does not adjust the stacking order of the current window in Mozilla-based browsers (thus the “Put Me in Back” button in Listing 15-23 doesn’t work in those browsers). But a script in a window can invoke the `focus()` method of another window to bring that other window to the front (provided a scriptable linkage, such as the `window.opener` property, exists between the two windows).

The minute you create another window for a user in your Web site environment, you must pay attention to window layer management. With browser windows so easily activated by the slightest mouse click, a user can lose a smaller window behind a larger one in a snap. Most inexperienced users don’t think to check the Windows taskbar or browser menu bar (if the browser is so equipped) to see if a smaller window is still open and then activate it. If that subwindow is important to your site design, then you should present a button or other device in each window that enables users to safely switch among windows. The `window.focus()` method brings the referenced window to the front of all the windows.

Rather than supply a separate button on your page to bring a hidden window forward, you should build your window-opening functions in such a way that if the window is already open, the function automatically brings that window forward (as shown in Listing 15-23). This removes the burden of window management from your visitors.

The key to success with this method is making sure that your references to the desired windows are correct. Therefore, be prepared to use the `window.opener` property to refer to the main window if a subwindow needs to bring the main window back into focus.

**Form control elements**

The `blur()` and `focus()` methods apply primarily to text-oriented form controls: text input, select, and `textarea` elements.

Just as a camera lens blurs when it goes out of focus, a text object “blurs” when it loses focus — when someone clicks or tabs out of the field. Under script control, `blur()` deselects whatever may be selected in the field, and the text insertion pointer leaves the field. The pointer does not proceed to the next field in tabbing order, as it does if you perform a blur by tabbing out of the field manually.

For a text object, having focus means that the text insertion pointer is flashing in that text object’s field. Giving a field focus is like opening it up for human editing.

Setting the focus of a text field or `textarea` does not, by itself, enable you to place the cursor at any specified location in the field. The cursor usually appears at the beginning of the text. To prepare a field for entry to remove the existing text, use both the `focus()` and `select()` methods in series.

There is a caveat about using `focus()` and `select()` together to preselect the content of a text field for immediate editing: Many versions of Internet Explorer fail to achieve the desired results due to an internal timing problem. You can work around this problem (and remain

*elementObject.blur()*

compatible with other browsers) by initiating the focus and selection actions through a `setTimeout()` method. See Chapter 43 on the CD-ROM on data validation for an example.

A common design requirement is to position the insertion pointer at the end of a text field or `textarea` so that a user can begin appending text to existing content immediately. This is possible in IE4+ with the help of the `TextRange` object. The following script fragment moves the text insertion pointer to the end of a `textarea` element whose ID is `myTextarea`:

```
var range = document.getElementById("myTextarea").createTextRange();
range.move("textedit");
range.select();
```

You should be very careful in combining `blur()` or `focus()` methods with `onblur` and `onfocus` event handlers — especially if the event handlers display alert boxes. Many combinations of these events and methods can cause an infinite loop in which it is impossible to dismiss the alert dialog box completely. On the other hand, there is a useful combination for older browsers that don't offer a `disabled` property for text boxes. The following text field event handler can prevent users from entering text in a text field:

```
onfocus = "this.blur()";
```

Some operating systems and browsers enable you to give focus to elements such as buttons (including radio and checkbox buttons) and hypertext links (encompassing both `a` and `area` elements). Typically, once such an element has focus, you can accomplish the equivalent of a mouse click on the element by pressing the spacebar on the keyboard. This is helpful for accessibility to those who have difficulty using a mouse.

An unfortunate side effect of button focus in Win32 environments is that the focus highlight (a dotted rectangle) remains around the button after a user clicks it and until another object gets focus. You can eliminate this artifact for browsers and objects that implement the `onmouseup` event handler by including the following event handler in your buttons:

```
onmouseup = "this.blur()";
```

IE5.5+ recognizes the often undesirable effect of that dotted rectangle and lets scripts set the `hideFocus` property of an element to `true` to keep that rectangle hidden while still giving the element focus. It is a trade-off for the user, however, because there is no visual feedback about which element has focus.

## Other elements

For other kinds of elements that support the `focus()` method, you can bring an element into view in lieu of the `scrollIntoView()` method. `Link (a)` and `area` elements in Windows versions of IE display the dotted rectangle around them after a user brings focus to them. To eliminate that artifact, use the same

```
onmouseup = "this.blur()";
```

event handler (or IE5.5+ `hideFocus` property) as just described for form controls.

## Example

Listing 15-23 contains an example of using the `focus()` and `blur()` methods to tinker with changing the focus of windows. This example creates a two-window environment; from each window, you can bring the other window to the front. The main window uses the object returned by `window.open()` to assemble the reference to the new window. In the subwindow (whose content is created entirely on the fly by JavaScript), `self.opener` is summoned to refer to the original window, while `self.blur()` operates on the subwindow itself. Blurring one window and focusing on another window yields the same result of sending the window to the back of the pile.

*elementObject.blur()*Listing 15-23: The `window.focus()` and `window.blur()` Methods

```

<html>
  <head>
    <title>Window Focus() and Blur()</title>
    <script type="text/javascript">
      // declare global variable name
      var newWindow = null;

      function makeNewWindow() {
        // check if window already exists
        if (!newWindow || newWindow.closed) {
          // store new window object in global variable
          newWindow = window.open("", "", "width=250,height=250");
          // pause briefly to let IE3 window finish opening
          setTimeout("fillWindow()",100);
        } else {
          // window already exists, so bring it forward
          newWindow.focus();
        }
      }

      // assemble new content and write to subwindow
      function fillWindow() {
        var newContent = "<html><head><title>Another Sub
Window</title></head>";
        newContent += "<body bgColor='salmon'>";
        newContent += "<h1>A Salmon-Colored Subwindow.</h1>";
        newContent += "<form><input type='button' value='Bring Main to Front'
onclick='self.opener.focus()'>";
        newContent += "<form><input type='button' value='Put Me in Back'
onclick='self.blur()'>";
        newContent += "</form></body></html>";
        // write HTML to new window document
        newWindow.document.write(newContent);
        newWindow.document.close();
      }
    </script>
  </head>
  <body>
    <h1>Window focus() and blur() Methods</h1>
    <hr />
    <form>
      <input type="button" name="newOne" value="Show New Window"
onclick="makeNewWindow()" />
    </form>
  </body>
</html>

```

A key ingredient to the success of the `makeNewWindow()` function in Listing 15-23 is the first conditional expression. Because `newWind` is initialized as a `null` value when the page loads, that is its value the first time through the function. But after you open the subwindow the first time, `newWind` is assigned a value (the subwindow object) that remains intact even if the user closes the window. Thus, the value doesn't revert to `null` by itself. To catch the possibility that

***elementObject.clearAttributes()***

the user has closed the window, the conditional expression also sees if the window is closed. If it is, a new subwindow is generated, and that new window's reference value is reassigned to the `newWind` variable. On the other hand, if the window reference exists and the window is not closed, the `focus()` method brings that subwindow to the front.

You can see the `focus()` method for a text object in action in Chapter 25's description of the `select()` method for text objects.

**Related Items:** `window.open()`, `document.formObject.textObject.select()` methods.

**clearAttributes()**

**Returns:** Nothing.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `clearAttributes()` method removes all attributes from an element except the `name` and `id` values. Thus, styles and event handlers are removed, as are custom attributes assigned in either the HTML source code or later by script. You should know that the `clearAttributes()` method does not alter the length of the element's `attributes` collection because the collection always contains all possible attributes for an element. (See the `attributes` property for elements earlier in this chapter.)

This method is handy if you wish to construct an entirely new set of attributes for an element and prefer to start out with a blank slate. Be aware, however, that unless your scripts immediately assign new attributes to the element, the appearance of the element reverts to its completely unadorned form until you assign new attributes. This means that even positioned elements find their way back to their source code order until you assign a new positioning style. If you simply want to change the value of one or more attributes of an element, it is faster to use the `setAttribute()` method or adjust the corresponding properties.

To accomplish a result in NN6+/Moz1+ that simulates that of IE5+'s `clearAttributes()`, you must iterate through all attributes of an element and remove those attributes (via the `removeAttribute()` method) whose names are other than `id` and `name`.

**Example**

Use The Evaluator (Chapter 13) to examine the attributes of an element before and after you apply `clearAttributes()`. To begin, display the HTML for the table element on the page by entering the following statement into the upper text field:

```
myTable.outerHTML
```

Notice the attributes associated with the `<table>` tag. Look at the rendered table to see how attributes such as `border` and `width` affect the display of the table. Now, enter the following statement in the top text box to remove all removable attributes from this element:

```
myTable.clearAttributes()
```

First, look at the table. The border is gone, and the table is rendered only as wide as is necessary to display the content with no cell padding. Finally, view the results of the `clearAttributes()` method in the `outerHTML` of the table again:

```
myTable.outerHTML
```

The source code file has not changed, but the object model in the browser's memory reflects the changes you made.

**Related Items:** `attributes` property; `getAttribute()`, `setAttribute()`, `removeAttribute()`, `mergeAttributes()`, and `setAttributeNode()` methods.

***elementObject.click()*****click()**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN2+, Moz1+, Safari1+

The `click()` method lets a script perform nearly the same action as clicking an element. Prior to NN4 and IE4, the `click()` method invoked on a button did not trigger the `onclick` event handler for the object. This has significant impact if you expect the `onclick` event handler of a button to function even if a script performs the “click.” For earlier browser versions, you have to invoke the event handler statements directly. Also, just because a script is “clicking” a button, not all buttons in all platforms change their appearance in response. For example, NN4 on the Mac does not change the state of a checkbox when clicked remotely.

If you want to script the action of “clicking” a button, you can safely invoke the resulting event handler function directly. And if the element is a radio button or checkbox, handle the change of state directly (for example, set the `checked` property of a checkbox) rather than expect the browser to take care of it for you.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `click()` method. The page includes various types of buttons at the bottom. You can “click” the checkbox, for example, by entering the following statement in the topmost text field:

```
document.myForm2.myCheckbox.click()
```

If you use a recent browser version, you most likely can see the checkbox change states between checked and unchecked each time you execute the statement.

**Related Item:** `onclick` event handler.

**cloneNode(*deepBoolean*)**

**Returns:** Node object reference.

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `cloneNode()` method makes an exact copy of the current node object. This copy does not have a parent node or other relationship with any element once the copy exists (of course, the original node remains in place). The clone also does not become part of the document’s object model (the node tree) unless you explicitly insert or append the node somewhere on the page. The copy includes all element attributes, including the `id` attribute. Because the value returned by the `cloneNode()` method is a genuine Node object, you can operate on it with any Node object methods while it is still in the non-document object state.

The Boolean parameter of the `cloneNode()` method controls whether the copy of the node includes all child nodes (`true`) or just the node itself (`false`). For example, if you clone a paragraph element by itself, the clone consists only of the raw element (equivalent of the tag pair, including attributes in the start tag) and none of its content. But including child nodes makes sure that all content within that paragraph element is part of the copy. This parameter is optional in IE5 (defaulting to `false`), but it is required in other W3C-compatible browsers.

**Example**

Use The Evaluator (Chapter 13) to clone, rename, and append an element found in The Evaluator’s source code. Begin by cloning the paragraph element named `myP` along with all of its content. Enter the following statement into the topmost text field:

```
a = document.getElementById("myP").cloneNode(true)
```

***elementObject.componentFromPoint()***

The variable `a` now holds the clone of the original node, so you can change its `id` attribute at this point by entering the following statement:

```
a.setAttribute("id", "Dolly")
```

If you want to see the properties of the cloned node, enter `a` into the lower text field. The precise listing of properties you see depends on the browser you're using; in either case, you should be able to locate the `id` property, whose value is now `Dolly`.

As a final step, append this newly named node to the end of the `body` element by entering the following statement into the topmost text field:

```
document.body.appendChild(a)
```

You can now scroll down to the bottom of the page and see a duplicate of the content. But because the two nodes have different `id` attributes, they cannot confuse scripts that need to address one or the other.

**Related Items:** Node object (Chapter 14); `appendChild()`, `removeChild()`, `removeNode()`, `replaceChild()`, and `replaceNode()` methods.

**`componentFromPoint(x,y)`**

**Returns:** String.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `componentFromPoint()` method assists in some event-related tasks. You can use it for a kind of collision detection (in other words, to determine whether an event occurs inside or outside of a particular element). If the element has scrollbars, the method can provide additional information about the event such as precisely which component of the scrollbar the user activates.

A key aspect of this method is that you invoke it on any element that you want to use as the point of reference. For example, if you want to find out if a `mouseup` event occurs in an element whose ID is `myTable`, invoke the method as follows:

```
var result = document.getElementById("myTable").componentFromPoint(
    event.clientX, event.clientY);
```

Parameters passed to the method are `x` and `y` coordinates. These coordinates do not have to come from an event, but the most likely scenario links this method with an event of some kind. Mouse events (other than `onclick`) work best.

The value returned by the method is a string that provides details about where the coordinate point is with respect to the current element. If the coordinate point is inside the element's rectangle, the returned value is an empty string. Conversely, if the point is completely outside of the element, the returned value is the string `"outside"`. For scrollbar pieces, the list of possible returned values is quite lengthy (as shown in Table 15-8).

**Table 15-8: Returned Values for `componentFromPoint()`**

<b><i>Returned String</i></b>	<b><i>Element Component at Coordinate Point</i></b>
<code>scrollbarDown</code>	Scrollbar down arrow
<code>scrollbarHThumb</code>	Scrollbar thumb on horizontal bar
<code>scrollbarLeft</code>	Scrollbar left arrow

*Continued*

***elementObject.componentFromPoint()*****Table 15-8** (continued)

<b><i>Returned String</i></b>	<b><i>Element Component at Coordinate Point</i></b>
scrollbarPageDown	Scrollbar page-down region
scrollbarPageLeft	Scrollbar page-left region
scrollbarPageRight	Scrollbar page-right region
scrollbarPageUp	Scrollbar page-up region
scrollbarRight	Scrollbar right arrow
scrollbarUp	Scrollbar up arrow
scrollbarVThumb	Scrollbar thumb on vertical bar
handleBottom	Resize handle at bottom
handleBottomLeft	Resize handle at bottom left
handleBottomRight	Resize handle at bottom right
handleLeft	Resize handle at left
handleRight	Resize handle at right
handleTop	Resize handle at top
handleTopLeft	Resize handle at top left
handleTopRight	Resize handle at top right

You do not have to use this method for most collision or event detection, however. The event object's `srcElement` property returns a reference to whatever object receives the event.

### Example

Listing 15-24 demonstrates how the `componentFromPoint()` method can be used to determine exactly where a mouse event occurred. As presented, the method is associated with a `textarea` object that is specifically sized to display both vertical and horizontal scrollbars. As you click various areas of the `textarea` and the rest of the page, the status bar displays information about the location of the event with the help of the `componentFromPoint()` method.

The script utilizes a combination of the `event.srcElement` property and the `componentFromPoint()` method to help you distinguish how you can use each one for different types of event processing. The `srcElement` property is used initially as a filter to decide whether the status bar will reveal further processing about the `textarea` element's event details.

The `onmousedown` event handler in the `body` element triggers all event processing. IE events bubble up the hierarchy (and no events are cancelled in this page), so all `mousedown` events eventually reach the `body` element. Then, the `whereInWorld()` function can compare each `mousedown` event from any element against the `text area's` geography.

#### Listing 15-24: Using the `componentFromPoint()` Method

```
<html>
  <head>
    <title>componentFromPoint() Method</title>
    <script type="text/javascript">
```

***elementObject.contains()***

```

function whereInWorld(elem) {
    var x = event.clientX;
    var y = event.clientY;
    var component =
        document.getElementById("myTextarea").componentFromPoint(x,y);
    if (window.event.srcElement == document.getElementById("myTextarea")){
        if (component == "") {
            status = "mouseDown event occurred inside the element";
        } else {
            status = "mouseDown occurred on the element\'s " + component;
        }
    } else {

**Related Item:** event object.

## **contains()** (*elementObjectReference*)

**Returns:** Boolean.

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `contains()` method reports whether the current object contains another known object within its HTML containment hierarchy. Note that this is not geographical collision detection of overlapping elements, but rather the determination of whether one element is nested somewhere within another.

The scope of the `contains()` method extends as deeply within the current object's hierarchy as is necessary to locate the object. In essence, the `contains()` method examines all of the elements that are part of an element's `all` array. Therefore, you can use this method as a shortcut replacement for a `for` loop that examines each nested element of a container for the existence of a specific element.

The parameter to the `contains()` method is a reference to an object. If you have only the element's ID as a string to go by, you can use the `document.getElementById()` method to generate a valid reference to the nested element.

***elementObject.contains()*****Note**

An element always contains itself.

**Example**

Using The Evaluator (Chapter 13), see how the `contains()` method responds to the object combinations in each of the following statements as you enter them into the upper text box:

```
document.body.contains(document.all.myP)
document.all.myP.contains(document.all.item("myEM"))
document.all.myEM.contains(document.all.myEM)
document.all.myEM.contains(document.all.myP)
```

Feel free to test other object combinations within this page.

**Related Items:** `item()`, `document.getElementById()` methods.

**`detachEvent()`**

(See `attachEvent()`)

**`dispatchEvent(eventObject)`**

**Returns:** Boolean.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `dispatchEvent()` method allows a script to fire an event aimed at any object capable of supporting that event. This is the W3C event model way of generalizing mechanisms that earlier browsers sometimes mimic with object methods such as `click()` and `focus()`.

The process of generating one of these events is similar to the way a script generates a new node and inserts that node somewhere in the document object model. For events, however, the object that is created is an `Event` object, which is generated via the `document.createEvent()` method. An event generated in this manner is simply a specification about an event. Use properties of an event object to supply specifics about the event, such as its coordinates or mouse button. Then dispatch the event to a target object by invoking that target object's `dispatchEvent()` method and passing the newly created `Event` object as the sole parameter.

Interpreting the meaning of the Boolean value that the `dispatchEvent()` method returns is not straightforward. The browser follows the dispatched event through whatever event propagation is in effect for that object and event type (either bubbling or capture). If any of the event listener functions that are triggered by this dispatched event invoke the `preventDefault()` method, the `dispatchEvent()` method returns `false` to indicate that the event did not trigger the native action of the object; otherwise, the method returns `true`. Notice that this returned value indicates nothing about propagation type or how many event listeners run as a result of dispatching this event.

**Caution**

Although the `dispatchEvent()` method is implemented in NN6, the browser does not yet provide a way to generate new events from scratch. And if you attempt to redirect an existing event to another object via the `dispatchEvent()` method, the browser is prone to crashing. In other words, Mozilla-based browsers are much better candidates for scripts that utilize `dispatchEvent()`.

**Example**

Listing 15-25 demonstrates how to programmatically fire events using the W3C DOM `dispatchEvent()` method. Notice the syntax in the `doDispatch()` function for creating and

*elementObject.dispatchEvent()*

initializing a new mouse event, supported most reliably in Mozilla-based browsers. The behavior is identical to that of Listing 15-26, which demonstrates the IE5.5+ equivalent: `fireEvent()`.

**Listing 15-25: Using the `dispatchEvent()` Method**

```

<html>
  <head>
    <title></title>
    <style type="text/css">
      #mySPAN {font-style:italic}
    </style>
    <script type="text/javascript">
      // assemble a couple event object properties
      function getEventProps(evt) {
        var msg = "";
        var elem = evt.target;
        msg += "event.target.nodeName: " + elem.nodeName + "\n";
        msg += "event.target.parentNode: " + elem.parentNode.id + "\n";
        msg += "event button: " + evt.button;
        return msg;
      }

      // onClick event handlers for body, myP, and mySPAN
      function bodyClick(evt) {
        var msg = "Click event processed in BODY\n\n";
        msg += getEventProps(evt);
        alert(msg);
        checkCancelBubble(evt);
      }
      function pClick(evt) {
        var msg = "Click event processed in P\n\n";
        msg += getEventProps(evt);
        alert(msg);
        checkCancelBubble(evt);
      }
      function spanClick(evt) {
        var msg = "Click event processed in SPAN\n\n";
        msg += getEventProps(evt);
        alert(msg);
        checkCancelBubble(evt);
      }

      // cancel event bubbling if checkbox is checked
      function checkCancelBubble(evt) {
        if (document.controls.bubbleOn.checked) {
          evt.stopPropagation();
        }
      }

      // assign onClick event handlers to three elements
      function init() {
        document.body.onclick = bodyClick;
        document.getElementById("myP").onclick = pClick;
        document.getElementById("mySPAN").onclick = spanClick;
      }
    </script>
  </head>

            onclick="doDispatch('myBODY', event)" /></p>
        <p><input type="button" value="Fire Click Event on myP"
            onclick="doDispatch('myP', event)" /></p>
        <p><input type="button" value="Fire Click Event on mySPAN"
            onclick="doDispatch('mySPAN', event)" /></p>
    </form>
</body>
</html>

```

**Related Item:** `fireEvent()` method.

## `fireEvent("eventType" [, eventObjectRef])`

**Returns:** Boolean.

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

While some objects have methods that emulate physical events (for example, the `click()` and `focus()` methods), WinIE5.5+ generalizes the mechanism by letting a script direct any valid event to any object. The `fireEvent()` method is the vehicle.

One required parameter is the event type, formatted as a string. IE event types are coded just like the property names for event handlers (for example, `onclick`, `onmouseover`, and so on).

A second, optional parameter is a reference to an existing event object. This object can be an event that some user or system action triggers (meaning that the `fireEvent()` method is in a function invoked by an event handler). The existing event can also be an object created by the IE5.5+ `document.createEventObject()` method. In either case, the purpose of providing an

***elementObject.fireEvent()***

existing event object is to set the properties of the event object that the `fireEvent()` method creates. The event type is defined by the method's first parameter, but if you have other properties to set (for example, coordinates or a keyboard key code), then those properties are picked up from the existing object. Here is an example of a sequence that creates a new `mousedown` event, stuffs some values into its properties, and then fires the event at an element on the page:

```
var newEvent = document.createEventObject();
newEvent.clientX = 100;
newEvent.clientY = 30;
newEvent.cancelBubble = false;
newEvent.button = 1;
document.getElementById("myElement").fireEvent("onmousedown", newEvent);
```

Events generated by the `fireEvent()` method are just like regular IE `window.event` objects, and they have several important event object properties that the browser presets. Importantly, `cancelBubble` is set to `false` and `returnValue` is set to `true`—just like a regular user- or system-induced event. This means that if you want to prevent event bubbling and/or prevent the default action of the event's source element, then the event handler functions must set these event object properties just like normal event handling in IE.

The `fireEvent()` method returns a Boolean value that the `returnValue` property of the event determines. If the `returnValue` property is set to `false` during event handling, the `fireEvent()` method returns `false`. Under normal processing, the method returns `true`.

Although the W3C DOM Level 2 event model includes the `dispatchEvent()` method to accommodate script-generated events (and `Event` object methods to create event objects), Microsoft has so far elected to ignore the standard recommendation. While there is some similarity between the basic operations of `fireEvent()` and `dispatchEvent()`, the two methods diverge significantly in advanced applications (for example, the way events can propagate and the W3C notion of an `Event` object).

## Example

Listing 15-26 contains script code that shows how to programmatically fire events using the `fireEvent()` method. Three buttons in the example page enable you to direct a click event to each of the three elements that have event handlers defined for them. The events fired this way are artificial, generated via the `createEventObject()` method. For demonstration purposes, the `button` property of these scripted events is set to 3. This property value is assigned to the event object that eventually gets directed to an element. With event bubbling left on, the events sent via `fireEvent()` behave just like the physical clicks on the elements. Similarly, if you disable event bubbling, the first event handler to process the event cancels bubbling, and no further processing of that event occurs. Notice that event bubbling is cancelled within the event handlers that process the event. To prevent the clicks of the checkbox and action buttons from triggering the `body` element's `onclick` event handlers, event bubbling is turned off for the buttons right away.

### Listing 15-26: Using the `fireEvent()` Method

```
<html>
  <head>
    <title></title>
    <style type="text/css">
      #mySPAN {font-style:italic}
    </style>
```

*Continued*

***elementObject.fireEvent()*****Listing 15-26 (continued)**

```

<script type="text/javascript">
// assemble a couple event object properties
function getEventProps() {
    var msg = "";
    var elem = event.srcElement;
    msg += "event.srcElement.tagName: " + elem.tagName + "\n";
    msg += "event.srcElement.id: " + elem.id + "\n";
    msg += "event button: " + event.button;
    return msg;
}

// onClick event handlers for body, myP, and mySPAN
function bodyClick() {
    var msg = "Click event processed in BODY\n\n";
    msg += getEventProps();
    alert(msg);
    checkCancelBubble();
}
function pClick() {
    var msg = "Click event processed in P\n\n";
    msg += getEventProps();
    alert(msg);
    checkCancelBubble();
}
function spanClick() {
    var msg = "Click event processed in SPAN\n\n";
    msg += getEventProps();
    alert(msg);
    checkCancelBubble();
}

// cancel event bubbling if checkbox is checked
function checkCancelBubble() {
    event.cancelBubble = document.controls.bubbleOn.checked;
}

// assign onClick event handlers to three elements
function init() {
    document.body.onclick = bodyClick;
    document.getElementById("myP").onclick = pClick;
    document.getElementById("mySPAN").onclick = spanClick;
}

// invoke fireEvent() on object whose ID is passed as parameter
function doFire(objID) {
    var newEvt = document.createEventObject();
    newEvt.button = 3;
    document.all(objID).fireEvent("onclick", newEvt);
    // don't let button clicks bubble
    event.cancelBubble = true;
}
</script>
</head>
<body id="myBODY" onload="init()">

```

***elementObject*.getAdjacentText()**

```

<h1>fireEvent() Method</h1>
<hr />
<p id="myP">This is a paragraph <span id="mySPAN">(with a nested
  SPAN)</span> that receives click events.</p>
<hr />
<p><b>Control Panel</b></p>
<form name="controls">
  <p><input type="checkbox" name="bubbleOn"
    onclick="event.cancelBubble=true" />Cancel event bubbling.</p>
  <p><input type="button" value="Fire Click Event on BODY"
    onclick="doFire('myBODY')" /></p>
  <p><input type="button" value="Fire Click Event on myP"
    onclick="doFire('myP')" /></p>
  <p><input type="button" value="Fire Click Event on mySPAN"
    onclick="doFire('mySPAN')" /></p>
</form>
</body>
</html>

```

**Related Item:** `dispatchEvent()` method.

**focus()**

(See `blur()`)

**getAdjacentText("position")**

**Returns:** String.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `getAdjacentText()` method enables you to extract copies of plain-text components of an element object (in other words, without any HTML tag information). The sole parameter is one of four case-insensitive string constant values that indicate from where, in relation to the current object, the text should be extracted. The values are:

<b>Parameter Value</b>	<b>Description</b>
<code>beforeBegin</code>	Text immediately in front of the element's tag, back to the preceding tag
<code>afterBegin</code>	Text that begins inside the element tag, up to the next tag (whether it be a nested element or the element's end tag)
<code>beforeEnd</code>	Text immediately in front of the element's end tag, back to the preceding tag (whether it be a nested element or the element's start tag)
<code>afterEnd</code>	Text immediately following the element's end tag, forward until the next tag

If the current object has no nested elements, then the `afterBegin` and `beforeEnd` versions both return the same as the object's `innerText` property. When the current object is encased immediately within another element (for example, a `td` element inside a `tr` element), there is no text before the element's beginning or after the element's end so these values are returned as empty strings.

***elementObject.getAdjacentText()***

The strings returned from this method are roughly equivalent to values of text fragment nodes in the W3C DOM, but IE5+ treats these data pieces only as string data types rather than as text node types. W3C DOM equivalents for the four versions are:

```
document.getElementById("objName").previousSibling.nodeValue
document.getElementById("objName").firstChild.nodeValue
document.getElementById("objName").lastChild.nodeValue
document.getElementById("objName").nextSibling.nodeValue
```

**Example**

Use The Evaluator (Chapter 13) to examine all four adjacent text possibilities for the `myP` and nested `myEM` elements in that document. Enter each of the following statements into the upper text box, and view the results:

```
document.getElementById("myP").getAdjacentText("beforeBegin")
document.getElementById("myP").getAdjacentText("afterBegin")
document.getElementById("myP").getAdjacentText("beforeEnd")
document.getElementById("myP").getAdjacentText("afterEnd")
```

The first and last statements return empty strings because the `myP` element has no text fragments surrounding it. The `afterBegin` version returns the text fragment of the `myP` element up to, but not including, the EM element nested inside. The `beforeEnd` string picks up after the end of the nested EM element and returns all text to the end of `myP`.

Now, see what happens with the nested `myEM` element:

```
document.getElementById("myEM").getAdjacentText("beforeBegin")
document.getElementById("myEM").getAdjacentText("afterBegin")
document.getElementById("myEM").getAdjacentText("beforeEnd")
document.getElementById("myEM").getAdjacentText("afterEnd")
```

Because this element has no nested elements, the `afterBegin` and `beforeEnd` strings are identical—the same value as the `innerText` property of the element.

**Related Items:** `childNodes`, `data`, `firstChild`, `lastChild`, `nextSibling`, `nodeValue`, and `previousSibling` properties.

***getAttribute("attributeName" [, caseSensitivity])***

**Returns:** See text.

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `getAttribute()` method returns the value assigned to a specific attribute of the current object. You can use this method as an alternative to retrieving properties of an object, particularly when your script presents you with the attribute name as a string (in contrast to a fully formed reference to an object and its property). Thus, the following example statements yield the same data:

```
var mult = document.getElementById("mySelect").multiple;
var mult = document.getElementById("mySelect").getAttribute("multiple");
```

Returned value types from `getAttribute()` are either strings (including attribute values assigned as unquoted numeric values) or Booleans (for example, the `multiple` property of a `select` element object).

**Note**

The W3C DOM Level 2 standard recommends `getAttribute()` and `setAttribute()` for reading and writing element object attribute values, rather than reading and writing those values by way of their corresponding properties. While using these methods is certainly advisable for XML elements, the same DOM standard sends conflicting signals by defining all

***elementObject.getAttributeNode()***

kinds of properties for HTML element objects. Browsers, of course, will support access via properties well into the future, so don't feel obligated to change your ways just yet.

All browsers that support the `getAttribute()` method require one parameter, which is a string of the attribute name. By default, this parameter is not case-sensitive. Note that this has impact on custom attributes that you might assign to HTML or XML elements in your documents. Attribute names are automatically converted to lowercase when they are turned into properties of the object. Therefore, you must avoid reusing attribute names, even if you use different case letters in the source code assignments.

IE includes an optional extension to the method in the form of a second parameter that enables you to be more specific about the case-sensitivity of the first parameter. The default value of the second parameter is `false`, which means that the first parameter is not case-sensitive. A value of `true` makes the first parameter case-sensitive. This matters only if you use `setAttribute()` to add a parameter to an existing object and if the IE version of that method insists on case-sensitivity. The default behavior of `setAttribute()` respects the case of the attribute name. See also the discussion of the `setAttribute()` method later in this chapter with regard to `setAttribute()`'s influence over the IE `attributes` property.

### Example

Use The Evaluator (Chapter 13) to experiment with the `getAttribute()` method for the elements in the page. For IE4, use the `document.all` notation. IE5+ and W3C browsers understand the W3C standard `getElementById()` method of addressing an element. You can enter the following sample statements into the top text box to view attribute values.

IE4:

```
document.all.myTable.getAttribute("width")
document.all.myTable.getAttribute("border")
```

IE5+/W3C:

```
document.getElementById("myTable").getAttribute("width")
document.getElementById("myTable").getAttribute("border")
```

**Related Items:** `attributes` property; `document.createAttribute()`, `setAttribute()` methods.

### `getAttributeNode("attributeName")`

**Returns:** Attribute node object.

**Compatibility:** WinIE6+, MacIE-, NN6+, Moz1+, Safari1+

In the W3C DOM, an attribute is an object that inherits all the properties of a `Node` object (see Chapter 14). As its name implies, an attribute object represents a name–value pair of an attribute that is explicitly defined inside an element's tag. The ability to treat attributes as node objects is far more important when working with XML than HTML, but it is helpful to understand attribute nodes within the context of the W3C DOM object-oriented view of a document. Importantly, attribute nodes specifically are not recognized as nodes of a document hierarchy. Therefore, an attribute node is not a child node of the element that defines the attribute.

The “nodeness” of attributes comes into play when addressing the contents of an object's `attributes` property. The W3C `attributes` property builds on the DOM's formal structure by returning an object known (internally) as a *named node map*. Like an array, the named node map has a `length` property (facilitating for loop iteration through the map), plus several methods that allow for inserting, removing, reading, or writing attribute name–value pairs within the node map.

***elementObject.getAttributeNode()***

An attribute object inherits all the properties of the `Node` object. Table 15-9 lists the properties of an attribute object.

---

**Table 15-9: Attribute Object Properties  
of W3C DOM–Compatible Browsers**

---

```

attributes
childNodes
firstChild
lastChild
name
nextSibling
nodeName
nodeType
nodeValue
ownerDocument
parentNode
previousSibling
specified
Value

```

---

All of this is a long way to explain the W3C DOM `getAttributeNode()` method, which returns a W3C DOM attribute object. The sole parameter of the method is a case-insensitive string version of the attribute's name. You can then use any of the properties shown in Table 15-9 to get or set attribute values. Of course, HTML attributes are generally exposed as properties of HTML elements, so it is usually easier to read or write the object's properties directly.

### Example

Use The Evaluator (Chapter 13) to explore the `getAttributeNode()` method in NN6. The `Results` `textarea` element provides several attributes to check out. Because the method returns an object, enter the following statements into the bottom text field so you can view the properties of the attribute node object returned by the method:

```

document.getElementById("output").getAttributeNode("cols")
document.getElementById("output").getAttributeNode("rows")
document.getElementById("output").getAttributeNode("wrap")
document.getElementById("output").getAttributeNode("style")

```

All (except the last) statements display a list of properties for each attribute node object. The last statement, however, returns nothing because the `style` attribute is not specified for the element.

**Related Items:** `attributes` property; `getAttribute()`, `removeAttributeNode()`, `setAttributeNode()` methods.

`getAttributeNodeNS("namespaceURI", "localName")`

**Returns:** Attribute node object.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

***elementObject.getBoundingClientRect()***

This method returns a W3C DOM attribute object. The first parameter of the method is a URI string matching a URI assigned to a label in the document. The second parameter is the local name portion of the attribute you are getting.

**Related Items:** `attributes`, `namespaceURI`, `localName` properties; `getAttributeNode()`, `setAttributeNodeNS()` methods.

**`getAttributeNS("namespaceURI", "localName")`**

**Returns:** See text.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

This method returns the value assigned to a specific attribute of the current object when that attribute's name is defined by way of an XML namespace definition within the document. The first parameter of the method is a URI string matching a URI assigned to a namespace label in a tag defined earlier in the document. The second parameter is the local name portion of the attribute whose value you are getting.

Returned value types from `getAttributeNS()` are either strings (including attribute values assigned as unquoted numeric values) or Booleans (for example, the `multiple` property of a `select` element object).

**Related Items:** `attributes`, `namespaceURI`, `localName` properties; `getAttribute()`, `getAttributeNodeNS()`, `setAttributeNodeNS()` methods.

**`getBoundingClientRect()`**

**Returns:** `TextRectangle` object.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

IE5+ assigns to every content-holding element a rectangle that describes the space that the element occupies on the page. This rectangle is called a *bounding rectangle*, and it is expressed in the WinIE5+ object model as a `TextRectangle` object (even when the content is an image or some other kind of object). A `TextRectangle` object has four properties (`top`, `left`, `bottom`, and `right`) that are the pixel coordinates that define the rectangle. The `getBoundingClientRect()` method returns a `TextRectangle` object that describes the bounding rectangle of the current object. You can access an individual measure of an object's bounding rectangle, as in the following example:

```
var parTop = document.getElementById("myP").getBoundingClientRect().top;
```

For elements that consist of text, such as paragraphs, the dimensions of individual `TextRectangle`s for each line of text in the element influence the dimensions of the bounding rectangle. For example, if a paragraph contains two lines, and the second line extends only halfway across the width of the first line, the width of the second line's `TextRectangle` object is only as wide as the actual text in the second line. But because the first line extends close to the right margin, the width of the encompassing bounding rectangle is governed by that wider, first line `TextRectangle`. Therefore, an element's bounding rectangle is as wide as its widest line and as tall as the sum of the height of all `TextRectangle` objects in the paragraph.

Another method, `getClientRects()`, enables you to obtain a collection of line-by-line `TextRectangle` objects for an element.

**Example**

Listing 15-27 employs both the `getBoundingClientRect()` and `getClientRects()` methods in a demonstration of how they differ. A set of elements are grouped within a `span` element named `main`. The group consists of two paragraphs and an unordered list.

***elementObject.getBoundingClientRect()***

Two controls enable you to set the position of an underlying highlight rectangle to any line of your choice. A checkbox enables you to set whether the highlight rectangle should be only as wide as the line or the full width of the bounding rectangle for the entire `span` element.

All the code is located in the `hilite()` function. The `select` and `checkbox` elements invoke this function. Early in the function, the `getClientRecls()` method is invoked for the `main` element to capture a snapshot of all `TextRectangles` for the entire element. This array comes in handy when the script needs to get the coordinates of a rectangle for a single line, as chosen in the `select` element.

Whenever the user chooses a number from the `select` list and the value is less than the total number of `TextRectangle` objects in `clientRecls`, the function begins calculating the size and location of the underlying yellow highlighter. When the `Full Width` checkbox is checked, the left and right coordinates are obtained from the `getBoundingClientRect()` method because the entire `span` element's rectangle is the space you're interested in; otherwise, you pull the `left` and `right` properties from the chosen rectangle in the `clientRecls` array.

Next comes the assignment of location and dimension values to the `hiliter` object's `style` property. The `top` and `bottom` are always pegged to whatever line is selected, so the `clientRecls` array is polled for the chosen entry's `top` and `bottom` properties. The previously calculated `left` value is assigned to the `hiliter` object's `pixelLeft` property, while the width is calculated by subtracting the `left` from the `right` coordinates. Notice that the `top` and `left` coordinates also take into account any vertical or horizontal scrolling of the entire body of the document. If you resize the window to a smaller size, line wrapping throws off the original line count. However, an invocation of `hilite()` from the `onresize` event handler applies the currently chosen line number to whatever content falls in that line after resizing.

**Listing 15-27: Using `getBoundingClientRect()`**

```
<html>
  <head>
    <title>getClientRecls() and getBoundClientRect() Methods</title>
    <script type="text/javascript">
      function hilite() {
        var hTop, hLeft, hRight, hBottom, hWidth;
        var select = document.forms[0].choice;
        var n = parseInt(select.options[select.selectedIndex].value) - 1;
        var clientRecls = document.getElementById("main").getClientRecls();
        var mainElem = document.getElementById("main");
        if (n >= 0 && n < clientRecls.length) {
          if (document.forms[0].fullWidth.checked) {
            hLeft = mainElem.getBoundingClientRect().left;
            hRight = mainElem.getBoundingClientRect().right;
          } else {
            hLeft = clientRecls[n].left;
            hRight = clientRecls[n].right;
          }
          document.getElementById("hiliter").style.pixelTop =
            clientRecls[n].top + document.body.scrollTop;
          document.getElementById("hiliter").style.pixelBottom =
            clientRecls[n].bottom;
          document.getElementById("hiliter").style.pixelLeft =
            hLeft + document.body.scrollLeft;
          document.getElementById("hiliter").style.pixelWidth =
            hRight - hLeft;
          document.getElementById("hiliter").style.visibility = "visible";
        } else if (n > 0) {
```

*elementObject.getBoundingClientRect()*

```

        alert("The content does not have that many lines.");
        document.getElementById("hiliter").style.visibility = "hidden";
    }
}
</script>
</head>
<body onresize="hilite()">
  <h1>getClientRects() and getBoundClientRect() Methods</h1>
  <hr />
  <form>
    Choose a line to highlight: <select name="choice" onchange="hilite()">

    <div id="hiliter"
      style="position:absolute; background-color:yellow; z-index:-1;
      visibility:hidden">
    </div>
  </body>
</html>

```

Because the `z-index` style property of the `hiliter` element is set to `-1`, the element always appears beneath the primary content on the page. If the user selects a line number beyond the current number of lines in the main element, the `hiliter` element is hidden.

**Related Items:** `getClientRects()` method; `TextRectangle` object (Chapter 35).

***elementObject.getClientRects()*****getClientRects()**

**Returns:** Array of `TextRectangle` objects.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `getClientRects()` method returns an array of all `TextRectangle` objects that fall within the current object the moment the method is invoked. Each `TextRectangle` object has its own `top`, `left`, `bottom`, and `right` coordinate properties. You can then, for example, loop through all objects in this array to calculate the pixel width of each line. If you want to find out the aggregate height and/or maximum width of the entire collection, you can use the `getBoundingClientRect()` method as a shortcut.

**Example**

See Listing 15-27, which demonstrates the differences between `getClientRects()` and `getBoundingClientRect()` and shows how you can use the two together.

**Related Items:** `getBoundingClientRect()` method; `TextRectangle` object (Chapter 35).

**getElementsByTagName("tagName")**

**Returns:** Array of element objects.

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `getElementsByTagName()` method returns an array of all elements contained by the current object whose tags match the tag name supplied as the sole parameter to the method. The tag name parameter must be in the form of a string and is case-insensitive. The group of elements returned in the array includes only those elements that are within the containment scope of the current object. Therefore, if you have two table objects in a document and you invoke the `getElementsByTagName("td")` method on one of them, the list of returned table cell elements is confined to those cells within the current table object. The current element is not included in the returned array.

The method accepts a wildcard character ("\*") as a parameter to the `getElementsByTagName()` method. The resulting array of elements is nearly identical to what IE4+ returns via the `document.all` collection.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `getElementsByTagName()` method. Enter the following statements one at a time into the upper text box and study the results:

```
document.body.getElementsByTagName("div")
document.body.getElementsByTagName("div").length
document.getElementById("myTable").getElementsByTagName("td").length
```

Because the `getElementsByTagName()` method returns an array of objects, you can use one of those returned values as a valid element reference:

```
document.getElementsByTagName("form")[0].getElementsByTagName("input").length
```

**Related Items:** `getElementByTagNameNS()`, `getElementById()`, `tags()` methods.

**getElementsByTagNameNS("namespaceURI", "localName")**

**Returns:** Array of element objects.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

***elementObject.hasAttributes()***

This method returns an array of all elements contained by the current object (within an XML document) as specified in the two parameters. The first parameter of the method is a URI string matching a URI assigned to a label in the document. The second parameter is the local name portion of the attribute whose value you are getting.

Returned value types from `getAttributeNS()` are either strings (including attribute values assigned as unquoted numeric values) or Booleans (for example, the `multiple` property of a `select` element object).

**Related Items:** `attributes`, `namespaceURI`, `localName` properties; `getElementsByTagNameNS()`, `getElementById()`, `tags()` methods.

**`getExpression("attributeName")`**

**Returns:** String.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `getExpression()` method returns the text of the expression that was assigned to an element's attribute via the `setExpression()` method. The returned value is not the value of the expression, but rather the expression itself. If you want to find out the current value of the expression (assuming that the variables used are within the scope of your script), you can use the `eval()` function on the call to `getExpression()`. This action converts the string to a JavaScript expression and returns the evaluated result.

One parameter, a string version of the attribute name, is required.

**Example**

See Listing 15-32 for the `setExpression()` method. This listing demonstrates the kinds of values returned by `getExpression()`.

**Related Items:** `document.recalc()`, `removeExpression()`, `setExpression()` methods.

**`hasAttribute("attributeName")`**

**Returns:** Boolean.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `hasAttribute()` method returns `true` if the current object has an attribute whose name matches the sole parameter; it returns `false` otherwise.

**Related Items:** `hasAttributeNS()` and `hasAttributes()` methods.

**`hasAttributeNS("namespaceURI", "localName")`**

**Returns:** Boolean.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `hasAttributeNS()` method returns `true` if the current object has an attribute as identified by the two parameters; it returns `false` otherwise. The first parameter of the method is a URI string matching a URI assigned to a label in the document. The second parameter is the local name portion of the attribute whose value you are getting.

**Related Items:** `attributes`, `namespaceURI`, `localName` properties; `hasAttribute()` and `hasAttributes()` methods.

**`hasAttributes()`**

**Returns:** Boolean.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

***elementObject.hasAttributes()***

The `hasAttributes()` method returns `true` if the current object has any attributes explicitly assigned within the tag; it returns `false` otherwise.

**Related Items:** `hasAttribute()` and `hasAttributeNS()` methods.

**`hasChildNodes()`**

**Returns:** Boolean.

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `hasChildNodes()` method returns `true` if the current object has child nodes nested within; it returns `false` otherwise. A child node is not necessarily the same as a child element, so the following two expressions return `true` when the current object has at least one child node:

```
document.getElementById("myObject").hasChildNodes()
document.getElementById("myObject").childNodes.length > 0
```

You cannot use the second expression interchangeably with the following statement (which uses the IE-only `children` property):

```
document.getElementById("myObject").children.length > 0
```

You generally use the `hasChildNodes()` method in a conditional expression to make sure such nodes exist before performing operations on them:

```
if (document.getElementById("myObject").hasChildNodes() {
    statements that apply to child nodes
}
```

**Example**

Use The Evaluator (Chapter 13) to experiment with the `hasChildNodes()` method. If you enter the following statement into the topmost text box:

```
document.getElementById("myP").hasChildNodes()
```

the returned value is `true`. You can find out how many nodes there are by getting the `length` of the `childNodes` array:

```
document.getElementById("myP").childNodes.length
```

This expression reveals a total of three nodes: the two text nodes and the `em` element between them. Check out whether the first text node has any children:

```
document.getElementById("myP").childNodes[0].hasChildNodes()
```

The response is `false` because text fragments do not have any nested nodes. But check out the `em` element, which is the second child node of the `myP` element:

```
document.getElementById("myP").childNodes[1].hasChildNodes()
```

The answer is `true` because the `em` element has a text fragment node nested within it. Sure enough, the statement

```
document.getElementById("myP").childNodes[1].childNodes.length
```

yields a node count of 1. You can also go directly to the `em` element in your references:

```
document.getElementById("myEM").hasChildNodes()
document.getElementById("myEM").childNodes.length
```

***elementObject.insertAdjacentElement()***

If you want to see the properties of the text fragment node inside the `em` element, enter the following into the lower text box:

```
document.getElementById("myEM").childNodes[0]
```

You can see that the `data` and `nodeValue` properties for the text fragment return the text "all".

**Related Items:** `childNodes` property; `appendChild()`, `removeChild()`, `replaceChild()` methods.

***insertAdjacentElement("location", elementObject)***

**Returns:** Object.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `insertAdjacentElement()` method inserts an element object (coming from a variety of sources) in a specific position relative to the current object. Both parameters are required. The first must be one of four possible case-insensitive locations for the insertion, shown in the following table:

<i>Location</i>	<i>Description</i>
<code>beforeBegin</code>	Before the current element's start tag
<code>afterBegin</code>	After the start tag, but before any nested content
<code>beforeEnd</code>	Before the end tag, but after all other nested content
<code>afterEnd</code>	After the end tag

These locations are relative to the current object. The element type of the current object (a block-level or inline element) has great bearing on how the inserted element is rendered. For example, suppose you create a `b` element (using `document.createElement()`) and assign some inner text to it. You then use `insertAdjacentElement()` in an effort to insert this `b` element before some text in a `p` element. Because a `p` element is a block-level element, the location `beforeBegin` places the new `b` element before the start tag of the `p` element. This means, however, that the bold text appears in a text line above the start of the `p` element because a `<p>` tag begins a new block at the left margin of its container (unless instructed otherwise by stylesheets). The resulting HTML looks like the following:

```
<b>The new element.</b><p>The original paragraph element.</p>
```

To make the new `b` element a part of the `p` element — but in front of the existing `p` element's content — use the `afterBegin` location. The resulting HTML looks like the following:

```
<p><b>The new element.</b>The original paragraph element.</p>
```

To complete the demonstration of the four location types, the following is the result of the `beforeEnd` location:

```
<p>The original paragraph element. <b>The new element.</b></p>
```

and this is the result of the `afterEnd` location:

```
<p>The original paragraph element.</p><b>The new element.</b>
```

The object to be inserted is a reference to an element object. The object reference can come from any expression that evaluates to an element object or, more likely, from the result of the `document.createElement()` method. Bear in mind that the object generated

***elementObject.insertAdjacentElement()***

by `document.createElement()` initially has no content, and all attribute values are set to default values. Moreover, the object is passed to `insertAdjacentElement()` by reference, which means that there is only one instance of that object. If you attempt to insert that object in two places with two statements, the object is moved from the first location to the second. If you need to copy an existing object so that the original is not moved or otherwise disturbed by this method, use the `cloneNode()` method to specify the `true` parameter to capture all nested content of the node.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `insertAdjacentElement()` method. The goal of the experiment is to insert a new `h1` element above the `myP` element.

All actions require you to enter a sequence of statements in the topmost text box. Begin by storing a new element in the global variable `a`:

```
a = document.createElement("h1")
```

Give the new object some text:

```
a.innerHTML = "New Header"
```

Now, insert this element before the start of the `myP` object:

```
myP.insertAdjacentElement("beforeBegin", a)
```

Notice that you have not assigned an `id` property value to the new element. But because the element was inserted by reference, you can modify the inserted object by changing the object stored in the `a` variable:

```
a.style.color = "red"
```

The inserted element is also part of the document hierarchy, so you can access it through hierarchy references such as `myP.previousSibling`.

The parent element of the newly inserted element is the `body`. Thus, you can inspect the current state of the HTML for the rendered page by entering the following statement into the topmost text box:

```
document.body.innerHTML
```

If you scroll down past the first form, you can find the `<h1>` element that you added along with the `style` attribute.

**Related Items:** `document.createElement()`, `applyElement()` methods.

**`insertAdjacentHTML("location", "HTMLtext")`**

**`insertAdjacentText("location", "text")`**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

These two methods insert HTML or straight text at a location relative to the current element. They are intended for use after a page loads, rather than inserting content while the page loads (in which case you can use `document.write()` wherever you need evaluated content to appear on the page).

The first parameter must be one of four possible case-insensitive locations for the insertion, shown in the following table:

*elementObject.insertAdjacentHTML()*

<i>Location</i>	<i>Description</i>
<code>beforeBegin</code>	Before the current element's start tag
<code>afterBegin</code>	After the start tag, but before any nested content
<code>beforeEnd</code>	Before the end tag, but after all other nested content
<code>afterEnd</code>	After the end tag

These locations yield the same results as described in the `insertAdjacentElement()` function discussed earlier.

Whether you use `insertAdjacentHTML()` or `insertAdjacentText()` depends on the nature of your content and what you want the browser to do with it. If the content contains HTML tags that you want the browser to interpret and render as if it were part of the page source code, use the `insertAdjacentHTML()` method. All tags become objects in the document's object model. But if you want only to display some text (including HTML tags in their "raw" form), use `insertAdjacentText()`. The rendering engine does not interpret any tags included in the string passed as the second parameter. Instead, these tags are displayed as characters on the page. This distinction is identical to the one between the `innerHTML` and `innerText` properties.

The difference between `insertAdjacentHTML()` and `insertAdjacentElement()` is the nature of the content that you insert. The former enables you to accumulate the HTML as a string, while the latter requires the creation of an element object. Also, the two methods in this section work with IE4+ (including Mac versions), whereas `insertAdjacentElement()` requires the newer object model of WinIE5+.

If the HTML you pass as the second parameter of `insertAdjacentHTML()` contains `<script>` tags, you must set the `defer` attribute in the opening tag. This prevents script statements from executing as you insert them.

## Example

Use The Evaluator (Chapter 13) to experiment with these two methods. The example here demonstrates the result of employing both methods in an attempt to add some HTML to the beginning of the `myP` element.

Begin by assigning a string of HTML code to the global variable `a`:

```
a = "<b id='myB'>Important News!</b>"
```

Because this HTML is to go on the same line as the start of the `myP` paragraph, use the `afterBegin` parameter for the insert method:

```
myP.insertAdjacentHTML("afterBegin", a)
```

Notice that there is no space after the exclamation mark of the inserted HTML. But to prove that the inserted HTML is genuinely part of the document's object model, you can now insert the text of a space after the `b` element whose ID is `myB`:

```
myB.insertAdjacentText("afterEnd", " ")
```

Each time you evaluate the preceding statement (by repeatedly clicking the Evaluate button or pressing Enter with the cursor in the topmost field), an additional space is added.

***elementObject.insertAdjacentHTML()***

You should also see what happens when the string to be inserted with `insertAdjacentText()` contains HTML tags. Reload The Evaluator and enter the following two statements into the top-most field, evaluating each one in turn:

```
a = "<b id='myB'>Important News!</b>"
myP.insertAdjacentText("afterBegin", a)
```

The HTML is not interpreted but is displayed as plain text. There is no object named `myB` after executing this latest insert method.

**Related Items:** `innerText`, `innerHTML`, `outerText`, `outerHTML` properties; `insertAdjacentElement()`, `replaceAdjacentText()` methods.

***insertBefore(newChildNodeObject, referenceChildNode)***

**Returns:** Node object.

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `insertBefore()` method is the W3C DOM syntax for inserting a new child node into an existing element. Node references for both parameters must be valid Node objects (including those that `document.createElement()` generates).

The behavior of this method might seem counterintuitive at times. If you include the second parameter (a reference to an existing child node of the current element — optional in IE), the new child node is inserted before that existing one. But if you omit the second parameter (or its value is `null`), the new child node is inserted as the last child of the current element — in which case, the method acts the same as the `appendChild()` method. The true power of this method is summoned when you specify that second parameter; from the point of view of a parent element, you can drop a new child into any spot among its existing children. If an inserted node already exists in the document tree, it will be removed from its previous position.

Bear in mind that the `insertBefore()` method works from a parent element. Internet Explorer provides additional methods, such as `insertAdjacentElement()`, to operate from the perspective of what will become a child element.

**Example**

Listing 15-28 demonstrates how the `insertBefore()` method can insert child elements (`li`) inside a parent (`ol`) at different locations, depending on the second parameter. A text box enables you to enter your choice of text and/or HTML for insertion at various locations within the `ol` element. If you don't specify a position, the second parameter of `insertBefore()` is passed as `null` — meaning that the new child node is added to the end of the existing children. But choose a spot from the select list where you want to insert the new item. The value of each `select` list option is an index of one of the first three child nodes of the `ol` element.

**Listing 15-28: Using the insertBefore() Method**

```
<html>
  <head>
    <title>insertBefore() Method</title>
    <script type="text/javascript">
      function doInsert(form) {
        if (form.newText) {
          var newChild = document.createElement("LI");
          newChild.innerHTML = form.newText.value;
          var choice =
            form.itemIndex.options[form.itemIndex.selectedIndex].value;
```

***elementObject.isSupported()***

```

        var insertPoint = (isNaN(choice)) ?
            null : document.getElementById("myUL").childNodes[choice];
        document.getElementById("myUL").insertBefore(newChild,
            insertPoint);
    }
}
</script>
</head>
<body>
  <h1>insertBefore() Method</h1>
  <hr />
  <form onsubmit="return false">
    <p>Enter text or HTML for a new list item: <input type="text"
      name="newText" size="40" value="" /></p>
    <p>Before which existing item? <select name="itemIndex">
      <option value="null">None specified</option>
      <option value="0">1</option>
      <option value="1">2</option>
      <option value="2">3</option>
    </select></p>
    <input type="button" value="Insert Item"
      onclick="doInsert(this.form)" />
  </form>
  <ol id="myUL">
    <li>Originally the First Item</li>
    <li>Originally the Second Item</li>
    <li>Originally the Third Item</li>
  </ol>
</body>
</html>

```

**Related Items:** `appendChild()`, `replaceChild()`, `removeChild()`, `insertAdjacentElement()` methods.

## `isSupported("feature", "version")`

**Returns:** Boolean.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `isSupported()` method returns `true` if the current node supports required portions of the specified W3C DOM module and version; it returns `false` otherwise. The first parameter accepts any of the following case-sensitive DOM module name strings: `Core`, `XML`, `HTML`, `Views`, `StyleSheets`, `CSS`, `CSS2`, `Events`, `UIEvents`, `MouseEvents`, `MutationEvents`, `HTMLEvents`, `Range`, `Traversal`. The second parameter accepts a string representation of the major and minor DOM module version, such as `"2.0"` for DOM Level 2.

### Example

Use The Evaluator (Chapter 13) to experiment with the `isSupported()` method. If you have multiple versions of NN6 or later and Mozilla, try the following (and others) to see how the support for various modules has evolved:

```

document.body.isSupported("CSS", "2.0")
document.body.isSupported("CSS2", "2.0")
document.body.isSupported("Traversal", "2.0")

```

If you have access to Safari, try the same methods there to see the differences in modules supported compared to Mozilla-based browsers.

***elementObjectCollection.item()***

`item(index | "index" [, subIndex])`

**Returns:** Object.

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `item()` method works with most objects that are themselves collections of other objects. In W3C DOM terminology, these kinds of objects are known as *named node lists* (for objects such as nodes and attributes) or *HTML collections* (for objects such as elements of a form). You may call the `item()` method with a single numeric parameter that is the index value of the desired object within the collection. If you know the index number of the item, you can use JavaScript array syntax instead. The following two statements return the same object reference:

```
document.getElementById("myTable").childNodes.item(2)
document.getElementById("myTable").childNodes[2]
```

The method also supports a string of the ID of an object within the collection. (Integer values are required for the `attributes`, `rules`, and `TextRectangle` objects, however.) Additionally, if the collection has more than one object with the same ID (never a good idea except when necessary), a second numeric parameter enables you to select which identically named group you want (using zero-based index values within that subgroup). This obviously does not apply to collections, such as `attributes` and `rules`, which have no ID associated with them.

The method returns a reference to the object specified by the parameters.

## Example

Use The Evaluator (Chapter 13) to experiment with the `item()` method. Type the following statements into the topmost text box and view the results for each.

W3C and IE5:

```
document.getElementById("myP").childNodes.length
document.getElementById("myP").childNodes.item(0).data
document.getElementById("myP").childNodes.item(1).nodeName
```

W3C, IE4, and IE5:

```
document.forms[1].elements.item(0).type
```

IE4 and IE5:

```
document.all.item("myP").outerHTML
myP.outerHTML
```

In the last two examples, both statements return the same string. The first example is helpful when your script is working with a string version of an object's name. If your script already knows the object reference, the second approach is more efficient and compact.

**Related Items:** All object element properties that return collections (arrays) of other objects.

`mergeAttributes("sourceObject")`

**Returns:** Nothing.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `mergeAttributes()` method is a convenient way to propagate attributes in newly created elements without painstakingly adding attributes one at a time. Once you have an object whose attributes can function as a prototype for other elements, those attributes (except for the `id` attribute) can be applied to a newly created element instantaneously.

*elementObject.mergeAttributes()*

## Example

Listing 15-29 demonstrates the usage of `mergeAttributes()` in the process of replicating the same form input field while assigning a unique ID to each new field. So you can see the results as you go, I display the HTML for each input field in the field.

The `doMerge()` function begins by generating two new elements: a `p` element and an `input` element. Because these newly created elements have no properties associated with them, a unique ID is assigned to the `input` element via the `uniqueID` property. Attributes from the field in the source code (`field1`) are merged into the new `input` element. Thus, all attributes except `name` and `id` are copied to the new element. The `input` element is inserted into the `p` element, and the `p` element is appended to the document's `form` element. Finally, the `outerHTML` of the new element is displayed in its field. Notice that except for the `name` and `id` attributes, all others are copied. This includes stylesheet attributes and event handlers. To prove that the event handler works in the new elements, you can add a space to any one of them and press `Tab` to trigger the `onchange` event handler that changes the content to all uppercase characters.

### Listing 15-29: Using the `mergeAttributes()` Method

```
<html>
  <head>
    <title>mergeAttributes() Method</title>
    <script type="text/javascript">
      function doMerge(form) {
        var newPElem = document.createElement("p");
        var newInputElem = document.createElement("input");
        newInputElem.id = newInputElem.uniqueID;
        newInputElem.mergeAttributes(form.field1);
        newPElem.appendChild(newInputElem);
        form.appendChild(newPElem);
        newInputElem.value = newInputElem.outerHTML;
      }

      // called by onChange event handler of fields
      function upperMe(field) {
        field.value = field.value.toUpperCase();
      }
    </script>
  </head>
  <body>
    onload="document.expandable.field1.value =
document.expandable.field1.outerHTML">
    <h1>mergeAttributes() Method</h1>
    <hr />
    <form name="expandable" onsubmit="return false">
      <p><input type="button" value="Append Field 'Clone'"
onclick="doMerge(this.form)" /></p>
      <p><input type="text" name="field1" id="FIELD1" size="120" value=""
style="font-size:9pt" onchange="upperMe(this)" /></p>
    </form>
  </body>
</html>
```

**Related Items:** `clearAttributes()`, `cloneNode()`, `removeAttributes()` methods.

***elementObject.normalize()*****normalize()****Returns:** Nothing.**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

In the course of appending, inserting, removing, and replacing child nodes of an element, it is conceivable that two text nodes can end up adjacent to each other. While this typically has no effect on the rendering of the content, some XML-centric applications that rely heavily on the document node hierarchy to interpret content properly may not like having two text nodes sitting next to each other. The “proper” form of a node hierarchy is for a single text node to be bounded by other node types. The `normalize()` method sweeps through the child nodes of the current node object and combines adjacent text nodes into a single text node. The effect obviously impacts the number of child nodes of an element, but it also cleanses the nested node hierarchy.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `normalize()` method in Mozilla-based browsers. The following sequence adds a text node adjacent to one in the `myP` element. A subsequent invocation of the `normalize()` method removes the division between the adjacent text nodes.

Begin by confirming the number of child nodes of the `myP` element:

```
document.getElementById("myP").childNodes.length
```

Three nodes initially inhabit the element. Next, create a text node and append it as the last child of the `myP` element:

```
a = document.createTextNode("This means you!")
document.getElementById("myP").appendChild(a)
```

With the new text now rendered on the page, the number of child nodes increases to four:

```
document.getElementById("myP").childNodes.length
```

You can see that the last child node of `myP` is the text node you just created:

```
document.getElementById("myP").lastChild.nodeValue
```

But by invoking `normalize()` on `myP`, all adjacent text nodes are accumulated into single nodes:

```
document.getElementById("myP").normalize()
```

You can now see that the `myP` element is back to three child nodes, and the last child is a combination of the two previously distinct, but adjacent, text nodes:

```
document.getElementById("myP").childNodes.length
document.getElementById("myP").lastChild.nodeValue
```

**Related Items:** `document.createTextNode()`, `appendChild()`, `insertBefore()`, `removeChild()`, `replaceChild()` methods.

**releaseCapture()****setCapture(*containerBoolean*)****Returns:** Nothing.**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

You can instruct a single object on a page to capture all mouse events (`onmousedown`, `onmouseup`, `onmousemove`, `onmouseout`, `onmouseover`, `onclick`, and `ondblclick`) via the

*elementObject.releaseCapture()*

WinIE-specific `setCapture()` method. A primary scenario for mouse event capture is when some content appears on the page that you wish to leave as the center of user focus — items such as pull-down menus, context menus, or simulated modal window areas. When such items appear on the screen, you want the effect of blocking all mouse events except those that apply to the menu or currently visible pseudowindow. When the region disappears, mouse events can be released so that individual elements (such as buttons and links elsewhere on the page) respond to mouse events.

Event capture does not block the events. Instead, the events are redirected to the object set to capture all mouse events. Events bubble up from that point unless explicitly cancelled (see Chapter 25). For example, consider a document that has a `<body>` tag containing an `onclick` event handler that governs the entire document at all times. If you turn on event capture for a `div` somewhere in the document, the click event first goes to the `div`. That `div` might have an `onclick` event handler that looks to process click events when they occur in some of its child elements. If the event handler for the `div` does not also cancel the bubbling of that click event, the `body` element's `onclick` event handler eventually receives and processes the event, even though the `div` initially captured the event.

Deciding which object should capture events is an important design issue to confront. With event capture engaged, all mouse events (no matter where they occur) get funneled to the object set to capture the events. Therefore, if you design an application whose entire interface consists of clicking and dragging positionable elements, you can set one of those elements (or even the `document` object) to perform the capturing. For pop-up regions, however, it is generally more logical and convenient for your coding to assign the capture mechanism to the primary container of the pop-up content (usually a positioned `div`).

The `setCapture()` method has one optional Boolean parameter. The parameter controls whether mouse events on child elements within the capturing object are under control of the event capture mechanism. The default value (`true`) means that all mouse events targeted at elements within the current object go to the current object rather than to the original target — the most likely way you will use `setCapture()` for things such as pop-up and context menus. But if you specify `false` as the parameter, then mouse events occurring in child elements of the capturing container receive their events directly. From there, regular event bubbling upward from the target ensues (see Chapter 25).

You may encounter odd behavior when the region you set up to capture mouse events contains form elements such as text input fields and `select` lists. Because these elements require mouse events to gain focus for interaction, the event capture mechanism inhibits access to these items. To work around this behavior, you can examine the click event's `srcElement` property to see if the click was on one of these elements and script the focus of that element (or instruct the user to press the Tab key until the element gets focus manually).

Once an object is set to capture events, your other code must define which events actually do something; and decide whether events should bubble up beyond the capturing element. You need to worry about bubbling only if your design includes mouse event handlers in elements higher up the element containment hierarchy. You may not wish for those event handlers to fire while event capture is on; in this case, you need to cancel the bubbling of those events in the capturing object.

If your application design requires that the pop-up area be hidden and event handling be returned to normal (such as after the user makes a pop-up menu selection), use the `releaseCapture()` method in conjunction with hiding the container. Because event capture can be engaged for only one element at a time, you can release capture by invoking the `releaseCapture()` method from the container or from the `document` object.

***elementObject.releaseCapture()***

Event capture is automatically disengaged when the user performs any of the following actions:

- ♦ Gives focus to any other window
- ♦ Displays any system modal dialog window (for example, alert window)
- ♦ Scrolls the page
- ♦ Opens a browser context menu (by right-clicking)
- ♦ Tabs to give focus to the Address field in the browser window

Therefore, you may want to set the `document` object's `onlosecapture` event handler to hide any container that your script displays in concert with event capture.

Also be aware that even though mouse events may be captured to prevent mouse access to the rest of the page, keyboard events are not captured. Thus, using the event capture mechanism to simulate modal windows is not foolproof: a user can tab to any form element or link in the page and press the spacebar or Enter key to activate that element.

Event capture, as defined in the W3C DOM, operates differently from WinIE event capture. In the W3C DOM, you can instruct the browser to substitute event capture of any kind of event for the normal event bubbling behavior. For example, you can attach an event listener to the `body` element in such a way that it sees all click events aimed at elements contained by the `body` element before the events reach their target elements. (See Chapters 14 and 25 for more on the W3C DOM event model and how to integrate it into cross-browser applications.)

## Example

Listing 15-30 demonstrates the usage of `setCapture()` and `releaseCapture()` in a “quick-and-dirty” context menu for WinIE5+. The job of the context menu is to present a list of numbering styles for the ordered list of items on the page. Whenever the user brings up the context menu atop the `ol` element, the custom context menu appears. Event capture is turned on in the process to prevent mouse actions elsewhere on the page from interrupting the context menu choice. Even a click on the link set up as the title of the list is inhibited while the context menu is visible. A click anywhere outside of the context menu hides the menu. Clicking a choice in the menu changes the `listStyleType` property of the `ol` object and hides the menu. Whenever the context menu is hidden, event capture is turned off so that clicking on the page (such as the link) works as normal.

For this design, `onclick`, `onmouseover`, and `onmouseout` event handlers are assigned to the `div` element that contains the context menu. To trigger the display of the context menu, the `ol` element has an `oncontextmenu` event handler. This handler invokes the `showContextMenu()` function. In this function, event capture is assigned to the context menu `div` object. The `div` is also positioned at the location of the click before it is set to be visible. To prevent the system's regular context menu from also appearing, the event object's `returnValue` property is set to `false`.

Now that all mouse events on the page go through the `contextMenu` `div` object, let's examine what happens with different kinds of events triggered by user action. As the user rolls the mouse, a flood of `mouseover` and `mouseout` events fire. The event handlers assigned to the `div` manage these events. But notice that the two event handlers, `highlight()` and `unhighlight()`, perform action only when the `srcElement` property of the event is one of the menu items in the `div`. Because the page has no other `onmouseover` or `onmouseout` event handlers defined for elements up the containment hierarchy, you do not have to cancel event bubbling for these events.

*elementObject.releaseCapture()*

When a user clicks the mouse button, different things happen depending on whether event capture is enabled. Without event capture, the `click` event bubbles up from wherever it occurred to the `onclick` event handler in the `body` element. (An alert dialog box displays to let you know when the event reaches the `body`.) But with event capture turned on (the context menu is showing), the `handleClick()` event handler takes over to apply the desired choice whenever the click is atop one of the context menu items. For all `click` events handled by this function, the context menu is hidden and the `click` event is cancelled from bubbling up any higher (no alert dialog box appears). This takes place whether the user makes a choice in the context menu or clicks anywhere else on the page. In the latter case, all you need is for the context menu to go away like the real context menu does. For added insurance, the `onlosecapture` event handler hides the context menu when a user performs any of the actions just listed that cancel capture.

**Listing 15-30: Using `setCapture()` and `releaseCapture()`**

```

```

**Related Items:** `addEventListener()`, `dispatchEvent()`, `fireEvent()`, `removeEventListener()` **methods**; `onlosecapture` **event**; **Event object** (Chapter 25).

`removeAttribute("attributeName" [, caseSensitivity])`

**Returns:** Boolean (IE); Nothing (NN/DOM).

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

***elementObject.removeAttributeNode()***

If you create an attribute with the `setAttribute()` method, you can eliminate that attribute from the element object via the `removeAttribute()` method. The required parameter is the name of the attribute. IE4+ permits you to set and remove attributes such that the attribute names are case-sensitive. The default behavior of `removeAttribute()` in IE (the second parameter is a Boolean value) is `false`. Therefore, if you supply a value of `true` for the case-sensitivity parameter in `setAttribute()`, you should set the parameter to `true` in `removeAttribute()` to ensure a proper balance between created and removed attributes.

The W3C DOM (NN/Moz/Safari) version of the `removeAttribute()` method has a single parameter (a case-insensitive attribute name) and returns no value. The returned value in IE is `true` if the removal succeeds and `false` if it doesn't succeed (or the attribute is one that you set in some other manner).

**Example**

Use The Evaluator (Chapter 13) to experiment with the `removeAttribute()` method for the elements in the page. See the examples for the `setAttribute()` method later in this chapter, and enter the corresponding `removeAttribute()` statements in the top text box. Interleave statements using `getAttribute()` to verify the presence or absence of each attribute.

**Related Items:** `attributes` property; `document.createAttribute()`, `getAttribute()`, `setAttribute()` methods.

`removeAttributeNode(attributeNode)`

`setAttributeNode(attributeNode)`

**Returns:** Attribute object.

**Compatibility:** WinIE6+, MacIE-, NN6+, Moz1+, Safari1+

As discussed in the coverage of the `getAttributeNode()` method earlier in this chapter, the W3C DOM treats a name–value attribute pair as an attribute object. An attribute object is a distinct node within a named node map—a collection of attribute objects belonging to an element. Understanding named node maps and attribute objects is more useful in an XML environment where attributes can not only contain valuable data, but are not exposed to the document object model as properties you can access via script. Instead of accessing an object's properties, you work with the actual attributes.

If you want to insert an attribute in the formal W3C methodology, you can use `document.createAttribute()` to generate a new attribute object. Subsequent script statements assign values to the `nodeName` and `nodeValue` properties to give the attribute its traditional name–value pair. You can then insert that new attribute object into the attribute list of an object via the `setAttributeNode()` method. The sole parameter is an attribute object, and the return value is a reference to the newly inserted attribute object.

To remove an attribute node from an element using this syntax, employ the `removeAttributeNode()` method. Again, the sole parameter is an attribute object. If your script knows only the attribute's name, you can use `getAttributeNode()` to obtain a valid reference to the attribute object. The `removeAttributeNode()` method returns a reference to the removed attribute object. That object remains in the browser's memory, but it is not part of the document hierarchy. By capturing this removed attribute object in a variable, you have the flexibility to modify and assign it to another object elsewhere in the document.

In practice, you may rarely, if ever, need to address attributes as nodes. Other methods—notably `getAttribute()`, `removeAttribute()`, and `setAttribute()`—do the job when your scripts have only the name (as a string) of an attribute belonging to an element.

**`elementObject.removeAttributeNode()`****Example**

Use The Evaluator (Chapter 13) to experiment with the `setAttributeNode()` and `removeAttributeNode()` methods for the `p` element in the page. The task is to create and add a `style` attribute to the `p` element. Begin by creating a new attribute and storing it temporarily in the global variable `a`:

```
a = document.createAttribute("style")
```

Assign a value to the attribute object:

```
a.nodeValue = "color:red"
```

Now insert the new attribute into the `p` element:

```
document.getElementById("myP").setAttributeNode(a)
```

The paragraph changes color in response to the newly added attribute.

Due to the NN6 bug that won't allow the method to return a reference to the newly inserted attribute node, you can artificially obtain such a reference:

```
b = document.getElementById("myP").getAttributeNode("style")
```

Finally, use the reference to the newly added attribute to remove it from the element:

```
document.getElementById("myP").removeAttribute(b)
```

Upon removing the attribute, the paragraph resumes its initial color. See the example for the `setAttribute()` method later in this chapter to discover how you can perform this same kind of operation with `setAttribute()`.

**Related Items:** `attributes` property; `document.createAttribute()`, `getAttribute()`, `getAttributeNode()`, `setAttribute()` methods.

**`removeAttributeNS("namespaceURI", "localName")`**

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

This method removes the attribute specified in the two parameters. The first parameter of the method is a URI string matching a URI assigned to a label in the document. The second parameter is the local name portion of the attribute whose value you are removing.

**Related Items:** `attributes`, `namespaceURI`, `localName` properties; `removeAttribute()`, `getAttributeNS()`, and `setAttributeNS()` methods.

**`removeBehavior(ID)`**

**Returns:** Boolean.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `removeBehavior()` method detaches a behavior from an object. It assumes that the behavior was added to the object via the `addBehavior()` method. The return value of the `addBehavior()` method is a unique identifier for that particular behavior. This identifier is the required parameter for the `removeBehavior()` method. Thus, you can add two behaviors to an object and remove just one of them if so desired. If the removal succeeds, the `removeBehavior()` method returns `true`; otherwise, it returns `false`.

*elementObject.removeExpression()*

## Example

See Listings 15-19a and 15-19b earlier in this chapter for examples of how to use `addBehavior()` and `removeBehavior()`.

**Related Item:** `addBehavior()` method.

## `removeChild(nodeObject)`

**Returns:** Node object reference.

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `removeChild()` method erases a child element from the current element. Content associated with the child element is no longer visible on the page, and the object is no longer part of the document object hierarchy.

As destructive as that sounds, the specifications for the deleted object are not lost to the ether necessarily. The `removeChild()` method returns a reference to the removed node. By assigning this value to a variable, you can hold onto that object specification for insertion later in the session. You are free to use this value as a parameter to such methods as `appendChild()`, `replaceChild()`, `swapNode()`, and `insertBefore()`.

Remember that `removeChild()` is invoked from the point of view of a parent element. If you simply want to remove an element, you can do so more directly (in WinIE5+ only) with the `removeNode()` method.

## Example

You can see an example of `removeChild()` as part of Listing 15-21 earlier in this chapter.

**Related Items:** `appendChild()`, `replaceChild()`, `removeNode()` methods.

## `removeEventListener()`

(See `addEventListener()`)

## `removeExpression("propertyName")`

**Returns:** Boolean.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

If you assign an expression to an object property (including an object's `style` object) via the `setExpression()` method, you can remove it under script control with the `removeExpression()` method. The sole parameter is the name of the property in string form. Property names are case-sensitive.

The method returns `true` if the removal succeeds; otherwise, `false` is returned. Be aware that removing an expression does not alter the value that is currently assigned to the property. In other words, you can use `setExpression()` to set a property's value and then remove the expression so that no further changes are made when the document recalculates expressions. If this is your goal, however, you are probably better served by simply setting the property directly via scripting.

## Example

You can experiment with all three expression methods in The Evaluator (Chapter 13). The following sequence adds an expression to a stylesheet property of the `myP` element on the page and then removes it.

***elementObject.removeExpression()***

To begin, enter the number 24 in the bottom one-line text box in The Evaluator (but don't press Enter or click the List Properties button). This is the value used in the expression to govern the `fontSize` property of the `myP` object. Next, assign an expression to the `myP` object's `style` object by entering the following statement into the topmost text box:

```
myP.style.setExpression("fontSize","document.forms[0].inspector.value","JScript")
```

You can now enter different font sizes into the lower text box and have the values immediately applied to the `fontSize` property. (Keyboard events in the text box automatically trigger the recalculation.) The default unit is px, but you can also append other units (such as pt) to the value in the text field to see how different measurement units influence the same numeric value.

Before proceeding to the next step, enter a value other than 16 (the default `fontSize` value). Finally, enter the following statement in the topmost text box to disconnect the expression from the property:

```
myP.style.removeExpression("fontSize")
```

Notice that although you can no longer adjust the font size from the lower text box, the most recent value assigned to it still sticks to the element. To prove it, enter the following statement in the topmost text box to see the current value:

```
myP.style.fontSize
```

**Related Items:** `document.recalc()`, `getExpression()`, `setExpression()` methods.

***removeNode(removeChildrenFlag)***

**Returns:** Node object reference.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

You can use the `removeNode()` method to delete the current node from an element hierarchy in WinIE5+. The sole parameter is a Boolean value that directs the method to remove only itself (without its child nodes) or the node and all of its children (value of `true`). Exercise care with this method when you use a default parameter value of `false`: If the node has child nodes (for example, you attempt to remove a `table` but not its child nodes), IE5 can crash on you. However, you can safely remove the node and all of its children by passing `true` as the sole parameter.

The method returns a reference to the node object removed. This removed object is no longer accessible to the document object model. But the returned value contains all properties of the object as it existed before you removed it (including properties such as `outerHTML` and explicitly set stylesheet rules). Thus, you can use this value as a parameter to insert the node elsewhere in the document.

While the W3C DOM does not have a `removeNode()` method, the cross-browser method whose behavior most closely resembles `removeNode()` is the `removeChild()` method. The scope of the `removeChild()` method is one level up the object hierarchy from the object you use for the `removeNode()` method.

**Example**

Examine Listing 15-21 for the `appendChild()` method to understand the difference between `removeChild()` and `removeNode()`. In the `restore()` function, you can replace this statement

```
mainObj.removeChild(oneChild);
```

in IE5+ with

```
oneChild.removeNode(true);
```

*elementObject.replaceAdjacentText()*

The difference is subtle, but it is important to understand. See Listing 15-31 later in this chapter for another example of the `removeNode()` method.

**Related Items:** `Node` object; `appendChild()`, `cloneChild()`, `removeChild()`, `replaceChild()`, `replaceNode()` methods.

`replaceAdjacentText("location", "text")`

**Returns:** String.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `replaceAdjacentText()` method enables you to replace one chunk of document text with another in a specific position relative to the current object. Be aware that this method works only for plain text and not HTML tags. The returned value is the string of the text that you replace.

Both parameters are required. The first must be one of four possible case-insensitive locations for the insertion, shown in the following table:

<i>Location</i>	<i>Description</i>
<code>beforeBegin</code>	Before the current element's start tag
<code>afterBegin</code>	After the start tag, but before any nested content
<code>beforeEnd</code>	Before the end tag, but after all other nested content
<code>afterEnd</code>	After the end tag

This method is best used with inline (rather than block) elements when specifying the `beforeBegin` and `afterEnd` parameters. For example, if you attempt to use `replaceAdjacentText()` with `beforeBegin` on the second of two consecutive paragraph elements, the replacement text is inserted into the end of the first paragraph. You can think of the `replaceAdjacentText()` method in terms of text fragment nodes. The method replaces the text fragment node (given any one of the four position parameters) with new text. Replacing the text of a simple element with either the `afterBegin` or `beforeEnd` locations is the same as assigning that text to the object's `innerText` property.

## Example

Use The Evaluator (Chapter 13) to experiment with the `replaceAdjacentText()` method. Enter each of the following statements into the top text box and watch the results in the `myP` element (and its nested `myEM` element) below the solid rule:

```
document.getElementById("myEM").replaceAdjacentText("afterBegin", "twenty")
```

Notice that the `myEM` element's new text picks up the behavior of the element. In the meantime, the replaced text (`all`) is returned by the method and displayed in the Results box:

```
document.getElementById("myEM").replaceAdjacentText("beforeBegin", "We need ")
```

All characters of the text fragment, including spaces, are replaced. Therefore, you may need to supply a trailing space, as shown here, if the fragment you replace has a space:

```
document.getElementById("myP").replaceAdjacentText("beforeEnd", " good people.")
```

***elementObject.replaceAdjacentText()***

This is another way to replace the text fragment following the `myEM` element, but it is also relative to the surrounding `myP` element. If you now attempt to replace text after the end of the `myP` block-level element,

```
document.getElementById("myP").replaceAdjacentText("afterEnd", "Hooray!")
```

the text fragment is inserted after the end of the `myP` element's tag set. The fragment is just kind of floating in the document object model as an unlabeled text node.

**Related Items:** `innerText`, `outerText` properties; `getAdjacentText()`, `insertAdjacentHTML()`, `insertAdjacentText()` methods.

***replaceChild(newNodeObject, oldNodeObject)***

**Returns:** Node object reference.

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `replaceChild()` method enables you to swap an existing child node object for a new node object. Parameters for the `replaceChild()` method are node object references, and they must be in the order of the new object followed by the object you want to replace. The old object must be an immediate child node of the parent used to invoke the method, and the new object must also be a "legal" child element within the document containment hierarchy.

The method returns a reference to the child object that you replaced with the new object. This reference can be used as a parameter to any of the node-oriented insertion or replacement methods.

Remember that `replaceChild()` is invoked from the point of view of a parent element. If you simply want to change an element, you can do so more directly in WinIE5+ with the `swapNode()` or `replaceNode()` method.

**Example**

You can see an example of `replaceChild()` as part of Listing 15-21 (for the `appendChild` property) earlier in this chapter.

**Related Items:** `appendChild()`, `removeChild()`, `replaceNode()`, `swapNode()` methods.

***replaceNode("newNodeObject")***

**Returns:** Node object reference.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `replaceNode()` method is related to the `replaceChild()` method, but you invoke this method on the actual node you want to replace (instead of the object's parent). The sole parameter is a reference to a valid node object, which you can generate via the `document.createElement()` method or copy from an existing node. The value returned from the method is a reference to the object that you replace. Thus, you can preserve a copy of the replaced node by storing the results in a variable for use later.

If the node you replace contains other nodes, the `replaceNode()` method removes all contained nodes of the original from the document. Therefore, if you want to change a wrapper node but want to maintain the original children, your script must capture the children and put them back into the new node as shown in the following example.

**Example**

Listing 15-31 demonstrates three node-related methods: `removeNode()`, `replaceNode()`, and `swapNode()`. These methods work in WinIE5+ only.

*elementObject.replaceNode()*

The page rendered from Listing 15-31 begins with a `ul` type list of four items. Four buttons control various aspects of the node structure of this list element. The first button invokes the `replace()` function, which changes the `ul` type to `ol`. To do this, the function must temporarily tuck away all child nodes of the original `ul` element so that they can be added back into the new `ol` element. At the same time, the old `ul` node is stored in a global variable (`oldNode`) for restoration in another function.

To replace the `ul` node with an `ol`, the `replace()` function creates a new, empty `ol` element and assigns the `myOL` ID to it. Next, the children (`li` elements) are stored en masse as an array in the variable `innards`. The child nodes are then inserted into the empty `ol` element, using the `insertBefore()` method. Notice that as each child element from the `innards` array is inserted into the `ol` element, the child element is removed from the `innards` array. That's why the loop to insert the child nodes is a `while` loop that constantly inserts the first item of the `innards` array to the new element. Finally, the `replaceNode()` method puts the new node in the old node's place, while the old node (just the `ul` element) is stored in `oldNode`.

The `restore()` function operates in the inverse direction of the `replace()` function. The same juggling of nested child nodes is required.

The third button invokes the `swap()` function, whose script exchanges the first and last nodes. The `swapNode()` method, like the others in this discussion, operates from the point of view of the node. Therefore, the method is attached to one of the swapped nodes, while the other node is specified as a parameter. Because of the nature of the `ol` element, the number sequence remains fixed but the text of the `li` node swaps.

To demonstrate the `removeNode()` method, the fourth function removes the last child node of the list. Each call to `removeNode()` passes the `true` parameter to guarantee that the text nodes nested inside each `li` node are also removed. Experiment with this method by setting the parameter to `false` (the default). Notice how the parent-child relationship changes when you remove the `li` node.

**Listing 15-31: Using Node-Related Methods**

```
<html>
  <head>
    <title>removeNode(), replaceNode(), and swapNode() Methods</title>
    <script type="text/javascript">
      // store original node between changes
      var oldNode;

      // replace UL node with OL
      function replace() {
        if (document.getElementById("myUL")) {
          var newNode = document.createElement("OL");
          newNode.id = "myOL";
          var innards = document.getElementById("myUL").children;
          while (innards.length > 0) {
            newNode.insertBefore(innards[0]);
          }
          oldNode = document.getElementById("myUL").replaceNode(newNode);
        }
      }

      // restore OL to UL
      function restore() {
```

*Continued*

**`elementObject.replaceNode()`****Listing 15-31 (continued)**

```

    if (document.getElementById("myOL") && oldNode) {
        var innards = document.getElementById("myOL").children;
        while (innards.length > 0) {
            oldNode.insertBefore(innards[0]);
        }
        document.getElementById("myOL").replaceNode(oldNode);
    }
}

// swap first and last nodes
function swap() {
    if (document.getElementById("myUL")) {
        document.getElementById("myUL").firstChild.swapNode(
            document.getElementById("myUL").lastChild);
    }
    if (document.getElementById("myOL")) {
        document.getElementById("myOL").firstChild.swapNode(
            document.getElementById("myOL").lastChild);
    }
}

// remove last node
function remove() {
    if (document.getElementById("myUL")) {
        document.getElementById("myUL").lastChild.removeNode(true);
    }
    if (document.getElementById("myOL")) {
        document.getElementById("myOL").lastChild.removeNode(true);
    }
}
</script>
</head>
<body>
<h1>Node Methods</h1>
<hr />
Here is a list of items:
<ul id="myUL">
<li>First Item</li>
<li>Second Item</li>
<li>Third Item</li>
<li>Fourth Item</li>
</ul>
<form>
<input type="button" value="Change to OL List"
onclick="replace()" />&nbsp;&nbsp; <input type="button"
value="Restore LI List" onclick="restore()" />&nbsp;&nbsp; <input
type="button" value="Swap First/Last" onclick="swap()" />&nbsp;&nbsp; <input
type="button" value="Remove Last" onclick="remove()" />
</form>
</body>
</html>

```

You can accomplish the same functionality shown in Listing 15-31 in a cross-browser fashion using the W3C DOM. In place of the `removeNode()` and `replaceNode()` methods, use `removeChild()` and `replaceChild()` methods to shift the point of view (and object references)

***elementObject.setActive()***

to the parent of the `ul` and `ol` objects: the `document.body`. Also, you need to change the `document.all` references to `document.getElementById()`.

**Related Items:** `removeChild()`, `removeNode()`, `replaceChild()`, `swapNode()` methods.

**`scrollIntoView(topAlignFlag)`**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN7+, Moz1+, Safari-

The `scrollIntoView()` method scrolls the page (vertically and/or horizontally as needed) such that the current object is visible within the window or frame that contains it. A single parameter, a Boolean value, controls the location of the element within the viewable space. A value of `true` (the default) causes the element to be displayed so that its top is aligned with the top of the window or frame (provided the document beneath it is long enough to allow this amount of scrolling). But a value of `false` causes the bottom of the element to align with the bottom of the viewable area. In most cases, you want the former so that the beginning of a page section is at the top of the viewable area. But if you don't want a user to see content below a certain element when you jump to the new view, use the `false` parameter.

For form elements, you must use the typical form element reference (`document.formName.elementName.scrollIntoView()`) unless you also specify an ID attribute for the element (`document.getElementById("elementID").scrollIntoView()`).

**Example**

Use The Evaluator (Chapter 13) to experiment with the `scrollIntoView()` method. Resize the browser window height so that you can see only the topmost text box and the Results text area. Enter each of the following statements into the top text box and see where the `myP` element comes into view:

```
myP.scrollIntoView()
myP.scrollIntoView(false)
```

Expand the height of the browser window until you can see part of the table lower on the page. If you enter

```
myTable.scrollIntoView(false)
```

into the top text box, the page scrolls to bring the bottom of the table to the bottom of the window. But if you use the default parameter (`true` or empty),

```
myTable.scrollIntoView()
```

the page scrolls as far as it can in an effort to align the top of the element as closely as possible to the top of the window. The page cannot scroll beyond its normal scrolling maximum (although if the element is a positioned element, you can use dynamic positioning to place it wherever you want—including “off the page”). Also, if you shrink the window and try to scroll the top of the table to the top of the window, be aware that the `table` element contains a `caption` element so the `caption` is flush with the top of the window.

**Related Items:** `window.scroll()`, `window.scrollBy()`, `window.scrollTo()` methods.

**`setActive()`**

**Returns:** Nothing.

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `setActive()` method lets a script designate an element object as the active element. However, unlike the `focus()` method, the window does not scroll the active element into

***elementObject.setActive()***

view. Any `onFocus` event handler defined for the element fires when `setActive()` is invoked, without the browser giving the element focus.

**Example**

Use The Evaluator (Chapter 13) to compare the `setActive()` and `focus()` methods. With the page scrolled to the top and the window sized so that you cannot see the sample checkbox near the bottom of the page, enter the following statement into the top text box:

```
document.forms[1].myCheckbox.setActive()
```

Scroll down to see that the checkbox has operational focus (press the spacebar to see). Now, scroll back to the top and enter the following:

```
document.forms[1].myCheckbox.focus()
```

This time, the checkbox gets focus and the page automatically scrolls the object into view.

**Related Item:** `focus()` method.

`setAttribute("attributeName", value[, caseSensitivity])`

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `setAttribute()` method assigns a new value to an existing attribute of the current object or inserts an entirely new attribute name–value pair among the attributes of the current object. This method represents an alternative syntax to setting a property of the object directly.

 **Note**

The W3C DOM Level 2 standard recommends `getAttribute()` and `setAttribute()` for reading and writing element object attribute values, rather than reading and writing those values by way of their corresponding properties. While using these methods is certainly advisable for XML elements, the same DOM standard sends conflicting signals by defining all kinds of properties for HTML element objects. Browsers, of course, will support access via properties well into the future, so don't feel obligated to change your ways just yet.

The first two parameters of `setAttribute()` are required. The first is the name of the attribute. The default behavior of this method respects the case of the attribute name. Therefore, if you use `setAttribute()` to adjust the value of an existing attribute in default mode, the first parameter must match the case of the attribute as known by the object model for the current document. Remember that all names of all attributes assigned as inline source code attributes are automatically converted to lowercase letters.

A value you assign to the attribute is the second parameter. For cross-browser compatibility, the value should be either a string or Boolean data type.

IE provides an optional third parameter to control the case-sensitivity issue for the attribute name. The default value (`true`) has a different impact on your object depending on whether you use `setAttribute()` to assign a new attribute or reassign an existing one. In the former case, the third parameter as `true` means that the attribute name assigned to the object observes the case of the first parameter. In the latter case, the third parameter as `true` means that the attribute isn't reassigned unless the first parameter matches the case of the attribute currently associated with the object. Instead, a new attribute with a different case sequence is created.

Attempting to manage the case-sensitivity of newly created attributes is fraught with peril, especially if you try to reuse names but with different case sequences. I strongly recommend using default case-sensitivity controls for `setAttribute()` and `getAttribute()`.

***elementObject.setAttributeNodeNS()***

IE4+ imposes some limitations on the action resulting from the `setAttribute()` method. Any attribute you add via `setAttribute()` does not become part of the `attributes` collection associated with the element. While you can extract the value of such a newly added attribute via `getAttribute()`, you cannot access the new attribute from the `attributes` collection. Thus, after creating a new attribute as follows:

```
document.getElementById("myTable").setAttribute("currYear",
    (new Date()).getFullYear());
```

you can access that attribute value through either of the following two statements:

```
var tableYear = document.getElementById("myTable").getAttribute("curryear");
var tableYear = document.getElementById("myTable").currYear;
```

However, you cannot access the attribute value with the following statement:

```
var tableYear = document.getElementById("myTable").attributes["currYear"];
```

See also the W3C DOM facilities for treating attributes as node objects in the discussions of the `getAttributeNode()` and `removeAttributeNode()` methods earlier in this chapter.

## Example

Use The Evaluator (Chapter 13) to experiment with the `setAttribute()` method for the elements in the page. For IE4, use the `document.all` notation; IE5+ and W3C browsers understand the W3C standard `getElementById()` method of addressing an element.

Setting attributes can have immediate impact on the layout of the page (just as setting an object's properties can). Enter the following sample statements into the top text box to view attribute values.

IE4+:

```
document.all.myTable.setAttribute("width", "80%")
document.all.myTable.setAttribute("border", "5")
```

IE5+/W3C:

```
document.getElementById("myTable").setAttribute("width", "80%")
document.getElementById("myTable").setAttribute("border", "5")
```

**Related Items:** `attributes` property; `document.createAttribute()`, `getAttribute()`, `getAttributeNode()`, `removeAttribute()`, `removeAttributeNode()`, `setAttributeNode()` methods.

## `setAttributeNode()`

(See `removeAttributeNode()`)

## `setAttributeNodeNS("attributeNode")`

**Returns:** Attribute object.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

This method inserts or replaces an attribute in the current element. The sole parameter is an attribute object, and the return value is a reference to the newly inserted attribute object. When the method is invoked, the browser looks for a pairing of local name and namespace URI between the nodes. If there is a match, the node replaces the matched node; otherwise, the node is inserted.

**Related Items:** `attributes`, `namespaceURI`, `localName` properties; `removeAttributeNS()`, `getAttributeNS()`, and `setAttributeNS()` methods.

***elementObject.setAttributeNS()***

`setAttributeNS("namespaceURI", "qualifiedName", "value")`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

This method inserts or replaces an attribute in the current element, as specified in the three parameters. The first parameter of the method is a URI string matching a URI assigned to a label in the document. The second parameter is the local name portion of the attribute whose value you are getting. If a match is found among these parameters, the value in the third parameter is assigned to the existing attribute; otherwise, the value is inserted as a new attribute.

**Related Items:** `attributes`, `namespaceURI`, `localName` **properties**; `removeAttributeNS()`, `getAttributeNS()`, and `setAttributeNodeNS()` **methods**.

`setCapture(containerBoolean)`

(See `releaseCapture()`)

`setExpression("propertyName", "expression", ["language"])`

**Returns:** Nothing.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

Use the `setExpression()` method to assign the result of an executable expression to the value of an element object property. This method can assign values to both HTML element objects and style objects that belong to them.

The `setExpression()` method is a scripted way of assigning expressions to attributes. But you can also assign expressions directly to stylesheet definitions in the HTML tag of an element using the `expression()` syntax, as in the following example:

```
<p style="width:expression(document.body.style.width * 0.75)">
```

The `setExpression()` method requires three parameters. The first parameter is the name of the property (in string form) to which you assign the expression. Property names are case-sensitive. The second parameter is a string form of the expression to be evaluated to supply a value for the property. Expressions can refer to global variables or properties of other objects in the same document (provided the property is anything other than an array). An expression may also contain math operators.

Pay close attention to the data type of the evaluated value of the expression. The value must be a valid data type for the property. For example, the URL of the body background image must be a string. But for numeric values, you can generally use number and string types interchangeably because the values are converted to the proper type for the property. Even for expressions that evaluate to numbers, encase the expression inside quotes. It may not be necessary in all cases, but if you get into the habit of using quotes, you'll have fewer problems for strings or complex expressions that require them.

You are not limited to using JavaScript as the language for the expression because you can also specify the scripting language of the expression in the optional third parameter. Acceptable parameter values for the language are

```
JScript  
JavaScript  
VBScript
```

For all intents and purposes, JScript and JavaScript are the same. Both languages are ECMA-262 compatible. JScript is the default value for the `language` parameter.

*elementObject.setExpression()*

One reason to use `setExpression()` for dynamic properties is to let the property always respond to the current conditions on the page. For example, if you set a property that is dependent on the current width of the body, then you want a recalculation that is applied to the property if the user resizes the window. The browser automatically responds to many events and updates any dynamic properties. In essence, the browser recalculates the expressions and applies the new values to the property. Keyboard events, in particular, trigger this kind of automatic recalculation for you. But if your scripts perform actions on their own (in other words, not triggered by events), then your scripts need to force the recalculation of the expressions. The `document.recalc()` method takes care of this, but you must invoke it to force the recalculation of dynamic properties in these cases.

## Example

Listing 15-32 shows the `setExpression()`, `recalc()`, and `getExpression()` methods at work in a DHTML-based clock. Figure 15-1 shows the clock. As time clicks by, the bars for hours, minutes, and seconds adjust their widths to reflect the current time. At the same time, the `innerHTML` of `span` elements to the right of each bar display the current numeric value for the bar.

The dynamically calculated values in this example are based on the creation of a new date object over and over again to get the current time from the client computer clock. It is from the date object (stored in the variable called `now`) that the hour, minute, and second values are retrieved. Some other calculations are involved so that a value for one of these time components is converted into a pixel value for the width of the bars. The bars are divided into 24 (for the hours) and 60 (for the minutes and seconds) parts, so the scale for the two types differs. For the 60-increment bars in this application, each increment is set to 5 pixels (stored in `shortWidth`); the 24-increment bars are 2.5 times the `shortWidth`.

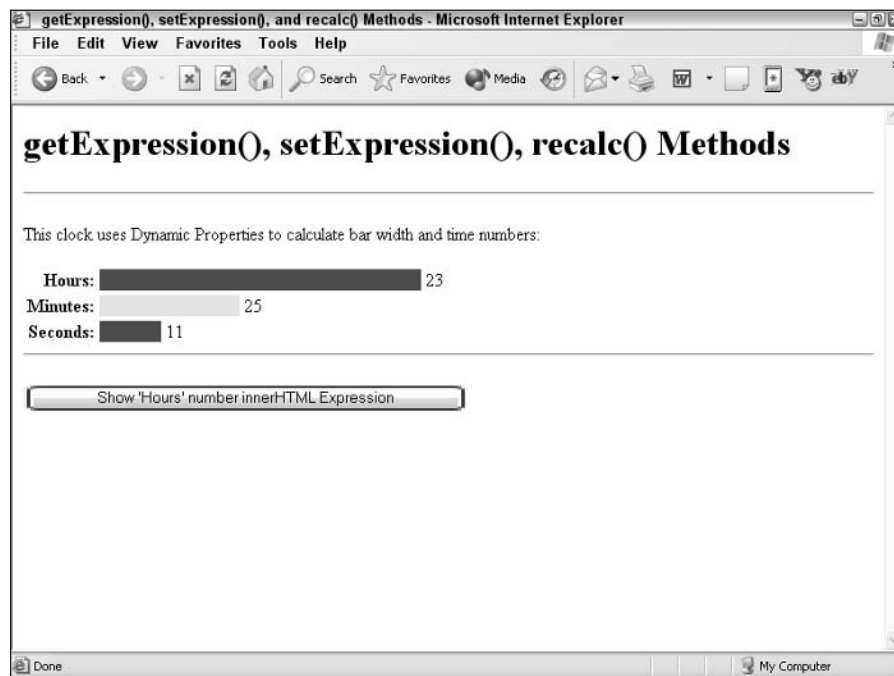

Figure 15-1: A bar graph clock created with dynamic expressions.

***elementObject.setExpression()***

As the document loads, the three `span` elements for the colored bars are given no width, which means that they assume the default width of zero. But after the page loads, the `onload` event handler invokes the `init()` function, which sets the initial values for each bar's width and the text (`innerHTML`) of the three labeled spans. Once these initial values are set, the `init()` function invokes the `updateClock()` function.

In the `updateClock()` function, a new date object is created for the current instant. The `document.recalc()` method is called, instructing the browser to recalculate the expressions that were set in the `init()` function and assign the new values to the properties. To keep the clock "ticking," the `setTimeout()` method is set to invoke this same `updateClock()` function in one second.

To see what the `getExpression()` method does, you can click the button on the page. It simply displays the returned value for one of the attributes that you assign using `setExpression()`.

**Listing 15-32: Dynamic Properties**

```
<html>
  <head>
    <title>getExpression(), setExpression(), and recalc() Methods</title>
    <style type="text/css">
      th {text-align:right}
      span {vertical-align:bottom}
    </style>
    <script type="text/javascript">
      var now = new Date();
      var shortWidth = 5;
      var multiple = 2.5;

      function init() {
        with (document.all) {
          hoursBlock.style.setExpression("width","now.getHours() *
            shortWidth * multiple","jscript");
          hoursLabel.setExpression("innerHTML","now.getHours()","jscript");
          minutesBlock.style.setExpression("width","now.getMinutes() *
            shortWidth","jscript");
          minutesLabel.setExpression("innerHTML","now.getMinutes()",
            "jscript");
          secondsBlock.style.setExpression("width","now.getSeconds() *
            shortWidth","jscript");
          secondsLabel.setExpression("innerHTML","now.getSeconds()",
            "jscript");
        }
        updateClock();
      }

      function updateClock() {
        now = new Date();
        document.recalc();
        setTimeout("updateClock()",1000);
      }

      function showExpr() {
        alert("Expression for the \'Hours\' innerHTML property is:\r\n" +
          document.getElementById("hoursLabel").getExpression("innerHTML") +
          ".");
      }
    </script>
  </head>
</html>
```

*elementObjectCollection.tags()*

```

</script>
</head>
<body onload="init()">
  <h1>getExpression(), setExpression(), recal() Methods</h1>
  <hr />
  <p>This clock uses Dynamic Properties to calculate bar width and time
  numbers:</p>
  <table border="0">
    <tr>
      <th>Hours:</th>
      <td><span id="hoursBlock" style="background-color:red"></span>
      &nbsp;<span id="hoursLabel"></span></td>
    </tr>
    <tr>
      <th>Minutes:</th>
      <td><span id="minutesBlock" style="background-color:yellow"></span>
      &nbsp;<span id="minutesLabel"></span></td>
    </tr>
    <tr>
      <th>Seconds:</th>
      <td><span id="secondsBlock" style="background-color:green"></span>
      &nbsp;<span id="secondsLabel"></span></td>
    </tr>
  </table>
  <hr />
  <form>
    <input type="button" value="Show 'Hours' number innerHTML Expression"
    onclick="showExpr()" />
  </form>
</body>
</html>

```

**Related Items:** `document.recalc()`, `removeExpression()`, `setExpression()` methods.

**swapNode(*otherNodeObject*)**

**Returns:** Node object reference.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `swapNode()` method exchanges the positions of two nodes within an element hierarchy. Contents of both nodes are preserved in their entirety during the exchange. The single parameter must be a valid node object (perhaps created with `document.createElement()` or copied from an existing node). A return value is a reference to the object whose `swapNode()` method was invoked.

**Example**

See Listing 15-31 (the `replaceNode()` method) for an example of the `swapNode()` method in action.

**Related Items:** `removeChild()`, `removeNode()`, `replaceChild()`, `replaceNode()` methods.

**tags("tagName")**

**Returns:** Array of element objects.

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

***elementObjectCollection.tags()***

The `tags()` method does not belong to every element, but it is a method of every collection of objects (such as `all`, `forms`, and `elements`). The method is best thought of as a kind of filter for the elements that belong to the current collection. For example, to get an array of all `p` elements inside a document, use this expression:

```
document.all.tags("P")
```

You must pass a parameter string consisting of the tag name you wish to extract from the collection. The tag name is case-insensitive.

The return value is an array of references to the objects within the current collection whose tags match the parameter. If there are no matches, the returned array has a length of zero. If you need cross-browser compatibility, use the `getElementsByTagName()` method described earlier in this chapter, and pass a wildcard value of `"*"`.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `tags()` method. Enter the following statements one at a time into the upper text box and study the results:

```
document.all.tags("div")
document.all.tags("div").length
myTable.all.tags("td").length
```

Because the `tags()` method returns an array of objects, you can use one of those returned values as a valid element reference:

```
document.all.tags("form")[1].elements.tags("input").length
```

**Related Item:** `getElementsByTagName()` method.

***urns("behaviorURN")***

**Returns:** Array of element objects.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `urns()` method does not belong to every element, but it is a method of every collection of objects. You must pass a parameter string consisting of the URN (Uniform Resource Name) of a behavior resource (most typically `.htc`) assigned to one or more elements of the collection. The parameter does not include the extension of the filename. If there is no matching behavior URN for the specified parameter, the `urns()` method returns an array of zero length. This method is related to the `behaviorUrns` property, which contains an array of behavior URNs assigned to a single element object.

**Example**

In case the `urns()` method is reconnected in the future, you can add a button and function to Listing 15-19b that reveals whether the `makeHot.htc` behavior is attached to the `myP` element. Such a function looks like this:

```
function behaviorAttached() {
    if (document.all.urns("makeHot")) {
        alert("There is at least one element set to \'makeHot\'.");
    }
}
```

**Related Item:** `behaviorUrns` property.

## Event handlers

`onactivate`  
`onbeforedeactivate`  
`ondeactivate`

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `onactivate` and `ondeactivate` event handlers are very similar to the `onfocus` and `onblur` event handlers, respectively. If an element receives focus, the `onactivate` event fires for that element just before the `onfocus` event fires; conversely, just prior to the element losing focus, events fire in the sequence `onbeforedeactivate`, `ondeactivate`, `onblur`. Only elements that, by their nature, can accept focus (for example, links and form input controls) or that have a `tabindex` attribute set can become the active element (and therefore fire these events).

WinIE5.5+ maintains the original `onfocus` and `onblur` event handlers. But because the behaviors are so close to those of the `onactivate` and `ondeactivate` events, I don't recommend mixing the old and new event handler names in your coding style. If you script exclusively for WinIE5.5+, you can use the new terminology throughout.

### Example

You can modify Listing 15-34 later in this chapter by substituting `onactivate` for `onfocus` and `ondeactivate` for `onblur`.

Use The Evaluator (Chapter 13) to experiment with the `onbeforedeactivate` event handler. To begin, set the `myP` element so it can accept focus:

```
myP.tabIndex = 1
```

If you repeatedly press the Tab key, the `myP` paragraph will eventually receive focus — indicated by the dotted rectangle around it. To see how you can prevent the element from losing focus, assign an anonymous function to the `onbeforedeactivate` event handler, as shown in the following statement:

```
myP.onbeforedeactivate = new Function("event.returnValue=false")
```

Now you can press Tab all you like or click other focusable elements all you like, and the `myP` element will not lose focus until you reload the page (which clears away the event handler). Please do not do this on your pages unless you want to infuriate and alienate your site visitors.

**Related Items:** `onblur`, `onfocus` event handlers.

## `onbeforecopy`

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `onbeforecopy` event handler fires before the actual copy action takes place whenever the user initiates a content copy action via the Edit menu (including the Ctrl+C keyboard shortcut) or the right-click context menu. If the user accesses the Copy command via the Edit or context menu, the `onbeforecopy` event fires before either menu displays. In practice, the event may fire twice even though you expect it only once. Just because the `onbeforecopy` event fires, it does not guarantee that a user will complete the copy operation (for example, the context menu may close before the user makes a selection).

Unlike paste-related events, the `onbeforecopy` event handler does not work with form input elements. Just about any other HTML element is fair game, however.

**elementObject.onbeforecopy****Example**

You can use the `onbeforecopy` event handler to preprocess information prior to an actual copy action. In Listing 15-33, the function invoked by the second paragraph element's `onbeforecopy` event handler selects the entire paragraph so that the user can select any character(s) in the paragraph to copy the entire paragraph into the clipboard. You can paste the results into the text area to verify the operation. By assigning the paragraph selection to the `onbeforecopy` event handler, the page notifies the user about what the copy operation will entail prior to making the menu choice. Had the operation been deferred to the `oncopy` event handler, the selection would have been made after the user chose Copy from the menu.

**Listing 15-33: The `onbeforecopy` Event Handler**

```

    </form>
  </body>
</html>
```

**Related Items:** `onbeforecut`, `oncopy` event handlers.

**onbeforecut**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `onbeforecut` event handler fires before the actual cut action takes place whenever the user initiates a content cut via the Edit menu (including the Ctrl+X keyboard shortcut) or the right-click context menu. If the user accesses the Cut command via the Edit or context menu, the `onbeforecut` event fires before either menu displays. In practice, the event may fire twice even though you expect it only once. Just because the `onbeforecut` event fires, it does not

***elementObject.onbeforepaste***

guarantee that a user will complete the cut operation (for example, the context menu may close before the user makes a selection). If you add the `onbeforecut` event handler to an HTML element, the context menu usually disables the Cut menu item. But assigning a JavaScript call to this event handler brings the Cut menu item to life.

**Example**

You can use the `onbeforecut` event handler to preprocess information prior to an actual cut action. You can try this by editing a copy of Listing 15-33, changing the `onbeforecopy` event handler to `onbeforecut`. Notice that in its original form, the example does not activate the Cut item in either the context or Edit menu when you select some text in the second paragraph. But by assigning a function to the `onbeforecut` event handler, the menu item is active, and the entire paragraph is selected from the function that is invoked.

**Related Items:** `onbeforecopy`, `oncut` event handlers.

**onbeforedeactivate**

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

(See `onactivate` event handler)

**onbeforeeditfocus**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `onbeforeeditfocus` event handler is triggered whenever you edit an element on a page in an environment such as Microsoft's DHTML Editing ActiveX control or with the editable page content feature of IE5.5+. This discussion focuses on the latter scenario because it is entirely within the scope of client-side JavaScript. The `onbeforeeditfocus` event fires just before the element receives its focus. (There may be no onscreen feedback that editing is turned on unless you script it yourself.) The event fires each time a user clicks the element, even if the element just received edit focus elsewhere in the same element.

**Example**

Use The Evaluator (Chapter 13) to explore the `onbeforeeditfocus` in WinIE5.5+. In the following sequence, you assign an anonymous function to the `onbeforeeditfocus` event handler of the `myP` element. The function turns the text color of the element to red when the event handler fires:

```
myP.onbeforeeditfocus = new Function("myP.style.color='red'")
```

Now turn on content editing for the `myP` element:

```
myP.contentEditable = true
```

If you now click inside the `myP` element on the page to edit its content, the text turns to red before you begin editing. In a page scripted for this kind of user interface, you would include some control that turns off editing and changes the color to normal.

**Related Items:** `document.designMode`, `contentEditable`, `isContentEditable` properties.

**onbeforepaste**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

Like `onbeforecopy` and `onbeforecut`, the `onbeforepaste` event occurs just prior to the display of either the context or menu bar Edit menu when the current object is selected (or has a selection within it). The primary value of this event comes when you use scripts to control the

***elementObject.onbeforepaste***

copy-and-paste process of a complex object. Such an object may have multiple kinds of data associated with it, but your script captures only one of the data types. Or, you may want to put some related data about the copied item (for example, the `id` property of the element) into the clipboard. By using the `onbeforepaste` event handler to set the `event.returnValue` property to `false`, you guarantee that the pasted item is enabled in the context or Edit menu (provided the clipboard is holding some content). A handler invoked by `onpaste` should then apply the specific data subset from the clipboard to the currently selected item.

**Example**

See Listing 15-45 for the `onpaste` event handler (later in this chapter) to see how the `onbeforepaste` and `onpaste` event handlers work together.

**Related Items:** `oncopy`, `oncut`, `onpaste` event handlers.

**onblur**

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `onblur` event fires when an element that has focus is about to lose focus because some other element is about to receive focus. For example, a text input element fires the `onblur` event when a user tabs from that element to the next one inside a form. The `onblur` event of the first element fires before the `onfocus` event of the next element.

The availability of the `onblur` event has expanded with succeeding generations of script-capable browsers. In the earlier versions, `blur` and `focus` were largely confined to text-oriented input elements (including the `select` element). These are safe to use with all scriptable browser versions. The `window` object received the `onblur` event handler starting with NN3 and IE4. IE4 also extended the event handler to more form elements, predominantly on the Windows operating system because that OS has a user interface clue (the dotted rectangle) when items such as buttons and links receive focus (so that you may act upon them by pressing the keyboard's spacebar). For IE5+, the `onblur` event handler is available to virtually every HTML element. For most of those elements, however, `blur` and `focus` are not possible unless you assign a value to the `tabindex` attribute of the element's tag. For example, if you assign `tabindex="1"` inside a `<p>` tag, the user can bring focus to that paragraph (highlighted with the dotted rectangle in Windows) by clicking the paragraph or pressing the Tab key until that item receives focus in sequence.

If you plan to use the `onblur` event handler on window or text-oriented input elements, be aware that there might be some unexpected and undesirable consequences of scripting for the event. For example, in IE, a `window` object that has focus loses focus (and triggers the `onblur` event) if the user brings focus to any element on the page (or even clicks a blank area on the page). Similarly, the interaction between `onblur`, `onfocus`, and the `alert()` dialog box can be problematic with text input elements. This is why I generally recommend using the `onchange` event handler to trigger form validation routines. If you should employ both the `onblur` and `onchange` event handler for the same element, the `onchange` event fires before `onblur`. For more details about using this event handler for data validation, see Chapter 43 on the CD-ROM.

WinIE5.5+ adds the `ondeactivate` event handler, which fires immediately before the `onblur` event handler. Both the `onblur` and `ondeactivate` events can be blocked if the `onbeforedeactivate` event handler function sets `event.returnValue` to `false`.

**Example**

More often than not, a page author uses the `onblur` event handler to exert extreme control over the user, such as preventing a user from exiting out of a text box unless that user types

something into the box. This is not a Web-friendly practice, and it is one that I discourage because there are intelligent ways to ensure a field has something typed into it before a form is submitted (see Chapter 43 on the CD-ROM). Listing 15-34 simply demonstrates the impact of the `tabindex` attribute in a WinIE5 element with respect to the `onblur` and `onfocus` events. Notice that as you press the Tab key, only the second paragraph issues the events even though all three paragraphs have event handlers assigned to them.

### Listing 15-34: `onblur` and `onfocus` Event Handlers

```
<html>
  <head>
    <title>onblur and onblur Event Handlers</title>
    <script type="text/javascript">
      function showBlur() {
        var id = event.srcElement.id;
        alert("Element \"" + id + "\" has blurred.");
      }

      function showFocus() {
        var id = event.srcElement.id;
        alert("Element \"" + id + "\" has received focus.");
      }
    </script>
  </head>

```

**Related Items:** `blur()`, `focus()` **methods**; `ondeactivate`, `onbeforedeactivate`, `onfocus`, `onactivate` **event handlers**.

## onclick

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `onclick` event fires when a user presses down (with the primary mouse button) and releases the button with the pointer atop the element (both the down and up strokes must be within the rectangle of the same element). The event also fires with non-mouse click equivalents in operating systems such as Windows. For example, you can use the keyboard to give

***elementObject.onclick***

focus to a clickable object and then press the spacebar or Enter key to perform the same action as clicking the element. In IE, if the element object supports the `click()` method, the `onclick` event fires with the invocation of that method (notice that this does not apply to Navigator or other browsers).

The `onclick` event is closely related to other mouse events. The other related events are `onmousedown`, `onmouseup`, and `ondblclick`. The `onmousedown` event fires when the user makes contact with the mouse switch on the downstroke of a click action. Next comes the `onmouseup` event (when the contact breaks). Only then does the `onclick` event fire—provided that the `onmousedown` and `onmouseup` events have fired in the same object. See the discussions on the `onmousedown` and `onmouseup` events later in this chapter for examples of their usage.

Interaction with the `ondblclick` event is simple: the `onclick` event fires first (after the first click), followed by the `ondblclick` event (after the second click). See the discussion of the `ondblclick` event handler later in this chapter for more about the interaction of these two event handlers.

When used with objects that have intrinsic actions when users click them (namely links and areas), the `onclick` event handler can perform all of the action—including navigating to the destination normally assigned to the `href` attribute of the element. For example, to be compatible with all scriptable browsers, you can make an image clickable if you surround its tag with an `<a>` link tag. This lets the `onclick` event of that tag substitute for the missing `onclick` event handler of earlier `<img>` tags. If you assign an `onclick` event handler without special protection, the event handler will execute and the intrinsic action of the element will be carried out. Therefore, you need to block the intrinsic action. To accomplish this, the event handler must evaluate to the statement `return false`. You can do this in two ways. The first is to append a `return false` statement to the script statement assigned to the event handler:

```
<a href="#" onclick="yourFunction(); return false"><img...></a>
```

As an alternative, you can let the function invoked by the event handler supply the `false` part of the `return false` statement, as shown in the following sequence:

```
function yourFunction() {  
    [statements that do something here]  
    return false;  
}  
...  
<a href="#" onclick="return yourFunction()"><img...></a>
```

Either methodology is acceptable. A third option is to not use the `onclick` event handler at all, but assign a `javascript: pseudo-URL` to the `href` attribute (see the `Link` object in Chapter 19).

The event model in IE4+ provides one more way to prevent the intrinsic action of an object from firing when a user clicks it. If the `onclick` event handler function sets the `returnValue` property of the event object to `false`, the intrinsic action is cancelled. Simply include the following statement in the function invoked by the event handler:

```
event.returnValue = false;
```

The event model of the W3C DOM has a different approach to cancelling the default action. In the event handler function for an event, invoke the `eventObj.cancelDefault()` method.

A common mistake made by scripting beginners is to use a `submit` type input button as a button intended to perform some script action rather than submitting a form. The typical scenario is an input element of type `submit` assigned an `onclick` event handler to perform some local action. The `submit` input button has an intrinsic behavior, just like links and areas. While you can block the intrinsic behavior, as just described, you should use an input element of type `button`.

If you are experiencing difficulty with an implementation of the `onclick` event handler (such as trying to find out which mouse button was used for the click), it may be that the operating system or default browser behavior is getting in the way of your scripting. But you can usually get what you need via the `onmousedown` event handler. (The `onmouseup` event may not fire when you use the secondary mouse button to click an object.) Use the `onclick` event handler whenever possible to capture user clicks because this event behaves most like users are accustomed to in their daily computing work. But fall back on `onmousedown` in an emergency.

## Example

The `onclick` event handler is one of the simplest to grasp and use. Listing 15-35 demonstrates its interaction with the `ondblclick` event handler and shows you how to prevent a link's intrinsic action from activating when combined with `click` events. As you click and/or double-click the link, the status bar displays a message associated with each event. Notice that if you double-click, the `click` event fires first with the first message immediately replaced by the second. For demonstration purposes, I show both backward-compatible ways of cancelling the link's intrinsic action. In practice, decide on one style and stick with it.

### Listing 15-35: Using `onclick` and `ondblclick` Event Handlers

```
<html>
  <head>
    <title>onclick and ondblclick Event Handlers</title>
    <script type="text/javascript">
      var timeout;
      function clearOutput() {
        document.getElementById("clickType").innerHTML = "";
      }
      function showClick() {
        document.getElementById("clickType").innerHTML = "single";
        clearTimeout(timeout);
        timeout = setTimeout("clearOutput()", 3000);
      }

      function showDbClick() {
        document.getElementById("clickType").innerHTML = "double";
        clearTimeout(timeout);
        timeout = setTimeout("clearOutput()", 3000);
      }
    </script>
  </head>
  <body>
    <h1>onclick and ondblclick Event Handlers</h1>
    <hr />
    <a href="#" onclick="showClick();return false"
      ondblclick="return showDbClick()">A sample link.</a>
    (Click type: <span id="clickType"></span>)
  </body>
</html>
```

**Related Items:** `click()` method; `oncontextmenu`, `ondblclick`, `onmousedown`, `onmouseup` event handlers.

**elementObject.oncontextmenu****oncontextmenu**

**Compatibility:** WinIE5+, MacIE-, NN7+, Moz1+, Safari-

The `oncontextmenu` event fires when the user clicks an object with the secondary (usually the right-hand) mouse button. The only click-related events that fire with the secondary button are `onmousedown` and `oncontextmenu`.

To block the intrinsic application menu display of the `oncontextmenu` event, use any of the three event cancellation methodologies available in WinIE5+ (as just described in the `onclick` event handler description: two variations of evaluating the event handler to return `false`; assigning `false` to the `event.returnValue` property). It is not uncommon to wish to block the context menu from appearing so that users are somewhat inhibited from downloading copies of images or viewing the source code of a frame. Be aware, however, that if a user turns Active Scripting off in WinIE5+, the event handler cannot prevent the context menu from appearing.

Another possibility for this event is to trigger the display of a custom context menu constructed with other DHTML facilities. In this case, you must also disable the intrinsic context menu so that both menus do not display at the same time.

**Example**

See Listing 15-30 earlier in this chapter for an example of using the `oncontextmenu` event handler with a custom context menu.

**Related Items:** `releaseCapture()`, `setCapture()` methods.

**oncontrolselect**

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `oncontrolselect` event fires just before a user makes a selection on an editable element while the page is in edit mode. It's important to note that it is the element itself that is selected in order to trigger this event, not the content within the element.

**Related Items:** `onresizeend`, `onresizestart` event handlers.

**oncopy****oncut**

**Compatibility:** WinIE5+, MacIE4+, NN-, Moz-, Safari-

The `oncopy` and `oncut` events fire immediately after the user or script initiates a copy or cut edit action on the current object. Each event is preceded by its associated “before” event, which fires before any Edit or context menu appears (or before the copy or cut action, if initiated by keyboard shortcut).

Use these event handlers to provide edit functionality to elements that don't normally allow copying or cutting. In such circumstances, you need to enable the Copy or Cut menu items in the context or Edit menu by setting the `event.returnValue` for the `onbeforecopy` or `onbeforecut` event handlers to `false`. Then your `oncopy` or `oncut` event handlers must manually stuff a value into the clipboard by way of the `setData()` method of the `clipboardData` object. If you use the `setData()` method in your `oncopy` or `oncut` event handler, you must also set the `event.returnValue` property to `false` in the handler function to avoid the default copy or cut action from wiping out your clipboard contents.

Because you are in charge of what data is stored in the clipboard, you are not limited to a direct copy of the data. For example, you might wish to store the value of the `src` property of an image object so that the user can paste it elsewhere on the page.

In the case of the `oncut` event handler, your script is also responsible for cutting the element or selected content from the page. To eliminate all of the content of an element, you can set the element's `innerHTML` or `innerText` property to an empty string. For a selection, use the `selection.createRange()` method to generate a `TextRange` object whose contents you can manipulate through the `TextRange` object's methods.

## Example

Listing 15-36 shows both the `onbeforecut` and `oncut` event handlers in action (as well as `onbeforepaste` and `onpaste`). Notice how the `handleCut()` function not only stuffs the selected word into the `clipboardData` object, but it also erases the selected text from the table cell element from where it came. If you replace the `onbeforecut` and `oncut` event handlers with `onbeforecopy` and `oncopy` (and change `handleCut()` to not eliminate the inner text of the event source element), the operation works with copy and paste instead of cut and paste. I demonstrate this later in the chapter in Listing 15-45.

### Listing 15-36: Cutting and Pasting under Script Control

```
<html>
  <head>
    <title>onbeforecut and oncut Event Handlers</title>
    <style type="text/css">
      td {text-align:center}
      th {text-decoration:underline}
      .blanks {text-decoration:underline}
    </style>
    <script type="text/javascript">
      function selectWhole() {
        var obj = window.event.srcElement;
        var range = document.body.createTextRange();
        range.moveToElementText(obj);
        range.select();
        event.returnValue = false;
      }

      function handleCut() {
        var rng = document.selection.createRange();
        clipboardData.setData("Text",rng.text);
        var elem = event.srcElement;
        elem.innerHTML = "";
        event.returnValue = false;
      }

      function handlePaste() {
        var elem = window.event.srcElement;
        if (elem.className == "blanks") {
          elem.innerHTML = clipboardData.getData("Text");
        }
        event.returnValue = false;
      }

      function handleBeforePaste() {
        var elem = window.event.srcElement;
        if (elem.className == "blanks") {
```

*Continued*

*elementObject.oncopy*Listing 15-36 (*continued*)

```

        event.returnValue = false;
    }
}
</script>
</head>
<body>
<h1>onbeforecut and oncut Event Handlers</h1>
<hr />

class="blanks">&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;</span> is so <span
id="blank2" class="blanks">&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;</span>!"</p>
<button onclick="location.reload()">Reset</button>
</body>
</html>

```

**Related Items:** *onbeforecopy*, *onbeforecut*, *onbeforepaste*, and *onpaste* event handlers.

*ondblclick*

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The *ondblclick* event fires after the second click of a double-click sequence. The timing between clicks depends on the client's mouse control panel settings. The *onclick* event also fires, but only after the first of the two clicks.

In general, it is rarely a good design to have an element perform one task when the mouse is single-clicked and a different task if double-clicked. With the event sequence employed in modern browsers, this isn't practical anyway (the *onclick* event always fires, even when the user double-clicks). But it is not uncommon to have the mouse down action perform some helper action. You see this in most icon-based file systems: if you click a file icon, it is highlighted at

mouse down to select the item; you can double-click the item to launch it. In either case, one event's action does not impede the other nor confuse the user.

### Example

See Listing 15-35 (for the `onclick` event handler) to see the `ondblclick` event in action.

**Related Items:** `onclick`, `onmousedown`, `onmouseup` event handlers.

## ondrag, ondragend, ondragstart

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `ondrag` event fires after the `ondragstart` event and continues firing repeatedly while the user drags a selection or object on the screen. Unlike the `onmousemove` event, which fires only as the cursor moves on the screen, the `ondrag` event continues to fire even when the cursor is stationary. In the WinIE5+ environment, users can drag objects to other browser windows or other applications. The event fires while the dragging extends beyond the browser window.

Because the event fires regardless of what is underneath the dragged object, you can use it in a game or training environment in which the user has only a fixed amount of time to complete a dragging operation (for example, matching similar pairs of objects). If the browser accommodates downloadable cursors, the `ondrag` event could cycle the cursor through a series of cursor versions to resemble an animated cursor.

Understanding the sequence of drag-related events during a user drag operation can be helpful if your scripts need to micromanage the actions (usually not necessary for basic drag-and-drop operations). Consider the drag-and-drop operation shown in Figure 15-2.

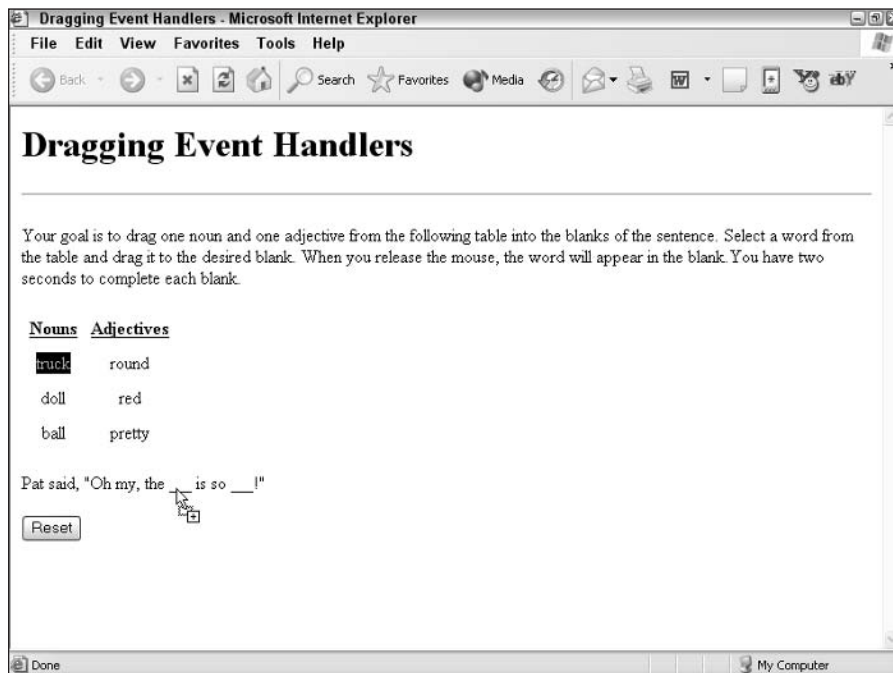

Figure 15-2: A typical drag-and-drop operation.

**elementObject.ondrag**

It helps to imagine that the cells of the table with draggable content are named like spreadsheet cells: “truck” is cell A1; “round” is B1; “doll” is A2; and so on. During the drag operation, many objects are the targets of a variety of drag-related events. Table 15-10 lists the event sequence and the event targets.

**Table 15-10: Events and Their Targets  
During a Typical Drag-and-Drop Operation**

<i>Event</i>	<i>Target</i>	<i>Discussion</i>
ondragstart	cell A1	The very first event that fires during a drag-and-drop operation.
ondrag	cell A1	Fires continually on this target throughout the entire operation. Other events get interspersed, however.
ondragenter	cell A1	Even though the cursor hasn't moved from cell A1 yet, the <code>ondragenter</code> event fires upon first movement within the source element.
ondragover	cell A1	Fires continually on whatever element the cursor rests on at that instant. If the user simply holds the mouse button down and does not move the cursor during a drag, the <code>ondrag</code> and <code>ondragover</code> events fire continually, alternating between the two.
(repetition)	cell A1	<code>ondrag</code> and <code>ondragover</code> events fire alternately while the cursor remains atop cell A1.
ondragenter	table	The table element, represented by the border and/or cell padding, receives the <code>ondragenter</code> event when the cursor touches its space.
ondragleave	cell A1	Notice that the <code>ondragleave</code> event fires after the <code>ondragenter</code> event fires on another element.
ondrag	cell A1	Still firing away.
ondragover	table	The source element for this event shifts to the <code>table</code> because that's what the cursor is “over” at this instant. If the cursor doesn't move from this spot, the <code>ondrag</code> (cell A1) and <code>ondragover</code> (table) events continue to fire in turn.
ondragenter	cell B1	The drag is progressing from the <code>table</code> border space to cell B1.
ondragleave	table	
ondrag	cell A1	The <code>ondrag</code> event continues to fire on the cell A1 object.
ondragover	cell B1	The cursor is atop cell B1 now, so the <code>ondragover</code> event fires for that object. Fires multiple times (depending on the speed of the computer and the user's drag action), alternating with the previous <code>ondrag</code> event.
		[More of the same as the cursor progresses from cell B1 through the table border again to cell B2, the <code>table</code> again, cell B3, and the outermost edge of the <code>table</code> .]
ondragenter	body	Dragging is free of the <code>table</code> and is floating free on the bare <code>body</code> element.
ondragleave	table	Yes, you just left the <code>table</code> .
ondrag	cell A1	Still alive and receiving this event.
ondragover	body	That's where the cursor is now. Fires multiple times (depending on the speed of the computer and the user's drag action), alternating with the previous <code>ondrag</code> event.
ondragenter	blank1	The cursor reaches the <code>span</code> element whose ID is <code>blank1</code> , where the empty underline is.
ondragleave	body	Just left the <code>body</code> for the blank.

<i>Event</i>	<i>Target</i>	<i>Discussion</i>
ondrag	cell A1	Still kicking.
ondragover	blank1	That's where the cursor is now. Fires multiple times (depending on the speed of the computer and the user's drag action), alternating with the previous <code>ondrag</code> event.
ondrop	blank1	The <code>span</code> element gets the notification of a recent drop.
ondragend	cell A1	The original source element gets the final word that dragging is complete. This event fires even if the drag does not succeed because the drag does not end on a drop target.

In practice, some of the events shown in Table 15-10 may not fire. Much has to do with how many event handlers you trap that need to execute scripts along the way. The other major factor is the physical speed at which the user performs the drag-and-drop operation (which interacts with the CPU processing speed). The kinds of events that are most likely to be skipped are the `ondragenter` and `ondragleave` events, and perhaps some `ondragover` events if the user flies over an object before its `ondragover` event has a chance to fire.

Despite this uncertainty about drag-related event reliability, you can count on several important ones to fire all the time. The `ondragstart`, `ondrop` (if over a drop target), and `ondragend` events — as well some interstitial `ondrag` events — will definitely fire in the course of dragging on the screen. All but `ondrop` direct their events to the source element, while `ondrop` fires on the target.

## Example

Listing 15-37 shows several drag-related event handlers in action. The page resembles the example in Listing 15-36, but the scripting behind the page is quite different. In this example, the user is encouraged to select individual words from the Nouns and Adjectives columns and drag them to the blanks of the sentence. To beef up the demonstration, Listing 15-37 shows you how to pass the equivalent of array data from a drag source to a drag target. At the same time, the user has a fixed amount of time (two seconds) to complete each drag operation.

The `ondragstart` and `ondrag` event handlers are placed in the `<body>` tag because those events bubble up from any element that the user tries to drag. The scripts invoked by these event handlers filter the events so that the desired action is triggered only by the “hot” elements inside the table. This approach to event handlers prevents you from having to duplicate event handlers (or IE `<script for=>` tags) for each table cell.

The `ondragstart` event handler invokes `setupDrag()`. This function cancels the `ondragstart` event except when the target element (the one about to be dragged) is one of the `td` elements inside the table. To make this application smarter about what kind of word is dragged to which blank, it passes not only the word's text, but also some extra information about the word. This lets another event handler verify that a noun has been dragged to the first blank, while an adjective has been dragged to the second blank. To help with this effort, class names are assigned to the `td` elements to distinguish the words from the Nouns column from the words of the Adjectives column. The `setupDrag()` function generates an array consisting of the `innerText` of the event's source element plus the element's class name. But the `event.dataTransfer` object cannot store array data types, so the `Array.join()` method converts the array to a string with a colon separating the entries. This string, then, is stuffed into the `event.dataTransfer` object. The object is instructed to render the cursor display during the drag-and-drop operation so that when the cursor is atop a drop target, the cursor

**elementObject.ondrag**

is the “copy” style. Finally, the `setupDrag()` function is the first to execute in the drag operation, so a timer is set to the current clock time to time the drag operation.

The `ondrag` event handler (in the body) captures the `ondrag` events that are generated by whichever table cell element is the source element for the action. Each time the event fires (which is a lot during the action), the `timeIt()` function is invoked to compare the current time against the reference time (global timer) set when the drag starts. If the time exceeds two seconds (2,000 milliseconds), an alert dialog box notifies the user. To close the alert dialog box, the user must unclick the mouse button to end the drag operation.

To turn the blank `span` elements into drop targets, their `ondragenter`, `ondragover`, and `ondrop` event handlers must set `event.returnValue` to `false`; also, the `event.dataTransfer.dropEffect` property should be set to the desired effect (copy in this case). These event handlers are placed in the `p` element that contains the two `span` elements, again for simplicity. Notice, however, that the `cancelDefault()` functions do their work only if the target element is one of the `span` elements whose ID begins with “blank.”

As the user releases the mouse button, the `ondrop` event handler invokes the `handleDrop()` function. This function retrieves the string data from `event.dataTransfer` and restores it to an array data type (using the `String.split()` method). A little bit of testing makes sure that the word type (“noun” or “adjective”) is associated with the desired blank. If so, the source element’s text is set to the drop target’s `innerText` property; otherwise, an error message is assembled to help the user know what went wrong.

**Listing 15-37: Using Drag-Related Event Handlers**

```
<html>
  <head>
    <title>Dragging Event Handlers</title>
    <style type="text/css">
      td {text-align:center}
      th {text-decoration:underline}
      .blanks {text-decoration:underline}
    </style>
    <script type="text/javascript">
      var timer;

      function setupDrag(){
        if (event.srcElement.tagName != "TD") {
          // don't allow dragging for any other elements
          event.returnValue = false;
        } else {
          // setup array of data to be passed to drop target
          var passedData = [event.srcElement.innerText,
            event.srcElement.className];
          // store it as a string
          event.dataTransfer.setData("Text", passedData.join(":"));
          event.dataTransfer.effectAllowed = "copy";
          timer = new Date();
        }
      }

      function timeIt() {
        if (event.srcElement.tagName == "TD" && timer) {
          if ((new Date()) - timer > 2000) {
            alert("Sorry, time is up. Try again.");
          }
        }
      }
    </script>
  </head>
  <body>
    <table border="1">
      <tr>
        <td>Blank 1</td>
        <td>Blank 2</td>
      </tr>
    </table>
  </body>
</html>
```

```

        timer = 0;
    }
}
}

function handleDrop() {
    var elem = event.srcElement;
    var passedData = event.dataTransfer.getData("Text");
    var errMsg = "";
    if (passedData) {
        // reconvert passed string to an array
        passedData = passedData.split(":");
        if (elem.id == "blank1") {
            if (passedData[1] == "noun") {
                event.dataTransfer.dropEffect = "copy";
                event.srcElement.innerHTML = passedData[0];
            } else {
                errMsg = "You can't put an adjective into the noun
                    placeholder.";
            }
        } else if (elem.id == "blank2") {
            if (passedData[1] == "adjective") {
                event.dataTransfer.dropEffect = "copy";
                event.srcElement.innerHTML = passedData[0];
            } else {
                errMsg = "You can't put a noun into the adjective
                    placeholder.";
            }
        }
        if (errMsg) {
            alert(errMsg);
        }
    }
}

function cancelDefault() {
    if (event.srcElement.id.indexOf("blank") == 0) {
        event.dataTransfer.dropEffect = "copy";
        event.returnValue = false;
    }
}
</script>

  <button onclick="location.reload()">Reset</button>
</body>
</html>

```

One event handler not shown in Listing 15-37 is `ondragend`. You can use this event to display the elapsed time for each successful drag operation. Because the event fires on the drag source element, you can implement it in the `<body>` tag and filter events similar to the way the `ondragstart` or `ondrag` event handlers filter events for the `td` element.

**Related Items:** `event.dataTransfer` object; `ondragenter`, `ondragleave`, `ondragover`, `ondrop` event handlers.

**ondragenter****ondragleave****ondragover**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

These events fire during a drag operation. When the cursor enters the rectangular space of an element on the page, the `ondragenter` event fires on that element. Immediately thereafter, the `ondragleave` event fires on the element from which the cursor came. While this may seem to occur out of sequence from the physical action, the events always fire in this order. Depending on the speed of the client computer's CPU and the speed of the user's dragging action, one or the other of these events may not fire—especially if the physical action outstrips the computer's capability to fire the events in time.

The `ondragover` event fires continually while a dragged cursor is atop an element. In the course of dragging from one point on the page to another, the `ondragover` event target changes with the element beneath the cursor. If no other drag-related events are firing (the mouse button is still down in the drag operation, but the cursor is not moving), the `ondrag` and `ondragover` events fire continually, alternating between the two.

You should have the `ondragover` event handler of a drop target element set the event `.returnValue` property to `false`. See the discussion of the `ondrag` event handler earlier in this chapter for more details on the sequence of drag-related events.

## Example

Listing 15-38 shows the `ondragenter` and `ondragleave` event handlers in use. The simple page displays (via the status bar) the time of entry to one element of the page. When the dragged cursor leaves the element, the `ondragleave` event handler hides the status bar message. No drop target is defined for this page, so when you drag the item, the cursor remains as the “no drop” cursor.

### Listing 15-38: Using `ondragenter` and `ondragleave` Event Handlers

```
<html>
  <head>
    <title>ondragenter and ondragleave Event Handlers</title>
    <script type="text/javascript">
      function showEnter() {
        status = "Entered at: " + new Date();
        event.returnValue = false;
      }
      function clearMsg() {
        status = "";
        event.returnValue = false;
      }
    </script>
  </head>
  <body>
    <h1 ondragenter="showEnter()" ondragleave="clearMsg()">
      ondragenter and ondragleave Event Handlers</h1>
    <hr />
    <p>Select any character(s) from this paragraph, and slowly drag it around
      the page. When the dragging action enters the large header above, the
      status bar displays when the onDragEnter event handler fires. When you
      leave the header, the message is cleared via the onDragLeave event
      handler.</p>
  </body>
</html>
```

**Related Items:** `ondrag`, `ondragend`, `ondragstart`, `ondrop` event handlers.

## ondragstart

(See `ondrag`)

## ondrop

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `ondrop` event fires on the drop target element as soon as the user releases the mouse button at the end of a drag-and-drop operation. Microsoft recommends that you denote a drop target by applying the `ondragenter`, `ondragover`, and `ondrop` event handlers to the target element. In each of those event handlers, you should set the `dataTransfer.dropEffect` to the transfer effect you wish to portray in the drag-and-drop operation (signified by a different cursor for each type). These settings should match the `dataTransfer.effectAllowed` property that is usually set in the `ondragstart` event handler. Each of the three drop-related handlers should also override the default event behavior by setting the `event.returnValue` property to

***elementObject.ondrop***

false. See the discussion of the `ondrag` event handler earlier in this chapter for more details on the sequence of drag-related events.

**Example**

See Listing 15-37 of the `ondrag` event handler to see how to apply the `ondrop` event handler in a typical drag-and-drop scenario.

**Related Items:** `event.dataTransfer` object; `ondrag`, `ondragend`, `ondragenter`, `ondragleave`, `ondragover`, `ondragstart` event handlers.

**onfilterchange**

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `onfilterchange` event fires whenever an object's visual filter switches to a new state or a transition completes (a transition may be extended over time). Only objects that accommodate filters and transitions in IE (primarily block elements and form controls) receive the event.

A common usage of the `onfilterchange` event is to trigger the next transition within a sequence of transition activities. This may include an infinite loop transition, for which the object receiving the event toggles between two transition states. If you don't want to get into a loop of that kind, place the different sets of content into their own positionable elements and use the `onfilterchange` event handler in one to trigger the transition in the other.

**Example**

Listing 15-39 demonstrates how the `onfilterchange` event handler can trigger a second transition effect after another one completes. The `onload` event handler triggers the first effect. Although the `onfilterchange` event handler works with most of the same objects in IE4 as IE5, the filter object transition properties are not reflected in a convenient form. The syntax shown in Listing 15-39 uses the new ActiveX filter control found in IE5.5+ (described in Chapter 30).

**Listing 15-39: Using the `onFilterChange` Event Handler**

```
<html>
  <head>
    <title>onfilterchange Event Handler</title>
    <script type="text/javascript">
      function init() {
        image1.filters[0].apply();
        image2.filters[0].apply();
        start();
      }

      function start() {
        image1.style.visibility = "hidden";
        image1.filters[0].play();
      }

      function finish() {
        // verify that first transition is done (optional)
        if (image1.filters[0].status == 0) {
          image2.style.visibility = "visible";
          image2.filters[0].play();
        }
      }
    </script>
  </head>
</html>
```

```

    }
  </script>
</head>
<body onload="init()">
  <h1>onfilterchange Event Handler</h1>
  <hr />
  <p>The completion of the first transition ("circle-in") triggers the
    second ("circle-out"). <button onclick="location.reload()">Play It
    Again</button></p>
  <div id="image1"
    style="visibility:visible; position:absolute; top:150px; left:150px;
    filter:progID:DXImageTransform.Microsoft.Iris(irisstyle='CIRCLE',
    motion='in')" onfilterchange="finish()">
    
  </div>
  <div id="image2"
    style="visibility:hidden; position:absolute; top:150px; left:150px;
    filter:progID:DXImageTransform.Microsoft.Iris(irisstyle='CIRCLE',
    motion='out')">
    
  </div>
</body>
</html>

```

**Related Item:** filter object.

## onfocus

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `onfocus` event fires when an element receives focus, usually following some other object losing focus. (The element losing focus receives the `onblur` event before the current object receives the `onfocus` event.) For example, a text input element fires the `onfocus` event when a user tabs to that element while navigating through a form via the keyboard. Clicking an element also gives that element focus, as does making the browser the frontmost application on the client desktop.

The availability of the `onfocus` event has expanded with succeeding generations of script-capable browsers. In earlier versions, `blur` and `focus` were largely confined to text-oriented input elements such as the `select` element. The `window` object received the `onfocus` event handler starting with NN3 and IE4. IE4 also extended the event handler to more form elements, predominantly on the Windows operating system because that OS has a user interface clue (the dotted rectangle) when items such as buttons and links receive focus (so that users may act upon them by pressing the keyboard's spacebar). For IE5+, the `onfocus` event handler is available to virtually every HTML element. For most of those elements, however, you cannot use `blur` and `focus` unless you assign a value to the `tabindex` attribute of the element's tag. For example, if you assign `tabindex="1"` inside a `<p>` tag, the user can bring focus to that paragraph (highlighted with the dotted rectangle in Windows) by clicking the paragraph or pressing the Tab key until that item receives focus in sequence.

WinIE5.5 adds the `onactivate` event handler, which fires immediately before the `onfocus` event handler. You can use one or the other, but there is little need to include both event handlers for the same object unless you temporarily wish to block an item from receiving focus. To prevent an object from receiving focus in IE5.5+, include an `event.returnValue=false` statement in the `onactivate` event handler for the same object. In other browsers, you can usually get away with assigning `onfocus="this.blur()"` as an event handler for elements such as

***elementObject.onfocus***

form controls. However, this is not a foolproof way to prevent a user from changing a control's setting. Unfortunately, there are few reliable alternatives, short of disabling the control.

**Example**

See Listing 15-34 earlier in this chapter for an example of the `onfocus` and `onblur` event handlers.

**Related Items:** `onactivate`, `onblur`, `ondeactivate` event handlers.

**onhelp**

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `onhelp` event handler fires in Windows whenever an element of the document has focus and the user presses the F1 function key on a Windows PC. As of MacIE5, the event fires only on the window (in other words, event handler specified in the `<body>` tag) and does so via the dedicated Help key on a Mac keyboard. Browser Help menu choices do not activate this event. To prevent the browser's Help window from appearing, the event handler must evaluate to return `false` (for IE4+) or set the `event.returnValue` property to `false` (IE5+). Because the event handler can be associated with individual elements of a document in the Windows version, you can create a context-sensitive help system. However, if the focus is in the Address field of the browser window, you cannot intercept the event. Instead, the browser's Help window appears.

**Example**

Listing 15-40 is a rudimentary example of a context-sensitive help system that displays help messages tailored to the kind of text input required by different text fields. When the user gives focus to either of the text fields, a small legend appears to remind the user that help is available by a press of the F1 help key. MacIE5 provides only generic help.

**Listing 15-40: Creating Context-Sensitive Help**

```
<html>
  <head>
    <title>onhelp Event Handler</title>
    <script type="text/javascript">
      function showNameHelp() {
        alert("Enter your first and last names.");
        event.cancelBubble = true;
        return false;
      }
      function showYOBHelp() {
        alert("Enter the four-digit year of your birth. For example: 1972");
        event.cancelBubble = true;
        return false;
      }
      function showGenericHelp() {
        alert("All fields are required.");
        event.cancelBubble = true;
        return false;
      }
      function showLegend() {
        document.getElementById("legend").style.visibility = "visible";
      }
      function hideLegend() {
```

*elementObject.onkeydown*

```

        document.getElementById("legend").style.visibility = "hidden";
    }
    function init() {
        var msg = "";
        if (navigator.userAgent.indexOf("Mac") != -1) {
            msg = "Press \'help\' key for help.";
        } else if (navigator.userAgent.indexOf("Win") != -1) {
            msg = "Press F1 for help.";
        }
        document.getElementById("legend").style.visibility = "hidden";
        document.getElementById("legend").innerHTML = msg;
    }
</script>
</head>
<body onload="init()" onhelp="return showGenericHelp()">
    <h1>onhelp Event Handler</h1>
    <hr />
    <p id="legend" style="visibility:hidden; font-size:10px">&nbsp;</p>
    <form>
        Name: <input type="text" name="name" size="30" onfocus="showLegend()"
            onblur="hideLegend()" onhelp="return showNameHelp()" /><br />
        Year of Birth: <input type="text" name="YOB" size="30"
            onfocus="showLegend()" onblur="hideLegend()"
            onhelp="return showYOBHelp()" />
    </form>
</body>
</html>

```

---

**Related Items:** `window.showHelp()`, `window.showModalDialog()` methods.

**onkeydown****onkeypress****onkeyup**

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

When someone presses and releases a keyboard key, a sequence of three events fires in quick succession. The `onkeydown` event fires when the key makes its first contact. This is followed immediately by the `onkeypress` event. When contact is broken by the key release, the `onkeyup` event fires. If you hold a character key down until it begins auto-repeating, the `onkeydown` and `onkeypress` events fire with each repetition of the character.

The sequence of events can be crucial in some keyboard event handling. Consider the scenario that wants the focus of a series of text fields to advance automatically after the user enters a fixed number of characters (for example, date, month, and two-digit year). By the time the `onkeyup` event fires, the character associated with the key press action is already added to the field and you can accurately determine the length of text in the field, as shown in this simple example:

```

<html>
<head>
<script type="text/javascript">
function jumpNext(fromFld, toFld) {
    if (fromFld.value.length == 2) {
        document.forms[0].elements[toFld].focus();
        document.forms[0].elements[toFld].select();
    }
}

```

**elementObject.onkeydown**

```
}
</script>
</head>
<body>
<form>
Month: <input name="month" type="text" size="3" value=""
      onkeyup="jumpNext(this, day)" maxlength="2" />
Day: <input name="day" type="text" size="3" value=""
     onkeyup="jumpNext(this, year)" maxlength="2" />
Year: <input name="year" type="text" size="3" value=""
      onkeyup="jumpNext(this, month)" maxlength="2" />
</form>
</body>
</html>
```

These three events do not fire for all keys of the typical PC keyboard on all browser versions that support keyboard events. The only keys that you can rely on supporting the events in all browsers shown in the preceding compatibility chart are the alphanumeric keys represented by ASCII values. This includes keys such as the spacebar and Enter (Return on the Mac), but it excludes all function keys, arrow keys, and other navigation keys. Modifier keys, such as Shift, Ctrl (PC), Alt (PC), Command (Mac), and Option (Mac), generate some events on their own (depending on browser and version). However, functions invoked by other key events can always inspect the pressed states of these modifier keys.

The `onkeydown` event handler works in Mozilla-based browsers only starting with Mozilla 1.4 (and Netscape 7.1).

Scripting keyboard events almost always entails examining which key is pressed so that some processing or validation can be performed on that key press. This is where the situation gets very complex if you are writing for cross-browser implementation. In some cases, even writing just for Internet Explorer gets tricky because non-alphanumeric keys generate only the `onkeydown` and `onkeyup` events.

In fact, to fully comprehend keyboard events, you need to make a distinction between *key codes* and *character codes*. Every PC keyboard key has a key code associated with it. This key code is always the same regardless of what other keys you press at the same time. Only the alphanumeric keys (letters, numbers, spacebar, and so on), however, generate character codes. The code represents the typed character produced by that key. The value might change if you press a modifier key. For example, if you type the “A” key by itself, it generates a lowercase “a” character (character code 97); if you also hold down the Shift key, that same key produces an uppercase “A” character (character code 65). The key code for that key (65 for Western language keyboards) remains the same no matter what.

That brings us, then, to where these different codes are made available to scripts. In all cases, the code information is conveyed as one or two properties of the browser’s event object. IE’s event object has only one such property—`keyCode`. It contains key codes for `onkeydown` and `onkeyup` events, but character codes for `onkeypress` events. The NN6/Moz1 event object, on the other hand, contains two separate properties: `charCode` and `keyCode`. You can find more details and examples about these event object properties in Chapter 25.

The bottom-line script consideration is to use either `onkeydown` or `onkeyup` event handlers when you want to look for non-alphanumeric key events (for example, function keys, arrow and page navigation keys, and so on). To process characters as they appear in text boxes, use the `onkeypress` event handler. You can experiment with these events and codes in Listing 15-41 as well as in examples from Chapter 25.

## Common keyboard event tasks

WinIE4+ enables you to modify the character that a user who is editing a text box enters. The `onkeypress` event handler can modify the `event.keyCode` property and allow the event to continue (in other words, don't evaluate to return false or set the `event.returnValue` property to false). The following IE function (invoked by an `onkeypress` event handler) makes sure text entered into a text field is all uppercase, even if you type it as lowercase:

```
function assureUpper() {
    if (event.keyCode >= 97 && event.keyCode <= 122) {
        event.keyCode = event.keyCode - 32;
    }
}
```

Doing this might confuse (or frustrate) users, so think carefully before implementing such a plan.

To prevent a keyboard key press from becoming a typed character in a text field, the `onkeypress` event handler prevents the default action of the event. For example, the following HTML page shows how to inspect a text field's entry for numbers only:

```
<html>
<head>
<title>Keyboard Capture</title>
<script type="text/javascript">
function checkIt(evt) {
    var charCode = (evt.charCode) ? evt.charCode : ((
        evt.which) ? evt.which : evt.keyCode);
    if (charCode > 31 && (charCode < 48 || charCode > 57)) {
        alert("Please make sure entries are numbers only.");
        return false;
    }
    return true;
}
</script>
</head>

<body>
<form>
Enter any positive integer: <input type="text" name="numeric"
    onkeypress="return checkIt(event)">
</form>
</body>
</html>
```

Whenever a user enters a non-number, the user receives a warning and the character is not appended to the text box's text.

Keyboard events also enable you to script the submission of a form when a user presses the Enter (Return on the Mac) key within a text box. The ASCII value of the Enter/Return key is 13. Therefore, you can examine each key press in a text box and submit the form whenever value 13 arrives, as shown in the following function:

```
function checkForEnter(evt) {
    evt = (evt) ? evt : event;
    var charCode = (evt.charCode) ? evt.charCode : ((
        evt.which) ? evt.which : evt.keyCode);
    if (charCode == 13) {
        document.forms[0].submit();
        return false;
    }
}
```

***elementObject.onkeydown***

```

    }
    return true;
}

```

By assigning the `checkForEnter()` function to each field's `onkeypress` event handler, you suddenly add some extra power to a typical HTML form.

You can intercept Ctrl+keyboard combinations (letters only) in HTML pages most effectively in Internet Explorer, but only if the browser itself does not use the combination. In other words, you cannot redirect Ctrl+key combinations that the browser uses for its own control. The `onkeypress` `keyCode` value for Ctrl+combinations ranges from 1 through 26 for letters A through Z (except for those used by the browser, in which case no keyboard event fires).

**Example**

Listing 15-41 is a working laboratory that you can use to better understand the way keyboard event codes and modifier keys work in IE5+ and W3C browsers. The actual code of the listing is less important than watching the page while you use it. For every key or key combination that you press, the page shows the `keyCode` value for the `onkeydown`, `onkeypress`, and `onkeyup` events. If you hold down one or more modifier keys while performing the key press, the modifier key name is highlighted for each of the three events. Note that when run in NN6+, the `keyCode` value is not the character code (which doesn't show up in this example for NN6+). Also, you may need to click the NN6+ page for the `document` object to recognize the keyboard events.

The best way to watch what goes on during keyboard events is to press and hold a key to see the key codes for the `onkeydown` and `onkeypress` events. Then release the key to see the code for the `onkeyup` event. Notice, for instance, that if you press the A key without any modifier key, the `onkeydown` event key code is 65 (A) but the `onkeypress` key code in IE (and the `charCode` property in NN6+) is 97 (a). If you then repeat the exercise but hold the Shift key down, all three events generate the 65 (A) key code (and the Shift modifier labels are highlighted). Releasing the Shift key causes the `onkeyup` event to show the key code for the Shift key.

In another experiment, press any of the four arrow keys. No key code is passed for the `onkeypress` event because those keys don't generate those events. They do, however, generate `onkeydown` and `onkeyup` events.

Spend some time with this lab, and try all kinds of keys and key combinations until you understand the way the events and key codes work.

**Related Item:** `String.fromCharCode()` method.

**onlosecapture**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

***elementObject.onmousedown***

The `onlosecapture` event handler fires whenever an object that has event capture turned on no longer has that capture. Event capture is automatically disengaged when the user performs any of the following actions:

- ♦ Gives focus to any other window
- ♦ Displays any system modal dialog box (for example, alert window)
- ♦ Scrolls the page
- ♦ Opens a browser context menu (right-clicking)
- ♦ Tabs to give focus to the Address field in the browser window

A function associated with the `onlosecapture` event handler should perform any cleanup of the environment due to an object no longer capturing mouse events.

**Example**

See Listing 15-30 earlier in this chapter for an example of how to use `onlosecapture` with an event-capturing scenario for displaying a context menu. The `onlosecapture` event handler hides the context menu when the user performs any action that causes the menu to lose mouse capture.

**Related Items:** `releaseCapture()`, `setCapture()` methods.

**onmousedown****onmouseup**

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `onmousedown` event handler fires when the user presses any button of a mouse. The `onmouseup` event handler fires when the user releases the mouse button, provided the object receiving the event also received an `onmousedown` event. When a user performs a typical click of the mouse button atop an object, mouse events occur in the following sequence: `onmousedown`, `onmouseup`, `onclick`. But if the user presses the mouse atop an object and then slides the cursor away from the object, only the `onmousedown` event fires.

These events enable authors and designers to add more application-like behavior to images that act as action or icon buttons. If you notice the way most buttons work, the appearance of the button changes while you press the mouse button and reverts to its original style when you release the mouse button (or you drag the cursor out of the button). These events enable you to emulate that behavior.

The event object created with every mouse button action has a property that reveals which mouse button the user pressed. NN4's event model calls that property the `which` property. IE4+ and NN6+/Moz1+ call it the `button` property (but with different values for the buttons). It is most reliable to test for the mouse button number on either the `onmousedown` or `onmouseup` event, rather than on `onclick`. The `onclick` event object does not always contain the button information.

**Example**

To demonstrate a likely scenario of changing button images in response to rolling atop an image, pressing down on it, releasing the mouse button, and rolling away from the image, Listing 15-42 presents a pair of small navigation buttons (left- and right-arrow buttons). Because the image object is not part of the document object model for NN2 or IE3 (which reports itself as Navigator version 2), the page is designed to accept all browsers. Only those browsers that support precached images and image swapping (and thus pass the test for the presence of the

*elementObject.onmousemove*

IE4+ and W3C browsers simplify the implementation of this kind of three-state image button by allowing you to assign the event handlers directly to `img` element objects. Wrapping images inside links is a backward-compatibility approach that allows older browsers to respond to clicks on images for navigation or other scripting tasks.

**Related Item:** `onclick` event handler.

## `onmouseenter`

## `onmouseleave`

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

WinIE5.5 introduced the `onmouseenter` and `onmouseleave` event handlers. Both event handlers operate just like the `onmouseover` and `onmouseout` event handlers, respectively. Microsoft simply offers an alternate terminology. The old and new events continue to fire in IE5.5+. The old ones fire just before the new ones for each act of moving the cursor atop, and exiting from atop, the object. If you are scripting exclusively for IE5.5+, you should use the new terminology; otherwise, stay with the older versions.

### Example

You can modify Listing 15-43 with the IE5.5 syntax by substituting `onmouseenter` for `onmouseover` and `onmouseleave` for `onmouseout`. The effect is the same.

**Related Items:** `onmouseover`, `onmouseout` event handlers.

## `onmousemove`

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `onmousemove` event handler fires whenever the cursor is atop the current object and the mouse is moved, even by a single pixel. You do not have to press the mouse button for the event to fire, although the event is most commonly used in element dragging — especially in NN/Mozilla, where no `ondrag` event handler is available.

Even though the granularity of this event can be at the pixel level, you should not use the number of event firings as a measurement device. Depending on the speed of cursor motion and the performance of the client computer, the event may not fire at every pixel location.

In NN4, you cannot assign the `onmousemove` event handler to any object by way of tag attributes. But you can use the NN4 event capturing mechanism to instruct (via scripting) a `window`, `document`, or `layer` object to capture `mouseMove` events. This allows for NN4 scripts to produce positioned element (`layer`) dragging. In IE4+ and W3C DOM-compatible browsers, however, you can assign the `onmousemove` event handler to any element (although you can drag only with positioned elements). When designing a page that encourages users to drag multiple items on a page, it is most common to assign the `onmousemove` event handler to the `document` object and let all such events bubble up to the document for processing.

### Example

See Chapters 39 and 56 on the CD-ROM for examples of using mouse events to control element dragging on a page.

**Related Items:** `ondrag`, `onmousedown`, `onmouseup` event handlers.

***elementObject.onmouseout***

onmouseout

onmouseover

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `onmouseover` event fires for an object whenever the cursor rolls into the rectangular space of the object on the screen. The `onmouseout` event handler fires when you move the cursor outside the object's rectangle. These events most commonly display explanatory text about an object in the window's status bar and effect image swapping (so-called mouse rollovers). Use the `onmouseover` event handler to change the state to a highlighted version; use the `onmouseout` event handler to restore the image or status bar to its normal setting.

While these two events have been in object models of scriptable browsers since the beginning, they were not available to most objects in earlier browsers. IE4+ and W3C DOM-compatible browsers provide support for these events on every element that occupies space on the screen. IE5.5+ includes an additional pair of event handlers — `onmouseenter` and `onmouseleave` — that duplicate the `onmouseover` and `onmouseout` events but with different terminology. The old event handlers fire just before the new versions.

**Note**

The `onmouseout` event handler commonly fails to fire if the event is associated with an element that is near a frame or window edge and the user moves the cursor quickly outside of the current frame.

**Example**

Listing 15-43 uses the U.S. Pledge of Allegiance with four links to demonstrate how to use the `onmouseover` and `onmouseout` event handlers. Notice that for each link, the handler runs a general-purpose function that sets the window's status message. The function returns a `true` value, which the event handler call evaluates to replicate the required `return true` statement needed for setting the status bar. In one status message, I supply a URL in parentheses to let you evaluate how helpful you think it is for users.

**Listing 15-43: Using `onmouseover` and `onmouseout` Event Handlers**

```
<html>
  <head>
    <title>onmouseover and onmouseout Event Handlers</title>
    <script type="text/javascript">
      function setStatus(msg) {
        status = msg;
        return true;
      }

      // destination of all link HREFs
      function emulate() {
        alert("Not going there in this demo.");
      }
    </script>
  </head>
  <body>

onmouseout="return setStatus('')">allegiance</a> to the <a
href="javascript:emulate()"
onmouseover="return setStatus('Learn about the U.S. flag
(http://lcweb.loc.gov)'"
onmouseout="return setStatus('')">flag</a> of the <a
href="javascript:emulate()"
onmouseover="return setStatus('View info about the U.S. government')"
onmouseout="return setStatus('')">United States of America</a>, and to
the Republic for which it stands, one nation <a
href="javascript:emulate()"
onmouseover="return setStatus('Read about the history of this phrase in
the Pledge')"
onmouseout="return setStatus('')">under God</a>, indivisible, with
liberty and justice for all.
</body>
</html>

```

**Related Items:** `onmouseenter`, `onmouseleave`, `onmousemove` event handlers.

## onpaste

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `onpaste` event fires immediately after the user or script initiates a paste edit action on the current object. The event is preceded by the `onbeforepaste` event, which fires prior to any edit or context menu that appears (or before the paste action if initiated by keyboard shortcut).

Use this event handler to provide edit functionality to elements that don't normally allow pasting. In such circumstances, you need to enable the Paste menu item in the context or Edit menu by setting the event.`returnValue` for the `onbeforepaste` event handler to `false`. Then your `onpaste` event handler must manually retrieve data from the clipboard (by way of the `getData()` method of the `clipboardData` object) and handle the insertion into the current object.

Because you are in charge of what data is stored in the clipboard, you are not limited to a direct copy of the data. For example, you might wish to store the value of the `src` property of an image object so that you can paste it elsewhere on the page.

## Example

Listing 15-44 demonstrates how to use the `onbeforepaste` and `onpaste` event handlers (in conjunction with `onbeforecopy` and `oncopy`) to let scripts control the data-transfer process during a copy-and-paste user operation. A table contains words to be copied (one column of nouns, one column of adjectives) and then pasted into blanks in a paragraph. The `onbeforecopy` and `oncopy` event handlers are assigned to the `table` element because the events from the `td` elements bubble up to the `table` container and there is less HTML code to contend with.

Inside the paragraph, two `span` elements contain underscored blanks. To paste text into the blanks, the user must first select at least one character of the blanks. (See Listing 15-37, which gives a drag-and-drop version of this application.) The `onbeforepaste` event handler in the paragraph (which gets the event as it bubbles up from either `span`) sets the event.`returnValue` property to `false`, thus allowing the Paste item to appear in the context and Edit menus (not a normal occurrence in HTML body content).

***elementObject.onpaste***

At paste time, the `innerHTML` property of the target span is set to the text data stored in the clipboard. The `event.returnValue` property is set to `false` here, as well, to prevent normal system pasting from interfering with the controlled version.

**Listing 15-44: Using `onbeforepaste` and `onpaste` Event Handlers**

```

<html>
  <head>
    <title>onbeforepaste and onpaste Event Handlers</title>
    <style type="text/css">
      td {text-align:center}
      th {text-decoration:underline}
      .blanks {text-decoration:underline}
    </style>
    <script type="text/javascript">
      function selectWhole() {
        var obj = window.event.srcElement;
        var range = document.body.createTextRange();
        range.moveToElementText(obj);
        range.select();
        event.returnValue = false;
      }
      function handleCopy() {
        var rng = document.selection.createRange();
        clipboardData.setData("Text",rng.text);
        event.returnValue = false;
      }

      function handlePaste() {
        var elem = window.event.srcElement;
        if (elem.className == "blanks") {
          elem.innerHTML = clipboardData.getData("Text");
        }
        event.returnValue = false;
      }
      function handleBeforePaste() {
        var elem = window.event.srcElement;
        if (elem.className == "blanks") {
          event.returnValue = false;
        }
      }
    </script>
  </head>

  class="blanks">&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;</span> is so <span
  id="blank2" class="blanks">&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;&nbsp;</span>!"</p>
<button onclick="location.reload()">Reset</button>
</body>
</html>
```

**Related Items:** oncopy, oncut, onbeforepaste event handlers.

## onpropertychange

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `onpropertychange` event fires in WinIE5+ whenever a script modifies an object's property. This includes changes to the properties of an object's style. Changing properties by way of the `setAttribute()` method also triggers this event.

A script can inspect the nature of the property change because the `event.propertyName` property contains the name (as a string) of the property that was just changed. In the case of a change to an object's style object, the `event.propertyName` value begins with "style." as in `style.backgroundColor`.

You can use this event handler to localize any object-specific post-processing of changes to an object's properties. Rather than include the post-processing statements inside the function that makes the changes, you can make that function generalized (perhaps to modify properties of multiple objects).

## Example

Listing 15-45 shows how you can respond programmatically to an object's properties being changed. The page generated by the listing contains four radio buttons that alter the `innerHTML` and `style.color` properties of a paragraph. The paragraph's `onpropertychange` event handler invokes the `showChange()` function, which extracts information about the event and displays the data in the status bar of the window. Notice how the property name includes `style.` when you modify the stylesheet property.

### Listing 15-45: Using the `onPropertyChange` Property

```
<html>
<head>
  <title>onpropertychange Event Handler</title>
```

*Continued*

**elementObject.onpropertychange****Listing 15-45 (continued)**

```

<script type="text/javascript">
function normalText() {
    myP.innerText = "This is a sample paragraph.";
}
function shortText() {
    myP.innerText = "Short stuff.";
}
function normalColor() {
    myP.style.color = "black";
}
function hotColor() {
    myP.style.color = "red";
}
function showChange() {
    var objID = event.srcElement.id;
    var propName = event.propertyName;
    var newValue = eval(objID + "." + propName);
    status = "The " + propName + " property of the " + objID;
    status += " object has changed to \"" + newValue + "\".";
}
</script>
</head>
<body>
<h1>onpropertychange Event Handler</h1>
<hr />

paragraph.</p>
<form>
    Text: <input type="radio" name="btn1" checked="checked"
onclick="normalText()" />Normal <input type="radio" name="btn1"
onclick="shortText()" />Short<br />
    Color: <input type="radio" name="btn2" checked="checked"
onclick="normalColor()" />Black <input type="radio" name="btn2"
onclick="hotColor()" />Red
</form>
</body>
</html>

```

**Related Items:** style property; setAttribute() method.

**onreadystatechange**

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `onreadystatechange` event handler fires whenever the ready state of an object changes. See details about these states in the discussion of the `readyState` property earlier in this chapter (and notice the limits for IE4). The change of state does not guarantee that an object is, in fact, ready for script statements to access its properties. Always check the `readyState` property of the object in any script that the `onreadystatechange` event handler invokes.

This event fires for objects that are capable of loading data: `applet`, `document`, `frame`, `frameset`, `iframe`, `img`, `link`, `object`, `script`, and XML objects. The event doesn't fire for other types of objects unless a Microsoft DHTML behavior is associated with the object. The `onreadystatechange` event does not bubble, nor can you cancel it.

**Related Item:** `readyState` property.

## onresize

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `onresize` event handler fires whenever an object is resized in response to a variety of user or scripted actions. Most elements include this event handler, provided the object has dimensional style attributes (for example, height, width, or position) assigned to it.

In IE4+ and NN6+/Moz1+, the `onresize` event does not bubble. Resizing the browser window or frame does not cause the window's `onload` event handler to fire.

### Example

If you want to capture the user's resizing of the browser window (or frame), you can assign a function to the `onresize` event handler either via script

```
window.onresize = handleResize;
```

or by an HTML attribute of the body element:

```
<body onresize="handleResize()">
```

**Related Item:** `window.resize()` method.

## onresizeend

## onresizestart

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `onresizeend` and `onresizestart` event handlers fire only on a resizable object in Windows edit mode.

**Related Item:** `oncontrolselect` event handler.

## onselectstart

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `onselectstart` event handler fires when a user begins to select content on the page. Selected content can be inline text, images, or text within an editable text field. If the user selects more than one object, the event fires in the first object affected by the selection.

### Example

Use the page from Listing 15-46 to see how the `onselectstart` event handler works when a user selects across multiple elements on a page. As the user begins a selection anywhere on the page, the ID of the object receiving the event appears in the status bar. Notice that the event doesn't fire until you actually make a selection. When no other element is under the cursor, the `body` element fires the event.

#### Listing 15-46: Using the `onselectstart` Event Handler

```
<html>
  <head>
    <title>onselectstart Event Handler</title>
```

*Continued*

**elementObject.onselectstart****Listing 15-46 (continued)**

```

# Window and Frame Objects

---

**A** quick look at the basic document object model diagram in Chapter 14 (see Figure 14-1) reveals that the `window` object is the outermost, most global container of all document-related objects that you script with JavaScript. All HTML and JavaScript activity takes place inside a window. That window may be a standard Windows, Mac, or XWindows application-style window, complete with scrollbars, toolbars, and other “chrome;” you can also generate windows that have only some of a typical window’s chrome. A frame is also a window, even though a frame doesn’t have many accoutrements beyond scroll bars. The `window` object is where everything begins in JavaScript references to objects. IE4+, NN6+, and W3C browsers treat the `frameset` as a special kind of `window` object, so that it is also covered in this chapter.

Of all the objects associated with browser scripting, the `window` and `window`-related objects have by far the most object-specific terminology associated with them. This necessitates a rather long chapter to keep the discussion in one place. Use the running footers as a navigational aid through this substantial collection of information.

## Window Terminology

The `window` object is often a source of confusion when you first learn about the document object model. A number of synonyms for `window` objects muck up the works: `top`, `self`, `parent`, and `frame`. Aggravating the situation is that these terms are also properties of a `window` object. Under some conditions, a window is its own parent, but if you define a `frameset` with two frames, you have only one parent among a total of three `window` objects. It doesn’t take long before the whole subject can make your head hurt.

If you do not use frames in your Web applications, all of these headaches never appear. But if frames are part of your design plan, you should get to know how frames affect the object model.

## Frames

The application of frames has become a religious issue among Web designers: some swear by them; others swear at them. I believe there can be compelling reasons to use frames at times. For example, if you

### In This Chapter

Scripting communication among multiple frames

Creating and managing new windows

Controlling the size, position, and appearance of the browser window

Details of `window`, `frame`, `frameset`, and `iframe` objects

have a document that requires considerable scrolling to get through, you may want to maintain a static set of navigation controls visible at all times. By placing those controls — be they links or image maps — in a separate frame, you have made the controls available for immediate access, regardless of the scrolled condition of the main document.

## Creating frames

The task of defining frames in a document remains the same whether or not you're using JavaScript. The simplest framesetting document consists of tags that are devoted to setting up the frameset, as follows:

```
<html>
<head>
<title>My Frameset</title>
</head>
<frameset>
  <frame name="Frame1" src="document1.html">
  <frame name="Frame2" src="document2.html">
</frameset>
</html>
```

The preceding HTML document, which the user never sees, defines the frameset for the entire browser window. Each frame must have a URL reference (specified by the `src` attribute) for a document to load into that frame. For scripting purposes, assigning a name to each frame with the `name` attribute greatly simplifies scripting frame content.

## The frame object model

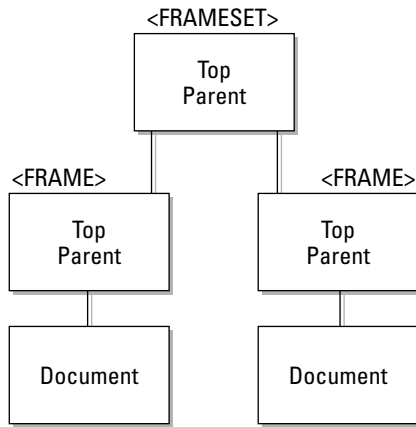

Perhaps the key to successful frame scripting is understanding that the object model in the browser's memory at any given instant is determined by the HTML tags in the currently loaded documents. All canned object model graphics in this book, such as Figure 16-1, do not reflect the precise object model for your document or document set.

For a single, frameless document, the object model starts with just one `window` object, which contains one document, as shown in Figure 16-1. In this simple structure, the `window` object is the starting point for all references to any loaded object. Because the window is always there — it must be there for a document to load into — a reference to any object in the document can omit a reference to the current window.

In a simple two-framed frameset model (see Figure 16-2), the browser treats the container of the initial, framesetting document as the parent window. The only visible evidence that the document exists is that the framesetting document's title appears in the browser window title bar.

**Figure 16-1:** The simplest window–document relationship.

**Figure 16-2:** The parent and frames are part of the object model.

Each `<frame>` tag inside the `<frameset>` tag set creates another window object into which a document is loaded. Each of those frames, then, has a document object associated with it. From the point of view of a given document, it has a single window container, just as in the model shown in Figure 16-1. And although the parent object is not visible to the user, it remains in the object model in memory. The presence of the parent often makes it a convenient repository for variable data that need to be shared by multiple child frames or must persist between loading of different documents inside a child frame.

In even more complex arrangements, as shown in Figure 16-3, a child frame itself may load a framesetting document. In this situation, the difference between the parent and top objects starts to come into focus. The top window is the only one in common with all frames in Figure 16-3. As you see in a moment, when frames need to communicate with other frames (and their documents), you must fashion references to the distant object via the window object that they all have in common.

**Figure 16-3:** Three generations of window objects.

## Referencing frames

The purpose of an object reference is to help JavaScript locate the desired object in the object model currently held in memory. A reference is a road map for the browser to follow, so that it can track down, say, the value of a particular text field in a particular document. Therefore, when you construct a reference, think about where the script appears in the object model and how the reference can help the browser determine where it should go to find the distant object. In a two-generation scenario, such as the one shown in Figure 16-2, three intergenerational references are possible:

- ♦ Parent-to-child
- ♦ Child-to-parent
- ♦ Child-to-child

Assuming that you need to access an object, function, or variable in the relative's frame, the following are the corresponding reference structures: `frameName.objFuncVarName`; `parent.objFuncVarName`; `parent.frameName.objFuncVarName`.

The rule is this: Whenever a reference must point to another frame, begin the reference with the `window` object that the two destinations have in common. To demonstrate that rule on the complex model in Figure 16-3, if the left-hand child frame's document needs to reference the document at the bottom right of the map, the reference structure is

```
top.frameName.frameName.document. . . .
```

Follow the map from the `top` `window` object down through two frames to the final document. JavaScript has to take this route, so your reference must help it along.

## Top versus parent

After seeing the previous object maps and reference examples, you may be wondering, Why not use `top` as the leading object in all trans-frame references? From an object model point of view, you'll have no problem doing that: A parent in a two-generation scenario is also the `top` window. What you can't count on, however, is your framesetting document always being the `top` window object in someone's browser. Take the instance where a Web site loads other Web sites into one of its frames. At that instant, the `top` window object belongs to someone else. If you always specify `top` in references intended just for your parent window, your references won't work and will probably lead to script errors for the user. My advice, then, is to use `parent` in references whenever you mean one generation above the current document.

## Preventing framing

You can use your knowledge of `top` and `parent` references to prevent your pages from being displayed inside another Web site's frameset. Your top-level document must check whether it is loaded into its own `top` or `parent` window. When a document is in its own `top` window, a reference to the `top` property of the current window is equal to a reference to the current window (the `window` synonym `self` seems most grammatically fitting here). If the two values are not equal, you can script your document to reload itself as a top-level document. When it is critical that your document be a top-level document, include the script in Listing 16-1 in the Head portion of your document:

**Listing 16-1: Prevention from Getting “Framed”**

```
<script type="text/javascript">
if (top != self) {
    top.location = location;
}
</script>
```

Your document may appear momentarily inside the other site’s frameset, but then the slate is wiped clean, and your top-level document rules the browser window.

## Ensuring framing

When you design a Web application around a frameset, you may want to make sure that a page always loads the complete frameset. Consider the possibility that a visitor adds only one of your frames to a bookmarks list. On the next visit, only the bookmarked page appears in the browser, without your frameset, which may contain valuable navigation aids to the site.

A script can make sure that a page always loads into its frameset by comparing the URLs of the `top` and `self` windows. If the URLs are the same, it means that the page needs to load the frameset. Listing 16-2 shows the simplest version of this technique, which loads a fixed frameset. The listing includes a workaround for an NN4-specific behavior that prevents printing a frame. (NN4 for Windows and UNIX reloads a page into a separate hidden window for printing and runs any immediate scripts in the process.) For a more complete implementation that passes a parameter to the frameset so that it opens a specific page in one of the frames, see the `location.search` property in Chapter 17.

**Listing 16-2: Forcing a Frameset to Load**

```
<script type="text/javascript">
var isNav4 = (navigator.appName == "Netscape" &&
    parseInt(navigator.appVersion) == 4);
if (top.location.href == window.location.href) {
    if (isNav4) {
        if (window.innerWidth != 0) {
            top.location.href = "myFrameset.html";
        }
    } else {
        top.location.href = " myFrameset.html";
    }
}
</script>
```

## Switching from frames to frameless

Some sites load themselves in a frameset by default and offer users the option of getting rid of the frames. Only IE4+ and W3C browsers let you modify a frameset's `cols` or `rows` properties on the fly to simulate adding or removing frames from the current view (see the `frame-set` element object later in this chapter). In other browsers, you cannot dynamically change the makeup of a frameset after it has loaded, but you can load the content page of the frameset into the main window. Simply include a button or link whose action loads that document into the `top` window object:

```
top.location.href = "mainBody.html";
```

A switch back to the frame version entails nothing more complicated than loading the framesetting document.

## Inheritance versus containment

Scripters who have experience in object-oriented programming environments probably expect frames to inherit properties, methods, functions, and variables defined in a parent object. That's not the case with scriptable browsers. You can, however, still access those parent items when you make a call to the item with a complete reference to the parent. For example, if you want to define a deferred function in the framesetting parent document that all frames can share, the scripts in the frames refer to that function with this reference:

```
parent.myFunc()
```

You can pass arguments to such functions and expect returned values.

## Frame synchronization

A pesky problem for some scripters' plans is that including immediate scripts in the framesetting document is dangerous. Such scripts tend to rely on the presence of documents in the frames being created by this framesetting document. But if the frames have not yet been created and their documents have not yet loaded, the immediate scripts will likely crash and burn.

One way to guard against this problem is to trigger all such scripts from the frameset's `onload` event handler. In theory, this handler won't trigger until all documents have successfully loaded into the child frames defined by the frameset. Unfortunately, IE4+ for Windows has a nasty bug that fires the `onload` event handler in the frameset even if the loading has been interrupted by the browser's Stop button or a press of the Esc key. At the same time, be careful with `onload` event handlers in the documents going into a frameset's frames. If one of those scripts relies on the presence of a document in another frame (one of its brothers or sisters), you're doomed to eventual failure. Anything coming from a slow network or server to a slow modem can get in the way of other documents loading into frames in the ideal order.

One way to work around these problems is to create a Boolean variable in the parent document to act as a flag for the successful loading of subsidiary frames. When a document loads into a frame, its `onload` event handler can set that flag to `true` to indicate that the document has loaded. Any script that relies on a page being loaded should use an `if` construction to test the value of that flag before proceeding.

Despite the horrible WinIE4+ bug just described, it is best to construct the code so that the parent's `onload` event handler triggers all the scripts that you want to run after loading. You should also test your pages thoroughly for any residual effects that may accrue if someone resizes a window or clicks Reload.

## Blank frames

Often, you may find it desirable to create a frame in a frameset but not put any document in it until the user has interacted with various controls or other user interface elements in other frames. Most modern browsers have a somewhat empty document in one of their internal URLs (`about:blank`). However, this URL is not guaranteed to be available on all browsers. If you need a blank frame, let your framesetting document write a generic HTML document to the frame directly from the `src` attribute for the frame, as shown in the skeletal code in Listing 16-3. Loading an “empty” HTML document requires no additional transactions.

### Listing 16-3: Creating a Blank Frame

```
<html>
<head>
<script type="text/javascript">
<!--
function blank() {
    return "<html></html>";
}
//-->
</script>
</head>
<frameset>
    <frame name="Frame1" src="someURL.html">
    <frame name="Frame2" src="javascript:parent.blank()">
</frameset>
</html>
```

## Viewing frame source code

Studying other scripters' work is a major learning tool for JavaScript (or any programming language). With most scriptable browsers you can easily view the source code for any frame, including those frames whose content is generated entirely or in part by JavaScript. Click the desired frame to activate it (a subtle border may appear just inside the frame on some browser versions, but don't be alarmed if the border doesn't appear). Then select Frame Source (or equivalent) from the View menu (or right-click submenu). You can also print or save a selected frame.

## Frames versus frame element objects

With the expansion of object models that expose every HTML element to scripting (IE4+ and W3C DOM-compatible browsers), a terminology conflict comes into play. Everything that you have read about frames thus far in the chapter refers to the original object model, where a frame is just another kind of window, with a slightly different referencing approach. That still holds true, even in the latest browsers.

**window**

But when the object model also exposes HTML elements, the notion of the `frame` element object is somewhat distinct from the frame object of the original model. The `frame` element object represents an object whose properties are dominated by the attributes you set inside the `<frame>` tag. This provides access to settings, such as the frame border and scrollability—the kinds of properties that are not exposed to the original frame object.

References to the `frame` and `frame` element objects are also different. You've seen plenty of examples of how to reference an old-fashioned frame earlier in this chapter. But access to a `frame` element object is either via the element's `id` attribute or through the child node relationship of the enclosing `frameset` element (you cannot use the `parentNode` property to back your way out of the current document to the `frame` element that encloses the document). The way I prefer is to assign an `id` attribute to `<frame>` tags and access the `frame` element object by way of the `document` object that lives in the parent (or top) of the `frameset` hierarchy. Therefore, to access the `frameBorder` property of a `frame` element object from a script living in any frame of a `frameset`, the syntax is

```
parent.document.all.frameIID.frameBorder
```

or, for IE5+/NN6+/W3C

```
parent.document.getElementById("frameIID").frameBorder
```

When the reference goes through the `frame` element object you can still reach the `document` object in that frame via the element object's `contentWindow` or `contentDocument` properties (see the `frame` element object later in this chapter).

**window**

## Syntax

Creating a window:

```
var windowObject = window.open([parameters]);
```

Accessing window properties or methods:

```
window.property | method([parameters])
```

```
self.property | method([parameters])
```

```
windowObject.property | method([parameters])
```

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

## About this object

The `window` object has the unique position of being at the top of the object hierarchy, encompassing even the almighty `document` object. This exalted position gives the `window` object a number of properties and behaviors unlike those of any other object.

Chief among its unique characteristics is that because everything takes place in a window, you can usually omit the `window` object from object references. You've seen this behavior in previous chapters when I invoked document methods, such as `document.write()`. The complete reference is `window.document.write()`. But because the activity was taking place in the window that held the document running the script, that window was assumed to be part of the reference. For single-frame windows, this concept is simple enough to grasp.

As previously stated, among the list of properties for the `window` object is one called `self`. This property is synonymous with the `window` object itself (which is why it shows up in hierarchy diagrams as an object). Having a property of an object that is the same name as the object may sound confusing, but this situation is not that uncommon in object-oriented environments. I discuss the reasons why you may want to use the `self` property as the window's object reference in the `self` property description that follows.

As indicated earlier in the syntax definition, you don't always have to specifically create a `window` object in JavaScript code. After you start your browser, it usually opens a window. That window is a valid `window` object, even if the window is blank. Therefore, after a user loads your page into the browser, the `window` object part of that document is automatically created for your script to access as it pleases.

One conceptual trap to avoid is believing that a `window` object's event handler or custom property assignments outlive the document whose scripts make the assignments. Except for some obvious physical properties of a window, each new document that loads into the window starts with a clean slate of window properties and event handlers.

Your script's control over an existing (already open) window's user interface elements varies widely with the browser and browser version for which your application is intended. Before the version 4 browsers, the only change you can make to an open window is to the status line at the bottom of the browser window. With IE4+ and NN4+, however, you can control such properties as the size, location, and (with signed scripts in Navigator and Mozilla) the presence of "chrome" elements (toolbars and scrollbars, for example) on the fly. Many of these properties can be changed beyond specific safe limits only if you cryptographically sign the scripts (see Chapter 46 on the CD-ROM) and/or the user grants permission for your scripts to make those modifications.

Window properties are far more flexible on all browsers when your scripts generate a new window (with the `window.open()` method): You can influence the size, toolbar, or other view options of a window. Recent browser versions provide even more options for new windows, including the position of the window and whether the window should even display a title bar. Again, if an option can conceivably be used to deceive a user (for example, silently hiding one window that monitors activity in another window), signed scripts and/or user permission are necessary.

The `window` object is also the level at which a script asks the browser to display any of three styles of dialog boxes (a plain alert dialog box, an OK/Cancel confirmation dialog box, or a prompt for user text entry). Although dialog boxes are extremely helpful for cobbling together debugging tools for your own use (see Chapter 45 on the CD-ROM), they can be very disruptive to visitors who navigate through Web sites. Because most JavaScript dialog boxes are modal (that is, you cannot do anything else in the browser until you dismiss the dialog box), use them sparingly, if at all. Remember that some users may create macros on their computers to visit sites unattended. Should such an automated access of your site encounter a modal dialog box, it is trapped on your page until a human intervenes.

All dialog boxes generated by JavaScript identify themselves as being generated by JavaScript. This is primarily a security feature to prevent deceitful scripts from creating system- or application-style dialog boxes that convince visitors to enter private information. It should also discourage dialog box usage in Web page design. And that's good, because dialog boxes tend to annoy users.

With the exception of the IE-specific modal and modeless dialog boxes (see the `window.showModalDialog()` and `window.showModeless()` methods), JavaScript dialog boxes are not particularly flexible in letting you fill them with text or graphic elements beyond the basics. In fact, you can't even change the text of the dialog box buttons or add a button. With DHTML-capable browsers, you can use positioned `div` or `iframe` elements to simulate dialog box behavior in a cross-browser way.

With respect to the W3C DOM, the window is outside the scope of the standard through DOM Level 2. The closest that the standard comes to acknowledging a window at all is the `document.defaultView` property, which evaluates to the `window` object in today's browsers (predominantly Mozilla). But the formal DOM standard specifies no properties or methods for this "view" object.

## Properties

`appCore`

`Components[]`

`controllers[]`

`prompter`

`sidebar`

**Values:** See text.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

NN6+/Mozilla provides scriptable access to numerous services that are part of the `xpconnect` package ("xp" stands for "cross-platform"). These services allow scripts to work with COM objects and the mozilla.org XUL (XML-based User Interface Language) facilities — lengthy

**windowObject.appCore**

subjects that extend well beyond the scope of this book. You can begin to explore this subject within the context of Mozilla-based browsers and scripting at <http://www.mozilla.org/scriptable/>.

**clientInformation**

**Value:** navigator object.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

In an effort to provide scriptable access to browser-level properties while avoiding reference to the Navigator browser brand, Microsoft provides the `clientInformation` property. Its value is identical to that of the `navigator` object—an object name that is also available in IE. Use the `navigator` object for cross-browser applications. (See Chapter 38 on the CD-ROM.)

**Related Items:** navigator object.

**clipboardData**

**Value:** Object.

Read/Write

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

Use the `clipboardData` object to transfer data for such actions as cutting, copying, and pasting under script control. The object contains data of one or more data types associated with a transfer operation. Use this property only when editing processes via the Edit menu (or keyboard equivalents) or context menu controlled by script—typically in concert with edit-related event handlers.

Working with the `clipboardData` object requires knowing about its three methods, shown in Table 16-1. Familiarity with the edit-related event handlers (“before” and “after” versions of cut, copy, and paste) is also helpful (see Chapter 15).

**Table 16-1: window.clipboardData Object Methods**

<i>Method</i>	<i>Returns</i>	<i>Description</i>
<code>clearData([format])</code>	Nothing	Removes data from the clipboard. If no format parameter is supplied, all data is cleared. Data formats can be one or more of the following strings: Text, URL, File, HTML, Image.
<code>getData(format)</code>	String	Retrieves data of the specified format from the clipboard. The format is one of the following strings: Text, URL, File, HTML, Image. The clipboard is not emptied when you get the data, so that the data can be retrieved in several sequential operations.
<code>setData(format, data)</code>	Boolean	Stores string data in the clipboard. The format is one of the following strings: Text, URL, File, HTML, Image. For non-text data formats, the data must be a string that specifies the path or URL to the content. Returns <code>true</code> if the transfer to the clipboard is successful.

You cannot use the `clipboardData` object to transfer data between pages that originate from different domains or arrive via different protocols (`http` versus `https`).

## Example

See Listings 15-30 and 15-39 to see how the `clipboardData` object is used with a variety of edit-related event handlers.

**Related Items:** `event.dataTransfer` property; `onbeforecopy`, `onBeforeCut`, `onbeforepaste`, `oncopy`, `oncut`, `onpaste` event handlers.

## closed

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

When you create a subwindow with the `window.open()` method, you may need to access object properties from that subwindow, such as setting the value of a text field. Access to the subwindow is via the `window` object reference that is returned by the `window.open()` method, as in the following code fragment:

```
var newWind = window.open("someURL.html", "subWind");
...
newWind.document.entryForm.ZIP.value = "00000";
```

In this example, the `newWind` variable is not linked “live” to the window, but is only a reference to that window. If the user should close the window, the `newWind` variable still contains the reference to the now missing window. Thus, any script reference to an object in that missing window will likely cause a script error. What you need to know before accessing items in a subwindow is whether the window is still open.

The `closed` property returns `true` if the `window` object has been closed either by script or by the user. Any time you have a script statement that can be triggered after the user has an opportunity to close the window, test for the `closed` property before executing that statement.

## Example

In Listing 16-4, I have created a basic window opening and closing example. The script begins by initializing a global variable, `newWind`, which is used to hold the object reference to the second window. This value needs to be global so that other functions can reference the window for tasks, such as closing.

For this example, the new window contains some HTML code written dynamically to it, rather than loading an existing HTML file into it. Therefore, the URL parameter of the `window.open()` method is left as an empty string. Next comes a brief delay to allow Internet Explorer (especially versions 3 and 4) to catch up with opening the window so that content can be written to it. The delay (using the `setTimeout()` method described later in this chapter) invokes the `finishNewWindow()` function, which uses the global `newWind` variable to reference the window for writing. The `document.close()` method closes writing to the document—a different kind of close than a window close. A separate function, `closeWindow()`, is responsible for closing the subwindow.

As a final test, an `if` condition looks at two conditions: 1) if the `window` object has ever been initialized with a value other than `null` (in case you click the window closing button before ever having created the new window) and 2) if the window’s `closed` property is `null` or `false`. If either condition is true, the `close()` method is sent to the second window.

**windowObject.closed****Listing 16-4: Checking Before Closing a Window**

```
<html>
  <head>
    <title>window.closed Property</title>
    <script type="text/javascript">
      // initialize global var for new window object
      // so it can be accessed by all functions on the page
      var newWind;

      // make the new window and put some stuff in it
      function newWindow() {
        newWind = window.open("", "subwindow", "height=200,width=200");
        setTimeout("finishNewWindow()", 100);
      }
      function finishNewWindow() {
        var output = "";
        output += "<html><body><h1>A Sub-window</h1>";
        output += "<form><input type='button' value='Close Main Window'";
        output += "onclick='window.opener.close()'></form></body></html>";
        newWind.document.write(output);
        newWind.document.close();
      }

      // close subwindow, including ugly workaround for IE3
      function closeWindow() {
        if (newWind && !newWind.closed) {
          newWind.close();
        }
      }
    </script>
  </head>
  <body>
    <form>
      <input type="button" value="Open Window"
        onclick="newWindow()" /><br />
      <input type="button" value="Close it if Still Open"
        onclick="closeWindow()" />
    </form>
  </body>
</html>
```

To complete the example of the window opening and closing, notice that the subwindow is given a button whose `onclick` event handler closes the main window. In modern browsers, the user is presented with an alert asking to confirm the closure of the main browser window.

**Related Items:** `window.open()`, `window.close()` methods.

**Components**

(See `appCore`)

**controllers**

(See `appCore`)

## crypto pkcs11

**Values:** Object references.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `crypto` and `pkcs11` properties return references to browser objects that are relevant to internal public-key cryptography mechanisms. These subjects are beyond the scope of this book, but you can read more about Netscape's efforts on this front at <http://www.mozilla.org/projects/security/>.

## defaultStatus

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

After a document is loaded into a window or frame, the status bar's message field can display a string that is visible any time the mouse pointer is not atop an object that takes precedence over the status bar (such as a link object or an image map). The `window.defaultStatus` property is normally an empty string, but you can set this property at any time. Any setting of this property will be temporarily overridden when a user moves the mouse pointer atop a link object (see `window.status` property for information about customizing this temporary status bar message).

Probably the most common time to set the `window.defaultStatus` property is when a document loads into a window. You can do this as an immediate script statement that executes from the Head or Body portion of the document or as part of a document's `onload` event handler.

### Example

Unless you plan to change the default status bar text while a user spends time at your Web page, the best time to set the property is when the document loads. In Listing 16-5, notice how I also read this property to reset the status bar in an `onmouseout` event handler. Setting the `status` property to empty also resets the status bar to the `defaultStatus` setting.

#### Listing 16-5: Setting the Default Status Message

```
<html>
  <head>
    <title>window.defaultStatus property</title>
    <script type="text/javascript">
      window.defaultStatus = "Welcome to my Web site.";
    </script>
  </head>
  <body>
    <a href="http://www.microsoft.com"
      onmouseover="window.status = 'Visit Microsoft\'s Home page.';return true"
      onmouseout="window.status = '';return true">Microsoft</a>
    <p><a href="http://mozilla.org"
      onmouseover="window.status = 'Visit Mozilla\'s Home page.';return true"
      onmouseout="window.status = window.defaultStatus;return
      true">Mozilla</a></p>
  </body>
</html>
```

***windowObject.defaultStatus***

If you need to display single or double quotes in the status bar (as in the second link in Listing 16-5), use escape characters (`\ ' and \"`) as part of the strings being assigned to these properties. Although Safari 1.0 sets the value correctly when the page loads, rolling the cursor around empty areas of the page causes the scripted default message to disappear.

**Related Items:** `window.status` property.

**dialogArguments**

**Value:** Varies.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `dialogArguments` property is available only in a window that is generated by the IE-specific `showModalDialog()` or `showModelessDialog()` methods. Those methods allow a parameter to be passed to the dialog box window, and the `dialogArguments` property lets scripts inside the dialog box window's scripts access that parameter value. The value can be in the form of a string, number, or JavaScript array (convenient for passing multiple values).

**Example**

See Listing 16-39 for the `window.showModalDialog()` method to see how arguments can be passed to a dialog box and retrieved via the `dialogArguments` property.

**Related Items:** `window.showModalDialog()`, `window.showModelessDialog()` methods.

**dialogHeight****dialogWidth**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

Scripts in a document located inside an IE-specific modal or modeless dialog box (generated by `showModalDialog()` or `showModelessDialog()`) can read or modify the height and width of the dialog box window via the `dialogHeight` and `dialogWidth` properties. Scripts can access these properties from the main window only for modeless dialog boxes, which remain visible while the user can control the main window contents.

Values for these properties are strings and include the unit of measure, the pixel (px).

**Example**

Dialog boxes sometimes provide a button or icon that reveals more details or more complex settings for advanced users. You can create a function that handles the toggle between two sizes. The following function assumes that the document in the dialog box has a button whose label also toggles between "Show Details" and "Hide Details." The button's `onclick` event handler invokes the function as `toggleDetails(this)`.

```
function toggleDetails(btn) {
    if (dialogHeight == "200px") {
        dialogHeight = "350px";
        btn.value = "Hide Details";
    } else {
        dialogHeight = "200px";
        btn.value = "Show Details";
    }
}
```

In practice, you also have to toggle the `display` stylesheet property of the extra material between `none` and `block` to make sure that the dialog box does not display scrollbars in the smaller dialog box version.

**Related Items:** `window.dialogLeft`, `window.dialogTop` properties.

`dialogLeft`

`dialogTop`

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

Scripts in a document located inside an IE-specific modal or modeless dialog box (generated by `showModalDialog()` or `showModelessDialog()`) can read or modify the left and top coordinates of the dialog box window via the `dialogLeft` and `dialogTop` properties. Scripts can access these properties from the main window only for modeless dialog boxes, which remain visible while the user can control the main window contents.

Values for these properties are strings and include the unit of measure, the pixel (px). If you attempt to change these values so that any part of the dialog box window would be outside the video monitor, the browser overrides the settings to keep the entire window visible.

### Example

Although usually not a good idea because of the potentially jarring effect on a user, you can reposition a dialog box window that has been resized by script (or by the user if you let the dialog box be resizable). The following statements in a dialog box window document's script recenters the dialog box window.

```
dialogLeft = (screen.availWidth/2) - (parseInt(dialogWidth)/2) + "px";  
dialogHeight = (screen.availHeight/2) - (parseInt(dialogHeight)/2) + "px";
```

Note that the `parseInt()` functions are used to read the numeric portion of the `dialogWidth` and `dialogHeight` properties so that the values can be used for arithmetic.

**Related Items:** `window.dialogHeight`, `window.dialogTopWidth` properties.

`directories`

`locationbar`

`menubar`

`personalbar`

`scrollbars`

`statusbar`

`toolbar`

**Value:** Object.

Read/Write (with signed scripts)

**Compatibility:** WinIE-, MacIE-, NN4+, Moz1+, Safari-

Beyond the rectangle of the content region of a window (where your documents appear), the Netscape browser window displays an amalgam of bars and other features known collectively as *chrome*. All browsers can elect to remove these chrome items when creating a new window (as part of the third parameter of the `window.open()` method), but until signed scripts were available in Navigator 4, these items could not be turned on and off in the main browser window or any existing window.

**windowObject.directories**

Navigator 4 promoted these elements to first-class objects contained by the `window` object. Navigator 6 added one more feature, called the directories bar—a frame-like device that can be opened or hidden from the left edge of the browser window. At the same time, however, NN6+/Mozilla browsers no longer permit hiding and showing the browser window's scrollbars. Chrome objects have but one property: `visible`. Reading this Boolean value (possible without signed scripts) lets you inspect the visitor's browser window for the elements currently engaged.

Changing the visibility of these items on the fly alters the relationship between the inner and outer dimensions of the browser window. If you must carefully size a window to display content, you should adjust the chrome elements before sizing the window. Before you start changing chrome visibility before the eyes of your page visitors, weigh the decision carefully. Experienced users have fine-tuned the look of their browser windows to just the way they like them. If you mess with that look, you may anger your visitors. Fortunately, changes you make to a chrome element's visibility are not stored to the user's preferences. However, the changes you make survive an unloading of the page. If you change the settings, be sure you first save the initial settings and restore them with an `onunload` event handler.

**Tip**

The Macintosh menu bar is not part of the browser's window chrome. Therefore, its visibility cannot be adjusted from a script.

**Example**

In Listing 16-6, you can experiment with the look of a browser window with any of the chrome elements turned on and off. To run this script, you must either sign the scripts or turn on codebase principals (see Chapter 46 on the CD-ROM). Java must also be enabled to use the signed script statements.

As the page loads, it stores the current state of each chrome element. One button for each chrome element triggers the `toggleBar()` function. This function inverts the visible property for the chrome object passed as a parameter to the function. Finally, the Restore button returns visibility to their original settings. Notice that the `restore()` function is also called by the `onunload` event handler for the document. Also, if you load this example into NN6+, non-fatal script errors occur when the scrollbars are turned on or off.

**Listing 16-6: Controlling Window Chrome**

```
<html>
  <head>
    <title>Bars Bars Bars</title>
    <script type="text/javascript">
      // store original outer dimensions as page loads
      var originalLocationbar = window.locationbar.visible;
      var originalMenubar = window.menubar.visible;
      var originalPersonalbar = window.personalbar.visible;
      var originalScrollbars = window.scrollbars.visible;
      var originalStatusbar = window.statusbar.visible;
      var originalToolbar = window.toolbar.visible;

      // generic function to set inner dimensions
      function toggleBar(bar) {
        netscape.security.PrivilegeManager.enablePrivilege(
          "UniversalBrowserWrite");
      }
    </script>
  </head>
</html>
```

```

    bar.visible = !bar.visible;
    netscape.security.PrivilegeManager.revertPrivilege(
        "UniversalBrowserWrite");
}
// restore settings
function restore() {
    netscape.security.PrivilegeManager.enablePrivilege(
        "UniversalBrowserWrite");
    window.locationbar.visible = originalLocationbar;
    window.menubar.visible = originalMenubar;
    window.personalbar.visible = originalPersonalbar;
    window.scrollbars.visible = originalScrollbars;
    window.statusbar.visible = originalStatusbar;
    window.toolbar.visible = originalToolbar;
    netscape.security.PrivilegeManager.revertPrivilege(
        "UniversalBrowserWrite");
}
</script>
</head>
<body onunload="restore()">
  <form>
    <b>Toggle Window Bars</b><br />
    <input type="button" value="Location Bar"
    onclick="toggleBar(window.locationbar)" /><br />
    <input type="button" value="Menu Bar"
    onclick="toggleBar(window.menubar)" /><br />
    <input type="button" value="Personal Bar"
    onclick="toggleBar(window.personalbar)" /><br />
    <input type="button" value="Scrollbars"
    onclick="toggleBar(window.scrollbars)" /><br />
    <input type="button" value="Status Bar"
    onclick="toggleBar(window.statusbar)" /><br />
    <input type="button" value="Tool Bar"
    onclick="toggleBar(window.toolbar)" /><br />
    <hr />
    <input type="button" value="Restore Original Settings"
    onclick="restore()" /><br />
  </form>
</body>
</html>

```

---

**Related Items:** `window.open()` method.

## document

**Value:** Object.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

I list the `document` property here primarily for completeness. Each `window` object contains a single `document` object (although in Navigator 4, a window may also contain layers, each of which has a `document` object, as described in Chapter 39 on the CD-ROM). The value of the `document` property is the `document` object, which is not a displayable value. Instead, you use the `document` property as you build references to properties and methods of the document and to other objects contained by the document, such as a form and its elements. To load a

**windowObject.document**

different document into a window, use the `location` object (see Chapter 17). The document object is described in detail in Chapter 18.

**Related Items:** document object.

**event**

**Value:** Object.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari1+

IE4+ and Safari treat the `event` object as a property of the `window` object. Navigator 4+ and the W3C DOM (as well as Safari here, too) pass an instance of the `Event` object as an argument to event handler functions. The connection with the `window` object is relatively inconsequential, because all action involving the `event` object occurs in event handler functions. The only difference is that the object can be treated as a more global object when one event handler function invokes another. Instead of having to pass the `event` object parameter to the next function, functions can access the `event` object directly (with or without the `window.` prefix in the reference).

For complete details about the `event` object in all browsers, see Chapter 25.

**Related Items:** event object.

**external**

**Value:** Object.

Read-Only

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `external` property is useful only when the browser window is a component in another application. The property provides a gateway between the current browser window and the application that acts as a host to the browser window component.

With WinIE4+ acting as a component to the host operating system, the `external` property can be used to access several methods that influence behaviors outside of the browser. Perhaps the three most useful methods to regular Web page scripters are `AddDesktopComponent()`, `AddFavorite()`, and `NavigateAndFind()`. The first two methods display the same kind of alert dialog box that users get after making these choices from the browser or desktop menus, so that you won't be able to sneak your Web site onto desktops or Favorites listings without the visitor's approval. Table 16-2 describes the parameters for these three methods.

**Table 16-2: Popular window.external Object Methods**

<b>Method</b>	<b>Description</b>
<code>AddDesktopComponent</code> ("URL", "type", left, top, width, height)	Adds a Web site or image to the Active Desktop (if turned on in the user's copy of Windows). The <code>type</code> parameter value is either <code>website</code> or <code>image</code> . Dimensional parameters (optional) are all integer values.
<code>AddFavorite</code> ("URL", "title")	Adds the specified URL to the user's Favorites list. The optional title string parameter is how the URL should be listed in the menu (if missing, the URL appears in the list).
<code>NavigateAndFind</code> ("URL", "findString", "target")	Navigates to the URL in the first parameter and opens the page in the target frame (an empty string opens in the current frame). The <code>findString</code> is text to be searched for on that page and highlighted when the page loads.

## Example

The first example asks the user if it is okay to add a Web site to the Active Desktop. If Active Desktop is not enabled, the user is given the choice of enabling it at this point.

```
external.AddDesktopComponent("http://www.nytimes.com","website", 200, 100,
    400, 400);
```

In the next example, the user is asked to approve the addition of a URL to the Favorites list. The user can follow the normal procedure for filing the item in a folder in the list.

```
external.AddFavorite("http://www.dannyg.com/update11.html",
    "JSBible 5 Support Center");
```

The final example assumes that a user makes a choice from a `select` list of items. The `onchange` event handler of the `select` list invokes the following function to navigate to a fictitious page and locate listings for a chosen sports team on the page.

```
function locate(list) {
    var choice = list.options[list.selectedIndex].value;
    external.NavigateAndFind("http://www.collegesports.net/scores.html",
        choice, "scores");
}
```

## frameElement

**Values:** frame or iframe object reference.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

If the current window exists as a result of a `<frame>` or `<iframe>` tag, the window's `frameElement` property returns a reference to the hosting element. As is made clear in the discussion later in this chapter about the frame element object, a reference to a frame or iframe element provides access to the properties that echo the attributes of the HTML element object. For a window that is not part of a frameset, the `frameElement` property returns `null`.

The convenience of this property becomes apparent when a single document is loaded into multiple framesets. A script in the document can still refer to the containing frame element, even when the ID of the element changes from one frameset to another. The frameset element is also accessible via the `parentElement` property of the `frameElement` property:

```
var frameSetObj = self.frameElement.parentElement;
```

A reference to the frameset element opens possibilities of adjusting frame sizes.

**Related Items:** frame, iframe objects.

## frames

**Value:** Array.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

In a multiframe window, the top or parent window contains any number of separate frames, each of which acts as a full-fledged window object. The `frames` property (note the plural use of the word as a property name) plays a role when a statement must reference an object located in a different frame. For example, if a button in one frame is scripted to load a document in another frame, the button's event handler must be able to tell JavaScript precisely where to display the new HTML document. The `frames` property assists in that task.

***windowObject.frames***

To use the `frames` property to communicate from one frame to another, it should be part of a reference that begins with the `parent` or `top` property. This lets JavaScript make the proper journey through the hierarchy of all currently loaded objects to reach the desired object. To find out how many frames are currently active in a window, use this expression:

```
parent.frames.length
```

This expression returns a number indicating how many frames the parent window defines. This value does not, however, count further nested frames, should a third generation of frame be defined in the environment. In other words, no single property exists that you can use to determine the total number of frames in the browser window if multiple generations of frames are present.

The browser stores information about all visible frames in a numbered (indexed) array, with the first frame (that is, the topmost `<frame>` tag defined in the framesetting document) as number 0:

```
parent.frames[0]
```

Therefore, if the window shows three frames (whose indexes are `frames[0]`, `frames[1]`, and `frames[2]`, respectively), the reference for retrieving the `title` property of the document in the second frame is

```
parent.frames[1].document.title
```

This reference is a road map that starts at the parent window and extends to the second frame's document and its `title` property. Other than the number of frames defined in a parent window and each frame's name (`top.frames[i].name`), no other values from the frame definitions are directly available from the frame object via scripting until you get to IE4 and NN6/W3C (see the `frame` element object later in this chapter). In these browsers, individual frame element objects have several properties that reveal `<frame>` tag attributes.

Using index values for frame references is not always the safest tactic, however, because your frameset design may change over time, in which case the index values will also change. Instead, you should take advantage of the `name` attribute of the `<frame>` tag, and assign a unique, descriptive name to each frame. A value you assign to the `name` attribute is also the name that you use for `target` attributes of links to force a linked page to load in a frame other than the one containing the link. You can use a frame's name as an alternative to the indexed reference. For example, in Listing 16-7, two frames are assigned distinctive names. To access the title of a document in the `JustAKid2` frame, the complete object reference is

```
parent.JustAKid2.document.title
```

with the frame name (case-sensitive) substituting for the `frames[1]` array reference. Or, in keeping with JavaScript flexibility, you can use the object name in the array index position:

```
parent.frames["JustAKid2"].document.title
```

The supreme advantage to using frame names in references is that no matter how the frameset structure may change over time, a reference to a named frame will always find that frame, although its index value (that is, position in the frameset) may change.

## Example

Listings 16-7 and 16-8 demonstrate how JavaScript treats values of frame references from objects inside a frame. The same document is loaded into each frame. A script in that document extracts information about the current frame and the entire frameset. Figure 16-4 shows the results after loading the HTML document in Listing 16-7.

**Listing 16-7: Framesetting Document for Listing 16-8**

```
<html>
  <head>
    <title>window.frames property</title>
  </head>
  <frameset cols="50%,50%">
    <frame name="JustAKid1" src="lst16-08.htm" />
    <frame name="JustAKid2" src="lst16-08.htm" />
  </frameset>
</html>
```

A call to determine the number (length) of frames returns 0 from the point of view of the current frame referenced. That's because each frame here is a window that has no nested frames within it. But add the `parent` property to the reference, and the scope zooms out to take into account all frames generated by the parent window's document.

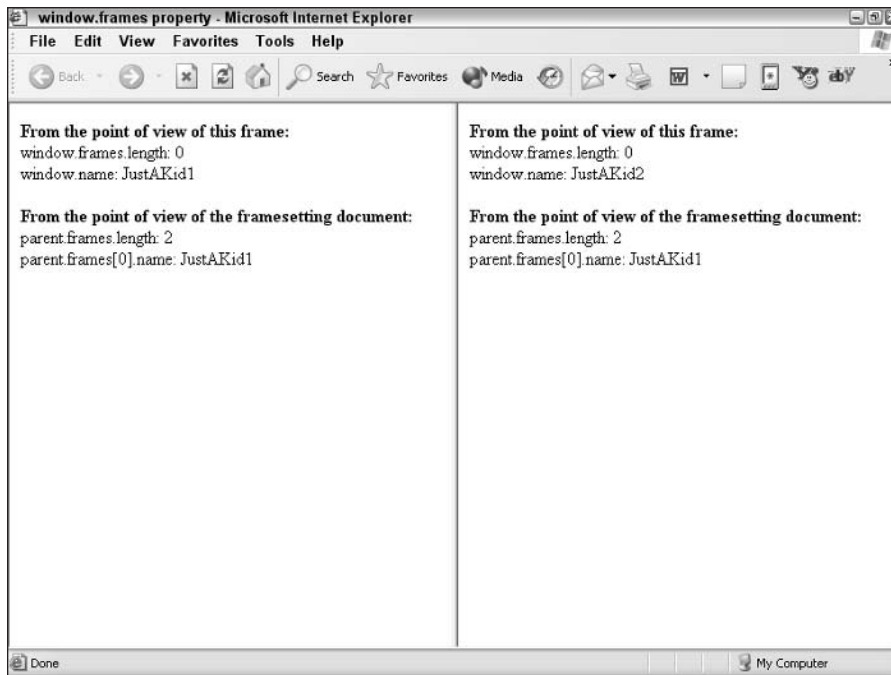

**Listing 16-8: Showing Various Window Properties**

```
<html>
  <head>
    <title>Window Revealer II</title>
    <script type="text/javascript">
      function gatherWindowData() {
        var msg = "";
        msg += "<p><b>From the point of view of this frame:</b><br />";
        msg += "window.frames.length: " + window.frames.length + "<br />";
        msg += "window.name: " + window.name + "</p>";
        msg += "<p><b>From the point of view of the framesetting<br />";
        msg += "document:</b><br />";
        msg += "parent.frames.length: " + parent.frames.length + "<br />";
        msg += "parent.frames[0].name: " + parent.frames[0].name + "</p>";
        return msg;
      }
    </script>
  </head>
  <body>
    <script type="text/javascript">
      document.write(gatherWindowData());
    </script>
  </body>
</html>
```

The last statement in the example shows how to use the array syntax (brackets) to refer to a specific frame. All array indexes start with 0 for the first entry. Because the document asks for the name of the first frame (`parent.frames[0]`), the response is `JustAKid1` for both frames.

**Related Items:** `frame`, `frameset` objects; `window.parent`, `window.top` properties.

***windowObject.history***

**Figure 16-4:** Property readouts from both frames loaded from Listing 16-7.

**history**

**Value:** Object.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

(See the discussion of the `history` object in Chapter 17.)

**innerHeight****innerWidth****outerHeight****outerWidth**

**Value:** Integer.

Read/Write (see text)

**Compatibility:** WinIE-, MacIE-, NN4+, Moz1+, Safari1+

NN4+ lets scripts adjust the height and width of any window, including the main browser window by setting properties. This adjustment can be helpful when your page shows itself best with the browser window sized to a particular height and width. Rather than relying on the user to size the browser window for optimum viewing of your page, you can dictate the size of the window (although the user can always manually resize the main window). And because you can examine the operating system of the visitor via the `navigator` object (see Chapter 38 on the CD-ROM), you can size a window to adjust for the differences in font and form element rendering on different platforms.

*windowObject.innerHeight*

Supporting browsers provide two different points of reference for measuring the height and width of a window: inner and outer. Both are measured in pixels. The inner measurements are that of the active document area of a window (sometimes known as a window's content region). If the optimum display of your document depends on the document display area being a certain number of pixels high and/or wide, the `innerHeight` and `innerWidth` properties are the ones to set.

In contrast, the outer measurements are of the outside boundary of the entire window, including whatever chrome is showing in the window: scroll bars, status bar, and so on. Setting the `outerHeight` and `outerWidth` is generally done in concert with a reading of screen object properties (see Chapter 38 on the CD-ROM). Perhaps the most common usage of the outer properties is to set the browser window to fill the available screen area of the visitor's monitor.

A more efficient way of modifying both outer dimensions of a window is with the `window.resizeTo()` method, which is also available in IE4+. The method takes pixel width and height (as integer values) as parameters, thus accomplishing a window resizing in one statement. Be aware that resizing a window does not adjust the location of a window. Therefore, just because you set the outer dimensions of a window to the available space returned by the screen object doesn't mean that the window will suddenly fill the available space on the monitor. Application of the `window.moveTo()` method is necessary to ensure the top-left corner of the window is at screen coordinates 0,0.

Despite the freedom that these properties afford the page author, Netscape and Mozilla-based browsers have built in a minimum size limitation for scripts that are not cryptographically signed. You cannot set these properties such that the outer height and width of the window is smaller than 100 pixels on a side. This limitation is to prevent an unsigned script from setting up a small or nearly invisible window that monitors activity in other windows. With signed scripts, however, windows can be made smaller than 100 × 100 pixels with the user's permission. IE4+ maintains a smaller minimum size to prevent resizing a window to zero size.

 **Caution**

Users may dislike your scripts messing with their browser window sizes and positions. NN7+/Moz1+/Safari do not allow scripts to resize windows.

### Example

In Listing 16-9, a number of buttons let you see the results of setting the `innerHeight`, `innerWidth`, `outerHeight`, and `outerWidth` properties in NN4 and NN6. Later browsers and Safari ignore scripted adjustments to these properties.

#### Listing 16-9: Setting Window Height and Width

```
<html>
  <head>
    <title>Window Sizer</title>
    <script type="text/javascript">
      // store original outer dimensions as page loads
      var originalWidth = window.outerWidth;
      var originalHeight = window.outerHeight;
      // generic function to set inner dimensions
```

*Continued*

**windowObject.innerHeight****Listing 16-9 (continued)**

```

function setInner(width, height) {
    window.innerWidth = width;
    window.innerHeight = height;
}
// generic function to set outer dimensions
function setOuter(width, height) {
    window.outerWidth = width;
    window.outerHeight = height;
}
// restore window to original dimensions
function restore() {
    window.outerWidth = originalWidth;
    window.outerHeight = originalHeight;
}
</script>
</head>
<body>
  <form>
    <b>Setting Inner Sizes</b><br />
    <input type="button" value="600 Pixels Square"
      onclick="setInner(600,600)" /><br />
    <input type="button" value="300 Pixels Square"
      onclick="setInner(300,300)" /><br />
    <input type="button" value="Available Screen Space"
      onclick="setInner(screen.availWidth, screen.availHeight)" /><br />
    <hr />
    <b>Setting Outer Sizes</b><br />
    <input type="button" value="600 Pixels Square"
      onclick="setOuter(600,600)" /><br />
    <input type="button" value="300 Pixels Square"
      onclick="setOuter(300,300)" /><br />
    <input type="button" value="Available Screen Space"
      onclick="setOuter(screen.availWidth, screen.availHeight)" /><br />
    <hr />
    <input type="button" value="Cinch up for Win95"
      onclick="setInner(273,304)" /><br />
    <input type="button" value="Cinch up for Mac"
      onclick="setInner(273,304)" /><br />
    <input type="button" value="Restore Original"
      onclick="restore()" /><br />
  </form>
</body>
</html>

```

**Related Items:** `window.resizeTo()`, `window.moveTo()` **methods**; `screen` **object**; `navigator` **object**.

**Loading**

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

This NN4-specific property allows you to query whether the window is still loading content. The property returns `true` if the page is still loading and `false` if the page has completed loading all of its content.

## location

**Value:** Object.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

(See the discussion of the `location` object in Chapter 17.)

## locationbar

(See *directories*.)

## name

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

All `window` objects can have names assigned to them. Names are particularly useful for working with frames, because a good naming scheme for a multiframe environment can help you determine precisely which frame you're working with in references coming from other frames.

The main browser window, however, has no name attached to it by default. Its value is an empty string. There aren't many reasons to assign a name to the window, because JavaScript and HTML provide plenty of other ways to refer to the `window` object (the `top` property, the `_top` constant for `target` attributes, and the `opener` property from subwindows).

If you want to attach a name to the main window, you can do so by setting the `window.name` property at any time. But be aware that because this is one window property whose life extends beyond the loading and unloading of any given document, chances are that your scripts would use the reference in only one document or frameset. Unless you restore the default empty string, your programmed window name will be present for any other document that loads later. My suggestion in this regard is to assign a name in a window's or frameset's `onload` event handler, and then reset it to empty in a corresponding `onunload` event handler:

```
<body onload="self.name = 'Main'" onunload="self.name = ''">
```

You can see an example of this application in Listing 16-16, where setting a parent window name is helpful for learning the relationships among parent and child windows.

**Related Items:** `top` property; `window.open()`, `window.sizeToContent()` methods.

## navigator

**Value:** Object.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Although the `navigator` object appears as a property of the `window` object only in the most recent browsers, the `navigator` object has been around since the very beginning (see Chapter 38 on the CD-ROM). In previous browsers, the `navigator` object was referenced as a standalone object. And because you can omit any reference to the `window` object for a `window` object's properties, you can use the same window-less reference syntax for compatibility across all scriptable browsers (at least for the `navigator` object properties that exist across all browsers). That's the way I recommend referring to the `navigator` object.

## Example

This book is littered with examples of using the `navigator` object, primarily for performing browser detection. You can find examples of specific `navigator` object properties in Chapter 38 on the CD-ROM.

**Related Items:** `navigator` object.

***windowObject.offscreenBuffering*****offscreenBuffering****Value:** Boolean or string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

IE4+ by default initially renders a page in a buffer (a chunk of memory) before it is blasted to the video screen. You can control this behavior explicitly by modifying the `window.offscreenBuffering` property.

The default value of the property is the string `auto`. You can also assign Boolean `true` or `false` to the property to override IE's normal automatic handling of this behavior.

**Example**

If you want to turn off buffering for an entire page, include the following statement at the beginning of your script statements:

```
window.offscreenBuffering = false;
```

**onerror****Value:** Function.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari-

The `onerror` property is an exception to the rule of this book to not describe event handlers as properties within object reference sections. The reason is that the `onerror` event brings along some special properties that are useful to control by setting the event handler property in scripts.

Recent browsers (IE5+, NN4+, and W3C) are designed to prevent script errors from being intrusive if a user encounters a script error while loading or interacting with a page. Even so, even the subtle hints about problems (messages or icons in the status bar) can be confusing for users who have no idea what JavaScript is. JavaScript lets you turn off the display of script error windows or messages as someone executes a script on your page. The question is: When should you turn off these messages?

Script errors generally mean that something is wrong with your script. The error may be the result of a coding mistake or, conceivably, a bug in JavaScript (perhaps on a platform version of the browser that you haven't been able to test). If such errors occur, often the script won't continue to do what you intended. Hiding the script error from yourself during development would be foolhardy, because you'd never know whether unseen errors are lurking in your code. It can be equally dangerous to turn off error dialog boxes for users who may believe that the page is operating normally, when, in fact, it's not. Some data values may not be calculated or displayed correctly.

That said, I can see some limited instances of when you may want to keep such dialog box windows from appearing. For example, if you know for a fact that a platform-specific bug trips the error message without harming the execution of the script, you may want to prevent that error alert dialog box from appearing in the files posted to your Web site. You should do this only after extensive testing to ensure that the script ultimately behaves correctly, even with the bug or error.

 **Note**

IE fires the `onerror` event handler only for runtime errors. This means that if you have a syntactical error in your script that trips the browser as the page loads, the `onerror` event doesn't fire, and you cannot trap that error message. Moreover, if the user has the IE script debugger installed, any code you use to prevent browser error messages from appearing will not work.

***windowObject.onerror***

When the browser starts, the `window.onerror` property is `<undefined>`. In this state, all errors are reported via the normal JavaScript error window or message. To turn off error alerts, set the `window.onerror` property to invoke a function that does absolutely nothing:

```
function doNothing() { return true; }
window.onerror = doNothing;
```

To restore the error messages, reload the page.

You can, however, also assign a custom function to the `window.onerror` property. This function then handles errors in a more friendly way under your script control. Whenever error messages are turned on (the default behavior), a script error (or Java applet or class exception) invokes the function assigned to the `onerror` property, passing three parameters:

- ♦ Error message
- ♦ URL of document causing the error
- ♦ Line number of the error

You can essentially trap for all errors and handle them with your own interface (or no user notification at all). The last statement of this function must be `return true` if you do not want the JavaScript script error message to appear.

If you are using LiveConnect to communicate with a Java applet directly from your scripts, you can use the same scheme to handle any exception that Java may throw. A Java exception is not necessarily a mistake kind of error: Some methods assume that the Java code will trap for exceptions to handle special cases (for example, reacting to a user's denial of access when prompted by a signed script dialog box). See Chapter 44 on the CD-ROM for an example of trapping for a specific Java exception. Also, see Chapter 31 for JavaScript exception handling introduced for W3C DOM-compatible browsers.

## Example

In Listing 16-10, one button triggers a script that contains an error. I've added an error handling function to process the error so that it opens a separate window and fills in a `textarea` form element (see Figure 16-5). A Submit button is also provided to mail the bug information to a support center e-mail address—an example of how to handle the occurrence of a bug in your scripts.

### Listing 16-10: Controlling Script Errors

```
<html>
  <head>
    <title>Error Dialog Control</title>
    <script type="text/javascript">
      // function with invalid variable value
      function goWrong() {
        var x = fred;
      }
      // turn off error dialogs
      function errOff() {
        window.onerror = doNothing;
      }
    </script>
  </head>
  <body>
    <div>
      <input type="button" value="Go Wrong" />
    </div>
  </body>
</html>
```

*Continued*

**windowObject.onerror****Listing 16-10 (continued)**

```

// turn on error dialogs with hard reload
function errOn() {
    window.onerror = handleError;
}

// assign default error handler
window.onerror = handleError;

// error handler when errors are turned off...prevents error dialog
function doNothing() { return true; }
function handleError(msg, URL, lineNum) {
    var errWind = window.open("", "errors", "height=270,width=400");
    var wintxt = "<html><body bgcolor=red>";
    wintxt += "<b>An error has occurred on this page. Please report it to
    Tech Support.</b>";
    wintxt += "<form method=POST enctype='text/plain'
    action=mailto:support4@dannyg.com >";
    wintxt += "<textarea name='errMsg' cols=45 rows=8 wrap=VIRTUAL>";
    wintxt += "Error: " + msg + "\n";
    wintxt += "URL: " + URL + "\n";
    wintxt += "Line: " + lineNum + "\n";
    wintxt += "Client: " + navigator.userAgent + "\n";
    wintxt += "-----\n";
    wintxt += "Please describe what you were doing when the error
    occurred:";
    wintxt += "</textarea><br />";
    wintxt += "<input type=SUBMIT value='Send Error Report'>";
    wintxt += "<input type=button value='Close' onclick='self.close()'>";
    wintxt += "</form></body></html>";
    errWind.document.write(wintxt);
    errWind.document.close();
    return true;
}
</script>
</head>
<body>
    <form name="myform">
        <input type="button" value="Cause an Error" onclick="goWrong()" />
        <p><input type="button" value="Turn Off Error Dialogs"
        onclick="errOff()" /> <input type="button"
        value="Turn On Error Dialogs" onclick="errOn()" /></p>
    </form>
</body>
</html>

```

I provide a button that performs a hard reload, which, in turn, resets the `window.onerror` property to its default value. With error dialog boxes turned off, the error handling function does not run.

**Related Items:** `location.reload()` method; JavaScript exception handling (Chapter 31); debugging scripts (Chapter 45 on the CD-ROM).

**Figure 16-5:** An example of a self-reporting error window.

## opener

**Value:** Window object reference.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN3+, Moz1+, Safari1+

Many scripters make the mistake of thinking that a new browser window created with the `window.open()` method has a child–parent relationship similar to the one that frames have with their parents. That’s not the case at all. New browser windows, once created, have a very slim link to the window from whence they came: via the `opener` property. The purpose of the `opener` property is to provide scripts in the new window with a valid reference back to the original window. For example, the original window may contain some variable values or general-purpose functions that a new window at this Web site wants to use. The original window may also have form elements whose settings are either of value to the new window or get set by user interaction in the new window.

Because the value of the `opener` property is a reference to a genuine `window` object, you can begin references with the property name. Or, you may use the more complete `window.opener` or `self.opener` reference. But the reference must then include some object or property of that original window, such as a window method or a reference to something contained by that window’s document.

If a subwindow opens yet another subwindow, the chain is still valid, albeit one step longer. The third window can reach the main window with a reference that begins

```
opener.opener...
```

It’s a good idea for the third window to store in a global variable the value of `opener.opener` while the page loads. Thus, if the user closes the second window, the variable can be used to start a reference to the main window.

When a script that generates a new window is within a frame, the `opener` property of the subwindow points to that frame. Therefore, if the subwindow needs to communicate with the main window’s parent or another frame in the main window, you have to very carefully build a reference to that distant object. For example, if the subwindow needs to get the checked property of a checkbox in a sister frame of the one that created the subwindow, the reference is

```
opener.parent.sisterFrameName.document.formName.checkboxName.checked
```

**windowObject.opener**

It is a long way to go, indeed, but building such a reference is always a case of mapping out the path from where the script is to where the destination is, step-by-step.

**Example**

To demonstrate the importance of the `opener` property, take a look at how a new window can define itself from settings in the main window (see Listing 16-11). The `doNew()` function generates a small subwindow and loads the file in Listing 16-12 into the window. Notice the initial conditional statements in `doNew()` to make sure that if the new window already exists, it comes to the front by invoking the new window's `focus()` method. You can see the results in Figure 16-6.

**Listing 16-11: Contents of a Main Window Document That Generates a Second Window**

```
<html>
  <head>
    <title>Master of all Windows</title>
    <script type="text/javascript">
      var myWind;
      function doNew() {
        if (!myWind || myWind.closed) {
          myWind = window.open("lst16-12.htm", "subWindow",
            "height=200,width=350,resizable");
        } else {
          // bring existing subwindow to the front
          myWind.focus();
        }
      }
    </script>
  </head>
  <body>
    <form name="input">
      Select a color for a new window: <input type="radio" name="color"
        value="red" checked="checked" />Red <input type="radio" name="color"
        value="yellow" />Yellow <input type="radio" name="color"
        value="blue" />Blue <input type="button" name="storage"
        value="Make a Window" onclick="doNew()" />
      <hr />
      This field will be filled from an entry in another window: <input
        type="text" name="entry" size="25" />
    </form>
  </body>
</html>
```

---

**Listing 16-12: References to the opener Property**

```

<html>
  <head>
    <title>New Window on the Block</title>
    <script type="text/javascript">
      function getColor() {
        // shorten the reference
        colorButtons = self.opener.document.forms[0].color;
        // see which radio button is checked
        for (var i = 0; i < colorButtons.length; i++) {
          if (colorButtons[i].checked) {
            return colorButtons[i].value;
          }
        }
        return "white";
      }
    </script>
    <script type="text/javascript">
      document.write("<body bgcolor='" + getColor() + "'>")
    </script>
  </head>
  <body>
    <h1>This is a new window.</h1>
    <form>
      <input type="button" value="Who's in the Main window?"
      onclick="alert(self.opener.document.title)" />
      <p>Type text here for the main window: <input type="text" size="25"
      onchange="self.opener.document.forms[0].entry.value = this.value"
    /></p>
    </form>
  </body>
</html>

```

In the `getColor()` function, the multiple references to the radio button array can be very long. To simplify the references, the `getColor()` function starts out by assigning the radio button array to a variable I arbitrarily call `colorButtons`. That shorthand now stands in for lengthy references as I loop through the radio buttons to determine which button is checked and retrieve its value property.

A button in the second window simply fetches the title of the opener window's document. Even if another document loads in the main window in the meantime, the `opener` reference still points to the main window: Its `document` object, however, will change.

Finally, the second window contains a text input object. Enter any text there that you like and either tab or click out of the field. The `onchange` event handler updates the field in the opener's document (provided that document is still loaded).

**Related Items:** `window.open()`, `window.focus()` methods.

***windowObject.outerHeight***

**Figure 16-6:** The main and subwindows, inextricably linked via the `window.opener` property.

`outerHeight`

`outerWidth`

(See `innerHeight` and `innerWidth`, earlier)

`pageXOffset`

`pageYOffset`

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4+, Moz1+, Safari1+

The top-left corner of the content (inner) region of the browser window is an important geographical point for scrolling documents. When a document is scrolled all the way to the top and flush left in the window (or when a document is small enough to fill the browser window without displaying scrollbars), the document's location is said to be 0,0, meaning zero pixels from the top and zero pixels from the left. If you were to scroll the document, some other coordinate point of the document would be under that top-left corner. That measure is called the page offset, and the `pageXOffset` and `pageYOffset` properties let you read the pixel value of the document at the inner window's top-left corner: `pageXOffset` is the horizontal offset, and `pageYOffset` is the vertical offset.

The value of these measures becomes clear if you design navigation buttons in your pages to carefully control paging of content being displayed in the window. For example, you might have a two-frame page in which one of the frames features navigation controls, while the other displays the primary content. The navigation controls take the place of scrollbars,

which, for aesthetic reasons, are turned off in the display frame. Scripts connected to the simulated scrolling buttons can determine the `pageYOffset` value of the document and then use the `window.scrollTo()` method to position the document precisely to the next logical division in the document for viewing.

IE4+ has corresponding values as `body` object properties: `body.scrollLeft` and `body.scrollTop` (see Chapter 18).

## Example

The script in Listing 16-13 is an unusual construction that creates a frameset and creates the content for each of the two frames all within a single HTML document (see “frame Element Object” later in the chapter for more details). The purpose of this example (not available in Safari 1.0) is to provide you with a playground to become familiar with the page offset concept and how the values of these properties correspond to physical activity in a scrollable document.

In the left frame of the frameset are two fields that are ready to show the pixel values of the right frame’s `pageXOffset` and `pageYOffset` properties. The content of the right frame is a 30-row table of fixed width (800 pixels). Mouse click events are captured by the document level (see Chapter 18), allowing you to click any table or cell border or outside the table to trigger the `showOffsets()` function in the right frame. That function is a simple script that displays the page offset values in their respective fields in the left frame.

### Listing 16-13: Viewing the `pageXOffset` and `pageYOffset` Properties

```
<html>
  <head>
    <title>Master of all Windows</title>
    <script type="text/javascript">
      function leftFrame() {
        var output = "<html><body<h3>Page Offset Values</h3><hr \\/>\n";
        output += "<form>PageXOffset:<input type='text' name='xOffset'
          size='4' \\/><br \\/>\n";
        output += "PageYOffset:<input type='text' name='yOffset' size='4'
          \\/><br \\/>\n";
        output += "<\\/form><\\/body><\\/html>";
        return output;
      }

      function rightFrame() {
        var output = "<html><head><script type='text/javascript'>\n";
        output += "function showOffsets() {\n";
        output += "parent.readout.document.forms[0].xOffset.value =
          self.pageXOffset;\n";
        output += "parent.readout.document.forms[0].yOffset.value =
          self.pageYOffset;\n}\n";
        output += "document.captureEvents(Event.CLICK);\n";
        output += "document.onclick = showOffsets;\n";
        output += "<\\/script><\\/head><body><h3>Content Page<\\/h3>\n";
        output += "Scroll this frame and click on a table border to view " +
          "page offset values.<br \\/><hr \\/>\n";
        output += "<table border='5' width='800'>";
      }
    <\\/script>
  <\\/head>
<\\/html>
```

*Continued*

## Listing 16-13 (continued)

```

var oneRow = "<td>Cell 1</td><td>Cell 2</td><td>Cell 3</td>
<td>Cell 4</td>" + "<td>Cell 5</td>";
for (var i = 1; i <= 30; i++) {
    output += "<tr><td><b>Row " + i + "</b></td>" + oneRow +
        "</tr>";
}
output += "</table></body></html>";
return output;
}
</script>
</head>
<frameset cols="30%,70%">
    <frame name="readout" src="javascript:parent.leftFrame()" />
    <frame name="display" src="javascript:parent.rightFrame()" />
</frameset>
</html>

```

To gain an understanding of how the offset values work, scroll the window slightly in the horizontal direction and notice that the `pageXOffset` value increases; the same goes for the `pageYOffset` value as you scroll down. Remember that these values reflect the coordinate in the document that is currently under the top-left corner of the window (frame) holding the document. You can see an IE4+ version of this example in Listing 18-20. A cross-browser version would require very little browser branching.

**Related Items:** `window.innerHeight`, `window.innerWidth`, `body.scrollLeft`, `body.scrollTop` properties; `window.scrollBy()`, `window.scrollTo()` methods.

## parent

**Value:** Window object reference.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `parent` property (and the `top` property that follows later in this section) comes into play primarily when a document is to be displayed as part of a multiframe window. The HTML documents that users see in the frames of a multiframe browser window are distinct from the document that specifies the frameset for the entire window. That document, though still in the browser's memory (and appearing as the URL in the location field of the browser), is not otherwise visible to the user (except in the Source View).

If scripts in your visible documents need to reference objects or properties of the frameset window, you can reference those frameset window items with the `parent` property (do not, however, expand the reference by preceding it with the `window` object, as in `window.parent.propertyName`, because this causes problems in early browsers). In a way, the `parent` property seems to violate the object hierarchy because, from a single frame's document, the property points to a level seemingly higher in precedence. If you didn't specify the `parent` property or instead specified the `self` property from one of these framed documents, the object reference is to the frame only, rather than to the outermost framesetting window object.

A nontraditional but perfectly legal way to use the `parent` object is as a means of storing temporary variables. Thus, you could set up a holding area for individual variable values or even an array of data. These values can then be shared among all documents loaded into the frames, including when documents change inside the frames. You have to be careful,

however, when storing data in the parent on the fly (that is, in response to user action in the frames). Variables can revert to their default values (that is, the values set by the parent's own script) if the user resizes the window in early browsers.

A child window can also call a function defined in the parent window. The reference for such a function is

```
parent.functionName([parameters])
```

At first glance, it may seem as though the `parent` and `top` properties point to the same framesetting `window` object. In an environment consisting of one frameset window and its immediate children, that's true. But if one of the child windows was, itself, another framesetting window, then you wind up with three generations of windows. From the point of view of the "youngest" child (for example, a window defined by the second frameset), the `parent` property points to its immediate parent, whereas the `top` property points to the first framesetting window in this chain.

On the other hand, a new window created via the `window.open()` method has no parent-child relationship to the original window. The new window's `top` and `parent` point to that new window. You can read more about these relationships in the "Frames" section earlier in this chapter.

## Example

To demonstrate how various `window` object properties refer to window levels in a multiframe environment, use your browser to load the Listing 16-14 document. It, in turn, sets each of two equal-size frames to the same document: Listing 16-15. This document extracts the values of several window properties, plus the `document.title` properties of two different window references.

### Listing 16-14: Framesetting Document for Listing 16-15

```
<html>
  <head>
    <title>The Parent Property Example</title>
    <script type="text/javascript">
      self.name = "Framesetter";
    </script>
  </head>
  <frameset cols="50%,50%" onunload="self.name = ''">
    <frame name="JustAKid1" src="lst16-15.htm" />
    <frame name="JustAKid2" src="lst16-15.htm" />
  </frameset>
</html>
```

### Listing 16-15: Revealing Various Window-Related Properties

```
<html>
  <head>
    <title>Window Revealer II</title>
    <script type="text/javascript">
      function gatherWindowData() {
```

*Continued*

**windowObject.parent****Listing 16-15 (continued)**

```
var msg = "";
msg = msg + "top name: " + top.name + "<br />";
msg = msg + "parent name: " + parent.name + "<br />";
msg = msg + "parent.document.title: " + parent.document.title +
"<br />";
msg = msg + "window name: " + window.name + "<br />";
msg = msg + "self name: " + self.name + "<br />";
msg = msg + "self.document.title: " + self.document.title;
return msg;
}
</script>
</head>
<body>
<script type="text/javascript">
document.write(gatherWindowData());
</script>
</body>
</html>
```

In the two frames (see Figure 16-7), the references to the `window` and `self` object names return the name assigned to the frame by the frameset definition (`JustAKid1` for the left frame, `JustAKid2` for the right frame). In other words, from each frame's point of view, the `window` object is its own frame. References to `self.document.title` refer only to the document loaded into that window frame. But references to the top and parent windows (which are one and the same in this example) show that those object properties are shared between both frames.

**Figure 16-7:** Parent and top properties being shared by both frames.

**windowObject.screen**

A couple other fine points are worth highlighting. First, the name of the framesetting window is set as Listing 16-14 loads, rather than in response to an `onload` event handler in the `<frameset>` tag. The reason for this is that the name must be set in time for the documents loading in the frames to get that value. If I had waited until the frameset's `onload` event handler, the name wouldn't be set until after the frame documents had loaded. Second, I restore the parent window's name to an empty string when the framesetting document unloads. This is to prevent future pages from getting confused about the window name.

**Related Items:** `window.frames`, `window.self`, `window.top` properties.

**personalbar**

(See directories)

**returnValue**

**Value:** Any data type.

Read/Write

**Compatibility:** WinIE4+, MacIE5+, NN-, Moz-, Safari-

Scripts use the `returnValue` property in a document that loads into the IE-specific modal dialog box. A modal dialog box is generated via the `showModalDialog()` method, which returns whatever data has been assigned to the `returnValue` property of the dialog box window before it closes. This is possible because script processing in the main window freezes while the modal dialog box is visible. As the dialog box closes, a value can be returned to the main window's script right where the modal dialog box was invoked, and the main window's script resumes executing statements.

**Example**

See Listing 16-39 for the `showModalDialog()` method for an example of how to get data back from a dialog box in IE4+.

**Related Items:** `showModalDialog()` method.

**screen**

**Value:** screen object.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Although the `screen` object appears as a property of the `window` object only in the most recent browsers, the `screen` object is also available in NN4 (see Chapter 38 on the CD-ROM), but as a standalone object. Because you can omit any reference to the `window` object for a `window` object's properties, the same window-less reference syntax can be used for compatibility across all browsers that support the `screen` object. That's the way I recommend referring to the `screen` object.

**Example**

See Chapter 38 on the CD-ROM for examples of using the `screen` object to determine the video monitor characteristics of the computer running the browser.

**Related Items:** `screen` object.

**windowObject.screenLeft**

screenLeft

screenTop

**Value:** Integer.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

WinIE5+ provides the `screenLeft` and `screenTop` properties of the `window` object to let you read the pixel position (relative to the top-left 0,0 coordinate of the video monitor) of what Microsoft calls the *client area* of the browser window. The client area excludes most window chrome, such as the title bar, address bar, and the window sizing bar. Therefore, when the WinIE5+ browser window is maximized (meaning that no sizing bars are exposed), the `screenLeft` property of the window is 0, while the `screenTop` property varies depending on the combination of toolbars the user has elected to display. For non-maximized windows, if the window has been positioned so that the top and/or left part of the client area are out of view, their property values will be negative integers.

These two properties are read-only. You can position the browser window via the `window.moveTo()` and `window.moveBy()` methods, but these methods position the top-left corner of the entire browser window, not the client area. IE browsers, through version 6, do not provide properties for the position of the entire browser window.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `screenLeft` and `screenTop` properties. Start with the browser window maximized (if you are using Windows). Enter the following property name into the top text box:

```
window.screenLeft
```

Click the Evaluate button to see the current setting. Unmaximize the window and drag it around the screen. Each time you finish dragging, click the Evaluate button again to see the current value. Do the same for `window.screenTop`.

**Related Items:** `window.moveTo()`, `window.moveBy()` methods.

screenX

screenY

**Value:** Integer.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

NN6+/Moz/Safari provide the `screenX` and `screenY` properties to read the position of the outer boundary of the browser window relative to the top-left coordinates (0,0) of the video monitor. The browser window includes the 4-pixel wide window sizing bars that surround Win32 windows. Therefore, when the WinNN6+ browser window is maximized, the values for both `screenX` and `screenY` are -4. Netscape does not provide the equivalent measures of the browser window client area as found in the `screenLeft` and `screenTop` properties of IE5+. You can, however, find out if various toolbars are visible in the browser window (see `window.directories`).

Although you can assign a value to either property, current versions of supporting browsers do not adjust the window position in response. Moving and resizing windows by script is considered by many Web surfers to be unacceptable behavior.

## Example

Use The Evaluator (Chapter 13) to experiment with the `screenX` and `screenY` properties. Start with the browser window maximized (if you are using Windows). Enter the following property name into the top text box:

```
window.screenY
```

Click the Evaluate button to see the current setting. Unmaximize the window and drag it around the screen. Each time you finish dragging, click the Evaluate button again to see the current value. Do the same for `window.screenY`.

**Related Items:** `window.moveTo()`, `window.moveBy()` methods.

## scrollbars

(See directories)

## scrollMaxX

## scrollMaxY

**Value:** Integer.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN7.1+, Moz1.4+, Safari1-

The NN7.1+/Mozilla1.4+ `scrollMaxX` and `scrollMaxY` properties let you determine the maximum horizontal and vertical scrolling extents of a window. Scrolling is possible only if the window displays scrollbars along the desired axis. Values are pixel integers.

**Related Items:** `scrollX`, `scrollY` properties.

## scrollX

## scrollY

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The NN6+/Mozilla/Safari `scrollX` and `scrollY` properties let you determine the horizontal and vertical scrolling of a window. Scrolling is possible only if the window displays scroll bars along the desired axis. Values are pixel integers.

Although the IE DOM does not provide similar properties for the window, the same information can be derived from the `body.scrollLeft` and `body.scrollTop` properties.

## Example

Use The Evaluator (Chapter 13) to experiment with the `scrollX` and `scrollY` properties. Enter the following property into the top text box:

```
window.scrollY
```

Now manually scroll the page down so that you can still see the Evaluate button. Click the button to see how far the window has scrolled along the y-axis.

**Related Items:** `body.scrollLeft`, `body.scrollTop` properties.

**windowObject.self****self****Value:** Window object reference.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Just as the `window` object reference is optional, so too is the `self` property when the object reference points to the same window as the one containing the reference. In what may seem to be an unusual construction, the `self` property represents the same object as the `window`. For instance, to obtain the title of the document in a single-frame window, you can use any of the following three constructions:

```
window.document.title
self.document.title
document.title
```

Although `self` is a property of a window, you should not combine the references within a single-frame window script (for example, don't begin a reference with `window.self`, which has been known to cause numerous scripting problems). Specifying the `self` property, though optional for single-frame windows, can help make an object reference crystal clear to someone reading your code (and to you, for that matter). Multiple-frame windows are where you need to pay particular attention to this property.

JavaScript is pretty smart about references to a statement's own window. Therefore, you can generally omit the `self` part of a reference to a same-window document element. But when you intend to display a document in a multiframe window, complete references (including the `self` prefix) to an object make it much easier on anyone who reads or debugs your code to track who is doing what to whom. You are free to retrieve the `self` property of any window. The value that comes back is a `window` object reference.

**Example**

Listing 16-16 uses the same operations as Listing 16-5 but substitutes the `self` property for all `window` object references. The application of this reference is entirely optional, but it can be helpful for reading and debugging scripts if the HTML document is to appear in one frame of a multiframe window — especially if other JavaScript code in this document refers to documents in other frames. The `self` reference helps anyone reading the code know precisely which frame was being addressed.

**Listing 16-16: Using the self Property**

```
<html>
  <head>
    <title>self Property</title>
    <script type="text/javascript">
      self.defaultStatus = "Welcome to my Web site.";
    </script>
  </head>
```

```
<body>
  <a href="http://www.microsoft.com"
  onmouseover="self.status = 'Visit Microsoft\'s Home page. ';return true;"
  onmouseout="self.status = '';return true;">Microsoft</a>
  <p><a href="http://mozilla.org"
  onmouseover="self.status = 'Visit Mozilla\'s Home page. ';return
  true;"
  onmouseout="self.status = self.defaultStatus;return
  true;">Mozilla</a></p>
</body>
</html>
```

---

**Related Items:** `window.frames`, `window.parent`, `window.top` properties.

## sidebar

(See `appCore`)

## status

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

At the bottom of the browser window is a status bar. Part of that bar includes an area that normally discloses the document loading progress or the URL of a link that the mouse is pointing to at any given instant. You can control the temporary content of that field by assigning a text string to the `window` object's `status` property. You should adjust the `status` property only in response to events that have a temporary effect, such as a link or image map area object's `onmouseover` event handler. When the `status` property is set in this situation, it overrides any other setting in the status bar. If the user then moves the mouse pointer away from the object that changes the status bar, the bar returns to its default setting (which may be empty on some pages). Note that Safari 1.0 doesn't always display the new text.

Use this window property as a friendlier alternative to displaying the URL of a link as a user rolls the mouse around the page. For example, if you'd rather use the status bar to explain the nature of the destination of a link, put that text into the status bar in response to the `onmouseover` event handler. But be aware that experienced Web surfers like to see URLs down there. Therefore, consider creating a hybrid message for the status bar that includes both a friendly description followed by the URL in parentheses. In multiframe environments, you can set the `window.status` property without having to worry about referencing the individual frame.

## Example

In Listing 16-17, the `status` property is set in a handler embedded in the `onmouseover` attribute of two HTML link tags. Notice that the handler requires a `return true` statement (or any expression that evaluates to `return true`) as the last statement of the handler. This statement is required or the status message will not display in all browsers.

*windowObject.status***Listing 16-17: Links with Custom Status Bar Messages**

```
<html>
  <head>
    <title>window.status Property</title>
  </head>
  <body>
    <a href="http://www.dannyg.com"
      onmouseover="window.status = 'Go to my Home page. (www.dannyg.com)';
      return true;">Home</a>
    <p><a href="http://mozilla.org"
      onmouseover="window.status = 'Visit Mozilla Home page. (mozilla.org)';
      return true;">Mozilla</a></p>
  </body>
</html>
```

As a safeguard against platform-specific anomalies that affect the behavior of `onmouseover` event handlers and the `window.status` property, you should also include an `onmouseout` event handler for links and client-side image map area objects. Such `onmouseout` event handlers should set the `status` property to an empty string. This setting ensures that the status bar message returns to the `defaultStatus` setting when the pointer rolls away from these objects. If you want to write a generalizable function that handles all window status changes, you can do so, but word the `onmouseover` attribute carefully so that the event handler evaluates to return `true`. Listing 16-18 shows such an alternative.

**Listing 16-18: Handling Status Message Changes**

```
<html>
  <head>
    <title>Generalizable window.status Property</title>
    <script type="text/javascript">
      function showStatus(msg) {
        window.status = msg;
        return true;
      }
    </script>
  </head>
  <body>
    <a href="http://www.example.com"
      onmouseover="return showStatus('Go to my Home page.')"
      onmouseout="return showStatus('')">Home</a>
    <p><a href="http://mozilla.org"
      onmouseover="return showStatus('Visit Mozilla Home page.')"
      onmouseout="return showStatus('')">Mozilla</a></p>
  </body>
</html>
```

Notice how the event handlers return the results of the `showStatus()` method to the event handler, allowing the entire handler to evaluate to return `true`.

One final example of setting the status bar (shown in Listing 16-19) also demonstrates how to create a simple scrolling banner in the status bar.

### Listing 16-19: Creating a Scrolling Banner

```
<html>
  <head>
    <title>Message Scroller</title>
    <script type="text/javascript">
      var msg = "Welcome to my world...";
      var delay = 150;
      var timerId;
      var maxCount = 0;
      var currCount = 1;

      function scrollMsg() {
        // set the number of times scrolling message is to run
        if (maxCount == 0) {
          maxCount = 3 * msg.length;
        }
        window.status = msg;
        // keep track of how many characters have scrolled
        currCount++;
        // shift first character of msg to end of msg
        msg = msg.substring(1, msg.length) + msg.substring(0, 1);
        // test whether we've reached maximum character count
        if (currCount >= maxCount) {
          timerID = 0; // zero out the timer
          window.status = ""; // clear the status bar
          return; // break out of function
        } else {
          // recursive call to this function
          timerID = setTimeout("scrollMsg()", delay);
        }
      }
    </script>
  </head>
  <body onload="scrollMsg()">
  </body>
</html>
```

Because the status bar is being set by a standalone function (rather than by an `onmouseover` event handler), you do not have to append a `return true` statement to set the status property. The `scrollMsg()` function uses more advanced JavaScript concepts, such as the `window.setTimeout()` method (covered later in this chapter) and string methods (covered in Chapter 27). To speed the pace at which the words scroll across the status bar, reduce the value of `delay`.

Many Web surfers (myself included) don't care for these scrollers that run forever in the status bar. Rolling the mouse over links disturbs the banner display. Use scrolling bars sparingly or design them to run only a few times after the document loads.

**windowObject.status****Tip**

Setting the `status` property with `onmouseover` event handlers has had a checkered career along various implementations in Navigator. A script that sets the status bar is always in competition against the browser itself, which uses the status bar to report loading progress. When a “hot” area on a page is at the edge of a frame, many times the `onmouseout` event fails to fire, thus preventing the status bar from clearing itself. Be sure to torture test any such implementations before declaring your page ready for public access.

**Related Items:** `window.defaultStatus` property; `onmouseover`, `onmouseout` event handlers; `link` object.

**statusbar****toolbar**

(See `locationbar`)

**top**

**Value:** Window object reference.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `window` object's `top` property refers to the topmost window in a frameset object hierarchy. For a single-frame window, the reference is to the same object as the window itself (including the `self` and `parent` properties), so do not include `window` as part of the reference. In a multiframe window, the top window is the one that defines the first frameset (in case of nested framesets). Users don't ever really see the top window in a multiframe environment, but the browser stores it as an object in its memory. The reason is that the top window has the road map to the other frames (if one frame should need to reference an object in a different frame), and its children frames can call upon it. Such a reference looks like

```
top.functionName([parameters])
```

For more about the distinction between the `top` and `parent` properties, see the in-depth discussion about scripting frames at the beginning of this chapter. See also the example of the `parent` property for listings that demonstrate the values of the `top` property.

**Related Items:** `window.frames`, `window.self`, `window.parent` properties.

**window**

**Value:** Window object.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Listing the `window` property as a separate property may be more confusing than helpful. The `window` property is the same object as the `window` object. You do not need to use a reference that begins with `window.window`. Although the `window` object is assumed for many references, you can use `window` as part of a reference to items in the same window or frame as the script statement that makes that reference. You should not, however, use `window` as a part of a reference involving items higher up in the hierarchy (`top` or `parent`).

**Methods****alert("message")**

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

***windowObject.alert()***

An alert dialog box is a modal window that presents a message to the user with a single OK button to dismiss the dialog box. As long as the alert dialog box is showing, no other application or window can be made active. The user must dismiss the dialog box before proceeding with any more work in the browser.

The single parameter to the `alert()` method can be a value of any data type, including representations of some unusual data types whose values you don't normally work with in JavaScript (such as complete objects). This makes the alert dialog box a handy tool for debugging JavaScript scripts. Anytime you want to monitor the value of an expression, use that expression as the parameter to a temporary `alert()` method in your code. The script proceeds to that point and then stops to show you the value. (See Chapter 45 on the CD-ROM for more tips on debugging scripts.)

What is often disturbing to application designers is that all JavaScript-created modal dialog boxes (via the `alert()`, `confirm()`, and `prompt()` methods) identify themselves as being generated by JavaScript or the browser. The purpose of this identification is to act as a security precaution against unscrupulous scripters who might try to spoof system or browser alert dialog boxes, inviting a user to reveal passwords or other private information. These identifying words cannot be overwritten or eliminated by your scripts. You can simulate a modal dialog box window in a cross-browser fashion with regular browser windows, but it is not as robust as a genuine modal window, which you can create in IE4+ via the `window.showModalDialog()` method.

Because the `alert()` method is of a global nature (that is, no particular frame in a multiframe environment derives any benefit from laying claim to the alert dialog box), a common practice is to omit all window object references from the statement that calls the method. Restrict the use of alert dialog boxes in your HTML documents and site designs. The modality of the windows is disruptive to the flow of a user's navigation around your pages. Communicate with users via forms or by writing to separate document window frames.

## Example

The parameter for the example in Listing 16-20 is a concatenated string. It joins together two fixed strings and the value of the browser's `navigator.appName` property. Loading this document causes the alert dialog box to appear, as shown in several configurations in Figure 16-8. The JavaScript Alert: line cannot be deleted from the dialog box in earlier browsers, nor can the title bar be changed in later browsers.

### Listing 16-20: Displaying an Alert Dialog Box

```
<html>
  <head>
    <title>window.alert() Method</title>
  </head>
  <body>
    <script type="text/javascript">
      alert("You are running the " + navigator.appName + " browser.")
    </script>
  </body>
</html>
```

---

**Related Items:** `window.confirm()`, `window.prompt()` methods.

***windowObject.back()***

**Figure 16-8:** Results of the `alert()` method in Listing 16-20 in Internet Explorer and Netscape Navigator.

**`back()`****`forward()`**

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

The purpose of the `window.back()` and `window.forward()` methods in NN4 is to offer a scripted version of the global back and forward navigation buttons, while allowing the `history` object to control navigation strictly within a particular window or frame—as it should. These window methods did not catch on in IE (and the `window` object is out of the scope of the W3C DOM Level 2), so you are better off staying with the `history` object’s methods for navigating through browser history. For more information about version compatibility and the back and forward navigation, see the `history` object in Chapter 17.

**Related Items:** `history.back()`, `history.forward()`, `history.go()` methods.

**`captureEvents(eventTypeList)`**

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

In Navigator 4, an event filters down from the `window` object and eventually reaches its intended target. For example, if you click a button, the click event first reaches the `window` object; then it goes to the `document` object; and eventually (in a split second) it reaches the button, where an `onclick` event handler is ready to act on that click.

The NN4 “trickle-down” event propagation mechanism allows `window`, `document`, and `layer` objects to intercept events and process them prior to reaching their intended targets (or preventing them from reaching their destinations entirely). But for one of these outer containers to grab an event, your script must instruct it to capture the type of event your application is interested in preprocessing. If you want the `window` object to intercept all events of a particular type, use the `window.captureEvents()` method to turn that facility on.

**Note**

NN6+ and W3C browsers have both a trickle-down and bubble-up event model combination. The syntax for using event capture in NN6+ is quite different from that in NN4. The discussions of the `captureEvents()`, `releaseEvents()`, `handleEvent()`, and `routeEvent()` methods of the `window`, `document`, and `layer` objects apply only to Navigator 4. If your DHTML page design does not need to support NN4, you can skip these discussions.

The `window.captureEvents()` method takes one or more event types as parameters. An event type is a constant value built inside the Navigator 4 `Event` object. One event type exists for every kind of event handler you see in all of the Navigator 4 document objects. The syntax is the event object name (`Event`) and the event name in all uppercase letters. For example, if you want the window to intercept all click events, the statement is

```
window.captureEvents(Event.CLICK);
```

For multiple events, add them as parameters, separated by the pipe (`|`) character:

```
window.captureEvents(Event.MOUSEDOWN | Event.KEYPRESS);
```

After an event type is captured by the `window` object, a function must be ready to deal with the event. For example, perhaps the function looks through all `Event.MOUSEDOWN` events and looks to see if the right mouse button was the one that triggered the event and what form element (if any) is the intended target. The goal is to perhaps display a pop-up menu (as a separate layer) for a right-click. If the click comes from the left mouse button, the event is routed to its intended target.

To associate a function with a particular event type captured by a `window` object, assign a function to the event. For example, to assign a custom `doClickEvent()` function to `click` events captured by the `window` object, use the following statement:

```
window.onclick = doClickEvent;
```

Note that the function name is assigned only as a reference name (no quotes or parentheses), not like an event handler within a tag. The function itself is like any function, but it has the added benefit of automatically receiving an instance of the `Event` object as a parameter. To turn off event capture for one or more event types, use the `window.releaseEvent()` method.

**Note**

Capturing events at the `window`, `document`, or `layer` level in NN4 does not always work the way you might like. This is especially true if your page contains tables. For example, capturing mouse events has no effect in the Windows version of NN4 unless the cursor is atop a cell border. Event capture works most reliably when a scriptable object has an event handler defined for it (even if it is an empty string) and the element is the target of the event (for example, you are about to type into a text field). For all other elements, events may simply not be captured at the document or window level.

## Example

The page in Listing 16-21 is an exercise in capturing and releasing click events in the `window` object. Whenever the window is capturing click events, the `flash()` function runs. In that function, the event is examined so that only if the `Control` key is also being held down and the name of the button starts with “button” does the document background color flash red. For all click events (that is, those directed at objects on the page capable of their own `onclick` event handlers), the click is processed with the `routeEvent()` method to make sure the target buttons execute their own `onclick` event handlers.

**windowObject.captureEvents()****Listing 16-21: Capturing Click Events in the Window**

```

<html>
  <head>
    <title>Window Event Capture</title>
    <script type="text/javascript">
      // function to run when window captures a click event
      function flash(e) {
        if (e.modifiers == Event.CONTROL_MASK &&
            e.target.name.indexOf("button") == 0) {
          document.bgColor = "red";
          setTimeout("document.bgColor = 'white'", 500);
        }
        // let event continue to target
        routeEvent(e);
      }

      // default setting to capture click events
      window.captureEvents(Event.CLICK);
      // assign flash() function to click events captured by window
      window.onclick = flash;
    </script>
  </head>
  <body bgcolor="white">
    <form name="buttons">
      <b>Turn window click event capture on or off (Default is "On")</b>
      <p><input name="captureOn" type="button" value="Capture On"
        onclick="window.captureEvents(Event.CLICK)" />&nbsp;  <input
        name="captureOff" type="button" value="Capture Off"
        onclick="window.releaseEvents(Event.CLICK)" /></p>
      <hr />
      <b>Ctrl+Click on a button to see if clicks are being captured by the
        window (background color will flash red):</b>
      <ul>
        <li><input name="button1" type="button" value="Informix"
          onclick="alert('You clicked on Informix.')" /></li>
        <li><input name="button2" type="button" value="Oracle"
          onclick="alert('You clicked on Oracle.')" /></li>
        <li><input name="button3" type="button" value="Sybase"
          onclick="alert('You clicked on Sybase.')" /></li>
      </ul>
    </form>
  </body>
</html>

```

When you try this page, also turn off window event capture. Now only the buttons' onclick event handlers execute, and the page does not flash red.

**Related Items:** `window.disableExternalCapture()`, `window.enableExternalCapture()`, `window.handleEvent()`, `window.releaseEvents()`, `window.routeEvent()` **methods.**

**clearInterval(*intervalIDnumber*)**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

***windowObject.clearTimeout()***

Use the `window.clearInterval()` method to turn off an interval loop action started with the `window.setInterval()` method. The parameter is the ID number returned by the `setInterval()` method. A common application for the JavaScript interval mechanism is animation of an object on a page. If you have multiple intervals running, each has its own ID value in memory. You can turn off any interval by its ID value. As soon as an interval loop stops, your script cannot resume that interval: It must start a new one, which generates a new ID value.

**Example**

See Listings 16-36 and 16-37 for an example of how `setInterval()` and `clearInterval()` are used together on a page.

**Related Items:** `window.setInterval()`, `window.setTimeout()`, `window.clearTimeout()` methods.

**`clearTimeout(timeoutIDnumber)`**

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Use the `window.clearTimeout()` method in concert with the `window.setTimeout()` method, as described later in this chapter, when you want your script to cancel a timer that is waiting to run its expression. The parameter for this method is the ID number that the `window.setTimeout()` method returns when the timer starts ticking. The `clearTimeout()` method cancels the specified timeout. A good practice is to check your code for instances where user action may negate the need for a running timer — and to stop that timer before it goes off.

**Example**

The page in Listing 16-22 features one text field and two buttons (see Figure 16-9). One button starts a countdown timer coded to last one minute (easily modifiable for other durations); the other button interrupts the timer at any time while it is running. When the minute is up, an alert dialog box lets you know.

**Listing 16-22: A Countdown Timer**

```
<html>
  <head>
    <title>Count Down Timer</title>
    <script type="text/javascript">
      var running = false;
      var endTime = null;
      var timerID = null;

      function startTimer() {
        running = true;
        now = new Date();
        now = now.getTime();
        // change last multiple for the number of minutes
        endTime = now + (1000 * 60 * 1);
        showCountDown();
      }
    </script>
  </head>
</html>
```

*Continued*

***windowObject.clearTimeout()*****Listing 16-22 (continued)**

```

function showCountDown() {
    var now = new Date();
    now = now.getTime();
    if (endTime - now <= 0) {
        stopTimer();
        alert("Time is up. Put down your pencils.");
    } else {
        var delta = new Date(endTime - now);
        var theMin = delta.getMinutes();
        var theSec = delta.getSeconds();
        var theTime = theMin;
        theTime += ((theSec < 10) ? ":0" : ":") + theSec;
        document.forms[0].timerDisplay.value = theTime;
        if (running) {
            timerID = setTimeout("showCountDown()",1000);
        }
    }
}

function stopTimer() {
    clearTimeout(timerID);
    running = false;
    document.forms[0].timerDisplay.value = "0:00";
}
</script>
</head>
<body>
<form>
<input type="button" name="startTime" value="Start 1 min. Timer"
onclick="startTimer()" /> <input type="button" name="clearTime"
value="Clear Timer" onclick="stopTimer()" />
<p><input type="text" name="timerDisplay" value="" /></p>
</form>
</body>
</html>

```

Notice that the script establishes three variables with global scope in the window: `running`, `endTime`, and `timerID`. These values are needed inside multiple functions, so they are initialized outside of the functions.

In the `startTimer()` function, you switch the running flag on, meaning that the timer should be going. Using some date functions (see Chapter 29), you extract the current time in milliseconds and add the number of milliseconds for the next minute (the extra multiplication by one is the place where you can change the amount to the desired number of minutes). With the end time stored in a global variable, the function now calls another function that compares the current and end times and displays the difference in the text field.

Early in the `showCountDown()` function, check to see if the timer has wound down. If so, you stop the timer and alert the user. Otherwise, the function continues to calculate the difference between the two times and formats the time in mm:ss format. As long as the `running` flag is set to `true`, the function sets the one-second timeout timer before repeating itself. To stop the timer before it has run out (in the `stopTimer()` function), the most important step is to cancel the timeout running inside the browser. The `clearTimeout()` method uses the global `timerID` value to do that. Then the function turns off the running switch and zeros out the display.

*windowObject.close()*

**Figure 16-9:** The countdown timer page as it displays the time remaining.

When you run the timer, you may occasionally notice that the time skips a second. It's not cheating. It just takes slightly more than one second to wait for the timeout and then finish the calculations for the next second's display. What you're seeing is the display catching up with the real time left.

**Related Items:** `window.setTimeout()` method.

## `close()`

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `window.close()` method closes the browser window referenced by the `window` object. Most likely, you will use this method to close subwindows created from a main document window. If the call to close the window comes from a window other than the new subwindow, the original `window` object must maintain a record of the subwindow object. You accomplish this by storing the value returned from the `window.open()` method in a global variable that will be available to other objects later (for example, a variable not initialized inside a function). If, on the other hand, an object inside the new subwindow calls the `window.close()` method, the `window` or `self` reference is sufficient.

Be sure to include a window as part of the reference to this method. Failure to do so may cause JavaScript to regard the statement as a `document.close()` method, which has different behavior (see Chapter 18). Only the `window.close()` method can close the window via a script. Closing a window, of course, forces the window to trigger an `onunload` event handler before the window disappears from view; but after you've initiated the `window.close()` method, you cannot stop it from completing its task. Moreover, `onunload` event handlers that attempt to execute time-consuming processes (such as submitting a form in the closing window) may not complete because the window can easily close before the process completes—a behavior that has no workaround (with the exception of the `onbeforeunload` event handler in IE4+).

***windowObject.close()***

While I'm on the subject of closing windows, a special case exists when a subwindow tries to close the main window (via a statement such as `self.opener.close()`) when the main window has more than one entry in its session history. As a safety precaution against scripts closing windows they did not create, modern browsers ask the user whether he or she wants the main window to close (via a browser-generated dialog box). This security precaution cannot be overridden except in NN4+/Moz via a signed script when the user grants permission to control the browser (see Chapter 46 on the CD-ROM).

**Example**

See Listing 16-4 (for the `window.closed` property), which provides a cross-platform example of applying the `window.close()` method across multiple windows.

**Related Items:** `window.open()`, `document.close()` methods.

**`confirm("message")`**

**Returns:** Boolean.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

A confirm dialog box presents a message in a modal dialog box along with OK and Cancel buttons. Such a dialog box can be used to ask a question of the user, usually prior to a script performing actions that will not be undoable. Querying a user about proceeding with typical Web navigation in response to user interaction on a form element is generally a disruptive waste of the user's time and attention. But for operations that may reveal a user's identity or send form data to a server, a JavaScript confirm dialog box may make a great deal of sense. Users can also accidentally click buttons, so you should provide avenues for backing out of an operation before it executes.

Because this dialog box returns a Boolean value (OK = `true`; Cancel = `false`), you can use this method as a comparison expression or as an assignment expression. In a comparison expression, you nest the method within any other statement where a Boolean value is required. For example:

```
if (confirm("Are you sure?")) {  
    alert("OK");  
} else {  
    alert("Not OK");  
}
```

Here, the returned value of the confirm dialog box provides the desired Boolean value type for the `if...else` construction (see Chapter 31).

This method can also appear on the right side of an assignment expression, as in

```
var adult = confirm("You certify that you are over 18 years old?");  
if (adult) {  
    //statements for adults  
} else {  
    //statements for children  
}
```

You cannot specify other alert icons or labels for the two buttons in JavaScript confirm dialog box windows.

The example in Listing 16-23 shows the user interface part of how you can use a confirm dialog box to query a user before clearing a table full of user-entered data. The line in the title bar, as shown in Figure 16-10, or the "JavaScript Confirm" legend in earlier browser versions cannot be removed from the dialog box.

**Listing 16-23: The Confirm Dialog Box**

```
<html>
  <head>
    <title>window.confirm() Method</title>
    <script type="text/javascript">
      function clearTable() {
        if (confirm("Are you sure you want to empty the table?")) {
          alert("Emptying the table..."); // for demo purposes
          //statements that actually empty the fields
        }
      }
    </script>
  </head>
  <body>
    <form>
      <!-- other statements that display and populate a large table -->
      <input type="button" name="clear" value="Reset Table"
        onclick="clearTable()" />
    </form>
  </body>
</html>
```

**Figure 16-10:** A JavaScript confirm dialog box in WinIE.

**Related Items:** `window.alert()`, `window.prompt()`, `form.submit()` methods.

## `createPopup()`

**Returns:** Pop-up object reference.

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

An IE pop-up window is a chrome-less rectangular space that overlaps the current window. Unlike the dialog boxes generated by the `showModalDialog()` and `showModelessDialog()` methods, the pop-up window's entire content must be explicitly controlled by script. That also goes for the size and location of the window. Generating the window via the `createPopup()` method simply creates the object in memory without displaying it. You can then use the reference to the pop-up window that is returned by the method to position the window, populate its content, and make it visible. See details in the description of the `popup` object later in this chapter.

## Example

See Listing 16-49 later in this chapter for an example of the `createPopup()` method.

**Related Items:** `popup` object.

**windowObject.execScript()**

`execScript("exprList" [, language])`

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The IE-specific `window.execScript()` method executes one or more script statements that are passed as string expressions. The first parameter is a string version of one or more script statements (multiple statements must be separated by semicolons). The second, optional parameter is the language interpreter the browser should use to execute the script statement. Acceptable values for the language are JavaScript, JScript, VBS, and VBScript. The default value is JScript, so you can omit the second parameter when supplying expressions in JavaScript.

Unlike the JavaScript core language `eval()` function (which also executes string versions of JavaScript statements), the `execScript()` method returns no values. Even so, the method operates within the global variable space of the window holding the current document. For example, if a document's script declares a global variable as follows

```
var myVar;
```

the `execScript()` method can read or write to that variable:

```
window.execScript("myVar = 10; myVar += 5");
```

After this statement runs, the global variable `myVar` has a value of 15.

## Example

Use The Evaluator (Chapter 13) to experiment with the `execScript()` method. The Evaluator has predeclared global variables for the lowercase letters a through z. Enter each of the following statements into the top text box and observe the results for each.

a

When first loaded, the variable is declared but assigned no value, so it is undefined.

```
window.execScript("a = 5")
```

The method returns no value, so the mechanism inside The Evaluator says that the statement is undefined.

a

The variable is now 5.

```
window.execScript("b = a * 50")
```

b

The `b` global variable has a value of 250. Continue exploring with additional script statements. Use semicolons to separate multiple statements within the string parameter.

**Related Items:** `eval()` function.

`find(["searchString" [, matchCaseBoolean, searchUpBoolean]])`

**Returns:** Boolean value for nondialog searches.

**Compatibility:** WinIE-, MacIE-, NN4+, Moz1+, Safari-

The `window.find()` method introduced in NN4 mimics the powers of the browser's Find dialog box, accessible from the Find button in the toolbar. This method was deactivated in NN6 but reactivated in NN7/Moz1.

***windowObject.handleEvent()***

If you specify no parameters, the browser's Find dialog box appears, just as if the user had clicked the Find button in the toolbar. With no parameters, this function does not return a value.

You can specify a search string as a parameter to the function. The search is based on simple string matching and is not in any way connected with the regular expression kind of search (see Chapter 42 on the CD-ROM). If the search finds a match, the browser scrolls to that matching word and highlights the word, just as if using the browser's own Find dialog box. The function also returns a Boolean `true` after a match is found. If no match is found in the document or no more matches occur in the current search direction (the default direction is from top to bottom), the function returns `false`.

Two optional Boolean parameters to the scripted find action let you specify whether the search should be case-sensitive and whether the search direction should be upward from the bottom of the document. These choices are identical to the ones that appear in the NN4+'s Find dialog box. Default behavior is case-insensitive and searches from top to bottom.

IE4+ also has a text search facility, but it is implemented in an entirely different way (using the `TextRange` object described in Chapter 35). The visual behavior also differs in that it does not highlight and scroll to a matching string in the text.

### Example

A simple call to the `window.find()` method looks as follows:

```
var success = window.find("contract");
```

And if you want the search to be case-sensitive, add at least one of the two optional parameters:

```
success = window.find(matchString, caseSensitive, backward);
```

Because this method works only in NN4, refer to discussions of the `TextRange` and `Range` objects in Chapter 35 on the CD-ROM for more modern implementations of body text searching.

**Related Items:** `TextRange`, `Range` objects (Chapter 35).

### `forward()`

(See `window.back()`)

### `handleEvent(event)`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

When you explicitly capture events in the NN4 window, document, or layer object (by invoking the `captureEvents()` method for that object), you can control where the events go after their initial capture. To let an event continue to its original target (for example, a button that was clicked by a user), you use the `routeEvent()` method. But if you want to redirect an event (or class of events) to a particular event handler elsewhere in the document, use the `handleEvent()` method.

Every NN4 object that has event handlers associated with it also has a `handleEvent()` method. Thus, if you are capturing click events in a window, you can redirect the events to, say, a particular button or link on the page because both of those objects know what to do with click events. Consider the following code excerpt:

```
<script type="text/javascript">
```

**windowObject.handleEvent()**

```
// function to run when window captures a click event
function doClicks(evt) {
    // send all clicks to the first link in the document
    document.links[0].handleEvent(evt);
}
// set window to capture click events
window.captureEvents(Event.CLICK);
// assign doClick() function to click events captured by window
window.onclick = doClicks;
</script>
```

The window is set up to capture all click events and invoke the `doClicks()` function each time the user clicks a clickable item in the window. In the `doClicks()` function is a single statement that instructs the first link in the document to handle the click event being passed as a parameter. The link must have an `onclick` event handler defined for this to be meaningful. Because an event object is passed along automatically, the link's event handler can examine event properties (for example, location of the click) and perhaps alter some of the link's properties before letting it perform its linking task. The preceding example is really showing how to use `handleEvent()` with a link object, rather than a window object. There is little opportunity for other objects to capture events that normally go to the window, but this method is part of every event-aware object in NN4.

The corresponding method in the W3C event model's capture mechanism is `dispatchEvent()`, and the IE5+ equivalent is `fireEvent()`.

See Chapter 25 for details and in-depth examples of working with event objects.

**Related Items:** `window.captureEvents()`, `window.releaseEvents()`, `window.routeEvent()` methods; event object.

**home()**

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

Like many of the window methods introduced in Navigator 4, the `window.home()` method provides an NN-specific scripted way of replicating the action of a toolbar button: the Home button. The action navigates the browser to whatever URL is set in the browser preferences for home page location. You cannot control the default home page of a visitor's browser.

**Related Items:** `window.back()`, `window.forward()` methods; `window.toolbar` property.

**moveBy(deltaX,deltaY)****moveTo(x,y)**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

As of version 4 browsers, JavaScript can adjust the location of a browser window on the screen (no longer available in Mozilla-based browsers, however). This applies to the main window or any subwindow generated by script. Netscape regards the possibility of a window moved out of screen view as a potential security hole, so signed scripts are needed in NN4+ to move a window off screen.

You can move a window to an absolute position on the screen or adjust it along the horizontal and/or vertical axis by any number of pixels, irrespective of the absolute pixel position.

***windowObject.moveBy()***

The coordinate space for the *x* (horizontal) and *y* (vertical) position is the entire screen, with the top-left corner representing 0,0. The point of the window you set with the `moveBy()` and `moveTo()` methods is the very top-left corner of the outer edge of the browser window. Therefore, when you move the window to point 0,0, that sets the window flush with the top-left corner of the screen. This may not be the equivalent of a truly maximized window for all browsers and operating systems, however, because a maximized window's coordinates may be negative by a handful of pixels.

If you try to adjust the position of the window in NN4 such that any edge falls beyond the screen area, the window remains at the edge of the screen—unless you are using a signed script and have the user's permission to adjust the window partially or completely off screen. Moving the only visible browser window entirely off screen is dangerous because the user has no way to get it back into view without quitting and relaunching the browser.

The difference between the `moveTo()` and `moveBy()` methods is that one is an absolute move, while the other is relative with respect to the current window position. Parameters you specify for `moveTo()` are the precise horizontal and vertical pixel counts on the screen where you want the upper-left corner of the window to appear. In contrast, the parameters for `moveBy()` indicate how far to adjust the window location in either direction. If you want to move the window 25 pixels to the right, you must still include both parameters, but the *y* value will be zero:

```
window.moveBy(25,0);
```

To move to the left, the first parameter must be a negative number.

## Example

Several examples of using the `window.moveTo()` and `window.moveBy()` methods are shown in Listing 16-24. The page presents four buttons, each of which performs a different kind of browser window movement.

### Listing 16-24: Window Boogie

```
<html>
  <head>
    <title>Window Gymnastics</title>
    <script type="text/javascript">
      var isNav4 = ((navigator.appName == "Netscape") &&
        (parseInt(navigator.appVersion) >= 4));

      // wait in onload for page to load and settle in IE
      function init() {
        // fill missing IE properties
        if (!window.outerWidth) {
          window.outerWidth = document.body.clientWidth;
          window.outerHeight = document.body.clientHeight + 30;
        }
        // fill missing IE4 properties
        if (!screen.availWidth) {
          screen.availWidth = 640;
          screen.availHeight = 480;
        }
      }
    </script>
  </head>
</html>
```

*Continued*

**windowObject.moveBy()****Listing 16-24 (continued)**

```
// function to run when window captures a click event
function moveOffScreen() {
  // branch for NN security
  if (isNav4) {
    netscape.security.PrivilegeManager.enablePrivilege(
      "UniversalBrowserWrite");
  }
  var maxX = screen.width;
  var maxY = screen.height;
  window.moveTo(maxX+1, maxY+1);
  setTimeout("window.moveTo(0,0)",500);
  if (isNav4) {
    netscape.security.PrivilegeManager.disablePrivilege(
      "UniversalBrowserWrite");
  }
}

// moves window in a circular motion
function revolve() {
  var winX = (screen.availWidth - window.outerWidth) / 2;
  var winY = 50;
  window.resizeTo(400,300);
  window.moveTo(winX, winY);

  for (var i = 1; i < 36; i++) {
    winX += Math.cos(i * (Math.PI/18)) * 5;
    winY += Math.sin(i * (Math.PI/18)) * 5;
    window.moveTo(winX, winY);
  }
}

// moves window in a horizontal zig-zag pattern
function zigzag() {
  window.resizeTo(400,300);
  window.moveTo(0,80);
  var incrementX = 2;
  var incrementY = 2;
  var floor = screen.availHeight - window.outerHeight;
  var rightEdge = screen.availWidth - window.outerWidth;
  for (var i = 0; i < rightEdge; i += 2) {
    window.moveBy(incrementX, incrementY);
    if (i%60 == 0) {
      incrementY = -incrementY;
    }
  }
}

// resizes window to occupy all available screen real estate
function maximize() {
  window.moveTo(0,0);
  window.resizeTo(screen.availWidth, screen.availHeight);
}
</script>
</head>
```

*windowObject.navigate()*

```

<body onload="init()">
  <form name="buttons">
    <b>Window Gymnastics</b>
    <ul>
      <li><input name="offscreen" type="button"
        value="Disappear a Second" onclick="moveOffScreen()" /></li>
      <li><input name="circles" type="button" value="Circular Motion"
        onclick="revolve()" /></li>
      <li><input name="bouncer" type="button" value="Zig Zag"
        onclick="zigzag()" /></li>
      <li><input name="expander" type="button" value="Maximize"
        onclick="maximize()" /></li>
    </ul>
  </form>
</body>
</html>

```

To run successfully in NN (prior to NN7), the first button requires that you have codebase principals turned on (see Chapter 46 on the CD-ROM) to take advantage of what would normally be a signed script. The `moveOffScreen()` function momentarily moves the window entirely out of view. Notice how the script determines the size of the screen before deciding where to move the window. After the journey off screen, the window comes back into view at the upper-left corner of the screen.

If using the Web sometimes seems like going around in circles, then the second function, `revolve()`, should feel just right. After reducing the size of the window and positioning it near the top center of the screen, the script uses a bit of math to position the window along 36 places around a perfect circle (at 10-degree increments). This is an example of how to control a window's position dynamically based on math calculations. IE complicates the job a bit by not providing properties that reveal the outside dimensions of the browser window.

To demonstrate the `moveBy()` method, the third function, `zigzag()`, uses a `for` loop to increment the coordinate points to make the window travel in a sawtooth pattern across the screen. The *x* coordinate continues to increment linearly until the window is at the edge of the screen (also calculated on the fly to accommodate any size monitor). The *y* coordinate must increase and decrease as that parameter changes direction at various times across the screen.

In the fourth function, you see some practical code (finally) that demonstrates how best to simulate maximizing the browser window to fill the entire available screen space on the visitor's monitor.

**Related Items:** `window.outerHeight`, `window.outerWidth` properties; `window.resizeBy()`, `window.resizeTo()` methods.

## navigate("URL")

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN-, Moz-, Safari-

The `window.navigate()` method is an IE-specific method that lets you load a new document into a window or frame. This method's action is the same as assigning a URL to the `location.href` property—a property that is available on all scriptable browsers. If your audience is entirely IE-based, this method is safe. Otherwise, I recommend the `location.href` property as the best navigation approach.

**windowObject.navigate()****Example**

Supply any valid URL as the parameter to the method, as in

```
window.navigate("http://www.dannyg.com");
```

**Related Items:** location object.

```
open("URL", "windowName" [,
"windowFeatures" ][, replaceFlag])
```

**Returns:** A window object representing the newly created window; null if method fails.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

With the `window.open()` method, a script provides a Web site designer with an immense range of options for the way a second or third Web browser window looks on the user's computer screen. Moreover, most of this control can work with all JavaScript-enabled browsers without the need for signed scripts. Because the interface elements of a new window are easier to envision, I cover those aspects of the `window.open()` method parameters first.

**Setting new window features**

The optional `windowFeatures` parameter is one string, consisting of a comma-separated list of assignment expressions (behaving something like HTML tag attributes). **Important:** For the best browser compatibility, do not put spaces after the commas. If you omit the third parameter, JavaScript creates the same type of new window you get from the New Web Browser menu choice in the File menu. But you can control which window elements appear in the new window with the third parameter. Remember this important rule: If you specify even one of the method's original set of third parameter values, all other features are turned off unless the parameters specify the features to be switched on. Table 16-3 lists the attributes that you can control for a newly created window in all browsers. Except where noted, all Boolean values default to yes if you do not specify the third parameter.

---

**Table 16-3: window.open() Method Attributes Controllable via Script**

---

<i>Attribute</i>	<i>Browsers</i>	<i>Description</i>
<code>alwaysLowered3</code>	NN4+	(Boolean) Always behind other browser windows
<code>alwaysRaised3</code>	NN4+	(Boolean) Always in front of other browser windows
<code>channelMode</code>	IE4+	(Boolean) Theater mode with channel band (default is no)
<code>copyhistory</code>	NN2+, IE3+	(Boolean) Duplicates Go menu history for new window
<code>dependent</code>	NN4+	(Boolean) Subwindow closes if the opener window closes
<code>directories</code>	NN2+, IE3+	(Boolean) "What's New" and other buttons in the row
<code>fullscreen</code>	IE4+	(Boolean) No title bar or menus (default is no)
<code>height</code>	NN2+, IE3+	(Integer) Content region height in pixels
<code>hotkeys</code>	NN4+	(Boolean) If true, disables menu shortcuts (except Quit and Security Info) when menu bar is turned off
<code>innerHeight4</code>	NN4+	(Integer) Content region height; same as old height property
<code>innerWidth4</code>	NN4+	(Integer) Content region width; same as old width property
<code>left</code>	NN6+, IE4+	(Integer) Horizontal position of top-left corner on screen
<code>location</code>	NN2+, IE3+	(Boolean) Field displaying the current URL
<code>menubar1</code>	NN2+, IE3+	(Boolean) Menu bar at top of window
<code>outerHeight4</code>	NN4+	(Integer) Visible window height

*windowObject.open()*

<i>Attribute</i>	<i>Browsers</i>	<i>Description</i>
<code>outerWidth</code> <sup>4</sup>	NN4+	(Integer) Visible window width
<code>resizable</code> <sup>2</sup>	NN2+, IE3+	(Boolean) Interface elements that allow resizing by dragging
<code>screenX</code> <sup>4</sup>	NN4+	(Integer) Horizontal position of top-left corner on screen
<code>screenY</code> <sup>4</sup>	NN4+	(Integer) Vertical position of top-left corner on screen
<code>scrollbars</code>	NN2+, IE3+	(Boolean) Displays scrollbars if document is larger than window
<code>status</code>	NN2+, IE3+	(Boolean) Status bar at bottom of window
<code>titlebar</code> <sup>3</sup>	NN4+	(Boolean) Title bar and all other border elements
<code>toolbar</code>	NN2+, IE3+	(Boolean) "Back," "Forward," and other buttons in the row
<code>top</code>	NN6+, IE4+	(Integer) Horizontal position of top-left corner on screen
<code>width</code>	NN2+, IE3+	(Integer) Content region width in pixels
<code>z-lock</code> <sup>3</sup>	NN4+	(Boolean) Window layer is fixed below browser windows

- 1 Not on Macintosh because the menu bar is not in the browser window; when off in MacNN4, displays an abbreviated Mac menu bar.
- 2 Macintosh windows are always resizable.
- 3 Requires a signed script.
- 4 Requires a signed script to size or position a window beyond safe threshold.

Boolean values are handled a bit differently than you might expect. The value for `true` can be either `yes`, `1`, or just the feature name by itself; for `false`, use a value of `no` or `0`. If you omit any Boolean attributes, they are rendered as `false`. Therefore, if you want to create a new window that shows only the toolbar and status bar and is resizable, the method looks like this:

```
window.open("newURL","NewWindow", "toolbar,status,resizable");
```

A new window that does not specify the height and width is set to the default size of the browser window that the browser creates from a File menu's New Web Browser command. In other words, a new window does not automatically inherit the size of the window making the `window.open()` method call. A new window created via a script is positioned somewhat arbitrarily, unless you use the window positioning attributes available in NN4+ and IE4+. Notice that the position attributes are different for each browser (`screenX` and `screenY` for NN; `left` and `top` for IE). You can include both sets of attributes in a single parameter string because the browser ignores attributes it doesn't recognize.

**Note**

Invoking `window.open()` via a window's `onload` and `onunload` event handlers has led to severe abuse in the form of unwanted pop-up advertising windows. Browsers that include "pop-up blockers" (such as Mozilla-based browsers) prevent the method from being invoked by these event handlers. With more browsers and users employing pop-up blockers every day, you should not even think about blasting pop-up ads to Web surfers.

## Netscape-only signed scripts

Many NN-specific attributes are deemed to be security risks and thus require signed scripts and the user's permission before they are recognized. If the user fails to grant permission, the secure parameter is ignored.

A couple of these attributes have different behaviors on different operating system platforms, due to the way the systems manage their application windows. For example, the `alwaysLowered`, `alwaysRaised`, and `z-locked` styles can exist in layers that range behind

**windowObject.open()**

Navigator's own windows in the Windows platform; on the Mac, however, such windows are confined to the levels occupied by Navigator. The difference is that Windows allows windows from multiple applications to interleave each other, while the Mac keeps each application's windows in contiguous layers.

To apply signed scripts to opening a new window with the secure window features, you must enable `UniversalBrowserWrite` privileges as you do for other signed scripts (see Chapter 46 on the CD-ROM). A code fragment that generates an `alwaysRaised` style window follows:

```
<script type="text/javascript" archive="myJar.jar" id="1">
function newRaisedWindow() {
    netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserWrite");
    var newWindow = window.open("", "", "height=100,width=300,alwaysRaised=yes");
    netscape.security.PrivilegeManager.disablePrivilege("UniversalBrowserWrite");
    var newContent = "<html><body><b> "On top of spaghetti!"</b>";
    newContent += "<form><center><input type='button' value='OK'";
    newContent += "onclick='self.close()'></center></form></body></html>";
    newWindow.document.write(newContent);
    newWindow.document.close();
}
</script>
```

You can experiment with the look and behavior of new windows with any combination of attributes with the help of the script in Listing 16-25. This page presents a table of all NN-specific new window Boolean attributes and creates a new 300 × 300 pixel window based on your choices. This page assumes that if you are using NN4, you have codebase principals turned on for signed scripts (see Chapter 46 on the CD-ROM).

Be careful with turning off the title bar and hotkeys. With the title bar off, the content appears to float in space, because absolutely no borders are displayed. With hotkeys still turned on, you can use `Ctrl+W` to close this borderless window (except on the Mac, for which the hotkeys are always disabled with the title bar off). This is how you can turn a computer into a kiosk by sizing a window to the screen's dimensions and setting the window options to `"titlebar=no,hotkeys=no,alwaysRaised=yes"`.

### Listing 16-25: New Window Laboratory

```
<html>
<head>
  <title>window.open() Options</title>
  <script type="text/javascript">
    var isNav4 = (navigator.appName == "Netscape" &&
      navigator.appVersion.charAt(0) >= 4) ? true : false;

    function makeNewWind(form) {
      if (isNav4) {
        netscape.security.PrivilegeManager.enablePrivilege(
          "UniversalBrowserWrite");
      }
      var attr = "width=300,height=300";
      for (var i = 0; i < form.elements.length; i++) {
        if (form.elements[i].type == "checkbox") {
          attr += "," + form.elements[i].name + "=";
          attr += (form.elements[i].checked) ? "yes" : "no";
        }
      }
      var newWind = window.open("bofright.htm","subwindow",attr);
    }
  </script>
</head>
<body>
  <form>
    <input type="checkbox" value="titlebar=no" /> titlebar=no
    <input type="checkbox" value="hotkeys=no" /> hotkeys=no
    <input type="checkbox" value="alwaysRaised=yes" /> alwaysRaised=yes
  </form>
  <input type="button" value="Open Window" />
</body>
</html>
```

*windowObject.open()*

```

        if (isNav4) {
            netscape.security.PrivilegeManager.revertPrivilege("CanvasAccess");
        }
    }
</script>
</head>

                name="forAll" value="Make New Window"
                onclick="makeNewWind(this.form)" /></td>
        </tr>
    </table>
</form>
<br />
</body>
</html>

```

***windowObject.open()*****Specifying a window name**

Getting back to the other parameters of `window.open()`, the second parameter is the name for the new window. Don't confuse this parameter with the document's title, which would normally be set by whatever HTML text determines the content of the window. A window name must be the same style of one-word identifier that you use for other object names and variables. This name is also an entirely different entity than the `window` object that the `open()` method returns. You don't use the name in your scripts. At most, the name can be used for `target` attributes of links and forms.

**Loading content into a new window**

A script generally populates a window with one of two kinds of information:

- ♦ An existing HTML document whose URL is known beforehand
- ♦ An HTML page created on the fly

To create a new window that displays an existing HTML document, supply the URL as the first parameter of the `window.open()` method. If your page is having difficulty loading a URL into a new page, try specifying the complete URL of the target document (instead of just the filename).

Leaving the first parameter as an empty string forces the window to open with a blank document, ready to have HTML written to it by your script (or loaded separately by another statement that sets that window's location to a specific URL). If you plan to write the content of the window on the fly, assemble your HTML content as one long string value and then use the `document.write()` method to post that content to the new window. If you plan to append no further writing to the page, also include a `document.close()` method at the end to tell the browser that you're finished with the layout (so that the `Layout:Complete` or `Done` message appears in the status bar, if your new window has one).

A call to the `window.open()` method returns a reference to the new window's object if the window opens successfully. This value is vitally important if your script needs to address elements of that new window (such as when writing to its document).

To allow other functions in your script to reference the subwindow, you should assign the result of a `window.open()` method to a global variable. Before writing to the new window the first time, test the variable to make sure that it is not a `null` value—the window may have failed to open because of low memory, for instance. If everything is okay, you can use that variable as the beginning of a reference to any property or object within the new window. For example:

```
var newWindow
...
function createNewWindow() {
    newWindow = window.open("", "");
    if (newWindow != null) {
        newWindow.document.write("<html><head><title>Hi!</title></head>");
    }
}
```

That global variable reference continues to be available for another function that perhaps closes the subwindow (via the `close()` method).

When scripts in the subwindow need to communicate with objects and scripts in the originating window, you must make sure that the subwindow has an `opener` property if the level of JavaScript in the visitor's browser doesn't automatically supply one. See the discussion about the `window.opener` property earlier in this chapter.

***windowObject.open()***

Invoking multiple `window.open()` methods with the same window name parameter (the second parameter) does not create additional copies of that window in Netscape browsers (although it does in Internet Explorer). JavaScript prevents you from creating two windows with the same name. Also be aware that a `window.open()` method does not bring an existing window of that name to the front of the window layers: Use `window.focus()` for that.

## Internet Explorer idiosyncracies

Creating subwindows in IE can be complicated at times by undesirable behavior by the browser. One of the most common problems occurs when you attempt to use `document.write()` to put content into a newly created window. IE, including some of the latest versions, fails to complete the window opening job before the script statement that uses `document.write()` executes. This causes a script error because the reference to the subwindow is not yet valid. To work around this, you should put the HTML assembly and `document.write()` statements in a separate function that gets invoked via a `setTimeout()` method after the window is created. You can see an example of this in Listing 16-26.

Another problem that affects IE is the occasional security violation (“access denied”) warning when a script attempts to access a subwindow. This problem goes away when the page that includes the script for opening and accessing the subwindow is served from an http server, rather than accessed from a local hard disk.

## Example

The page rendered by Listing 16-26 displays a single button that generates a new window of a specific size that has only the status bar turned on. The script here shows all the elements necessary to create a new window that has all the right stuff on most platforms. The new window object reference is assigned to a global variable, `newWindow`. Before a new window is generated, the script looks to see if the window has never been generated before (in which case `newWindow` would be `null`) or, for newer browsers, the window is closed. If either condition is true, the window is created with the `open()` method. Otherwise, the existing window is brought forward with the `focus()` method (NN3+ and IE4+).

Due to the timing problem that afflicts all IE generations, the HTML assembly and writing to the new window is separated into its own function that is invoked after a 50-millisecond delay (other browsers go along for the ride even if they could accommodate the assembly and writing without the delay). To build the string that is eventually written to the document, I use the `+=` (add-by-value) operator, which appends the string on the right side of the operator to the string stored in the variable on the left side. In this example, the new window is handed an `<h1>`-level line of text to display.

### Listing 16-26: Creating a New Window

```
<html>
  <head>
    <title>New Window</title>
    <script type="text/javascript">
      var newWindow;

      function makeNewWindow() {
        if (!newWindow || newWindow.closed) {
          newWindow = window.open("", "", "status,height=200,width=300");
          // force small delay for IE to catch up
          setTimeout("writeToWindow()", 50);
        }
      }
    </script>
  </head>
  <body>
    <input type="button" value="New Window" onclick="makeNewWindow()" />
  </body>
</html>
```

*Continued*

**windowObject.open()****Listing 16-26 (continued)**

```

    } else {
        // window's already open; bring to front
        newWindow.focus();
    }
}

function writeToWindow() {
    // assemble content for new window
    var newContent = "<html><head><title>One Sub Window</title></head>";
    newContent += "<body><h1>This window is brand new.</h1>";
    newContent += "</body></html>";
    // write HTML to new window document
    newWindow.document.write(newContent);
    newWindow.document.close(); // close layout stream
}
</script>
</head>
<body>
  <form>
    <input type="button" name="newOne" value="Create New Window"
      onclick="makeNewWindow()" />
  </form>
</body>
</html>

```

**Related Items:** `window.close()`, `window.blur()`, `window.focus()` methods; `window.closed` property.

**print()**

**Returns:** Nothing.

**Compatibility:** WinIE5+, MacIE5+, NN4+, Moz1+, Safari-

The `print()` method provides a scripted way of sending the window or a frame from a frameset to the printer. In all cases, the Print dialog box appears for the user to make the typical printer choices when printing manually. This prevents a rogue `print()` command from tying up a printer without the user's permission.

The precise behavior of the `print()` method varies a bit with the ways different browsers (not to mention operating systems) handle printing. In NN4+ (except for the Windows OS), you can print all frames of a frameset in one `print()` command when it is invoked for the framesetting (parent) document. NN4 for Windows, however, does not print the entire frameset at once. You can write a script that iterates through all frames and prints them with delays to let the content be sent to the print spooler:

```

function printFrames(n) {
    parent.frames[n++].print();
    if (n < parent.frames.length) {
        setTimeout("printFrames(" + n + ")", 5000);
    }
}

```

Invoke this function as `printFrames(0)`, and the function does the rest.

***windowObject.print()***

In IE5+, the print dialog box gives the user the choice of printing just one frame or all of the frames. Make sure that the `print()` method is invoked for the desired frame when you want only that frame to print. The browser defaults to printing just that frame.

WinIE5 introduced some print-specific event handlers that are triggered by scripted printing as well as manual printing. The events begin to fire after the user has accepted the Print dialog box. An `onbeforeprint` event handler can be used to show content that might be hidden from view but should appear in the printout. After the content has been sent to the print spooler, the `onafterprint` event can restore the page.

**Example**

Listing 16-27 is a frameset that loads Listing 16-28 into the top frame and a copy of the Bill of Rights into the bottom frame.

**Listing 16-27: Print Example Frameset**

```
<html>
  <head>
    <title>window.print() method</title>
  </head>
  <frameset rows="25%,75%">
    <frame name="controls" src="lst16-28.htm" />
    <frame name="display" src="bofright.htm" />
  </frameset>
</html>
```

Two buttons in the top control panel (see Listing 16-28) let you print the whole frameset (in those browsers and OSes that support it) or just the lower frame. To print the entire frameset, the reference includes the parent window; to print the lower frame, the reference is directed at the `parent.display` frame.

**Listing 16-28: Printing Control**

```
<html>
  <head>
    <title>Print()</title>
  </head>
  <body>
    <form>
      <input type="button" name="printWhole" value="Print Entire Frameset"
        onclick="parent.print()" />
      <p><input type="button" name="printFrame"
        value="Print Bottom Frame Only"
        onclick="parent.display.print()" /></p>
    </form>
  </body>
</html>
```

**windowObject.print()**

If you don't like some facet of the printed output, blame the browser's print engine, and not JavaScript. The `print()` method merely invokes the browser's regular printing routines.

**Related Items:** `window.back()`, `window.forward()`, `window.home()`, `window.find()` methods.

**prompt("message", "defaultReply")**

**Returns:** String of text entered by user or `null`.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The third kind of dialog box that JavaScript can display includes a message from the script author, a field for user entry, and two buttons (OK and Cancel, or Yes and No on Mac versions of Navigator 2 and 3). The script writer can supply a prewritten answer so that a user confronted with a prompt dialog box can click OK (or press Enter) to accept that answer without further typing. Supplying both parameters to the `window.prompt()` method is important. Even if you don't want to supply a default answer, enter an empty string as the second parameter:

```
prompt("What is your postal code?","");
```

If you omit the second parameter, JavaScript inserts the string `undefined` into the dialog box's field. This string is disconcerting to most Web page visitors.

The value returned by this method is a string in the dialog box's field when the user clicks the OK button. If you're asking the user to enter a number, remember that the value returned by this method is a string. You may need to perform data-type conversion with the `parseInt()` or `parseFloat()` functions (see Chapter 34) to use the returned values in math calculations.

When the user clicks the prompt dialog box's OK button without entering any text into a blank field, the returned value is an empty string (`" "`). Clicking on the Cancel button, however, makes the method return a `null` value. Therefore, the scripter must test for the type of returned value to make sure that the user entered some data that can be processed later in the script, as in

```
var entry = prompt("Enter a number between 1 and 10:","");
if (entry != null) {
    //statements to execute with the value
}
```

This script excerpt assigns the results of the prompt dialog box to a variable and executes the nested statements if the returned value of the dialog box is not `null` (if the user clicked the OK button). The rest of the statements then include data validation to make sure that the entry is a number within the desired range (see Chapter 43 on the CD-ROM).

It may be tempting to use the prompt dialog box as a handy user input device. But, as with the other JavaScript dialog boxes, the modality of the prompt dialog box is disruptive to the user's flow through a document and can also trap automated macros that some users activate to capture Web sites. In forms, HTML fields are better user interface elements for attracting user text entry. Perhaps the safest way to use a prompt dialog box is to have it appear when a user clicks a button element on a page—and then only if the information you require of the user can be provided in a single prompt dialog box. Presenting a sequence of prompt dialog boxes is downright annoying to users.

**Example**

The function that receives values from the prompt dialog box in Listing 16-29 (see the dialog box in Figure 16-11) does some data-entry validation (but certainly not enough for a commercial site). The function first checks to make sure that the returned value is neither `null`

*windowObject.releaseEvents()*

(Cancel) nor an empty string (the user clicked OK without entering any values). See Chapter 43 on the CD-ROM for more about data-entry validation.

### Listing 16-29: The Prompt Dialog Box

```
<html>
  <head>
    <title>window.prompt() Method</title>
    <script type="text/javascript">
      function populateTable() {
        var howMany = prompt("Fill in table for how many factors?","");
        if (howMany != null && howMany != "") {
          alert("Filling the table for " + howMany); // for demo
          //statements that validate the entry and
          //actually populate the fields of the table
        }
      }
    </script>
  </head>
  <body>
    <form>
      <!-- other statements that display and populate a large table -->
      <input type="button" name="fill" value="Fill Table..."
        onclick="populateTable()" />
    </form>
  </body>
</html>
```

**Figure 16-11:** The prompt dialog box displayed from Listing 16-29 in WinIE.

Notice one important user interface element in Listing 16-29. Because clicking the button leads to a dialog box that requires more information from the user, the button's label ends in an ellipsis (or, rather, three periods acting as an ellipsis character). The ellipsis is a common courtesy to let users know that a user interface element leads to a dialog box of some sort. Consistent with standalone applications, the user should be able to cancel out of that dialog box and return to the same screen state that existed before the button was clicked.

**Related Items:** `window.alert()`, `window.confirm()` method.

## `releaseEvents(eventTypeList)`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

If your scripts have enabled NN4-specific event capture for the `window` object (or `document` or `layer`, for that matter), you can turn off that capture with the `releaseEvents()` method.

**`windowObject.releaseEvents()`**

This method does not inhibit events from reaching their intended target. In fact, by releasing capture from a higher object, released events don't bother stopping at those higher objects anymore. Parameters for the `releaseEvents()` method are one or more event types. Each event type is its own entity, so if your window captures three event types at one point, you can release some or all of those event types as the visitor interacts with your page. For example, if the page loads and captures three types of events, as in

```
window.captureEvents(Event.CLICK | Event.KEYPRESS | Event.CHANGE);
```

you can later turn off window event capture for all but the `click` event:

```
window.releaseEvents(Event.KEYPRESS | Event.CHANGE);
```

The window still captures and processes `click` events, but `keypress` and `change` events go directly to their target objects.

An improved mechanism (removing an event listener) is implemented in NN6+/W3C browsers based on the W3C event model. See Chapters 14 and 25 for more information.

**Related Items:** `window.captureEvents()`, `window.routeEvent()` methods.

**`resizeBy(deltaX, deltaY)`  
`resizeTo(outerwidth, outerheight)`**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN4, Moz-, Safari1+

Starting with version 4 browsers, scripts can control the size of the current browser window on the fly (no longer available in Mozilla-based browsers). While you can set the individual inner and (in NN4) outer width and height properties of a window, the `resizeBy()` and `resizeTo()` methods let you adjust both axis measurements in one statement. In both instances, all adjustments affect the lower-right corner of the window: To move the top-left corner, use the `window.moveBy()` or `window.moveTo()` methods.

Each resize method requires a different kind of parameter. The `resizeBy()` method adjusts the window by a certain number of pixels along one or both axes. Therefore, it is not concerned with the specific size of the window beforehand—only by how much each axis is to change. For example, to increase the current window size by 100 pixels horizontally and 50 pixels vertically, the statement is

```
window.resizeBy(100, 50);
```

Both parameters are required, but if you only want to adjust the size in one direction, set the other to zero. You may also shrink the window by using negative values for either or both parameters.

You find a greater need for the `resizeTo()` method, especially when you know that on a particular platform the window needs adjustment to a specific width and height to best accommodate that platform's display of form elements. Parameters for the `resizeTo()` method are the actual pixel width and height of the outer dimension of the window—the same as NN4's `window.outerWidth` and `window.outerHeight` properties.

To resize the window such that it occupies all screen real estate (except for the Windows Taskbar and Macintosh menu bar), use the `screen` object properties that calculate the available screen space:

```
window.resizeBy(screen.availWidth, screen.availHeight);
```

***windowObject.resizeBy()***

This action, however, is not precisely the same in Windows as maximizing the window. To achieve that same effect, you must move the window to coordinates -4, -4 and add eight to the two parameters of `resizeBy()`:

```
window.moveTo(-4,-4);
window.resizeTo(screen.availWidth + 8, screen.availHeight + 8);
```

This hides the window's own 4-pixel wide border, as occurs during OS-induced window maximizing. See also the `screen` object discussion (see Chapter 38 on the CD-ROM) for more OS-specific details.

On some platforms, the dimensions are applied to the inner width and height, rather than outer. If a specific outer size is necessary, use the NN-specific `window.outerHeight` and `window.outerWidth` properties instead.

Navigator 4 imposes some security restrictions for maximum and minimum size for a window. For both methods, you are limited to the viewable area of the screen and visible minimums unless the page uses signed scripts (see Chapter 46 on the CD-ROM). With signed scripts and the user's permission, for example, you can adjust windows beyond the available screen borders.

## Example

You can experiment with the resize methods with the page in Listing 16-30. Two parts of a form let you enter values for each method. The one for `window.resize()` also lets you enter a number of repetitions to better see the impact of the values. Enter zero and negative values to see how those affect the method. Also test the limits of different browsers.

### Listing 16-30: Window Resize Methods

```
<html>
  <head>
    <title>Window Resize Methods</title>
    <script type="text/javascript">
      function doResizeBy(form) {
        var x = parseInt(form.resizeByX.value);
        var y = parseInt(form.resizeByY.value);
        var count = parseInt(form.count.value);
        for (var i = 0; i < count; i++) {
          window.resizeBy(x, y);
        }
      }
      function doResizeTo(form) {
        var x = parseInt(form.resizeToX.value);
        var y = parseInt(form.resizeToY.value);
        window.resizeTo(x, y);
      }
    </script>
  </head>
  <body>
    <form>
      <b>Enter the x and y increment, plus how many times the window should
      be resized by these increments:</b><br />
      Horiz:<input type="text" name="resizeByX" size="4" /> Vert:<input
      type="text" name="resizeByY" size="4" /> How Many:<input type="text"
      name="count" size="4" /> <input type="button" name="ResizeBy"
```

*Continued*

**windowObject.resizeBy()****Listing 16-30 (continued)**

```

value="Show resizeBy()" onclick="doResizeBy(this.form)" />
<hr />
<b>Enter the desired width and height of the current window:</b><br />
Width:<input type="text" name="resizeToX" size="4" /> Height:<input
type="text" name="resizeToY" size="4" /> <input type="button"
name="ResizeTo" value="Show resizeTo()"
onclick="doResizeTo(this.form)" />
</form>
</body>
</html>

```

**Related Items:** `window.outerHeight`, `window.outerWidth` **properties**; `window.moveTo()`, `window.sizeToContent()` **methods**.

**routeEvent(event)**

**Returns:** Nothing.

**Compatibility:** WinE-, MacIE-, NN4, Moz-, Safari-

If you turn on NN4-specific event capturing in the window, document, or layer objects (via their respective `captureEvents()` methods), the handlers you assign to those events really capture those events, preventing them from ever reaching their intended targets. For some page designs, this is intentional, because it allows the higher-level object to handle all events of a particular type. But if your goal is to perform some preprocessing of events before they reach their destination, you need a way to pass that event along its regular path. That's what the `routeEvent()` method is for.

Perhaps a more common reason for capturing events at the window (or similar) level is to look for special cases, such as when someone Ctrl+clicks on an element. In this case, even though the window event handler receives all `click` events, it performs further processing only when the `event.modifiers` property indicates the Ctrl key is also pressed and the `eventObj.target` property reveals the item being clicked is a link rather than a button. All other instances of the `click` event are routed on their way to their destinations. The event object knows where it's going, so that your `routeEvent()` method doesn't have to worry about that.

The parameter for the `routeEvent()` method is the event object that is passed to the function that processes the high-level event, as shown here:

```

function flashRed(evt) {
    [statements that filter specific events to flash background color red]
    routeEvent(evt);
}

```

The event object, `evt`, comes into the function while passing unmodified to the object that was clicked.

In the W3C DOM event model (as implemented in NN6+/Moz1+/Safari1+), a captured event continues onward to the target after event handlers higher up the containment chain finish their work.

**Example**

The `window.routeEvent()` method is used in the example for `window.captureEvents()`, Listing 16-21.

**Related Items:** `window.captureEvents()`, `window.releaseEvents()`, `window.handleEvent()` methods; event object (Chapter 25).

## `scroll(horizontalCoord, verticalCoord)`

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

The `window.scroll()` method was introduced in NN3 and has been implemented in all scriptable browsers since then. But in the meantime, the method has been replaced by the `window.scrollTo()` method, which is in more syntactic alliance with many other window methods. Use the `window.scroll()` method only if your audience is still using NN3; for an audience of NN4+ and IE4+, use the `window.scrollTo()` method instead.

The `window.scroll()` method takes two parameters, the horizontal (x) and vertical (y) coordinates of the document that is to be positioned at the top-left corner of the window or frame. You must realize that the window and document have two similar, but independent, coordinate schemes. From the window's point of view, the top-left pixel (of the content area) is point 0,0. All documents also have a 0,0 point: the very top-left of the document. The window's 0,0 point doesn't move, but the document's 0,0 point can move — via manual or scripted scrolling. Although `scroll()` is a window method, it seems to behave more like a document method, as the document appears to reposition itself within the window. Conversely, you can also think of the window moving to bring its 0,0 point to the designated coordinate of the document.

Although you can set values beyond the maximum size of the document or to negative values, the results vary from platform to platform. For the moment, the best usage of the `window.scroll()` method is as a means of adjusting the scroll to the very top of a document (`window.scroll(0,0)`) when you want the user to be at a base location in the document. For vertical scrolling within a text-heavy document, an HTML anchor may be a better alternative for now (though it doesn't readjust horizontal scrolling).

## Example

To demonstrate the `scroll()` method, Listing 16-31 defines a frameset with a document in the top frame (see Listing 16-32) and a control panel in the bottom frame (see Listing 16-33). A series of buttons and text fields in the control panel frame directs the scrolling of the document. I've selected an arbitrary, large GIF image to use in the example. To see results of some horizontal scrolling values, you may need to shrink the width of the browser window until a horizontal scrollbar appears in the top frame.

### Listing 16-31: A Frameset for the `scroll()` Demonstration

```
<html>
  <head>
    <title>
      window.scroll() Method
    </title>
  </head>
  <frameset rows="50%,50%">
    <frame src="lst16-32.htm" name="display" />
    <frame src="lst16-33.htm" name="control" />
  </frameset>
</html>
```

*windowObject.scroll()***Listing 16-32: The Image to Be Scrolled**

```
<html>
  <head>
    <title>
      Arch
    </title>
  </head>
  <body>
    <h1>
      A Picture is Worth...
    </h1>
    <hr />
    <center>
      <table border="3">
        <caption align="bottom">
          A Splendid Arch
        </caption>
        <tr>
          <td>
            
          </td>
        </tr>
      </table>
    </center>
  </body>
</html>
```

---

**Listing 16-33: Controls to Adjust Scrolling of the Upper Frame**

```
<html>
  <head>
    <title>
      Scroll Controller
    </title>

    <script type="text/javascript">
      function scroll(x,y) {
        parent.frames[0].scroll(x,y);
      }
      function customScroll(form) {
        parent.frames[0].scroll(parseInt(form.x.value),
          parseInt(form.y.value));
      }
    </script>
  </head>
  <body>
    <h2>
      Scroll Controller
    </h2>
    <hr />
    <form name="fixed">
      Click on a scroll coordinate for the upper frame:
      <p>
```

**windowObject.scrollBy()**

```

```

Notice that in the `customScroll()` function, JavaScript must convert the string values from the two text boxes to integers (with the `parseInt()` method) for the `scroll()` method to accept them. Nonnumeric data can produce very odd results. Also be aware that although this example shows how to adjust the scroll values in another frame, you can set such values in the same frame or window as the script, as well as in subwindows, provided that you use the correct object references to the window.

**Related Items:** `window.scrollBy()`, `window.scrollTo()` methods.

`scrollBy(deltaX, deltaY)`

`scrollTo(x, y)`

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

Modern browsers provide a related pair of window scrolling methods. The `window.scrollTo()` method is the newer version of the `window.scroll()` method. The two work identically to position a specific coordinate point of a document at the top-left corner of the inner window region.

In contrast, the `window.scrollBy()` method allows for relative positioning of the document. Parameter values indicate by how many pixels the document should scroll in the window (horizontally and vertically). Negative numbers are allowed if you want to scroll to the left and/or upward. The `scrollBy()` method comes in handy if you elect to hide the scrollbars of a window or frame and offer other types of scrolling controls for your users. For example, to scroll down one entire screen of a long document, you can use the `window.innerHeight` (in NN) or `document.body.clientHeight` (in IE) properties to determine what the offset from the current position would be:

```

// assign IE body clientHeight to window.innerHeight
if (document.body && document.body.clientHeight) {
  window.innerHeight = document.body.clientHeight;
}
window.scrollBy(0, window.innerHeight);

```

***windowObject.scrollBy()***

## Unwanted User Scrolling

Many Windows-compatible personal computers ship with a mouse that includes a scroll wheel that is activated by pressing down on the wheel and spinning the wheel. Be aware that even if your page design loads into frames or new windows that intentionally lack scrollbars, the page will be scrollable via this wheel if the document or its background image are larger than the window or frame. Users may not even be aware that they have scrolled the page (because there are no scroll bar visual clues). If this affects your design, you may need to build in a routine (via `setTimeout()`) that periodically sets the scroll of the window to 0,0.

To scroll upward, use a negative value for the second parameter:

```
window.scrollBy(0, -window.innerHeight);
```

Scrolling the document in Macintosh versions of NN4 and IE exhibits some buggy behavior. At times it appears as though you are allowed to scroll well beyond the document edges. In truth, the document has stopped at the border, but the window or frame may not have refreshed properly.

The window scroll methods are not the ones to use to produce the scrolling effect of a positioned element. That kind of animation is accomplished by adjusting `style` position properties (see Chapter 39 on the CD-ROM).

### Example

To work with the `scrollTo()` method, you can use Listings 16-31 through 16-33 (the `window.scroll()` method) but substitute `window.scrollTo()` for `window.scroll()`. The results should be the same. For `scrollBy()`, the example starts with the frameset in Listing 16-34. It loads the same content document as the `window.scroll()` example (see Listing 16-32), but the control panel (see Listing 16-35) provides input to experiment with the `scrollBy()` method.

### Listing 16-34: Frameset for ScrollBy Controller

```
<html>
  <head>
    <title>
      window.scrollBy() Method
    </title>
  </head>
  <frameset rows="50%,50%">
    <frame src="lst16-32.htm" name="display" />
    <frame src="lst16-35.htm" name="control" />
  </frameset>
</html>
```

Notice in Listing 16-35 that all references to window properties and methods are directed to the `display` frame. String values retrieved from text fields are converted to numbers with the `parseInt()` global function.

**Listing 16-35: ScrollBy Controller**

```

<html>
  <head>
    <title>
      ScrollBy Controller
    </title>

    <script type="text/javascript">
      function page(direction) {
        var pixFrame = parent.display;
        var deltaY = (pixFrame.innerHeight) ?
          pixFrame.innerHeight : pixFrame.document.body.scrollHeight;
        if (direction == "up") {
          deltaY = -deltaY;
        }
        parent.display.scrollBy(0, deltaY);
      }
      function customScroll(form) {
        parent.display.scrollBy(parseInt(form.x.value),
          parseInt(form.y.value));
      }
    </script>
  </head>
  <body>
    <b>ScrollBy Controller</b>
    <form name="custom">
      Enter an Horizontal increment <input type="text" name="x" value="0"
        size="4" /> and Vertical <input type="text" name="y" value="0"
        size="4" /> value.<br />
      Then <input type="button" value="click to scrollBy()"
        onclick="customScroll(this.form)" />
      <hr />
      <input type="button" value="PageDown" onclick="page('down')" /> <input
        type="button" value="PageUp" onclick="page('up')" />
    </form>
  </body>
</html>

```

**Related Items:** `window.pageXOffset`, `window.pageYOffset` **properties**; `window.scroll()` **method**.

`setInterval("expr", msecDelay [, language])`  
`setInterval(funcRef, msecDelay [, funcarg1, ..., funcargn])`

**Returns:** Interval ID integer.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

It is important to understand the distinction between the `setInterval()` and `setTimeout()` methods. Before the `setInterval()` method was part of JavaScript, authors replicated the behavior with `setTimeout()`, but the task often required reworking scripts a bit.

***windowObject.setInterval()***

Use `setInterval()` when your script needs to call a function or execute some expression repeatedly with a fixed time delay between calls to that function or expression. The delay is not at all like a wait state in some languages: Other processing does not halt while the delay is in effect. Typical applications include animation by moving an object around the page under controlled speed (instead of letting the JavaScript interpreter whiz the object through its path at CPU-dependent speeds). In a kiosk application, you can use `setInterval()` to advance “slides” that appear in other frames or as layers, perhaps changing the view every 10 seconds. Clock displays and countdown timers would also be suitable usage of this method (even though you see examples in this book that use the old-fashioned `setTimeout()` way to perform timer and clock functions).

In contrast, `setTimeout()` is best suited for those times when you need to carry out a function or expression one time in the future—even if that future is only a second or two away. See the discussion of the `setTimeout()` method later in this chapter for details on this application.

While the primary functionality of the `setInterval()` method is the same in all browsers, NN and IE offer some extra possibilities depending on the way you use parameters to the method. For simple invocations of this method, the same parameters work in all browsers that support the method. First, I address the parameters that all browsers have in common.

The first parameter of the `setInterval()` method is the name of the function or expression to run after the interval elapses. This item must be a quoted string. If the parameter is a function, no function arguments are allowed inside the function’s parentheses unless the arguments are literal strings (but see the next section, “Passing function parameters”).

The second parameter of this method is the number of milliseconds (1,000 per second) that JavaScript should use as the interval between invocations of the function or expression. Even though the measure is in extremely small units, don’t rely on 100 percent accuracy of the intervals. Various other internal processing delays may throw off the timing just a bit.

Just as with `setTimeout()`, `setInterval()` returns an integer value that is the ID for the interval process. That ID value lets you turn off the process with the `clearInterval()` method. That method takes the ID value as its sole parameter. This mechanism allows for the setting of multiple interval processes running, while giving your scripts the power to stop individual processes at any time without interrupting the others.

IE4+ uses the optional third parameter to specify the scripting language of the statement or function being invoked in the first parameter. As long as you are scripting exclusively in JavaScript (the same as JScript), there is no need to include this parameter.

## Passing function parameters

NN4+ provides a mechanism for easily passing evaluated parameters to a function invoked by `setInterval()`. To use this mechanism, the first parameter of `setInterval()` must not be a string, but rather a reference to the function (no trailing parentheses). The second parameter remains the amount of delay. But beginning with the third parameter, you can include evaluated function arguments as a comma-delimited list:

```
intervalID = setInterval(cycleAnimation, 500, "figure1");
```

The function definition receives those parameters in the same form as any function:

```
function cycleAnimation(elemID) {...}
```

***windowObject.setInterval()***

For use with a wider range of browsers, you can also cobble together the ability to pass parameters to a function invoked by `setInterval()`. Because the call to the other function is a string expression, you can use computed values as part of the strings via string concatenation. For example, if a function uses event handling to find the element that a user clicked (to initiate some animation sequence), that element's ID, referenced by a variable, can be passed to the function invoked by `setInterval()`:

```
function findAndCycle() {
    var elemID;
    // statements here that examine the event info
    // and extract the ID of the clicked element,
    // assigning that ID to the elemID variable
    intervalID = setInterval("cycleAnimation(" + elemID + ")", 500);
}
```

If you need to pass ever-changing parameters with each invocation of the function from `setInterval()`, look instead to using `setTimeout()` at the end of a function to invoke that very same function again.

## Example

The demonstration of the `setInterval()` method entails a two-framed environment. The framesetting document is shown in Listing 16-36.

### Listing 16-36: `setInterval()` Demonstration Frameset

```
<html>
  <head>
    <title>setInterval() Method</title>
  </head>
  <frameset rows="50%,50%">
    <frame src="lst16-37.htm" name="control" />
    <frame src="bofright.htm" name="display" />
  </frameset>
</html>
```

In the top frame is a control panel with several buttons that control the automatic scrolling of the Bill of Rights text document in the bottom frame. Listing 16-37 shows the control panel document. Many functions here control the interval, scrolling jump size, and direction, and they demonstrate several aspects of applying `setInterval()`.

Notice that in the beginning the script establishes a number of global variables. Three of them are parameters that control the scrolling; the last one is for the ID value returned by the `setInterval()` method. The script needs that value to be a global value so that a separate function can halt the scrolling with the `clearInterval()` method.

All scrolling is performed by the `autoScroll()` function. For the sake of simplicity, all controlling parameters are global variables. In this application, placement of those values in global variables helps the page restart autoscrolling with the same parameters as it had when it last ran.

Listing 16-37: **setInterval()** Control Panel

```

<html>
  <head>
    <title>ScrollBy Controller</title>
    <script type="text/javascript">
      var scrollSpeed = 500;
      var scrollJump = 1;
      var scrollDirection = "down";
      var intervalID;

      function autoScroll() {
        if (scrollDirection == "down") {
          scrollJump = Math.abs(scrollJump);
        } else if (scrollDirection == "up" && scrollJump > 0) {
          scrollJump = -scrollJump;
        }
        parent.display.scrollBy(0, scrollJump);
        if (parent.display.pageYOffset <= 0) {
          clearInterval(intervalID);
        }
      }

      function reduceInterval() {
        stopScroll();
        scrollSpeed -= 200;
        startScroll();
      }
      function increaseInterval() {
        stopScroll();
        scrollSpeed += 200;
        startScroll();
      }
      function reduceJump() {
        scrollJump -= 2;
      }
      function increaseJump() {
        scrollJump += 2;
      }
      function swapDirection() {
        scrollDirection = (scrollDirection == "down") ? "up" : "down";
      }
      function startScroll() {
        parent.display.scrollBy(0, scrollJump);
        if (intervalID) {
          clearInterval(intervalID);
        }
        intervalID = setInterval("autoScroll()",scrollSpeed);
      }
      function stopScroll() {
        clearInterval(intervalID);
      }
    </script>
  </head>
  <body onload="startScroll()">
    <b>AutoScroll by setInterval() Controller</b>
    <form name="custom">
      <input type="button" value="Start Scrolling"

```

**windowObject.setTimeout()**

```

onlick="startScroll()" /> <input type="button" value="Stop Scrolling"
onlick="stopScroll()" />
<p><input type="button" value="Shorter Time Interval"
onlick="reduceInterval()" /> <input type="button"
value="Longer Time Interval" onlick="increaseInterval()" /></p>
<p><input type="button" value="Bigger Scroll Jumps"
onlick="increaseJump()" /> <input type="button"
value="Smaller Scroll Jumps" onlick="reduceJump()" /></p>
<p><input type="button" value="Change Direction"
onlick="swapDirection()" /></p>
</form>
</body>
</html>

```

The `setInterval()` method is invoked inside the `startScroll()` function. This function initially “burps” the page by one `scrollJump` interval so that the test in `autoScroll()` for the page being scrolled all the way to the top doesn’t halt a page from scrolling before it gets started. Notice, too, that the function checks for the existence of an interval ID. If one is there, it is cleared before the new one is set. This is crucial within the design of the example page, because repeated clicking of the Start Scrolling button triggers multiple interval timers inside the browser. Only the most recent one’s ID would be stored in `intervalID`, allowing no way to clear the older ones. But this little side trip makes sure that only one interval timer is running. One of the global variables, `scrollSpeed`, is used to fill the delay parameter for `setInterval()`. To change this value on the fly, the script must stop the current interval process, change the `scrollSpeed` value, and start a new process.

The intensely repetitive nature of this application is nicely handled by the `setInterval()` method.

**Related Items:** `window.clearInterval()`, `window.setTimeout()` methods.

```

setTimeout("expr", msecDelay [, language])
setTimeout(functionRef, msecDelay [, funcarg1, ...,
funcargn])

```

**Returns:** ID value for use with `window.clearTimeout()` method.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The name of this method may be misleading, especially if you have done other kinds of programming involving timeouts. In JavaScript, a *timeout* is an amount of time (in milliseconds) before a stated expression evaluates. A timeout is not a wait or script delay, but rather a way to tell JavaScript to hold off executing a statement or function for a desired amount of time. Other statements following the one containing `setTimeout()` execute immediately.

Say that you have a Web page designed to enable users to interact with a variety of buttons or fields within a time limit (this is a Web page running at a free-standing kiosk). You can turn on the timeout of the window so that if no interaction occurs with specific buttons or fields lower in the document after, say, two minutes (120,000 milliseconds), the window reverts to the top of the document or to a help screen. To tell the window to switch off the timeout after a user does navigate within the allotted time, you need to have any button that the user interacts with call the other side of a `setTimeout()` method — the `clearTimeout()` method — to cancel the current timer. (The `clearTimeout()` method is explained earlier in this chapter.) Multiple timers can run concurrently and are completely independent of each other.

***windowObject.setTimeout()***

While the primary functionality of the `setTimeout()` method is the same in all browsers, NN and IE offer some extra possibilities depending on the way you use parameters to the method. For simple invocations of this method, the same parameters work in all browsers that support the method. I first address the parameters that all browsers have in common.

The expression that comprises the first parameter of the method `window.setTimeout()` is a quoted string that can contain either a call to any function or method or a standalone JavaScript statement. The expression evaluates after the time limit expires.

Understanding that this timeout does not halt script execution is very important. In fact, if you use a `setTimeout()` method in the middle of a script, the succeeding statements in the script execute immediately; after the delay time, the expression in the `setTimeout()` method executes. Therefore, I've found that the best way to design a timeout in a script is to plug it in as the last statement of a function: Let all other statements execute and then let the `setTimeout()` method appear to halt further execution until the timer goes off. In truth, however, although the timeout is "holding," the user is not prevented from performing other tasks. And after a timeout timer is ticking, you cannot adjust its time. Instead, clear the timeout and start a new one.

If you need to use `setTimeout()` as a delay inside a function, break the function into two parts, using the `setTimeout()` method as a bridge between the two functions. You can see an example of this in Listing 16-26, where IE needs a little delay to finish opening a new window before content can be written for it. If it weren't for the required delay, the HTML assembly and writing would have been accomplished in the same function that opens the new window.

It is not uncommon for a `setTimeout()` method to invoke the very function in which it lives. For example, if you have written a Java applet to perform some extra work for your page and you need to connect to it via LiveConnect, your scripts must wait for the applet to load and carry out its initializations. Although an `onload` event handler in the document ensures that the applet object is visible to scripts, it doesn't know whether the applet has finished its initializations. A JavaScript function that inspects the applet for a clue might need to poll the applet every 500 milliseconds until the applet sets some internal value indicating all is ready, as shown here:

```
var t;
function autoReport() {
  if (!document.myApplet.done) {
    t = setTimeout("autoReport()",500);
  } else {
    clearTimeout(t);
    // more statements using applet data //
  }
}
```

JavaScript provides no built-in equivalent for a `wait` command. The worst alternative is to devise a looping function of your own to trap script execution for a fixed amount of time. Unfortunately, this approach prevents other processes from being carried out, so you should consider reworking your code to rely on a `setTimeout()` method instead.

NN4+ provides a mechanism for passing parameters to functions invoked by `setTimeout()`. See the section "Passing function parameters" in the discussion of `window.setInterval()` for details on this and passing parameters in other browser versions.

As a note to experienced programmers, neither `setInterval()` nor `setTimeout()` spawn new threads in which to run their invoked scripts. When the timer expires and invokes a function, the process gets at the end of the queue of any pending script processing in the JavaScript execution thread.

## Example

When you load the HTML page in Listing 16-38, it triggers the `updateTime()` function, which displays the time (in hh:mm am/pm format) in the status bar. Instead of showing the seconds incrementing one by one (which may be distracting to someone trying to read the page), this function alternates the last character of the display between an asterisk and nothing, like a visual “heartbeat.”

### Listing 16-38: Display the Current Time

```
<html>
  <head>
    <title>Status Bar Clock</title>
    <script type="text/javascript">
      var flasher = false;
      // calculate current time, determine flasher state,
      // and insert time into status bar every second
      function updateTime() {
        var now = new Date();
        var theHour = now.getHours();
        var theMin = now.getMinutes();
        var theTime = "" + ((theHour > 12) ? theHour - 12 : theHour);
        theTime += ((theMin < 10) ? ":0" : ":") + theMin;
        theTime += (theHour >= 12) ? " pm" : " am";
        theTime += ((flasher) ? " " : "*");
        flasher = !flasher;
        window.status = theTime;
        // recursively call this function every second to keep timer going
        timerID = setTimeout("updateTime()",1000);
      }
    </script>
  </head>
  <body onload="updateTime()">
  </body>
</html>
```

In this function, the `setTimeout()` method works in the following way: Once the current time (including the flasher status) appears in the statusbar, the function waits approximately one second (1,000 milliseconds) before calling the same function again. You don't have to clear the `timerID` value in this application because JavaScript does it for you every time the 1,000 milliseconds elapse.

A logical question to ask is whether this application should be using `setInterval()` instead of `setTimeout()`. This is a case in which either one does the job. To use `setInterval()` here would require that the interval process start outside of the `updateTime()` function, because you need only one process running that repeatedly calls `updateTime()`. It would be a cleaner implementation in that regard, instead of the tons of timeout processes spawned by Listing 16-38. On the other hand, the application would not run in any browsers before NN4 or IE4, as Listing 16-38 does.

To demonstrate passing parameters, you can modify the `updateTime()` function to add the number of times it gets invoked to the display in the status bar. For that to work, the function must have a parameter variable so that it can catch a new value each time it is invoked by `setTimeout()`'s expression. For all browsers, the function would be modified as follows (unchanged lines are represented by the ellipsis):

**windowObject.setTimeout()**

```
function updateTime(i) {
    ...
    window.status = theTime + " (" + i + ")";
    // pass updated counter value with next call to this function
    timerID = setTimeout("updateTime(" + i+1 + ")",1000);
}
```

If you were running this exclusively in NN4+, which is likely, you could use its more convenient way of passing parameters to the function:

```
timerID = setTimeout(updateTime,1000, i+1);
```

In either case, the `onload` event handler would also have to be modified to get the ball rolling with an initial parameter:

```
onload = "updateTime(0)";
```

**Related Items:** `window.clearTimeout()`, `window.setInterval()`, `window.clearInterval()` methods.

**showHelp("URL",["contextID"])**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The IE-specific `showHelp()` method lets a script open a Winhelp window with a particular `.hlp` file. This method is specific to Win32 operating systems.

If your Winhelp file has context identifiers specified in various places, you can pass the ID as an optional second parameter. This lets the call to `showHelp()` navigate to a particular area of the `.hlp` file that applies to a specific element on the page.

See the Microsoft Visual Studio authoring environment for details on building Winhelp files.

**showModalDialog("URL"[, arguments][, features])****showModelessDialog("URL"[, arguments][, features])**

**Returns:** `returnValue` (modal) or `window` object (modeless).

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

IE4+ provides methods for opening a modal dialog box window, which always stays in front of the main browser window while making the main window inaccessible to the user. In WinIE5, Microsoft added the modeless type of dialog box, which also stays in front, but allows user access to whatever can be seen in the main window. You can load any HTML page or image that you like into the dialog box window, by providing a URL as the first parameter. Optional parameters let you pass data to a dialog box and give you considerable control over the look of the window. Unfortunately, these types of dialog box windows are not available in Navigator. At best, you can simulate modal and modeless dialog box windows, but the job is not for beginners.

The windows generated by both methods are (almost) full-fledged `window` objects with some extra properties that are useful for what these windows are intended to do. Perhaps the most important property is the `window.dialogArgument` property. This property lets a script read the data that is passed to the window via the second parameter of both `showModalDialog()` and `showModelessDialog()`. Passed data can be in any valid JavaScript data type, including objects and arrays.

***windowObject.showModalDialog()***

Displaying a modal dialog box has some ramifications for scripts. In particular, script execution in the main window halts at the statement that invokes the `showModalDialog()` method as long as the modal dialog box remains visible. Scripts are free to run in the dialog box window during this time. The instant the user closes the dialog box, execution resumes in the main window. A call to show a modeless dialog box, on the other hand, does not halt processing because scripts in the main page or dialog box window are allowed to communicate “live” with the other window.

## Retrieving dialog data

To send data back to the main window’s script from a modal dialog box window, a script in the dialog box window can set the `window.returnValue` property to any JavaScript value. It is this value that gets assigned to the variable receiving the returned value from the `setModalDialog()` method, as shown in the following example:

```
var specifications = window.showModalDialog("preferences.html");
```

The makeup and content of the returned data is in the hands of your scripts. No data is automatically returned for you.

Because a modeless dialog box coexists with your live main page window, returning data is not as straightforward as for a modal dialog box. The second parameter of the `showModelessDialog()` method takes on a special task that isn’t exactly the same as passing parameters to the dialog box. Instead, if you define a global variable or a function in the main window’s script, pass a reference to that variable or function as the second parameter to display the modeless dialog box. A script in the modeless dialog box can then point to that reference as the way to send data back to the main window before the dialog box closes (or when a user clicks something, such as an Apply button). This mechanism even allows for passing data back to a function in the main window. For example, say that the main window has a function defined as the following:

```
function receivePrefsDialogData(a, b, c) {  
    // statements to process incoming values //  
}
```

Then pass a reference to this function when opening the window:

```
dlog = showModelessDialog("prefs.html", receivePrefsDialogData);
```

A script statement in the dialog box window’s document can pick up that reference so that other statements can use it, such as a function for an Apply button’s `onclick` event handler:

```
var returnFunc = window.dialogArguments;  
...  
function apply(form) {  
    returnFunc(form.color.value, form.style.value, form.size.value);  
}
```

While this approach seems to block ways of getting parameters to the dialog box when it opens, you can always reference the dialog box in the main window’s script and set form or variable values directly:

```
dlog = showModelessDialog("prefs.html", receivePrefsDialogData);  
dlog.document.forms[0].userName.value = GetCookie("userName");
```

Be aware that a dialog box window opened with either of these methods does not maintain a connection to the originating window via the `opener` property. The `opener` property for both dialog box types is undefined.

***windowObject.showModalDialog()*****Dialog window features**

Both methods provide an optional third property that lets you specify visible features of the dialog box window. Omitting the property sets all features to their default values. All parameters are to be contained by a single string, and each parameter's name-value pair is in the form of CSS `attribute:value` syntax. Table 16-4 lists all of the window features available for the two window styles. If you are designing for compatibility with IE4, you are restricted to the modal dialog box and a subset of features, as noted in the table. All values listed as Boolean take only the following four values: `yes`, `no`, `1`, `0`.

**Table 16-4: IE Dialog Box Window Features**

<i>Feature</i>	<i>Type</i>	<i>Default</i>	<i>Description</i>
<code>center</code>	Boolean	<code>yes</code>	Whether to center dialog box (overridden by <code>dialogLeft</code> and/or <code>dialogTop</code> ).
<code>dialogHeight</code>	Length	<code>varies</code>	Outer height of the dialog box window. IE4 default length unit is <code>em</code> ; IE5+ is pixel ( <code>px</code> ).
<code>dialogLeft</code>	Integer	<code>varies</code>	Pixel offset of dialog box from left edge of screen.
<code>dialogTop</code>	Integer	<code>varies</code>	Pixel offset of dialog box from top edge of screen.
<code>dialogWidth</code>	Length	<code>varies</code>	Outer width of the dialog box window. IE4 default length unit is <code>em</code> ; IE5+ is pixel ( <code>px</code> ).
<code>edge</code>	String	<code>raised   sunken</code>	Border style.
<code>help</code>	Boolean	<code>yes</code>	Display Help icon in title bar.
<code>resizable</code>	Boolean	<code>no</code>	Dialog box is resizable (IE5+ only).
<code>status</code>	Boolean	<code>varies</code>	Display status bar at window bottom (IE5+ only). Default is <code>yes</code> for untrusted dialog box; <code>no</code> for trusted dialog box.

The CSS-type of syntax for these features lets you string multiple features together by separating each pair with a semicolon within the string. For example:

```
var dlogData = showModalDialog("prefs.html", defaultData,
    "dialogHeight:300px; dialogWidth:460px; help:no");
```

Although not explicitly listed as one of the window features, scroll bars are normally displayed in the window if the content exceeds the size assigned or available to the dialog box. If you don't want scroll bars to appear, have your dialog box document's script set the `document.body.scroll` property to `false` as the page opens.

**Dialog cautions**

A potential user problem to watch for is that typically a dialog box window does not open until the HTML file for the dialog box has loaded. Therefore, if there is substantial delay before a complex document loads, the user does not see any action indicating that something is happening. You may want to experiment with setting the `cursor` stylesheet property and restoring it when the dialog box's document loads.

One of the reasons I call a dialog box window an (almost) window object is that some normal behavior is not available in IE4. For example, if you load a frameset into the dialog box

**`windowObject.showModalDialog()`**

window, scripts in documents within the frames cannot refer back to the parent document to access variables or parent window methods. Thus, a button in a frame of an IE4 modal dialog box cannot issue `parent.close()` to close the dialog box. This anomaly is repaired in IE5+.

## Example

To demonstrate the two styles of dialog boxes, I have implemented the same functionality (setting some session visual preferences) for both modal and modeless dialog boxes. This tactic shows you how to pass data back and forth between the main page and both styles of dialog box windows.

The first example demonstrates how to use a modal dialog box. In the process, data is passed into the dialog box window and values are returned. Listing 16-39 is the HTML and scripting for the main page. A button's `onclick` event handler invokes a function that opens the modal dialog box. The dialog box's document (see Listing 16-40) contains several form elements for entering a user name and selecting a few color styles for the main page. Data from the dialog is fashioned into an array to be sent back to the main window. That array is initially assigned to a local variable, `prefs`, as the dialog box closes. If the user cancels the dialog box, the returned value is an empty string, so nothing more in `getPrefsData()` executes. But when the user clicks OK, the array comes back. Each of the array items is read and assigned to its respective form value or style property. These values are also preserved in the global `currPrefs` array. This allows the settings to be sent to the modal dialog box (as the second parameter to `showModalDialog()`) the next time the dialog box is opened.

### Listing 16-39: Main Page for `showModalDialog()`

```
<html>
  <head>
    <title>window.setModalDialog() Method</title>
    <script type="text/javascript">
      var currPrefs = new Array();

      function getPrefsData() {
        var prefs = showModalDialog("lst16-40.htm", currPrefs,
          "dialogWidth:400px; dialogHeight:300px");
        if (prefs) {
          if (prefs["name"]) {
            document.all.firstName.innerText = prefs["name"];
            currPrefs["name"] = prefs["name"];
          }
          if (prefs["bgColor"]) {
            document.body.style.backgroundColor = prefs["bgColor"];
            currPrefs["bgColor"] = prefs["bgColor"];
          }
          if (prefs["textColor"]) {
            document.body.style.color = prefs["textColor"];
            currPrefs["textColor"] = prefs["textColor"];
          }
          if (prefs["h1Size"]) {
            document.all.welcomeHeader.style.fontSize = prefs["h1Size"];
            currPrefs["h1Size"] = prefs["h1Size"];
          }
        }
      }
    </script>
  </head>
</html>
```

*Continued*

***windowObject.showModalDialog()*****Listing 16-39 (continued)**

```

        function init() {
            document.all.firstName.innerText = "friend";
        }
    </script>
</head>
<body bgcolor="#EEEEEE" style="margin:20px" onload="init()">
    <h1>window.setModalDialog() Method</h1>
    <hr />
    <h2 id="welcomeHeader">Welcome, <span id="firstName">&nbsp;</span>!</h2>
    <hr />
    <p>Use this button to set style preferences for this page: <button
        id="prefsButton" onclick="getPrefsData()">Preferences</button></p>
</body>
</html>

```

The dialog box's document, shown in Listing 16-40, is responsible for reading the incoming data (and setting the form elements accordingly) and assembling form data for return to the main window's script. Notice when you load the example that the `title` element of the dialog box's document appears in the dialog box window's title bar.

When the page loads into the dialog box window, the `init()` function examines the `window.dialogArguments` property. If it has any data, the data is used to preset the form elements to mirror the current settings of the main page. A utility function, `setSelected()`, preselects the option of a `select` element to match the current settings.

Buttons at the bottom of the page are explicitly positioned to be at the lower-right corner of the window. Each button invokes a function to do what is needed to close the dialog box. In the case of the OK button, the `handleOK()` function sets the `window.returnValue` property to the data that come back from the `getFormData()` function. This latter function reads the form element values and packages them in an array using the form elements' names as array indices. This helps keep everything straight back in the main window's script, which uses the index names, and is therefore not dependent upon the precise sequence of the form elements in the dialog box window.

**Listing 16-40: Document for the Modal Dialog**

```

<html>
  <head>
    <title>User Preferences</title>
    <script type="text/javascript">
      // Close the dialog
      function closeme() {
          window.close();
      }

      // Handle click of OK button
      function handleOK() {
          window.returnValue = getFormData();
          closeme();
      }

      // Handle click of Cancel button

```

***windowObject.showModalDialog()***

```

function handleCancel() {
    window.returnValue = "";
    closeme();
}

// Generic function converts form element name-value pairs
// into an array
function getFormData() {
    var form = document.prefs;
    var returnedData = new Array();
    // Harvest values for each type of form element
    for (var i = 0; i < form.elements.length; i++) {
        if (form.elements[i].type == "text") {
            returnedData[form.elements[i].name] = form.elements[i].value;
        } else if (form.elements[i].type.indexOf("select") != -1) {
            returnedData[form.elements[i].name] = form.elements[i].
                options[form.elements[i].selectedIndex].value;
        } else if (form.elements[i].type == "radio") {
            returnedData[form.elements[i].name] = form.elements[i].value;
        } else if (form.elements[i].type == "checkbox") {
            returnedData[form.elements[i].name] = form.elements[i].value;
        } else
            continue;
    }
    return returnedData;
}

// Initialize by setting form elements from passed data
function init() {
    if (window.dialogArguments) {
        var args = window.dialogArguments;
        var form = document.prefs;
        if (args["name"]) {
            form.name.value = args["name"];
        }
        if (args["bgColor"]) {
            setSelected(form.bgColor, args["bgColor"]);
        }
        if (args["textColor"]) {
            setSelected(form.textColor, args["textColor"]);
        }
        if (args["h1Size"]) {
            setSelected(form.h1Size, args["h1Size"]);
        }
    }
}

// Utility function to set a SELECT element to one value
function setSelected(select, value) {
    for (var i = 0; i < select.options.length; i++) {
        if (select.options[i].value == value) {
            select.selectedIndex = i;
            break;
        }
    }
    return;
}

// Utility function to accept a press of the

      style="width:80px" onclick="handleCancel()">Cancel</button>
  </div>
</body>
</html>

```

***windowObject.showModalDialog()***

One last convenience feature of the dialog box window is the `onkeypress` event handler in the text box. The function it invokes looks for the Enter key. If that key is pressed while the box has focus, the same `handleOK()` function is invoked, as if the user had clicked the OK button. This feature makes the dialog box behave as if the OK button is an automatic default, just as “real” dialog boxes.

You should observe several important structural changes that were made to turn the modal approach into a modeless one. Listing 16-41 shows the version of the main window modified for use with a modeless dialog box. Another global variable, `prefsDlog`, is initialized to eventually store the reference to the modeless window returned by the `showModelessWindow()` method. The variable gets used to invoke the `init()` function inside the modeless dialog box, but also as conditions in an `if` construction surrounding the generation of the dialog box. The reason this is needed is to prevent multiple instances of the dialog box being created (the button is still alive while the modeless window is showing). The dialog box won't be created again as long as there is a value in `prefsDlog`, and the dialog box window has not been closed (picking up the `window.closed` property of the dialog box window).

The `showModelessDialog()` method's second parameter is a reference to the function in the main window that updates the main document. As you see in a moment, that function is invoked from the dialog box when the user clicks the OK or Apply buttons.

**Listing 16-41: Main Page for `showModelessDialog()`**

```
<html>
  <head>
    <title>window.setModelessDialog() Method</title>
    <script type="text/javascript">
      var currPrefs = new Array();
      var prefsDlog;
      function getPrefsData() {
        if (!prefsDlog || prefsDlog.closed) {
          prefsDlog = showModelessDialog("1st16-42.htm", setPrefs,
            "dialogWidth:400px; dialogHeight:300px");
          prefsDlog.init(currPrefs);
        }
      }

      function setPrefs(prefs) {
        if (prefs["bgColor"]) {
          document.body.style.backgroundColor = prefs["bgColor"];
          currPrefs["bgColor"] = prefs["bgColor"];
        }
        if (prefs["textColor"]) {
          document.body.style.color = prefs["textColor"];
          currPrefs["textColor"] = prefs["textColor"];
        }
        if (prefs["h1Size"]) {
          document.all.welcomeHeader.style.fontSize = prefs["h1Size"];
          currPrefs["h1Size"] = prefs["h1Size"];
        }
        if (prefs["name"]) {
          document.all.firstName.innerText = prefs["name"];
          currPrefs["name"] = prefs["name"];
        }
      }
    </script>
  </head>
</html>
```

*Continued*

***windowObject.showModalDialog()*****Listing 16-41 (continued)**

```

        function init() {
            document.all.firstName.innerText = "friend";
        }
    </script>
</head>
<body bgcolor="#EEEEEE" style="margin:20px" onload="init()">
    <h1>window.setModelessDialog() Method</h1>
    <hr />
    <h2 id="welcomeHeader">Welcome, <span id="firstName">&nbsp;</span>!</h2>
    <hr />
    <p>Use this button to set style preferences for this page: <button
        id="prefsButton" onclick="getPrefsData()">Preferences</button></p>
</body>
</html>

```

Changes to the dialog box window document for a modeless version (see Listing 16-42) are rather limited. A new button is added to the bottom of the screen for an Apply button. As in many dialog box windows you see in Microsoft products, the Apply button lets current settings in dialog boxes be applied to the current document but without closing the dialog box. This approach makes experimenting with settings easier.

The Apply button invokes a `handleApply()` function, which works the same as `handleOK()`, except the dialog box is not closed. But these two functions communicate back to the main window differently than a modal dialog box. The main window's processing function is passed as the second parameter of `showModelessDialog()` and is available as the `window.dialogArguments` property in the dialog box window's script. That function reference is assigned to a local variable in both functions, and the remote function is invoked, passing the results of the `getFormData()` function as parameter values back to the main window.

**Listing 16-42: Document for the Modeless Dialog Box**

```

  <head>
    <title>User Preferences</title>
    <script type="text/javascript">
      // Close the dialog
      function closeme() {
          window.close();
      }

      // Handle click of OK button
      function handleOK() {
          var returnFunc = window.dialogArguments;
          returnFunc(getFormData());
          closeme();
      }

      // Handle click of Apply button
      function handleApply() {
          var returnFunc = window.dialogArguments;
          returnFunc(getFormData());
      }
    </script>
  </head>
  <body>
    <div style="border: 1px solid black; padding: 5px;">
      <div style="border-bottom: 1px solid black; padding-bottom: 5px;">
        <input type="text" value="Name" />
      </div>
      <div style="padding: 5px 5px 5px 100px;">
        <input type="button" value="OK" />
        <input type="button" value="Apply" />
        <input type="button" value="Cancel" />
      </div>
    </div>
  </body>
</html>

```

***windowObject.showModalDialog()***

```

// Handle click of Cancel button
function handleCancel() {
    window.returnValue = "";
    closeme();
}

// Generic function converts form element name-value pairs
// into an array
function getFormData() {
    var form = document.prefs;
    var returnedData = new Array();
    // Harvest values for each type of form element
    for (var i = 0; i < form.elements.length; i++) {
        if (form.elements[i].type == "text") {
            returnedData[form.elements[i].name] = form.elements[i].value;
        } else if (form.elements[i].type.indexOf("select") != -1) {
            returnedData[form.elements[i].name] = form.elements[i].
                options[form.elements[i].selectedIndex].value;
        } else if (form.elements[i].type == "radio") {
            returnedData[form.elements[i].name] = form.elements[i].value;
        } else if (form.elements[i].type == "checkbox") {
            returnedData[form.elements[i].name] = form.elements[i].value;
        } else
            continue;

---

The biggest design challenge you probably face with respect to these windows is deciding between a modal and modeless dialog box style. Some designers insist that modality has no place in a graphical user interface; others say that there are times when you need to focus the user on a very specific task before any further processing can take place. That's where a modal dialog box makes perfect sense.

**Related Items:** `window.open()` method.

## sizeToContent()

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The NN6+ `window.sizeToContent()` method can be a valuable aid in making sure that a window (especially a subwindow) is sized for the optimum display of the window's content. But you must also be cautious with this method, or it will do more harm than good.

Invoking the `sizeToContent()` method resizes the window so that all content is visible. Concerns about variations in OS-specific rendering become a thing of the past. Naturally, you should perform this action only on a window whose content at the most occupies a space smaller than the smallest video monitor running your code (typically 640 × 480 pixels, but conceivably much smaller for future versions of the browser used on handheld computers).

You can get the user in trouble, however, if you invoke the method twice on the same window that contains the resizing script. This action can cause the window to expand to a size that may exceed the pixel size of the user's video monitor. Successive invocations fail to cinch up the window's size to its content again. Multiple invocations are safe, however, on subwindows when the resizing script statement is in the main window.

## Example

Use The Evaluator (Chapter 13) in NN6 to try the `sizeToContent()` method. Assuming that you are running The Evaluator from the `Chap13` directory on the CD-ROM (or the directory copied as-is to your hard disk), you can open a subwindow with one of the other files in the directory, and then size the subwindow. Enter the following statements into the top text box:

```
a = window.open("lst13-02.htm", "")
a.sizeToContent()
```

The resized subwindow is at the minimum recommended width for a browser window, and at a height tall enough to display the little bit of content in the document.

**Related Item:** `window.resizeTo()` method.

## stop()

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

The Navigator-specific `stop()` method offers a scripted equivalent of clicking the Stop button in the toolbar. Availability of this method allows you to create your own toolbar on your page and hide the toolbar (in the main window with signed scripts or in a subwindow).

**windowObject.stop**

For example, if you have an image representing the Stop button in your page, you can surround it with a link whose action stops loading, as in the following:

```
<a href="javascript: void stop()"></a>
```

A script cannot stop its own document from loading, but it can stop loading of another frame or window. Similarly, if the current document dynamically loads a new image or a multimedia MIME type file as a separate action, the `stop()` method can halt that process. Even though the `stop()` method is a window method, it is not tied to any specific window or frame: Stop means stop.

**Related Items:** `window.back()`, `window.find()`, `window.forward()`, `window.home()`, `window.print()` methods.

## Event handlers

`onafterprint`

`onbeforeprint`

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

Each of these event handlers fires after the user has clicked the OK button in IE's Print dialog box. This goes for printing that is invoked manually (via menus and browser shortcut buttons) and the `window.print()` method.

Although printing is usually WYSIWYG, it is conceivable that you may want the printed version of a document to display more or less of the document than is showing at that instant. For example, you may have a special copyright notice that you want printed at the end of a page whenever it goes to the printer. In that case, the element with that content can have its `display` stylesheet property set to `none` when the page loads. Before the document is sent to the printer, a script needs to adjust that style property to display the element as a block item; after printing, have your script revert the setting to `none`.

Immediately after the user clicks the OK button in the Print dialog box, the `onbeforeprint` event handler fires. As soon as the page(s) is sent to the printer or spooler, the `onafterprint` event handler fires.

### Example

The following script fragment assumes that the page includes a `div` element whose stylesheet includes a setting of `display:none` as the page loads. Somewhere in the Head, the print-related event handlers are set as properties:

```
function showPrintCopyright() {
    document.all.printCopyright.style.display = "block";
}
function hidePrintCopyright() {
    document.all.printCopyright.style.display = "none";
}
window.onbeforeprint = showPrintCopyright;
window.onafterprint = hidePrintCopyright;
```

`onbeforeunload`

**Compatibility:** WinIE4+, MacIE5+, NN-, Moz-, Safari-

Any user or scripted action that normally forces the current page to be unloaded or replaced causes the `onbeforeunload` event handler to fire. Unlike the `onunload` event handler,

however, `onbeforeunload` is a bit better behaved when it comes to allowing complex scripts to finish before the actual unloading takes place. Moreover, you can assign a string value to the `event.returnValue` property in the event handler function. That string becomes part of a message in an alert window that gives the user a chance to stay on the page. If the user agrees to stay, the page does not unload, and any action that caused the potential replacement is cancelled.

## Example

The simple page in Listing 16-43 shows you how to give the user a chance to stay on the page.

### Listing 16-43: Using the `onbeforeunload` Event Handler

```
<html>
  <head>
    <title>onbeforeunload Event Handler</title>
    <script type="text/javascript">
      function verifyClose() {
        event.returnValue =
          "We really like you and hope you will stay longer.";
      }

      window.onbeforeunload = verifyClose;
    </script>
  </head>
  <body>
    <h1>onbeforeunload Event Handler</h1>
    <hr />
    <p>Use this button to navigate to the previous page: <button id="go"
      onclick="history.back()">Go Back</button></p>
  </body>
</html>
```

**Related Items:** `onunload` event handler.

## ondragdrop

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

With closer integration between the computer desktop and browsers these days, it is increasingly possible that shortcuts (or aliases) to Web URLs can be represented on our desktops and other kinds of documents. With NN4 (only), you can script awareness of dragging and dropping of such items onto the browser window. The window's `dragdrop` event fires whenever a user drops a file or other URL-filled object onto the window.

## Example

You can add an `ondragdrop` event handler to the `<body>` tag of your document and pass along the event object that has some juicy tidbits about the drop: the object on which the item was dropped and the URL of the item. The function called by the event handler receives the event object information and can process it from there. Because this event is a window event, you don't have to turn on `window.captureEvents()` to get the window to feel the effect of the event.

**windowObject.ondragdrop**

The juiciest tidbit of the event, the URL of the dropped item, can be retrieved only with a signed script and the user's permission (see Chapter 46 on the CD-ROM). Listing 16-44 shows a simple document that reveals the URL and screen location, as derived from the event object passed with the `dragdrop` event. You must have codebase principals turned on to get the full advantage of this listing, and it works best with Windows.

**Listing 16-44: Analyzing a dragdrop Event**

```
<html>
  <head>
    <title>DragDrop Event</title>
    <script type="text/javascript">
      function reportDrag(e) {
        var msg = "You dropped the file:\n";
        netscape.security.PrivilegeManager.enablePrivilege(
          "UniversalBrowserRead");
        msg += e.data;
        netscape.security.PrivilegeManager.disablePrivilege(
          "UniversalBrowserRead");
        msg += "\nonto the window object at screen location (";
        msg += e.screenX + ", " + e.screenY + ").";
        alert(msg);
        return false;
      }
    </script>
  </head>
  <body ondragdrop="return reportDrag(event)">
    <b>Drag and Drop a file onto this window</b>
  </body>
</html>
```

The `dragdrop` event is the only one that uses the `data` property of the NN4 event object. That property contains the URL. The `target` property reveals only the `window` object, but you can access the event object's `screenX` and `screenY` properties to get the location of the mouse release.

**Related Items:** event object (Chapter 25).

**onerror**

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

(See the discussion of the `window.onerror` property earlier in this chapter.)

**onhelp**

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The generic `onhelp` event handler is discussed in Chapter 15, but it also fires when the user activates the context-sensitive help within a modal or modeless dialog box. In the latter case, a user can click the Help icon in the dialog box's title bar, at which time the cursor changes to a question mark. The user can then click on any element in the window. At that second click, the `onhelp` event handler fires, and the event object contains information about the element clicked (the `event.srcElement` is a reference to the specific element), allowing a script to supply help about that element.

To prevent the browser's built-in help window from appearing, the event handler must evaluate to return `false` (IE4+) or set the `event.returnValue` property to `false` (IE5+).

### Example

The following script fragment can be embedded in the IE5+-only modeless dialog box code in Listing 16-44 to provide context-sensitive help within the dialog box. Help messages for only two of the form elements are shown here, but in a real application you add messages for the rest.

```
function showHelp() {
    switch (event.srcElement.name) {
        case "bgColor" :
            alert("Choose a color for the main window's background.");
            break;
        case "name" :
            alert("Enter your first name for a friendly greeting.");
            break;
        default :
            alert("Make preference settings for the main page styles.");
    }
    event.returnValue = false;
}
window.onhelp = showHelp
```

Because this page's help focuses on form elements, the `switch` construction cases are based on the `name` properties of the form elements. For other kinds of pages, the `id` properties may be more appropriate.

**Related Items:** event object (Chapter 25); switch construction (Chapter 31).

## onload

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `onload` event handler fires in the current window at the end of the document loading process (after all text and image elements have been transferred from the source file server to the browser, and after all plug-ins and Java applets have loaded and started running). At that point, the browser's memory contains all the objects and script components in the document that the browser can possibly know about.

The `onload` handler is an attribute of a `<body>` tag for a single-frame document or of the `<frameset>` tag for the top window of a multiple-frame document. When the handler is an attribute of a `<frameset>` tag, the event triggers only after all frames defined by that frameset have completely loaded.

Use either of the following scenarios to insert an `onload` handler into a document:

```
<html>
  <head>
  </head>
  <body [other attributes] onload="statementOrFunction">
    [body content]
  </body>
</html>
```

```
<html>
  <head>
  </head>
  <frameset [other attributes] onload="statementOrFunction">
```

**windowObject.onload**

```

    <frame>frame specifications</frame>
  </frameset>
</html>

```

This handler has a special capability when part of a frameset definition: The handler won't fire until the `onload` event handlers of all child frames in the frameset have fired. Therefore, if some initialization scripts depend on components existing in other frames, trigger them from the frameset's `onload` event handler. This brings up a good general rule of thumb for writing JavaScript: Scripts that execute during a document's loading should contribute to the process of generating the document and its objects. To act immediately on those objects, design additional functions that are called by the `onload` event handler for that window.

The type of operations suited for an `onload` event handler are those that can run quickly and without user intervention. Users shouldn't be penalized by having to wait for considerable post-loading activity to finish before they can interact with your pages. At no time should you present a modal dialog box as part of an `onload` handler. Users who design macros on their machines to visit sites unattended may get hung up on a page that automatically displays an alert, confirm, or prompt dialog box. On the other hand, an operation such as setting the `window.defaultStatus` property is a perfect candidate for an `onload` event handler, as are initializing event handlers as properties of element objects in the page.

**Note**

Browsers equipped with pop-up window blockers ignore all `window.open()` method calls in `onload` event handler functions.

**Related Items:** `onunload` event handler; `window.defaultStatus` property.

**onmove**

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

If a user drags an NN4 window around the screen, the action triggers a `move` event for the window object. When you assign a function to the event (for example, `window.onmove = handleMoves`), the function receives an event object whose `screenX` and `screenY` properties reveal the coordinate point (relative to the entire screen) of the top-left corner of the window after the move.

**Related Items:** event object (Chapter 25).

**onresize**

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari-

If a user resizes a window, the action causes the `onresize` event handler to fire for the window object. When you assign a function to the event (for example, `window.onresize = handleResizes`), the NN event object conveys `width` and `height` properties that reveal the outer width and height of the entire window. A window resize should not reload the document such that an `onload` event handler fires (although some early Navigator versions did fire the extra event).

**Note**

Resizing the Navigator 4 browser window, especially if that window contains positioned elements (as `div` or `layer` elements), causes serious problems not only for the content, but also for scripts in the page. Content can get jumbled, and scripts may disappear. Your only hope is to use an `onresize` event handler to reload the page and get back to a known point. For some ideas on handling this problem, see the article at [http://developer.netscape.com/viewsource/goodman\\_resize/goodman\\_resize.html](http://developer.netscape.com/viewsource/goodman_resize/goodman_resize.html). One point not covered in the article is that the Windows version of NN4 issues a `resize` event when scrollbars appear

***windowObject.onunload***

in a window. This `resize` event can make any reload-on-resize strategy turn into an infinite loop. To guard against this, you have to inspect the `window.innerWidth` and `window.innerHeight` properties to see if the window has really changed (the property values don't change when the scrollbars appear). Here is an example of script statements that go in the Head script of a page that has to worry about this problem in NN4:

```
var Nav4 = (navigator.appName == "Netscape" &&
  parseInt(navigator.appVersion) == 4);
if (Nav4) {
  var loadWidth = window.innerWidth;
  var loadHeight = window.innerHeight;
}

function restore() {
  if (loadWidth != window.innerWidth || loadHeight !=
  window.innerHeight) {
    history.go(0);
  }
}

if (Nav4)
  window.onresize = restore;
```

This problem does not occur in NN6+ or Mozilla-based browsers.

**Related Items:** event object (Chapter 25).

## onunload

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

An `unload` event reaches the current window just before a document is cleared from view. The most common ways windows are cleared are when new HTML documents are loaded into them or when a script begins writing new HTML on the fly for the window or frame.

Limit the extent of the `onunload` event handler to quick operations that do not inhibit the transition from one document to another. Do not invoke any methods that display dialog boxes. You specify `onunload` event handlers in the same places in an HTML document as the `onload` handlers: as a `<body>` tag attribute for a single-frame window or as a `<frameset>` tag attribute for a multiframe window. Both `onload` and `onunload` event handlers can appear in the same `<body>` or `<frameset>` tag without causing problems. The `onunload` event handler merely stays safely tucked away in the browser's memory, waiting for the `unload` event to arrive for processing as the document gets ready to clear the window.

Let me pass along one caution about the `onunload` event handler. Even though the event fires before the document goes away, don't burden the event handler with time-consuming tasks, such as generating new objects or submitting a form. The document will probably go away before the function completes, leaving the function looking for objects and values that no longer exist. The best defense is to keep your `onunload` event handler processing to a minimum.

**Note**

Browsers equipped with pop-up window blockers ignore all `window.open()` method calls in `onunload` event handler functions.

**Related Items:** `onload` event handler.

## frame

## frame Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
allowTransparency		
borderColor		
contentDocument		
contentWindow		
frameBorder		
height		
longDesc		
marginHeight		
marginWidth		
name		
noResize		
scrolling		
src		
width		

## Syntax

Accessing properties or methods of a frame element object from a frameset:

```
(IE4+)    document.all.frameID. property | method([parameters])
(IE5+/W3C) document.getElementById("frameID"). property | method([parameters])
```

Accessing properties or methods of a frame element from a frame document:

```
(IE4+)    parent.document.all.frameID. property | method([parameters])
(IE5+/W3C) parent.document.getElementById("frameID"). property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

As noted in the opening section of this chapter, a frame element object is distinct from the frame object that acts as a window object in a document hierarchy. The frame element object is available to scripts only when all HTML elements are exposed in the object model, as in IE4+, NN6+, Mozilla, and Safari.

Because the frame element object is an HTML element, it shares the properties, methods, and event handlers of all HTML elements, as described in Chapter 15. By and large, you access the frame element object to set or modify an attribute value in the <frame> tag. If so, you simplify matters if you assign an identifier to the id attribute of the tag. Your tag still needs a name attribute if your scripts refer to frames through the original object model (a parent.frameName reference). While there is no law against using the same identifier for

both `name` and `id` attributes, using different names to prevent potential conflict with references in browsers that recognize both attributes is best.

To modify the dimensions of a frame, you must go the `frameset` element object that defines the `cols` and `rows` attributes for the frameset. These properties can be modified on the fly in IE4+ and W3C DOM-compatible browsers.

## Properties

### allowTransparency

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE6+, MacIE-, NN-, Moz-, Safari-

The `allowTransparency` property indicates whether or not the frame's background is transparent. This property applies primarily to the `iframe` object, since framesets don't have background colors or images to show through a transparent frame.

### borderColor

**Value:** Hexadecimal triplet or color name string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

If a frame displays a border (as determined by the `frameborder` attribute of the `frame` element or `border` attribute of the `frameset` element), it can have a color set separately from the rest of the frames. The initial color (if different from the rest of the frameset) is usually set by the `borderColor` attribute of the `<frame>` tag. After that, scripts can modify settings as needed.

Modifying a single frame's border can be risky at times, depending on your color combinations. In practice, different browsers appear to follow different rules when it comes to negotiating conflicts or defining just how far a single frame's border extends into the border space. Color changes to individual frame borders do not always render. Verify your designs on as many browsers and operating system variations as you can to test your combinations.

## Example

Although you may experience problems changing the color of a single frame border, the W3C DOM syntax would look like the following if the script were inside the framesetting document:

```
document.getElementById("contentsFrame").borderColor = "red";
```

The IE-only version would be:

```
document.all["contentsFrame"].borderColor = "red";
```

These examples assume the frame name arrives to a script function as a string. If the script is executing in one of the frames of the frameset, add a reference to `parent` in the preceding statements.

**Related Items:** `frame.frameBorder`, `frameset.frameBorder` properties.

### contentDocument

**Value:** document object reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `contentDocument` property of a frame element object is nothing more than a reference to the document contained by that frame. This property bridges the gap between the frame

**frame.contentDocument**

element object and the frame object. Both of these objects contain the same `document` object, but from a scripting point of view, references most typically use the frame object to reach the document inside a frame, while the `frame` element is used to access properties equated with the `frame` tag's attributes. But if your script finds that it has a reference to the frame element object, you can use the `contentDocument` property to get a valid reference to the document, and therefore any other content of the frame.

**Example**

A framesetting document script might be using the ID of a `frame` element to read or adjust one of the element properties, and then need to perform some action on the content of the page through its `document` object. You can get the reference to the `document` object via a statement, such as the following:

```
var doc = document.getElementById("Frame3").contentDocument;
```

Then your script can, for example, dive into a form in the document:

```
var val = doc.mainForm.entry.value;
```

**Related Items:** `contentWindow` property; `document` object.

**contentWindow**

**Value:** `document` object reference.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN7+, Moz1+, Safari-

The `contentWindow` property of a `frame` element object is simply a reference to the window generated by that frame. This property provides access to the frame's window, which can then be used to reach the document inside the frame.

**Example**

You can get the reference to the window object associated with a frame via a statement, such as the following:

```
var win = document.getElementById("Frame3").contentWindow;
```

**Related Items:** `window` object.

**frameBorder**

**Value:** `yes` | `no` | `1` | `0` as strings.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `frameBorder` property offers scripted access to a `frame` element object's `frameborder` attribute setting. IE4+ does not respond well to modifying this property after the page has loaded.

Values for the `frameBorder` property are strings that substitute for Boolean values. Values `yes` or `1` mean that the border is (supposed to be) turned on; `no` or `0` turn off the border.

**Example**

The default value for the `frameBorder` property is `yes`. You can use this setting to create a toggle script (which, unfortunately, does not change the appearance in IE). The W3C-compatible version looks like the following:

**frame.longDesc**

```
function toggleFrameScroll(frameID) {
    var theFrame = document.getElementById(frameID);
    if (theFrame.frameBorder == "yes") {
        theFrame.frameBorder = "no";
    } else {
        theFrame.frameBorder = "yes";
    }
}
```

**Related Items:** `frameset.frameBorder` properties.

**height****width**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

IE4+ lets you retrieve the height and width of a frame element object. These values are not necessarily the same as the `document.body.clientHeight` and `document.body.clientWidth`, because the frame dimensions include chrome associated with the frame, such as scrollbars. These values are read-only. If you need to modify the dimensions of a frame, do so via the `frameset` element object's `rows` and/or `cols` properties. Reading integer values for a frame's height and width properties is much easier than trying to parse the `rows` and `cols` string properties.

**Example**

The following fragment assumes a `frameset` defined with two frames set up as two columns within the `frameset`. The statements here live in the `framesetting` document. They retrieve the current width of the left frame and increase the width of that frame by 10 percent. Syntax shown here is for the W3C DOM, but can be easily adapted to IE-only terminology.

```
var frameWidth = document.getElementById("leftFrame").width;
document.getElementById("mainFrameset").cols =
    (Math.round(frameWidth * 1.1)) + ",*";
```

Notice how the numeric value of the existing frame width is first increased by 10 percent and then concatenated to the rest of the string property assigned to the `frameset`'s `cols` property. The asterisk after the comma means that the browser should figure out the remaining width and assign it to the right-hand frame.

**Related Items:** `frameset` object.

**longDesc**

**Value:** URL string.

Read/Write

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `longDesc` property is the scripted equivalent of the `longdesc` attribute of the `<frame>` tag. This HTML 4.0 attribute is intended to provide browsers with a URL to a document that contains a long description of the element. Future browsers can use this feature to provide information about the frame for visually impaired site visitors.

**frame.marginHeight**

marginHeight

marginWidth

**Value:** Integer.

Read/Write

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

Browsers tend to automatically insert content within a frame by adding a margin between the content and the edge of the frame. These values are represented by the `marginHeight` (top and bottom edges) and `marginWidth` (left and right edges) properties. Although the properties are not read-only, changing the values after the frameset has loaded does not alter the appearance of the document in the frame. If you need to alter the margin(s) of a document inside a frame, adjust the `document.body.style` margin properties.

Also be aware that although the default values of these properties are empty (meaning when no `marginheight` or `marginwidth` attributes are set for the `<frame>` tag), margins are built into the page. The precise pixel count of those margins varies with operating system.

**Related Items:** `style` object (Chapter 26).**name****Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `name` property is the identifier associated with the frame for use as a frame reference. Scripts can reference the frame through the `name` property (e.g., `top.frames["myFrame"]`), which is typically assigned via the `name` attribute.

**noResize****Value:** Boolean.

Read/Write

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

Web designers commonly fix their framesets so that users cannot resize the frames (by dragging any divider border between frames). The `noResize` property lets you read and adjust that behavior of a frame after the page has loaded. For example, during some part of the interaction with a user on a page, you may allow the user to modify the frame size manually while in a certain mode. Or you may grant the user one chance to resize the frame. When the `onresize` event handler fires, a script sets the `noResize` property of the frame element to `false`. If you turn off resizing for a frame, all edges of the frame become non-resizable, regardless of the `noResize` value setting of adjacent frames. Turning off resizability has no effect on the ability of scripts to alter the sizes of frames via the frameset element object's `cols` or `rows` properties.

**Example**

The following statement turns off the ability for a frame to be resized:

```
parent.document.getElementById("myFrame1").noResize = true;
```

Because of the negative nature of the property name, it may be difficult to keep the logic straight (setting `noResize` to `true` means that resizability is turned off). Keep a watchful eye on your Boolean values.

**Related Items:** `frameset.cols`, `frameset.rows` properties.

## scrolling

**Value:** yes | no | 1 | 0 as strings.

Read/Write

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `scrolling` property lets scripts turn scrollbars on and off inside a single frame of a frameset. By default, `scrolling` is turned on unless overridden by the `scroll` attribute of the `<frame>` tag.

Values for the `scrolling` property are strings that substitute for Boolean values. Values `yes` or `1` mean that scrollbars are visible (provided there is more content than can be viewed without scrolling); `no` or `0` hide scrollbars in the frame. IE4+ also recognizes (and sets as default) the `auto` value.

**Note**

Although this property is read/write, changing its value by script does not alter a frame's appearance in WinIE5.5+, Mozilla browsers, or Safari.

**Example**

Listing 16-45 produces a frameset consisting of eight frames. The content for the frames is generated by a script within the frameset (via the `fillFrame()` function). Event handlers (`onclick`) in the `Body` of each frame invoke the `toggleFrameScroll()` function. Both ways of referencing the frame element object are shown, with the IE-only version commented out.

In the `toggleFrameScroll()` function, the `if` condition checks whether the property is set to something other than `no`. This allows the condition to evaluate to `true` if the property is set to either `auto` (the first time) or `yes` (as set by the function). Note that the scrollbars don't disappear from the frames in IE5.5+, NN6+, Moz, or Safari.

**Listing 16-45: Controlling the frame.scrolling Property**

```

<html>
  <head>
    <title>frame.scrolling Property</title>
    <script type="text/javascript">
      function toggleFrameScroll(frameID) {
        // IE5+/W3C version
        var theFrame = document.getElementById(frameID);
        // IE4+ version
        // var theFrame = document.all[frameID];

        if (theFrame.scrolling != "no") {
          theFrame.scrolling = "no";
        } else {
          theFrame.scrolling = "yes";
        }
      }

      // generate content for each frame
      function fillFrame(frameID) {
        var page = "<html><body onclick='parent.toggleFrameScroll(\"" +
          frameID + "\"" + "'><span style='font-size:24pt'>";
        page += "<p>This frame has the ID of:</p><p>" + frameID + ".</p>";
        page += "</span></body></html>";
        return page;
      }
    </script>
  </head>
  <body>
    <div style="display: flex; justify-content: space-around; border: 1px solid black; padding: 5px;">
      <div style="border: 1px solid black; padding: 5px; width: 45%; text-align: center;">
        <span style="font-size: 24pt; font-weight: bold; display: block; margin-bottom: 5px;">Frame 1</span>
        <p>This frame has the ID of: frame1.</p>
      </div>
      <div style="border: 1px solid black; padding: 5px; width: 45%; text-align: center;">
        <span style="font-size: 24pt; font-weight: bold; display: block; margin-bottom: 5px;">Frame 2</span>
        <p>This frame has the ID of: frame2.</p>
      </div>
    </div>
  </body>
</html>

```

*Continued*

## frame.scrolling

## Listing 16-45 (continued)

```
    }
  </script>
</head>
<frameset id="outerFrameset" cols="50%,50%">
  <frameset id="innerFrameset1" rows="25%,25%,25%,25%">
    <frame id="myFrame1" src="javascript:parent.fillFrame('myFrame1')" />
    <frame id="myFrame2" src="javascript:parent.fillFrame('myFrame2')" />
    <frame id="myFrame3" src="javascript:parent.fillFrame('myFrame3')" />
    <frame id="myFrame4" src="javascript:parent.fillFrame('myFrame4')" />
  </frameset>
  <frameset id="innerFrameset2" rows="25%,25%,25%,25%">
    <frame id="myFrame5" src="javascript:parent.fillFrame('myFrame5')" />
    <frame id="myFrame6" src="javascript:parent.fillFrame('myFrame6')" />
    <frame id="myFrame7" src="javascript:parent.fillFrame('myFrame7')" />
    <frame id="myFrame8" src="javascript:parent.fillFrame('myFrame8')" />
  </frameset>
</frameset>
</html>
```

## src

**Value:** URL string.

Read/Write

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `src` property of a frame element object offers an additional way of navigating to a different page within a frame (meaning other than assigning a new URL to the `location.href` property of the frame object). For backward compatibility with older browsers, however, continue using `location.href` for scripted navigation. Remember that the `src` property belongs to the frame element object, not the window object it represents. Therefore, references to the `src` property must be via the element's ID and/or node hierarchy.

**Example**

For best results, use fully formed URLs as value for the `src` property, as shown here:

```
parent.document.getElementById("mainFrame").src = "http://www.dannyg.com";
```

Relative URLs and `javascript:` pseudo-URLs will also work most of the time.

**Related Items:** `location.href` property.

## frameset Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
border		
borderColor		
cols		
frameBorder		
frameSpacing		
rows		

## Syntax

Accessing properties or methods of a frameset element object from a frameset:

```
(IE4+)    document.all.framesetID.property | method([parameters])
(IE5+/W3C) document.getElementById("framesetID").property |
method([parameters])
```

Accessing properties or methods of a frameset element from a frame document:

```
(IE4+)    parent.document.all.framesetID.property | method([parameters])
(IE5+/W3C) parent.document.getElementById("framesetID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

The frameset element object is the script-accessible equivalent of the element generated via the `<frameset>` tag. This element is different from the parent (window-type) object from the original object model. A frameset element object has properties and methods that impact the HTML element; in contrast, the window object referenced from documents inside frames via the `parent` or `top` window references contains a document and all the content that goes along with it.

When framesets are nested in one another, a node parent–child relationship exists between containing and contained framesets. For example, consider the following skeletal nested frameset structure:

```
<frameset id="outerFrameset" cols="30%, 70%">
  <frame id="frame1">
  <frameset id="innerFrameset" rows="50%,50%">
    <frame id="frame2">
    <frame id="frame3">
  </frameset>
</frameset>
```

When writing scripts for documents that go inside any of the frames of this structure, references to the framesetting window and frames are a flatter hierarchy than the HTML signifies. A script in any frame references the framesetting window via the `parent` reference; a script in any frame references another frame via the `parent.frameName` reference. In other words, the window objects of the frameset defined in a document are all siblings and share the same parent.

**frameset**

Such is not the case when viewing the preceding structure from the perspective of W3C node terminology. Parent–child relationships are governed by the nesting of HTML elements, irrespective of whatever windows get generated by the browser. Therefore, frame `frame2` has only one sibling, `frame3`. Both of those share one parent, `innerFrameset`. Both `innerFrameset` and `frame1` are children of `outerFrameset`. If your script were sitting on a reference to `frame2`, and you wanted to change the `cols` property of `outerFrameset`, you would have to traverse two generations of nodes:

```
frame2Ref.parentNode.parentNode.cols = "40%,60%";
```

What might confuse matters ever more in practice is that a script belonging to one of the frames must use window object terminology to jump out of the current `window` object to the frameset that generated the frame window for the document. In other words, there is no immediate way to jump directly from a document to the `frame` element object that defines the frame in which the document resides. The document's script accesses the node hierarchy of its frameset via the `parent.document` reference. But this reference is to the `document` object that contains the entire frameset structure. Fortunately, the W3C DOM provides the `getElementById()` method to extract a reference to any node nested within the document. Thus, a document inside one of the frames can access the `frame` element object just as if it were any element in a typical document (which it is):

```
parent.document.getElementById("frame2")
```

No reference to the containing frameset element object is necessary. Or, to make that column width change from a script inside one of the frame windows, the statement would be:

```
parent.document.getElementById("outerFrame").cols = "40%,60%";
```

The inner frameset is equally accessible by the same syntax.

## Properties

### **border**

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari1+

The `border` property of a frameset element object lets you read the thickness (in pixels) of the borders between frames of a frameset. If you do not specify a `border` attribute in the frameset's tag, the property is empty, rather than reflecting the actual border thickness applied by default.

### Example

Even though the property is read/write, changing the value does not change the thickness of the border you see in the browser. If you need to find the thickness of the border, a script reference from one of the frame's documents would look like the following:

```
var thickness = parent.document.all.outerFrameset.border;
```

**Related Items:** frameset.frameBorder property.

## borderColor

**Value:** Hexadecimal triplet or color name string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `borderColor` property lets you read the value of the color assigned to the `bordercolor` attribute of the frameset's tag. Although the property is read/write, changing the color by script does not alter the border colors rendered in the browser window. Attribute values set as color names are returned as hexadecimal triplets when you read the property value.

### Example

To retrieve the current color setting in a frameset, a script reference from one of the frame's documents would look like the following:

```
var borderColor = parent.document.all.outerFrameset.borderColor;
```

**Related Items:** `frame.borderColor`, `frameset.frameBorder` properties.

## cols rows

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `cols` and `rows` properties of a `frameset` element object let you read and modify the sizes of frames after the frameset has loaded. These two properties are defined in the W3C DOM. Values for both properties are strings, which may include percent symbols or asterisks. Therefore if you are trying to increase or decrease the size of a frame column or row gradually, you must parse the string for the necessary original values before performing any math on them (or, in IE4+, use the `frame` element object's `height` and `width` properties to gauge the current frame size in pixels).

Adjusting these two properties lets you completely modify the frameset. This includes adding or removing columns or rows to the frameset grid. Because a change in the frameset structure could impact scripts by changing the size of the frames array associated with the parent window or unloading documents that contain needed data, be sure to test your scripts with both states of your frameset. If you want to remove a frame from a frameset view, you might be safer to specify the size of zero for that particular row or column in the frameset. Of course a size of zero still leaves a one-pixel frame, but it is essentially invisible if borders are not turned on and the 1-pixel frame shares the same background color as the other frames. Another positive by-product of this technique is that you can restore the other frame with its document state identical from when it was hidden.

When you have nested framesets defined in a single document, be sure to reference the desired `frameset` element object. One object may be specifying the columns, while another (nested) one specifies the rows for the grid. Assign a unique ID to each `frameset` element so that references can be reliably directed to the proper object.

### Example

Listings 16-46 through 16-48 show the HTML for a frameset and two of the three documents that go into the frameset. The final document is an HTML version of the U.S. Bill of Rights, which is serving here as a content frame for the demonstration.

**frameset.cols**

The frameset listing (see Listing 16-46) shows a three-frame setup. Down the left column is a table of contents (see Listing 16-47). The right column is divided into two rows. In the top row is a simple control (see Listing 16-48) that hides and shows the table of contents frame. As the user clicks the hot text of the control (located inside a `span` element), the `onclick` event handler invokes the `toggleTOC()` function in the frameset.

Syntax used in this example is W3C-compatible. To modify this for IE-only, you replace `document.getElementById("outerFrameset")` with `document.all.outerFrameset` and `elem.firstChild.nodeValue` to `elem.innerText`. You can also branch within the scripts to accommodate both styles.

**Listing 16-46: Frameset and Script for Hiding/Showing a Frame**

```
<html>
  <head>
    <title>Hide/Show Frame Example</title>
    <script type="text/javascript">
      var origCols;
      function toggleTOC(elem, frm) {
        if (origCols) {
          showTOC(elem);
        } else {
          hideTOC(elem, frm);
        }
      }
      function hideTOC(elem, frm) {
        var frameset = document.getElementById("outerFrameset");
        origCols = frameset.cols;
        frameset.cols = "0,*";
      }
      function showTOC(elem) {
        if (origCols) {
          document.getElementById("outerFrameset").cols = origCols;
          origCols = null;
        }
      }
    </script>
  </head>
  <frameset id="outerFrameset" frameborder="no" cols="150,*">
    <frame id="TOC" name="TOCFrame" src="lst16-47.htm" />
    <frameset id="innerFrameset1" rows="80,*">
      <frame id="controls" name="controlsFrame" src="lst16-48.htm" />
      <frame id="content" name="contentFrame" src="bofright.htm" />
    </frameset>
  </frameset>
</html>
```

When a user clicks the hot spot to hide the frame, the script copies the original `cols` property settings to a global variable. The variable is used in `showTOC()` to restore the frameset to its original proportions. This allows a designer to modify the HTML for the frameset without also having to dig into scripts to hard-wire the restored size.

**Listing 16-47: Table of Contents Frame Content**

```
<html>
  <head>
    <title>Table of Contents</title>
  </head>
  <body bgcolor="#EEEEEE">
    <h3>
      Table of Contents
    </h3>
    <hr />
    <ul style="font-size:10pt">
      <li><a href="bofright.htm#article1" target="contentFrame">Article
        I</a></li>
      <li><a href="bofright.htm#article2" target="contentFrame">Article
        II</a></li>
      <li><a href="bofright.htm#article3" target="contentFrame">Article
        III</a></li>
      <li><a href="bofright.htm#article4" target="contentFrame">Article
        IV</a></li>
      <li><a href="bofright.htm#article5" target="contentFrame">Article
        V</a></li>
      <li><a href="bofright.htm#article6" target="contentFrame">Article
        VI</a></li>
      <li><a href="bofright.htm#article7" target="contentFrame">Article
        VII</a></li>
      <li><a href="bofright.htm#article8" target="contentFrame">Article
        VIII</a></li>
      <li><a href="bofright.htm#article9" target="contentFrame">Article
        IX</a></li>
      <li><a href="bofright.htm#article10" target="contentFrame">Article
        X</a></li>
    </ul>
  </body>
</html>
```

      onclick="parent.toggleTOC()">&lt;&lt;Hide/Show&gt;&gt;</span> Table of
      Contents</p>
  </body>
</html>
```

**Related Items:** frame object.

**frameset.frameBorder****frameBorder****Value:** yes | no | 1 | 0 as strings.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `frameBorder` property offers scripted access to a `frameset` element object's `frameborder` attribute setting. IE4+ does not respond well to modifying this property after the page has loaded.

Values for the `frameBorder` property are strings that substitute for Boolean values. Values `yes` or `1` mean that the border is (supposed to be) turned on; `no` or `0` turn off the border.

**Example**

The default value for the `frameBorder` property is `yes`. You can use this setting to create a toggle script (which, unfortunately, does not change the appearance in IE). The IE4+-compatible version looks like the following:

```
function toggleFrameScroll(framesetID) {
    var theFrameset = document.all(framesetID);
    if (theFrameset.frameBorder == "yes") {
        theFrameset.frameBorder = "no";
    } else {
        theFrameset.frameBorder = "yes";
    }
}
```

**Related Items:** `frame.frameBorder` properties.**frameSpacing****Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `frameSpacing` property of a `frameset` element object lets you read the spacing (in pixels) between frames of a `frameset`. If you do not specify a `framespacing` attribute in the `frameset`'s tag, the property is empty, rather than reflecting the actual border thickness applied by default (usually 2).

**Example**

Even though the property is read/write in IE4+, changing the value does not change the thickness of the frame spacing you see in the browser. If you need to find the spacing as set by the tag's attribute, a script reference from one of the frame's documents would look like the following:

```
var spacing = parent.document.all.outerFrameset.frameSpacing;
```

**Related Items:** `frameset.border` property.

## iframe Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

**iframe**

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
align		
allowTransparency		
contentDocument		
contentWindow		
height		
hspace		
longDesc		
marginHeight		
marginWidth		
name		
scrolling		
src		
vspace		
width		

## Syntax

Accessing properties or methods of an `iframe` element object from a containing document:

```
(IE4+)    document.all.iframeID. property | method([parameters])
(IE4+/NN6) window.frames["iframeName"]. property | method([parameters])
(IE5+/W3C) document.getElementById("iframeID"). property | method([parameters])
```

Accessing properties or methods of an `iframe` element from a document inside the `iframe` element:

```
(IE4+)    parent.document.all.iframeID. property | method([parameters])
(IE5+/W3C) parent.document.getElementById("iframeID"). property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

An `iframe` element allows HTML content from a separate source to be loaded within the body of another document. In some respects, the NN4 `layer` element was a precursor to the `iframe` concept, but unlike the `layer`, an `iframe` element is not inherently positionable. It is positionable the same way as any other HTML element, by assigning positioning attributes to a stylesheet associated with the `iframe`. Without explicit positioning, an `iframe` element appears in the body of a document in normal source code order of elements. Unlike a frame of a frameset, you can place an `iframe` arbitrarily in the middle of any document. If the frame changes size under script control, the surrounding content moves out of the way or cinches up.

What truly separates the `iframe` apart from other HTML elements is its ability to load and display external HTML files and, with the help of scripts, have different pages loaded into the `iframe` without disturbing the rest of the content of the main document. Pages loaded into the `iframe` can also have scripts and any other features that you may like to put into an HTML document (including XML in IE for Windows).

**iframe**

The `iframe` element has a rich set of attributes that let the HTML author control the look, size (height and width), and, to some degree, behavior of the frame. Most of those are accessible to scripts as properties of an `iframe` element object.

It is important to bear in mind that an `iframe` element is in many respects like a `frame` element, especially when it comes to window kinds of relationships. If you plant an `iframe` element in a document of the main window, that element shows up in the main window's object model as a `frame`, accessible via common `frames` terminology:

```
window.frames[i]
window.frames[frameName]
```

Within that `iframe` frame object is a document and all its contents. All references to the document objects inside the `iframe` must flow through the “portal” of the `iframe` frame.

Conversely, scripts in the document living inside an `iframe` can communicate with the main document via the `parent` reference. Of course, you cannot replace the content of the main window with another HTML document (using `location.href`, for instance) without destroying the `iframe` that was in the original document.

## Properties

### `align`

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `align` property governs how an `iframe` element aligns itself with respect to surrounding content on the page. Two of the possible values (`left` and `right`) position the `iframe` along the left and right edge (respectively) of the `iframe`'s containing element (usually the `body`). Just as with an image, when an `iframe` is floated along the left and right edges of a container, other content wraps around the element. Table 16-5 shows all possible values and their meanings.

**Table 16-5: Values of the `align` Property**

<i>Value</i>	<i>Description</i>
<code>absbottom</code>	Aligns the bottom of the <code>iframe</code> with the imaginary line that extends along character descenders of surrounding text.
<code>absmiddle</code>	Aligns the middle of the <code>iframe</code> with the center point between the surrounding text's top and <code>absbottom</code> .
<code>baseline</code>	Aligns the bottom of the <code>iframe</code> with the baseline of surrounding text.
<code>bottom</code>	Same as <code>baseline</code> in IE.
<code>left</code>	Aligns the <code>iframe</code> flush with left edge of the containing element.
<code>middle</code>	Aligns the imaginary vertical centerline of surrounding text with the same for the <code>iframe</code> element.
<code>right</code>	Aligns the <code>iframe</code> flush with the right edge of the containing element.
<code>texttop</code>	Aligns the top of the <code>iframe</code> element with the imaginary line that extends along the tallest ascender of surrounding text.
<code>top</code>	Aligns the top of the <code>iframe</code> element with the surrounding element's top.

**iframe.contentWindow**

As your script changes the value of the `align` property, the page automatically reflows the content to suit the new alignment.

**Example**

The default setting for an `iframe` alignment is `baseline`. A script can shift the `iframe` to be flush with the right edge of the containing element as follows:

```
document.getElementById("iframe1").align = "right";
```

**Related Items:** `iframe.hspace`, `iframe.vspace` properties.

**allowTransparency**

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE6+, MacIE-, NN-, Moz-, Safari-

The `allowTransparency` property indicates whether or not the frame's background is transparent. By setting this property to `true`, you allow a background color or image to show through the transparent frame.

**contentDocument**

**Value:** document object reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `contentDocument` property of an `iframe` element object is nothing more than a reference to the document contained by that frame. If your script finds that it has a reference to an `iframe` element object, you can use the `contentDocument` property to get a valid reference to the document, and therefore any other content of the frame.

**Example**

A document script might be using the ID of an `iframe` element to read or adjust one of the element properties; it then needs to perform some action on the content of the page through its `document` object. You can get the reference to the `document` object via a statement, such as the following:

```
var doc = document.getElementById("Frame3").contentDocument;
```

Then your script can, for example, dive into a form in the document:

```
var val = doc.mainForm.entry.value;
```

**Related Items:** `contentWindow` property; `document` object.

**contentWindow**

**Value:** document object reference.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN7+, Moz1+, Safari-

The `contentWindow` property of an `iframe` element object serves as a reference to the `window` object generated by the frame. You can then use this `window` object as a means of accessing the `document` object and any document elements.

**Related Items:** `contentDocument` property; `window` object.

**iframe.height**

height

width

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `height` and `width` properties provide access to the height and width of the `iframe` object, and allow you to alter the size of the frame. Both properties are specified in pixels.

hspace

vspace

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

These IE-specific properties allow for margins to be set around an `iframe` element. In general, `hspace` and `vspace` properties (and their HTML attributes) have been replaced by CSS margins and padding. These properties and their attributes are not recognized by any W3C standard (including HTML 4.0).

Values for these properties are integers representing the number of pixels of padding between the element and surrounding content. The `hspace` value assigns the same number of pixels to the left and right sides of the element; the `vspace` value is applied to both the top and bottom edges. Scripted changes to these values have no effect in WinIE5+.

**Related Items:** `style.padding` property.

longDesc

**Value:** URL string.

Read/Write

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `longDesc` property is the scripted equivalent of the `longdesc` attribute of the `<iframe>` tag. This HTML 4.0 attribute is intended to provide browsers with a URL to a document that contains a long description of the element. Future browsers can use this feature to provide information about the frame for visually impaired site visitors.

marginHeight

marginWidth

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Browsers tend to automatically insert content within a frame by adding a margin between the content and the edge of the frame. These values are represented by the `marginHeight` (top and bottom edges) and `marginWidth` (left and right edges) properties. Although the properties are not read-only, changing the values after the frameset has loaded does not alter the appearance of the document in the frame. If you need to alter the margin(s) of a document inside a frame, adjust the `document.body.style.margin` properties.

Also be aware that although the default values of these properties are empty (that is, when no `marginheight` or `marginwidth` attributes are set for the `<iframe>` tag), margins are built into the page. The precise pixel count of those margins varies with different operating systems.

**Related Items:** `style` object (Chapter 26).

## name

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `name` property is the identifier associated with the frame for use as a frame reference. Scripts can reference the frame through the `name` property (e.g., `window.frames["myIframe"]`), which is typically assigned via the `name` attribute.

## scrolling

**Value:** `yes` | `no` | `1` | `0` as strings.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `scrolling` property lets scripts turn scroll bars on and off inside an `iframe` element. By default, `scrolling` is turned on unless overridden by the `scroll` attribute of the `<iframe>` tag.

Values for the `scrolling` property are strings that substitute for Boolean values. Values `yes` or `1` mean that scroll bars are visible (provided there is more content than can be viewed without scrolling); `no` or `0` hide scrollbars in the frame. IE4+ also recognizes (and sets as default) the `auto` value.

## Example

The following `toggleIFrameScroll()` function accepts a string of the `iframe` element's ID as a parameter and switches between on and off scrollbars in the `iframe`. The `if` condition checks whether the property is set to something other than `no`. This test allows the condition to evaluate to `true` if the property is set to either `auto` (the first time) or `yes` (as set by the function).

```
function toggleFrameScroll(frameID) {
    // IE5 & NN6 version
    var theFrame = document.getElementById(frameID);
    // IE4+ version
    // var theFrame = document.all[frameID]
    if (theFrame.scrolling != "no") {
        theFrame.scrolling = "no";
    } else {
        theFrame.scrolling = "yes";
    }
}
```

**Related Items:** `frame.scrolling` property.

## src

**Value:** URL string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `src` property of an `iframe` element object offers an additional way of navigating to a different page within an inline frame (that is, other than assigning a new URL to the `location.href` property of the frame object). Remember that the `src` property belongs to the `iframe` element object, not the `window` object it represents. Therefore, references to the `src` property must be via the element's ID and/or node hierarchy.

**iframe.src****Example**

For best results, use fully formed URLs as value for the `src` property, as shown here:

```
document.getElementById("myIframe").src = "http://www.dannyg.com";
```

Relative URLs and `javascript:` pseudo-URLs also work most of the time.

**Related Items:** `location.href` property.

## popup Object

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>document</code>	<code>hide()</code>	
<code>isOpen</code>	<code>show()</code>	

## Syntax

Creating a popup object:

```
var popupObj = window.createPopup()
```

Accessing properties or methods of a popup object from a document in the window that created the pop-up:

```
popupObj.property | method([parameters])
```

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

## About this object

A popup object is a chrome-less window space, which overlaps the window whose document generates the pop-up. A pop-up also appears in front of any dialog boxes. Unlike the dialog box windows generated via IE's `showModalDialog()` and `showModelessDialog()` methods, your scripts must not only create the window, but also put content into it, and then define where on the screen and how big it will be.

Because the pop-up window has no chrome (that is, title bar, resize handles, and so forth), you should populate its content with a border and/or background color so that it stands out from the main window's content. The following statements reflect a typical sequence of creating, populating, and showing a popup object:

```
var popup = window.createPopup();
var popupBody = popup.document.body;
popupBody.style.border = "solid 2px black";
popupBody.style.padding = "5px";
popupBody.innerHTML = "<p>Here is some text in a popup window</p>";
popup.show(200,100, 200, 50, document.body);
```

The pop-up window that IE creates is, in fact, a window, but only from the point of view of the document that it contains. In other words, while the number of properties and methods for the popup object is small, the `parentWindow` property of the document inside the pop-up

**popupObject.isOpen**

points to a genuine `window` property. Even so, be aware that this pop-up does not appear as a distinct window among windows listed in the Windows Taskbar. If a user clicks outside of the pop-up or switches to another application, the pop-up disappears, and you must reinvoke the `show()` method by script (complete with dimension and position parameters) to force the pop-up to reappear.

When you assign content to a pop-up, you are also responsible for making sure that the content fits the size of the pop-up you specify. If the content runs past the rectangular space (body text word wraps within the pop-up's rectangle), no scroll bars appear.

## Properties

### document

**Value:** `document` object reference.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

Use the `document` property as a gateway to the content of a pop-up window. This property is the only access point available from the script that creates the pop-up to the pop-up itself. The most common application of this property is to set document properties governing the content of the pop-up window. For example, to give the pop-up a border (because the pop-up itself has no window chrome), the script that creates the window can assign values to the `style` property of the document in the pop-up window, as follows:

```
myPopup.document.body.style.border = "solid 3px gray";
```

Beware that the `document` object of a pop-up window may not implement the full flexibility you know about primary window `document` objects. For example, you are not allowed to assign a URL to the `document.URL` property in a pop-up window.

### Example

Use The Evaluator (Chapter 13) to experiment with the `popup` object and its properties. Enter the following statements into the top text box. The first statement creates a pop-up window, whose reference is assigned to the `a` global variable. Next, a reference to the body of the pop-up's document is preserved in the `b` variable for the sake of convenience. Further statements work with these two variables.

```
a = window.createPopup()
b = a.document.body
b.style.border = "solid 2px black"
b.style.padding = "5px"
b.innerHTML = "<P>Here is some text in a popup window</P>"
a.show(200,100, 200, 50, document.body)
```

See the description of the `show()` method for details on the parameters.

**Related Items:** `document` object.

### isOpen

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

While a pop-up window is visible, its `isOpen` property returns `true`; otherwise the property returns `false`. Because any user action in the browser causes the pop-up to hide itself, the property is useful only for script statements that are running on their own after the pop-up is made visible.

**popupObject.isOpen()****Example**

Use The Evaluator (Chapter 13) to experiment with the `isOpen` property. Enter the following statements into the top text box. The sequence begins with a creation of a simple pop-up window, whose reference is assigned to the `a` global variable. Note that the final statement is actually two statements, designed so that the second statement executes while the pop-up window is still open.

```
a = window.createPopup();
a.document.body.innerHTML = "<p>Here is a popup window</p>";
a.show(200,100, 200, 50, document.body); alert("Popup is open:" + a.isOpen);
```

If you then click into the main window to hide the pop-up, you will see a different result if you enter the following statement into the top text box by itself:

```
alert("Popup is open:" + a.isOpen);
```

**Related Items:** `popup.show()` method.

**Methods**

`hide()`

`show(left, top, width, height[, positioningElementRef])`

**Returns:** Nothing.

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

After you have created a `popup` object with the `window.createPopup()` method and populated it with content, you must explicitly show the window via the `show()` method. If the window is hidden because a user clicked the main browser window somewhere, the `show()` method (and all its parameters) must be invoked again. To have a script hide the window, invoke the `hide()` method for the `popup` object.

The first four parameters of the `show()` method are required and define the pixel location and size of the pop-up window. By default, the coordinate space for the `left` and `top` parameters is the video display. Thus, a `left` and `top` setting of zero places the pop-up in the upper-left corner of the video screen. But you can also define a different coordinate space by adding an optional fifth parameter. This parameter must be a reference to an element on the page. To confine the coordinate space to the content region of the browser window, specify the `document.body` object as the positioning element reference.

**Example**

Listing 16-49 demonstrates both the `show()` and `hide()` methods for a `popup` object. A click of the button on the page invokes the `selfTimer()` function, which acts as the main routine for this page. The goal is to produce a pop-up window that “self-destructs” five seconds after it appears. Along the way, a message in the pop-up counts down the seconds.

A reference to the pop-up window is preserved as a global variable, called `popup`. After the `popup` object is created, the `initContent()` function stuffs the content into the pop-up by way of assigning `style` properties and some `innerHTML` for the body of the document that is automatically created when the pop-up is generated. A `span` element is defined so that another function later on can modify the content of just that segment of text in the pop-up. Notice that the assignment of content to the pop-up is predicated on the pop-up window having been initialized (by virtue of the `popup` variable having a value assigned to it) and that the pop-up window is not showing. Although invoking `initContent()` under any other circumstances is probably impossible, the validation of the desired conditions is good programming practice.

*popupObject.hide()*

Back in `selfTimer()`, the `popup` object is displayed. Defining the desired size requires some trial and error to make sure the pop-up window comfortably accommodates the text that is put into the pop-up in the `initContent()` function.

With the pop-up window showing, now is the time to invoke the `countDown()` function. Before the function performs any action, it validates that the pop-up has been initialized and is still visible. If a user clicks the main window while the counter is counting down, this changes the value of the `isOpen` property to `false`, and nothing inside the `if` condition executes.

This `countDown()` function grabs the inner text of the `span` and uses `parseInt()` to extract just the integer number (using base 10 numbering, because we're dealing with zero-leading numbers that can potentially be regarded as octal values). The condition of the `if` construction decreases the retrieved integer by one. If the decremented value is zero, then the time is up, and the pop-up window is hidden with the `popup` global variable returned to its original, `null` value. But if the value is other than zero, then the inner text of the `span` is set to the decremented value (with a leading zero), and the `setTimeout()` method is called upon to reinvoke the `countDown()` function in one second (1,000 milliseconds).

### Listing 16-49: Hiding and Showing a Pop-up

```
<html>
  <head>
    <title>popup Object</title>
    <script type="text/javascript">
      var popup;
      function initContent() {
        if (popup && !popup.isOpen) {
          var popBody = popup.document.body;
          popBody.style.border = "solid 3px red";
          popBody.style.padding = "10px";
          popBody.style.fontSize = "24pt";
          popBody.style.textAlign = "center";
          var bodyText = "<P>This popup will self-destruct in ";
          bodyText += "<span id='counter'>05</span>";
          bodyText += " seconds...</P>";
          popBody.innerHTML = bodyText;
        }
      }
      function countDown() {
        if (popup && popup.isOpen) {
          var currCount = parseInt(popup.document.all.counter.innerText, 10);
          if (--currCount == 0) {
            popup.hide();
            popup = null;
          } else {
            popup.document.all.counter.innerText = "0" + currCount;
            setTimeout("countDown()", 1000);
          }
        }
      }
      function selfTimer() {
        popup = window.createPopup();
        initContent();
      }
    </script>
  </head>
</html>
```

*Continued*

**popupObject.hide()****Listing 16-49 (continued)**

```
        popup.show(200,200,400,100,document.body);
        setTimeout("countDown()", 1000);
    }
</script>
</head>
<body>
  <form>
    <input type="button" value="Impossible Mission"
      onclick="selfTimer()" />
  </form>
</body>
</html>
```

---

The `hide()` method here is invoked by a script that is running while the pop-up window is showing. Because a pop-up window automatically goes away if a user clicks the main window, it is highly unlikely that the `hide()` method would ever be invoked by itself in response to user action in the main window. If you want a script in the pop-up window to close the pop-up, use `parentWindow.close()`.

**Related Items:** `popup.isOpen` property, `window.createPopup()` method.

# Location and History Objects

---

Not all objects in the document object model are “things” you can see in the content area of the browser window. Each browser window or frame maintains a bunch of other information about the page you are currently visiting and where you have been. The URL of the page you see in the window is called the *location*, and browsers store this information in the `location` object. As you surf the Web, the browser stores the URLs of your past pages in the `history` object. You can manually view what that object contains by looking in the browser menu that enables you to jump back to a previously visited page. This chapter is all about these two nearly invisible, but important, objects.

Not only are these objects valuable to your browser, but they are also valuable to snoopers who might want to write scripts to see what URLs you’re viewing in another frame or the URLs of other sites you’ve visited in the last dozen mouse clicks. As a result, security restrictions built into browsers limit access to some of these objects’ properties (unless you use signed scripts in NN4+). For older browsers, these properties simply are not available from a script.

## location Object

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
hash	assign()	None
host	reload()	
hostname	replace()	
href		
pathname		
port		
protocol		
search		

### In This Chapter

Loading new pages and other media types via the `location` object

Security restrictions across frames

Navigating through the browser history under script control

**windowObject.location**

## Syntax

Loading a new document into the current window:

```
[window.]location.href = "URL";
```

Accessing `location` object properties or methods:

```
[window.]location.property | method([parameters])
```

## About this object

In its place one level below `window`-style objects in the original document object hierarchy, the `location` object represents information about the URL of any currently open window or of a specific frame. A multiple-frame window displays the parent window's URL in the Location (or Address) field of the browser. Each frame also has a `location` associated with it, although you may not see any overt reference to the frame's URL in the browser. To get URL information about a document located in another frame, the reference to the `location` object must include the window frame reference. For example, if you have a window consisting of two frames, Table 17-1 shows the possible references to the `location` objects for all frames comprising the Web presentation.

**Note**

Scripts cannot alter the URL displayed in the browser's Location/Address box. For security and privacy reasons, that text box cannot display anything other than the URL of a current page or URL in transit.

**Table 17-1: Location Object References in a Two-Frame Browser Window**

<i>Reference</i>	<i>Description</i>
<code>location</code> (or <code>window.location</code> )	URL of frame displaying the document that runs the script statement containing this reference
<code>parent.location</code>	URL information for parent window that defines the <code>&lt;frameset&gt;</code>
<code>parent.frames[0].location</code>	URL information for first visible frame
<code>parent.frames[1].location</code>	URL information for second visible frame
<code>parent.otherFrameName.location</code>	URL information for another named frame in the same frameset

Most properties of a `location` object deal with network-oriented information. This information involves various data about the physical location of the document on the network including the host server, the protocol being used, and other components of the URL. Given a complete URL for a typical WWW page, the `window.location` object assigns property names to various segments of the URL, as shown here:

```
http://www.example.com:80/promos/newproducts.html#giantGizmo
```

<b>Property</b>	<b>Value</b>
protocol	"http:"
hostname	"www.example.com"
port	"80"
host	"www.example.com:80"
pathname	"/promos/newproducts.html"
hash	"#giantGizmo"
href	"http://www.example.com:80/promos newproducts.html#giantGizmo"

The `window.location` object is handy when a script needs to extract information about the URL, perhaps to obtain a base reference on which to build URLs for other documents to be fetched as the result of user action. This object can eliminate a nuisance for Web authors who develop sites on one machine and then upload them to a server (perhaps at an Internet service provider) with an entirely different directory structure. By building scripts to construct base references from the directory location of the current document, you can construct the complete URLs for loading documents. You don't have to manually change the base reference data in your documents as you shift the files from computer to computer or from directory to directory. To extract the segment of the URL and place it into the enclosing directory, use the following:

```
var baseRef = location.href.substring(0,location.href.lastIndexOf("/") + 1);
```

**Security alert:** To allay fears of Internet security breaches and privacy invasions, scriptable browsers prevent your script in one frame from retrieving `location` object properties from other frames whose domain and server are not your own (unless you use signed scripts in NN4+ or the user has set the IE browser to trust your site). This restriction puts a damper on many scripters' well-meaning designs and aids for Web watchers and visitors. If you attempt such property accesses, however, you receive an "access denied" (or similar) security warning dialog box.

Setting the value of some `location` properties is the preferred way to control which document gets loaded into a window or frame. Though you may expect to find a method somewhere in JavaScript that contains a plain language "Go" or "Open" word (to simulate what you see in the browser menu bar), you "point your browser" to another URL by setting the `window.location.href` property to that URL, as in

```
window.location.href = "http://www.dannyg.com/";
```

The equals assignment operator (=) in this kind of statement is a powerful weapon. In fact, setting the `location.href` object to a URL of a different MIME type, such as one of the variety of sound and video formats, causes the browser to load those files into the plug-in or helper application designated in your browser's settings. The `location.assign()` method was originally intended for internal use by the browser, but it is available for scripters (although I don't recommend using it for navigation). Internet Explorer's object model includes a `window.navigate()` method that also loads a document into a window, but you can't use it for cross-browser applications.

Two other methods complement the `location` object's capability to control navigation. One method is the script equivalent of clicking Reload; the other method enables you to replace the current document's entry in the history with that of the next URL of your script's choice.

## Properties

### hash

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The *hash mark* (*#*) is a URL convention that directs the browser to an anchor located in the document. Any name you assign to an anchor (with the `<a name="..."> ...</a>` tag pair) becomes part of the URL after the hash mark. A `location` object's `hash` property is the name of the anchor part of the current URL (which consists of the hash mark and the name).

If you have written HTML documents with anchors and directed links to navigate to those anchors, you have probably noticed that although the destination location shows the anchor as part of the URL (for example, in the `Location` field), the window's `anchor` value does not change as the user manually scrolls to positions in the document where other anchors are defined. An anchor appears in the URL only when the window has navigated there as part of a link or in response to a script that adjusts the URL.

Just as you can navigate to any URL by setting the `window.location.href` property, you can navigate to another hash in the same document by adjusting only the `hash` property of the `location` without the hash mark (as shown in the following example). Such navigation, even within a document, sometimes causes IE to reload the document.

Listing 17-1 demonstrates how to use the `hash` property to access the anchor part of a URL. When you load the script in Listing 17-1, adjust the size of the browser window so only one section is visible at a time. When you click a button, the script navigates to the next logical section in the progression and eventually takes you back to the top.

### Listing 17-1: A Document with Anchors

```
<html>
  <head>
    <title>location.hash Property</title>
    <script type="text/javascript">
      function goNextAnchor(where) {
        window.location.hash = where;
      }
    </script>
  </head>
  <body>
    <h1><a id="start" name="start">Top</a></h1>
    <form>
      <input type="button" name="next" value="NEXT"
        onclick="goNextAnchor('sec1')"/>
    </form>
    <hr />
    <h1><a id="sec1" name="sec1">Section 1</a></h1>
    <form>
      <input type="button" name="next" value="NEXT"
        onclick="goNextAnchor('sec2')"/>
    </form>
```

**windowObject.location.host**

```
<hr />
<h1><a id="sec2" name="sec2">Section 2</a></h1>
<form>
  <input type="button" name="next" value="NEXT"
    onclick="goNextAnchor('sec3')" />
</form>
<hr />
<h1><a id="sec3" name="sec3">Section 3</a></h1>
<form>
  <input type="button" name="next" value="BACK TO TOP"
    onclick="goNextAnchor('start')" />
</form>
</body>
</html>
```

Anchor names are passed as parameters with each button's `onclick` event handler. Instead of going through the work of assembling a `window.location` value in the function by appending a literal hash mark and the value for the anchor, here I simply modify the `hash` property of the current window's location. This is the preferred, cleaner method.

If you attempt to read back the `window.location.hash` property in an added line of script, however, the window's actual URL probably will not have been updated yet, and the browser will appear to be giving your script false information. To prevent this problem in subsequent statements of the same function, construct the URLs of those statements from the same variable values you use to set the `window.location.hash` property—don't rely on the browser to give you the values you expect.

**Related Item:** `location.href` property.

## host

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `location.host` property describes both the hostname and port of a URL. The port is included in the value only when the port is an explicit part of the URL. If you navigate to a URL that does not display the port number in the Location field of the browser, the `location.host` property returns the same value as the `location.hostname` property.

Use the `location.host` property to extract the `hostname:port` part of the URL of any document loaded in the browser. This capability may be helpful for building a URL to a specific document that you want your script to access on the fly.

Use the documents in Listings 17-2 through 17-4 as tools to help you learn the values that the various `window.location` properties return. In the browser, open the file for Listing 17-2. This file creates a two-frame window. The left frame contains a temporary placeholder (see Listing 17-4) that displays some instructions. The right frame has a document (see Listing 17-3) that enables you to load URLs into the left frame and get readings on three different windows available: the parent window (which creates the multiframe window), the left frame, and the right frame.

**Listing 17-2: Frameset for the Property Picker**

```

<html>
  <head>
    <title>window.location Properties</title>
  </head>
  <frameset cols="50%,50%" border="1" bordercolor="black">
    <frame name="Frame1" src="lst17-04.htm" />
    <frame name="Frame2" src="lst17-03.htm" />
  </frameset>
</html>

```

**Listing 17-3: Property Picker**

```

<html>
  <head>
    <title>Property Picker</title>
    <script type="text/javascript">
      var isNav = (typeof netscape != "undefined") ? true : false;

      function fillLeftFrame() {
        newURL = prompt("Enter the URL of a document to show in the left
          frame:", "");
        if (newURL != null && newURL != "") {
          parent.frames[0].location = newURL;
        }
      }

      function showLocationData(form) {
        for (var i = 0; i <3; i++) {
          if (form.whichFrame[i].checked) {
            var windName = form.whichFrame[i].value;
            break;
          }
        }
        var theWind = "" + windName + ".location";
        if (isNav) {
          netscape.security.PrivilegeManager.enablePrivilege(
            "UniversalBrowserRead");
        }
        var theObj = eval(theWind);
        form.windName.value = windName;
        form.windHash.value = theObj.hash;
        form.windHost.value = theObj.host;
        form.windHostname.value = theObj.hostname;
        form.windHref.value = theObj.href;
        form.windPath.value = theObj.pathname;
        form.windPort.value = theObj.port;
        form.windProtocol.value = theObj.protocol;
        form.windSearch.value = theObj.search;
        if (isNav) {
          netscape.security.PrivilegeManager.disablePrivilege(
            "UniversalBrowserRead");
        }
      }
    </script>
  </head>
  <body>
    <div style="border: 1px solid black; padding: 5px;">

    <title>Opening Placeholder</title>
  </head>
  <body>
    Initial placeholder. Experiment with other URLs for this frame (see
    right).
  </body>
</html>

```

For the best results, open a URL to a Web document on the network from the same domain and server from which you load the listings (perhaps your local hard disk). If possible, load a document that includes anchor points to navigate through a long document. Click the Left frame radio button and then click the button that shows all properties. This action fills the table in the right frame with all the available `location` properties for the selected window.

**Related Items:** `location.port`, `location.hostname` properties.

**hostname**

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The hostname of a typical URL is the name of the server on the network that stores the document you view in the browser. For most Web sites, the server name includes not only the domain name, but also the `www.` prefix. The hostname does not, however, include the port number if the URL specifies such a number.

See Listings 17-2 through 17-4 for a set of related pages to help you view the hostname data for a variety of other pages.

**Related Items:** `location.host`, `location.port` properties.

## href

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Of all the `location` object properties, `href` (hypertext reference) is probably the one most often called upon in scripting. The `location.href` property supplies a string of the entire URL of the specified `window` object.

Using this property on the left side of an assignment statement is the JavaScript way of opening a URL for display in a window. Any of the following statements can load my Web site's index page into a single-frame browser window:

```
window.location = "http://www.dannyg.com";  
window.location.href = "http://www.dannyg.com";
```

At times, you may encounter difficulty by omitting a reference to a window. JavaScript may get confused and reference the `document.location` property. To prevent this confusion, the `document.location` property was deprecated (put on the no-no list) and replaced by the `document.URL` property. In the meantime, you can't go wrong by always specifying a window in the reference.

### Note

You should be able to omit the `href` property name when assigning a new URL to the `location` object (for example, `location = "http://www.dannyg.com"`). While this works in most browsers most of the time, some early browsers behave more reliably if you assign a URL explicitly to the `location.href` property. I recommend using `location.href` at all times.

Sometimes you must extract the name of the current directory in a script so another statement can append a known document to the URL before loading it into the window. Although the other `location` object properties yield an assortment of a URL's segments, none of them provides the full URL to the current URL's directory. But you can use JavaScript string manipulation techniques to accomplish this task. Listing 17-5 shows such a possibility.

Depending on your browser, the values for the `location.href` property may be encoded with ASCII equivalents of non-alphanumeric characters. Such an ASCII value includes the % symbol and the ASCII numeric value. The most common encoded character in a URL is the space: %20. If you need to extract a URL and display that value as a string in your documents, you can safely pass all such potentially encoded strings through the JavaScript `unescape()` function. For example, if a URL is `http://www.example.com/product%20list`, you can convert it by passing it through the `unescape()` function, as in the following example.

```
var plainURL = unescape(window.location.href);  
// result = "http://www.example.com/product list";
```

The inverse function, `escape()`, is available for sending encoded strings to CGI programs on servers. See Chapter 34 for more details on these functions.

Listing 17-5 shows how the `href` property can be used to view the directory URL of the current page. This example includes the `unescape()` function in front of the part of the script that captures the URL. This function serves cosmetic purposes by displaying the pathname in alert dialog boxes for browsers that normally display the ASCII-encoded version.

**Listing 17-5: Extracting the Directory of the Current Document**

```

<html>
  <head>
    <title>Extract pathname</title>
    <script type="text/javascript">
      // general purpose function to extract URL of current directory
      function getDirPath(URL) {
        var result = unescape(URL.substring(0,(URL.lastIndexOf("/") + 1));
        return result;
      }

      // handle button event, passing work onto general purpose function
      function showDirPath(URL) {
        alert(getDirPath(URL));
      }
    </script>
  </head>
  <body>
    <form>
      <input type="button" value="View directory URL"
        onclick="showDirPath(window.location.href)" />
    </form>
  </body>
</html>

```

**Related Items:** `location.pathname`, `document.location` **properties**; **String object** (Chapter 34).

**pathname****Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `pathname` component of a URL consists of the directory structure relative to the server's root volume. In other words, the root (the server name in an `http:` connection) is not part of the `pathname`. If the URL's path is to a file in the root directory, the `location.pathname` property is a single slash (/) character. Any other `pathname` starts with a slash character, indicating a directory nested within the root. The value of the `location.pathname` property also includes the document name.

See Listings 17-2 through 17-4 earlier in this chapter for a multiple-frame example you can use to view the `location.pathname` property for a variety of URLs of your choice.

**Related Item:** `location.href` property.

**port****Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

These days, few consumer-friendly Web sites need to include the port number as part of their URLs. You see port numbers mostly in the less-popular protocols, in URLs to sites used for private development purposes, or in URLs to sites that have no assigned domain names. You can retrieve the value with the `location.port` property. If you extract the value from one

URL and intend to build another URL with that component, be sure to include the colon delimiter between the server's IP address and port number.

If you have access to URLs containing port numbers, use the documents in Listings 17-2 through 17-4 to experiment with the output of the `location.port` property.

**Related Item:** `location.host` property.

## protocol

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The first component of any URL is the protocol used for the particular type of communication. For World Wide Web pages, the Hypertext Transfer Protocol (`http`) is the standard. Other common protocols you may see in your browser include HTTP-Secure (`https`), File Transfer Protocol (`ftp`), File (`file`), and Mail (`mailto`). Values for the `location.protocol` property include not only the name of the protocol, but also the trailing colon delimiter. Thus, for a typical Web page URL, the `location.protocol` property is

```
http:
```

Notice that the usual slashes after the protocol in the URL are not part of the `location.protocol` value. Of all the `location` object properties, only the full URL (`location.href`) reveals the slash delimiters between the protocol and other components.

See Listings 17-2 through 17-4 for a multiple-frame example you can use to view the `location.protocol` property for a variety of URLs. Also try loading an FTP site to see the `location.protocol` value for that type of URL.

**Related Item:** `location.href` property.

## search

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Perhaps you've noticed the long, cryptic URL that appears in the Location/Address field of your browser whenever you ask one of the WWW search services to look up matches for items you enter into the keyword field. The URL starts the regular way—with protocol, host, and pathname values. But following the more traditional URL are search commands that are submitted to the search engine (a CGI program running on the server). You can retrieve or set that trailing search query by using the `location.search` property.

Each search engine has its own formula for query submissions based on the designs of the HTML forms that obtain details from users. These search queries come in an encoded format that appears in anything but plain language. If you plan to script a search query, be sure you fully understand the search engine's format before you start assembling a string to assign to the `location.search` property of a window.

The most common format for search data is a series of name/value pairs. An equal symbol (=) separates a name and its value. Multiple name/value pairs have ampersands (&) between them. You should use the `escape()` function to convert the data into URL-friendly format, especially when the content includes spaces.

The `location.search` property also applies to any part of a URL after the filename, including parameters being sent to CGI programs on the server.

## Passing data among pages via URLs

It is not uncommon to want to preserve some pieces of data that exist in one page so that a script in another page can pick up where the script processing left off in the first page. You can achieve persistence across page loads through one of three techniques: the `document.cookie` (see Chapter 18), variables in framesetting documents, and the search string of a URL. That's really what happens when you visit search and e-commerce sites that return information to your browser. Rather than store, say, your search criteria on the server, they spit the criteria back to the browser as part of the URL. The next time you activate that URL, the values are sent to the server for processing (for example, to send you the next page of search results for a particular query).

Passing data among pages is not limited to client/server communication. You can use the search string strictly on the client-side to pass data from one page to another. Unless some CGI process on the server is programmed to do something with the search string, a Web server regurgitates the search string as part of the location data that comes back with a page. A script in the newly loaded page can inspect the search string (via the `location.search` property) and tear it apart to gather the data and put it into script variables. Take a look at Listings 17-6 through 17-8 to see a powerful application of this technique.

As mentioned in the opening of Chapter 16 about frames, you can force a particular HTML page to open inside the frameset for which it is designed. But with the help of the search string, you can reuse the same framesetting document to accommodate any number of content pages that go into one of the frames (rather than specifying a separate frameset for each possible combination of pages in the frameset). The listings in this section create a simple example of how to force a page to load in a frameset by passing some information about the page to the frameset. Thus, if a user has a URL to one of the content frames (perhaps it has been bookmarked by right-clicking the frame or it comes up as a search engine result), the page appears in its designated frameset the next time the user visits the page.

The fundamental task going on in this scheme has two parts. The first is in each of the content pages where a script checks whether the page is loaded inside a frameset. If the frameset is missing, a search string is composed and appended to the URL for the framesetting document. The framesetting document has its own short script that looks for the presence of the search string. If the string is there, the script extracts the search string data and uses it to load that specific page into the content frame of the frameset.

Listing 17-6 is the framesetting document. The `getSearchAsArray()` function is more complete than necessary for this simple example, but you can use it in other instances to convert any number of name/value pairs passed in the search string (in traditional format of `name1=value1&name2=value2&etc.`) into an array whose indexes are the names (making it easier for scripts to extract a specific piece of passed data). Version branching takes place because, for convenience, the `getSearchAsArray()` function uses text and array methods that don't exist in browsers prior to NN3 or IE4.

### Listing 17-6: A Smart Frameset

```
<html>
  <head>
    <title>Example Frameset</title>
    <script type="text/javascript">
      // Convert location.search into an array of values
      // indexed by name.
      function getSearchAsArray() {
        var results = new Array();
```

```

    var input = unescape(location.search.substr(1));
    if (input) {
        var srchArray = input.split("&");
        var tempArray = new Array();
        for (var i = 0; i < srchArray.length; i++) {
            tempArray = srchArray[i].split("=");
            results[tempArray[0]] = tempArray[1];
        }
    }
    return results;
}

function loadFrame() {
    if (location.search) {
        var srchArray = getSearchAsArray();
        if (srchArray["content"]) {
            self.content.location.href = srchArray["content"];
        }
    }
}
</script>
</head>
<frameset cols="250,*" onload="loadFrame()">
    <frame name="toc" src="lst17-07.htm" />
    <frame name="content" src="lst17-08.htm" />
</frameset>
</html>

```

Listing 17-7 is the HTML for the table of contents frame. Nothing elaborate goes on here, but you can see how normal navigation works for this simplified frameset.

### Listing 17-7: The Table of Contents

```

<html>
  <head>
    <title>Table of Contents</title>
  </head>
  <body bgcolor="#EEEEEE">
    <h3>Table of Contents</h3>
    <hr />
    <ul>
      <li><a href="lst17-08.htm" target="content">Page 1</a></li>
      <li><a href="lst17-08a.htm" target="content">Page 2</a></li>
      <li><a href="lst17-08b.htm" target="content">Page 3</a></li>
    </ul>
  </body>
</html>

```

Listing 17-8 shows one of the content pages. As the page loads, the `checkFrameset()` function is invoked. If the window does not load inside a frameset, the script navigates to the framesetting page, passing the current content URL as a search string. Notice that for browsers that support the `location.replace()` method, the loading of this page on its own does not get recorded to the browser's history and isn't accessed if the user hits the Back button.

**Listing 17-8: A Content Page**

```
<html>
  <head>
    <title>Page 1</title>
    <script type="text/javascript">
      function checkFrameset() {
        var isNav4 = (navigator.appName == "Netscape" &&
          parseInt(navigator.appVersion) == 4);
        if (parent == window) {
          // Don't do anything if running NN4
          // so that the frame can be printed on its own
          if (isNav4 && window.innerWidth == 0) {
            return;
          }
          // Use replace() to keep current page out of history
          location.replace("lst17-06.htm?content=" + escape(location.href));
        }
      }

      // Invoke the function
      checkFrameset();
    </script>
  </head>
  <body>
    <h1>Page 1</h1>
    <hr />
  </body>
</html>
```

In practice, I recommend placing the code for the `checkFrameset()` function and call to it inside an external `.js` library and linking that library into each content document of the frameset. That's why the function assigns the generic `location.href` property to the search string—you can use it on any content page.

The code in Listings 17-6 through 17-8 establishes a frameset containing two frames. In the left frame is a Table of Contents that allows you to navigate among three different pages, the first of which is initially displayed in the right frame. The interesting thing about the example is how you can specify a new page in the `content` parameter of the search property, and then the page is opened within the frameset. For example, the following URL would result in the page `hello.htm` being opened in the right frame:

```
lst17-06.htm?content=hello.htm
```

In this example URL, the frameset page is first opened due to the inclusion of the file `lst17-06.htm`, while the `hello.htm` file is specified as the value of the `content` parameter.

**Related Item:** `location.href` property.

## Methods

`assign("URL")`

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

In earlier discussions about the `location` object, I said that you navigate to another page by assigning a new URL to the `location` object or `location.href` property. The `location.assign()` method does the same thing. In fact, when you set the `location` object to a URL, JavaScript silently applies the `assign()` method. No particular penalty or benefit comes from using the `assign()` method, except perhaps to make your code more understandable to others.

**Related Item:** `location.href` property.

`reload(unconditionalGETBoolean)`

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

The `location.reload()` method may be named inappropriately because it makes you think of the Reload/Refresh button in the browser toolbar. The `reload()` method is actually more powerful than the Reload/Refresh button (a soft reload) in that it clears form control values that might otherwise survive the Reload/Refresh button. Note that MacIE and Safari do not preserve form control settings even with a soft reload.

Most form elements retain their screen states when you click Reload/Refresh. Text and `textarea` objects maintain whatever text is inside them; radio buttons and checkboxes maintain their checked status; `select` objects remember which item is selected. About the only items the Reload/Refresh button destroys are global variable values and any settable, but not visible, property (for example, the value of a hidden `input` object). I call this kind of reload a *soft reload*.

Browsers are frustratingly irregular about the ways they reload a document in the memory cache. In theory, an application of the `location.reload()` method should retrieve the page from the cache if the page is still available there (while the `history.go(0)` method should be even gentler, preserving form element settings). Adding a `true` parameter to the method is supposed to force an *unconditional GET* to the server, ignoring the cached version of the page. Yet when it is crucial for your application to get a page from the cache (for speed) or from the server (to guarantee a fresh copy), the browser behaves in just the opposite way you want it to behave. Meta tags supposedly designed to prevent caching of a page rarely, if ever, work. Some scripters have had success in reloading the page from the server by setting `location.href` to the URL of the page, plus a slightly different search string (for example, based on a string representation of the `Date` object) so that there is no match for the URL in the cache.

The bottom line is to be prepared to try different schemes to achieve the effect you want. And also be prepared to not get the results you need.

**windowObject.location.reload()**

Listing 17-9 provides a means of testing out the different outcomes of a soft reload versus a hard reload. Open this example page in a browser and click a radio button. Then enter some new text and make a choice in the `select` object. Clicking the Soft Reload/Refresh button invokes a method that reloads the document as if you had clicked the browser's Reload/Refresh button. It also preserves the visible properties of form elements. The Hard Reload button invokes the `location.reload()` method, which resets all objects to their default settings.

**Listing 17-9: Hard versus Soft Reloading**

```
<html>
  <head>
    <title>Reload Comparisons</title>
    <script type="text/javascript">
      function hardReload() {
        location.reload(true);
      }
      function softReload() {
        history.go(0);
      }
    </script>
  </head>
  <body>
    <form name="myForm">
      <input type="radio" name="rad1" value="1" />Radio 1<br />
      <input type="radio" name="rad1" value="2" />Radio 2<br />
      <input type="radio" name="rad1" value="3" />Radio 3
      <p><input type="text" name="entry" value="Original" /></p>
      <p><select name="theList">
        <option>Red</option>
        <option>Green</option>
        <option>Blue</option>
      </select></p>
      <hr />
      <input type="button" value="Soft Reload" onclick="softReload()" />
      <input type="button" value="Hard Reload" onclick="hardReload()" />
    </form>
  </body>
</html>
```

**Related Item:** `history.go()` method.

**replace("URL")**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

In a complex Web site, you may have pages that you do not want to appear in the user's history list. For example, a registration sequence may lead the user to one or more intermediate HTML documents that won't make much sense to the user later. You especially don't want users to see these pages again if they use the Back button to return to a previous URL. The `location.replace()` method navigates to another page, but it does not let the current page stay in the queue of pages accessible via the Back button.

Although you cannot prevent a document from appearing in the history list while the user views that page, you can instruct the browser to load another document into the window and replace the current history entry with the entry for the new document. This trick does not empty the history list but instead removes the current item from the list before the next URL is loaded. Removing the item from the history list prevents users from seeing the page again by clicking the Back button later.

Listing 17-10 shows how to use the `replace()` method to direct a Web browser to a new URL. Calling the `location.replace()` method navigates to another URL similarly to assigning a URL to the location. The difference is that the document doing the calling doesn't appear in the history list after the new document loads. Check the history listing (in your browser's usual spot for this information) before and after clicking Replace Me in Listing 17-10.

### Listing 17-10: Invoking the `location.replace()` Method

```
<html>
  <head>
    <title>location.replace() Method</title>
    <script type="text/javascript">
      function doReplace() {
        location.replace("lst17-01.htm");
      }
    </script>
  </head>
  <body>
    <form name="myForm">
      <input type="button" value="Replace Me" onclick="doReplace()" />
    </form>
  </body>
</html>
```

**Related Item:** `history` object.

## history Object

<i>Property</i>	<i>Method</i>	<i>Event Handler</i>
current	<code>back()</code>	(None)
length	<code>forward()</code>	
next	<code>go()</code>	
previous		

***windowObject.history***

## Syntax

Accessing `history` object properties or methods:

```
[window.]history.property | method([parameters])
```

## About this object

As a user surfs the Web, the browser maintains a list of URLs for the most recent stops. This list is represented in the scriptable object model by the `history` object. A script cannot surreptitiously extract actual URLs maintained in that list unless you use signed scripts (in NN4+ — see Chapter 46 on the CD-ROM) and the user grants permission. Under unsigned conditions, a script can methodically navigate to each URL in the history (by relative number or by stepping back one URL at a time), in which case the user sees the browser navigating on its own as if possessed by a spirit. Good Netiquette dictates that you do not navigate a user outside of your Web site without the user's explicit permission.

One application for the `history` object and its `back()` or `go()` methods is to provide the equivalent of a Back button in your HTML documents. That button triggers a script that checks for any items in the history list and then goes back one page. Your document doesn't have to know anything about the URL from which the user lands at your page.

As of NN4, the behavior of the Back and Forward buttons is also available through a pair of window methods: `window.back()` and `window.forward()`. The `history` object methods are not specific to a frame that is part of the reference. When the `parent.frameName.history.back()` method reaches the end of history for that frame, further invocations of that method are ignored.

IE's history mechanism is not localized to a particular frame of a frameset. Instead, the `history.back()` and `history.forward()` methods mimic the physical act of clicking the toolbar buttons. If you want to ensure cross-browser, if not cross-generational, behavior in a frameset, address references to the `history.back()` and `history.forward()` methods to the parent window.

You should use the `history` object and its methods with extreme care. Your design must be smart enough to “watch” what the user is doing with your pages (for example, by checking the current URL before navigating with these methods). Otherwise, you run the risk of confusing your user by navigating to unexpected places. Your script can also get into trouble because it cannot detect where the current document is in the Back-Forward sequence in history.

## Properties

`current`

`next`

`previous`

**Value:** String.

**Compatibility:** WinIE-, MacIE-, NN4+, Moz1+, Safari-

Read-Only

***windowObject.history.length***

To know where to go when you click the Back and Forward buttons, the browser maintains a list of URLs visited. To someone trying to invade your privacy and see what sites and pages you frequent, this information is valuable. That's why the three properties that expose the actual URLs in the history list are restricted to pages with signed scripts and whose visitors have given permission to read sensitive browser data (see Chapter 46 on the CD-ROM).

With signed scripts and permission, you can look through the entire array of history entries in any frame or window. Because the list is an array, you can extract individual items by index value. For example, if the array has 10 entries, you can see the fifth item by using normal array indexing methods:

```
var fifthEntry = window.history[4];
```

No property or method exists that directly reveals the index value of the currently loaded URL, but you can script an educated guess by comparing the values of the current, next, and previous properties of the `history` object against the entire list.

I personally don't like some unknown entity watching over my shoulder while I'm on the Net, so I respect that same feeling in others and therefore discourage the use of these powers unless the user is given adequate warning. The signed script permission dialog box does not offer enough detail about the consequences of revealing this level of information.

 **Note**

These properties were available in some form in NN3. Access to them required a short-lived security scheme called *data tainting*. That mechanism was never implemented fully and was replaced by signed scripts.

**Related Item:** `history.length` property.

## length

**Value:** Number.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Use the `history.length` property to count the items in the history list. Unfortunately, this nugget of information is not particularly helpful in scripting navigation relative to the current location because your script cannot extract anything from the place in the history queue where the current document is located. If the current document is at the top of the list (the most recently loaded), you can calculate relative to that location. But users can use the Go/View menu to jump around the history list as they like. The position of a listing in the history list does not change by virtue of navigating back to that document. A `history.length` of 1, however, indicates that the current document is the first one the user loaded since starting the browser software.

 **Note**

Safari 1.0 uniformly reports `history.length` as zero.

Listing 17-11 shows how to use the `length` property to notify users of how many pages they've visited.

**windowObject.history.length()****Listing 17-11: A Browser History Count**

```
<html>
  <head>
    <title>History Object</title>
    <script type="text/javascript">
      function showCount() {
        var histCount = window.history.length;
        if (histCount > 5) {
          alert("My, my, you've been busy. You have visited " + histCount +
            " pages so far.");
        } else {
          alert("You have been to " + histCount + " Web pages this
            session.");
        }
      }
    </script>
  </head>
  <body>
    <form>
      <input type="button" name="activity" value="My Activity"
        onclick="showCount()" />
    </form>
  </body>
</html>
```

**Related Items:** None.

## Methods

back()

forward()

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Prior to Navigator 4, the `back()` method acted identically to clicking the Back button in Navigator browsers. In Navigator 4, however, the `history.back()` method became window/frame-specific. Therefore, if you direct successive `back()` methods to a frame within a frameset, the method is ignored once it reaches the first document to be loaded into that frame. The Back button (and the `window.back()` method) unload the frameset and continue taking you back through the browser's global history.

If you deliberately lead a user to a dead end in your Web site, you should make sure that the HTML document provides a way to navigate back to a recognizable spot. Because you can easily create a new window that has no toolbar or menu bar (non-Macintosh browsers), you may end up stranding your users because they have no way of navigating out of a cul-de-sac in such a window. A button in your document should give the user a way back to the last location.

**`windowObject.history.back()`**

Unless you need to perform some additional processing prior to navigating to the previous location, you can simply place this method as the parameter to the event handler attribute of a button definition. To guarantee compatibility across all browsers, direct this method at the parent document when used from within a frameset.

Less likely to be scripted than the `history.back()` action is the method that performs the opposite action: navigating forward one step in the browser's history list. The only time you can confidently use the `history.forward()` method is to balance the use of the `history.back()` method in the same script—where your script closely keeps track of how many steps the script heads in either direction. Use the `history.forward()` method with extreme caution, and only after performing extensive user testing on your Web pages to make sure that you've covered all user possibilities. The same cautions about differences introduced in NN4 for `history.back()` apply equally to `history.forward()`: Forward progress extends only through the history listing for a given window or frame, not the entire browser history list.

Listings 17-12 and 17-13 provide a little workshop in which you can test the behavior of a variety of backward and forward navigation in different browsers. Some features work only in NN4+.

**Listing 17-12: Navigation Lab Frameset**

```
<html>
  <head>
    <title>Back and Forward</title>
  </head>
  <frameset cols="45%,55%">
    <frame name="controller" src="lst17-13.htm" />
    <frame name="display" src="lst17-01.htm" />
  </frameset>
</html>
```

**Listing 17-13: Navigation Lab Control Panel**

```
<html>
  <head>
    <title>Lab Controls</title>
  </head>
  <body>
    <b>Load a series of documents into the right frame by clicking some of
    these links (make a note of the sequence you click on):</b>
    <p><a href="lst17-01.htm" target="display">Listing 17-1</a><br />
      <a href="lst17-05.htm" target="display">Listing 17-5</a><br />
      <a href="lst17-09.htm" target="display">Listing 17-9</a><br /></p>
    <hr />
    <form name="input">
      <b>Click on the various buttons below to see the results in this
      frameset:</b>
      <ul>
```

*Continued*

**windowObject.history.back()****Listing 17-13 (continued)**

```

<li><b>NN4+</b> Substitute for toolbar buttons --
  <tt>window.back()</tt> and <tt>window.forward()</tt>:<input
    type="button" value="Back" onclick="window.back()" /><input
    type="button" value="Forward" onclick="window.forward()" /></li>
<li><tt>history.back()</tt> and <tt>history.forward()</tt> for
  righthand frame:<input type="button" value="Back"
    onclick="parent.display.history.back()" /><input type="button"
    value="Forward" onclick="parent.display.history.forward()" />
  </li>
<li><tt>history.back()</tt> for this frame:<input type="button"
  value="Back" onclick="history.back()" /></li>
<li><tt>history.back()</tt> for parent:<input type="button"
  value="Back" onclick="parent.history.back()" /></li>
</ul>
</form>
</body>
</html>

```

**Related Items:** `history.go()` method.

`go(relativeNumber | "URLOrTitleSubstring")`

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Use the `history.go()` method to script navigation within the history list currently stored in the browser. If you elect to use a URL as a parameter, however, that precise URL must already exist in the history listing. Therefore, do not regard this method as an alternate to setting the `window.location` object to a brand-new URL.

For navigating *n* steps in either direction along the history list, use the *relativeNumber* parameter of the `history.go()` method. This number is an integer value that indicates which item in the list to use, relative to the current location. For example, if the current URL is at the top of the list (that is, the Forward button in the toolbar is dimmed), you need to use the following method to jump to the URL two items backward in the list:

```
history.go(-2);
```

In other words, the current URL is the equivalent of `history.go(0)` (a method that reloads the window). A positive integer indicates a jump that many items forward in the history list. Thus, `history.go(-1)` is the same as `history.back()`, whereas `history.go(1)` is the same as `history.forward()`.

Alternatively, you can specify one of the URLs or document titles stored in the browser's history list (titles appear in the Go/View menu). As security and privacy concerns increased over time, this variant of the `go()` method has been reined in. It's best not to use the string parameter in your scripting.

Like most other history methods, your script finds it difficult to manage the history list or the current URL's spot in the queue. That fact makes it even more difficult for your script to intelligently determine how far to navigate in either direction or to which specific URL or title

*windowObject.history.go()*

matches it should jump. Use this method only for situations in which your Web pages are in strict control of the user's activity (or for designing scripts for yourself that automatically crawl around sites according to a fixed regimen). Once you give the user control over navigation, you have no guarantee that the history list will be what you expect, and any scripts you write that depend on a `history` object will likely break.

In practice, this method mostly performs a soft reload of the current window using the `0` parameter.

**Tip**

If you are developing a page for all scriptable browsers, be aware that Internet Explorer's `go()` method behaves a little differently than Netscape's. In IE4+, the matching string must be part of the URL and not part of the document title, as in Navigator. Additionally, the reloading of a page with `history.go(0)` often returns to the server to reload the page rather than reloading from the cache.

Listing 17-14 contains sample code that demonstrates how to navigate through the history list via the `go()` method. Fill in either the number or text field of the page in Listing 17-14 and then click the associated button. The script passes the appropriate kind of data to the `go()` method. Be sure to use negative numbers for visiting a page earlier in the history.

### Listing 17-14: Navigating to an Item in History

```
<html>
  <head>
    <title>history.go() Method</title>
    <script type="text/javascript">
      function doGoNum(form) {
        window.history.go(parseInt(form.histNum.value));
      }
      function doGoTxt(form) {
        window.history.go(form.histWord.value);
      }
    </script>
  </head>
  <body>
    <form>
      <b>Calling the history.go() method:</b>
      <hr />
      Enter a number (+/-):<input type="text" name="histNum" size="3"
        value="0" /> <input type="button" value="Go to Offset"
        onclick="doGoNum(this.form)" />
      <p>Enter a word in a title:<input type="text" name="histWord" />
        <input type="button" value="Go to Match"
        onclick="doGoTxt(this.form)" /></p>
    </form>
  </body>
</html>
```

# The Document and Body Objects

User interaction is a vital aspect of client-side JavaScript scripting, and most of the communication between script and user takes place by way of the `document` object and its components. Understanding the scope of the `document` object within each of the object models you support is key to implementing successful cross-browser applications.

Review the `document` object's place within the original object hierarchy. Figure 18-1 clearly shows that the `document` object is a pivotal point for a large percentage of objects. In the W3C DOM, the `document` object plays an even more important role as the container of all element objects delivered with the page: The `document` object is the root of the entire document tree.

**Figure 18-1:** The basic document object model hierarchy.

In fact, the `document` object and all that it contains is so big that I have divided its discussion into many chapters, each focusing on related object groups. This chapter looks at the `document` object and `body` object (which have conceptual relationships), while each of the succeeding chapters in this part of the book details objects contained by the `document` object.

## In This Chapter

Accessing arrays of objects contained by the `document` object

Writing new document content to a window or frame

Using the `body` element for IE window measurements

**document**

I must stress at the outset that many newcomers to JavaScript have the expectation that they can, on the fly, modify sections of a loaded page's content with ease: replace some text here, change a table cell there. However, understanding that these capabilities — an important part of what is called Dynamic HTML — are available only in more recent browsers, specifically IE4+/NN6+/Moz1+/Safari1+, is very important. Not only do these browsers expose every HTML element to script languages but they also automatically reflow the page when the size of content changes under script control. Pages on all previous browsers are limited to a small set of modifiable objects, such as images and form elements.

If your application requires compatibility with all scriptable browsers, you will be limited to changing only a handful of other invisible properties after the page loads. If these compatible pages need to modify their contents based on user input or timed updates, consider designing your pages so that scripts write the contents; then let the scripts rewrite the entire page with your new settings.

**document**

## Syntax

Accessing document object properties or methods:

```
[window.]document.property | method([parameters])
```

## About this object

A `document` object encompasses the totality of what exists inside the content region of a browser window or window frame (excluding toolbars, status lines, and so on). The document is a combination of the content and interface elements that make the Web page worth visiting. In more recent browsers, which treat HTML elements as nodes of a hierarchical tree, the `document` object is the root node—that from which all other nodes grow.

Because the `document` object isn't explicitly represented in an HTML document by tags or any other notation, the original designers of JavaScript and object models decided to make the `document` object the portal to many settings that were represented in HTML as belonging to the `body` element. That element's tag contains attributes for document-wide attributes, such as background color (`bgcolor`) and link colors in various states (`alink`, `link`, and `vlink`). The `body` element also served as an HTML container for forms, links, and anchors. The `document` object, therefore, assumed a majority of the role of the `body` element. But even then, the `document` object became the most convenient place to bind some properties that extend beyond the `body` element, such as the `title` element and the URL of the link that referred the user to the page. When viewed within the context of the HTML source code, the original `document` object is somewhat schizophrenic. Even so, the `document` object has worked well as the basis for references to original object model objects, such as forms, images, and applets.

This, of course, was before every HTML element, including the `body` element, was exposed as an object via modern object models. Amazingly, even with the IE4+ object model and W3C DOM—both of which treat the `body` element as an object separate from the `document` object—script compatibility with the original object model is quite easily accomplished. The `document` object has assumed a new schizophrenia, splitting its personality between the original object model and the one that places the `document` object at the root of the hierarchy, quite separate from the `body` element object it contains. The object knows which “face” to put on based on the rest of the script syntax that follows it. This means that quite often there are multiple ways to achieve the same reference. For example, you can use the following statement in all scriptable browsers to get the number of form objects in a document:

```
document.forms.length
```

In IE4+, you can also use

```
document.tags["FORM"].length
```

And in the W3C DOM as implemented in IE5+ and NN6+/Moz1+/Safari1+, you can use

```
document.getElementsByTagName("FORM").length
```

The more modern versions provide generic ways of accessing elements (the `tags` array in IE4+ and the `getElementsByTagName()` method in the W3C DOM) to meet the requirements of object models that expose every HTML (and XML) element as an object.

Promoting the `body` element to the ranks of exposed objects presented its own challenges to the new object model designers. The `body` element is the true “owner” of some properties that the original `document` object had to take on by default. Most properties that had belonged to the original `document` object were renamed in their transfer to the `body` element. For example, the original `document.aLinkColor` property is the `body.aLink` property in the new model. But the `bgColor` property has not been renamed. For the sake of code compatibility, the current versions of browsers recognize both properties, even though the W3C DOM (in an effort to push the development world ahead) has removed the old versions as properties of what it conceives as the `document` object.

As confusing as all of this may sound on the surface, understanding when to refer to the original `document` object and when to use the new syntax doesn't take long. It all depends on what you hang off the right edge of the reference. Original properties and methods are recognized as using the original `document` object; new properties and methods summon the powers of the new `document` object. It's all quite automatic. Thankfully.

## Properties

### activeElement

**Value:** Object reference.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

In IE4+, a script can examine the `document.activeElement` property to see which element currently has focus. The value returned is an element object reference. You can use any of the properties and methods listed in Chapter 15 to find out more about the object. Be aware that not all elements in all operating systems receive focus. For example, buttons in IE4 for the Macintosh do not receive focus.

Although the element used to generate a mouse or keyboard event will most likely have focus (except for MacIE4 buttons), don't rely on the `activeElement` property to find out which element generated an event. The IE `event.srcElement` property is far more reliable.

### Example

Use The Evaluator (Chapter 13) with IE4+ to experiment with the `activeElement` property. Type the following statement into the top text box:

```
document.activeElement.value
```

After you press the Enter key, the Results box shows the value of the text box you just typed into (the very same expression you just typed). But if you then click the Evaluate button, you will see the `value` property of that button object appear in the Results box.

**Related Items:** `event.srcElement` property.

**document.alinkColor**

alinkColor  
 bgColor  
 fgColor  
 linkColor  
 vlinkColor

**Value:** Hexadecimal triplet or color name string.

Mostly Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

These five properties are the script equivalent of the <body> tag attributes of the same name (although the property names are case-sensitive). All five settings can be read via scripting, but the ability to change some or all of these properties varies widely with browser and client platform. Table 18-1 shows a summary of which browsers and platforms can set which of the color properties; Mozilla and Safari browsers support all of the color properties.

**Table 18-1: Setting Document Colors on the Fly (Browser Versions)**

<i>Color Property</i>	<i>Navigator</i>			<i>Internet Explorer</i>		
	<i>Windows</i>	<i>Mac</i>	<i>UNIX</i>	<i>Windows</i>	<i>Mac</i>	<i>UNIX</i>
bgColor	All	4+	4+	All	All	4+
All others	6+	6+	6+	All	All	4+

Values for all color properties can be either the common HTML hexadecimal triplet value (for example, "#00FF00") or any of the Netscape color names. Internet Explorer recognizes these plain language color names, as well. But also be aware that some colors work only when the user has the monitor set to 16- or 24-bit color settings.

If you are scripting exclusively for IE4+ and NN6+, you should use the `document.body` object to access these properties.

### Example

I select some color values at random to plug into three settings of the ugly colors group for Listing 18-1. The smaller window displays a dummy button so that you can see how its display contrasts with color settings. Notice that the script sets the colors of the smaller window by rewriting the entire window's HTML code. After changing colors, the script displays the color values in the original window's text area. Even though some colors are set with the color constant values, properties come back in the hexadecimal triplet values. You can experiment to your heart's content by changing color values in the listing. Every time you change the values in the script, save the HTML file and reload it in the browser.

#### Listing 18-1: Tweaking the Color of Page Elements

```
<html>
  <head>
    <title>Color Me</title>
    <script type="text/javascript">
      // may be blocked at load time by browser popup blockers
      var newWindow = window.open("", "", "height=150,width=300");
```

**document.alinkColor**

```

function defaultColors() {
    return "bgcolor='#c0c0c0' vlink='#551a8b' link='#0000ff'";
}

function uglyColors() {
    return "bgcolor='yellow' vlink='pink' link='lawngreen'";
}

function showColorValues() {
    var result = "";
    result += "bgColor: " + newWindow.document.backgroundColor + "\n";
    result += "vlinkColor: " + newWindow.document.vlinkColor + "\n";
    result += "linkColor: " + newWindow.document.linkColor + "\n";
    document.forms[0].results.value = result;
}

// dynamically writes contents of another window
function drawPage(colorStyle) {
    // work around popup blockers
    if (!newWindow || newWindow.closed) {
        newWindow = window.open("", "", "height=150,width=300");
    }
    var thePage = "";
    thePage += "<html><head><title>Color Sampler</title></head><body ";
    if (colorStyle == "default") {
        thePage += defaultColors();
    } else {
        thePage += uglyColors();
    }
    thePage += ">Just so you can see the variety of items and color, <a ";
    thePage += "href='http://www.nowhere.com'>here's a link</a>, and <a ";
    thePage += "href='http://home.netscape.com'> here is another link </a> you can ";
    thePage += "use on-line to visit and see how its color differs from the standard ";
    thePage += "link.";
    thePage += "<form>";
    thePage += "<input type='button' name='sample' value='Just a ";
    thePage += "Button'>";
    thePage += "</form></body></html>";
    newWindow.document.write(thePage);
    newWindow.document.close();
    showColorValues();
}

// the following works properly only in Windows Navigator
function setColors(colorStyle) {
    if (colorStyle == "default") {
        document.backgroundColor = "#c0c0c0";
    } else {
        document.backgroundColor = "yellow";
    }
}

var newWindow = window.open("", "", "height=150,width=300");
</script>
</head>
<body>
    Try the two color schemes on the document in the small window.
    <form>

```

*Continued*

**document.alinkColor****Listing 18-1** (*continued*)

```

<input type="button" name="default" value='Default Colors'
onclick="drawPage('default')" /> <input type="button" name="weird"
value="Ugly Colors" onclick="drawPage('ugly')" />
<p><textarea name="results" rows="3" cols="20">
  </textarea></p>
<hr />
These buttons change the current document, but not correctly on all
platforms
<p><input type="button" name="default" value='Default Colors'
  onclick="setColors('default')" /> <input type="button" name="weird"
  value="Ugly Colors" onclick="setColors('ugly')" /></p>
</form>
</body>
</html>

```

To satisfy the curiosity of those who want to change the color of a loaded document on the fly, the preceding example includes a pair of buttons that set the color properties of the current document. If you're running browsers and versions capable of this power (see Table 18-1), everything will look fine; but in other platforms or earlier versions, you may lose the buttons and other document content behind the color. You can still click and activate these items, but the color obscures them. Unless you know for sure that users of your Web page use only browsers and clients empowered for background color changes, do not change colors by setting properties of an existing document.

**Related Items:** `body.aLink`, `body.bgColor`, `body.link`, `body.text`, `body.vLink` properties.

**anchors[]**

**Value:** Array of anchor objects.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Anchor objects (described in Chapter 19) are points in an HTML document marked with `<a name="">` tags. Anchor objects are referenced in URLs by a hash value between the page URL and anchor name. Like other object properties that contain a list of nested objects, the `document.anchors` property (notice the plural) delivers an indexed array of anchors in a document. Use the array references to pinpoint a specific anchor for retrieving any anchor property.

Anchor arrays begin their index counts with 0: The first anchor in a document, then, has the reference `document.anchors[0]`. And, as is true with any built-in array object, you can find out how many entries the array has by checking the `length` property. For example

```
var anchorCount = document.anchors.length;
```

The `document.anchors` property is read-only. To script navigation to a particular anchor, assign a value to the `window.location` or `window.location.hash` object, as described in Chapter 17's `location` object discussion.

**Example**

In Listing 18-2, I append an extra script to Listing 17-1 to demonstrate how to extract the number of anchors in the document. The document dynamically writes the number of anchors found in the document. You will not likely ever need to reveal such information to users of your page, and the `document.anchors` property is not one that you will call frequently. The object model defines it automatically as a document property while defining actual anchor objects.

## Listing 18-2: Using Anchors to Navigate Through a Page

```

<html>
  <head>
    <title>document.anchors Property</title>
    <script type="text/javascript">
      function goNextAnchor(where) {
        window.location.hash = where;
      }
    </script>
  </head>
  <body>
    <h1><a id="start" name="start">Top</a></h1>
    <form>
      <input type="button" name="next" value="NEXT"
        onclick="goNextAnchor('sec1')" />
    </form>
    <hr />
    <h1><a id="sec1" name="sec1">Section 1</a></h1>
    <form>
      <input type="button" name="next" value="NEXT"
        onclick="goNextAnchor('sec2')" />
    </form>
    <hr />
    <h1><a id="sec2" name="sec2">Section 2</a></h1>
    <form>
      <input type="button" name="next" value="NEXT"
        onclick="goNextAnchor('sec3')" />
    </form>
    <hr />
    <h1><a id="sec3" name="sec3">Section 3</a></h1>
    <form>
      <input type="button" name="next" value="BACK TO TOP"
        onclick="goNextAnchor('start')" />
    </form>
    <hr />
    <p>
      <script type="text/javascript">
        document.write("<i>There are " + document.anchors.length +
          " anchors defined for this document<\</i>")
      </script>
    </p>
  </body>
</html>

```

**Related Items:** anchor, location objects; document.links property.

## applets[]

**Value:** Array of applet objects.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `applets` property refers to Java applets defined in a document by the `<applet>` tag. An applet is not officially an object in the document until the applet loads completely.

**document.applets**

Most of the work you do with Java applets from JavaScript takes place via the methods and variables defined inside the applet. Although you can reference an applet according to its indexed array position within the `applets` array, you will more likely use the applet object's name in the reference to avoid any confusion.

**Example**

The `document.applets` property is defined automatically as the browser builds the object model for a document that contains applet objects. You will rarely access this property, except to determine how many applet objects a document has.

**Related Items:** `applet` object.

**bgColor**

(See `alinkColor`)

**body**

**Value:** `body` element object.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `document.body` property is a shortcut reference to the `body` element object in modern object models. As you can see in the discussion of the `body` element object later in this chapter, that object has many key properties that govern the look of the entire page. Because the `document` object is the root of all references within any window or frame, the `document.body` property is easier to use to get to the `body` properties, rather than longer references normally used to access HTML element objects in both the IE4+ and W3C object models.

**Example**

Use The Evaluator (Chapter 13) to examine properties of the `body` element object. First, to prove that the `document.body` is the same as the element object that comes back from longer references, enter the following statement into the top text box with either IE5+, NN6+, or some other W3C browser:

```
document.body == document.getElementsByTagName("body")[0]
```

Next, check out the `body` object's property listings later in this chapter and enter the listings into the top text box to review their results. For example:

```
document.body.bgColor  
document.body.tagName
```

**Related Items:** `body` element object.

**charset**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `charset` property reveals the character set used by the browser to render the current document (the NN6+/Moz1+ version of this property is called `characterSet`). You can find possible values for this property at

**document.compatMode**

```
ftp://ftp.isi.edu/in-notes/iana/assignments/character-sets
```

Each browser and operating system has its own default character set. Values may also be set via a `<meta>` tag.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `charset` property. To see the default setting applied to the page, enter the following statement into the top text box:

```
document.charset
```

If you are running IE5+ for Windows and you enter the following statement, the browser will apply a different character set to the page:

```
document.charset = "iso-8859-2"
```

If your version of Windows does not have that character set installed in the system, the browser may ask permission to download and install the character set.

**Related Items:** `characterSet`, `defaultCharset` properties.

**characterSet**

**Value:** String.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `characterSet` property reveals the character set used by the browser to render the current document (the IE4+ version of this property is called `charset`). You can find possible values for this property at

```
http://www.iana.org/assignments/character-sets
```

Each browser and operating system has its own default character set. Values may also be set via a `<meta>` tag.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `characterSet` property in NN6+/Moz1+. To see the default setting applied to the page, enter the following statement into the top text box:

```
document.charset
```

**Related Items:** `charset` property.

**compatMode**

**Value:** String.

Read-Only

**Compatibility:** WinIE6+, MacIE6+, NN7+, Moz1+, Safari-

The `compatMode` property reveals the compatibility mode for the document, as determined by the `DOCTYPE` element's content. The value for this property can be one of the following string constants: `BackCompat` or `CSS1Compat`. The default setting for the `compatMode` property is `BackCompat`.

**document.compatMode****Example**

You may find it useful to check the compatibility mode of a document in order to carry out processing specific to one of the modes. Following is an example of how you might branch to carry out processing for backward-compatible documents:

```
if (document.compatMode == "BackCompat") {  
    // perform backward compatible processing  
}
```

**Related Items:** *Standards Compatibility Modes* (Chapter 13).

**cookie**

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The cookie mechanism in a Web browser lets you store small pieces of information on the client computer in a reasonably secure manner. In other words, when you need some tidbit of information to persist at the client level while either loading diverse HTML documents or moving from one session to another, the cookie mechanism saves the day. The cookie is commonly used as a means to store the username and password you enter into a password-protected Web site. The first time you enter this information into a CGI-governed form, the CGI program has Navigator write the information back to a cookie on your hard disk (usually after encrypting the password). Rather than bothering you to enter the username and password the next time you access the site, the server searches the cookie data stored for that particular server and extracts the username and password for automatic validation processing behind the scenes.

Other applications of the cookie include storing user preferences and information about the user's previous visit to the site. Preferences may include font styles or sizes and whether the user prefers viewing content inside a frameset or not. As shown in Chapter 54 on the CD-ROM, a time stamp of the previous visit can allow a coded HTML page to display highlighted images next to content that has changed since the user's last visit, even if you have updated the page several times in the interim. Rather than hard-wiring "New" flags for *your* last visit, the scripts highlight what's new for the visitor.

**The cookie file**

Allowing some foreign CGI program to read from and write to your hard disk may give you pause, but browser cookie mechanisms don't just open up your drive's directory for the world to see (or corrupt). Instead, the cookie mechanism provides access to just one special text file (Navigator/Mozilla/Safari) or type of text file (Internet Explorer) located in a platform-specific spot on your drive.

In Mozilla-based browsers, for example, the cookie file is named `cookies.txt` and is located in a directory (whose name ends in `.slt`) within the browser's profile area. In Windows, that location is `C:\Windows\Application Data\Mozilla\Profiles\[profilename]\`; in Mac OSX, the location is `[user]/Library/Mozilla/Profiles/[profilename]/`. Internet Explorer for Windows uses a different filing system: all cookies for each domain are saved in a domain-specific file inside the `C:\Windows\Temporary Internet Files\` directory. Filenames begin with `Cookie:` and include the username and domain of the server that wrote the cookie. Safari cookies are recorded in an XML file named `Cookies.plist` within the `[user]/Library/Cookies/` directory.

A cookie file is a text file. If curiosity drives you to open a cookie file, I recommend you do so only with a copy saved in another directory or folder. Any alteration to the existing file can mess up whatever valuable cookies are stored there for sites you regularly visit. The data format for cookie files differs across browsers, in line with the different methodologies used for filing cookies. Inside the Netscape/Mozilla file (after a few comment lines warning you not to manually alter the file) are lines of tab-delimited text. Each return-delimited line contains one cookie's information. The cookie file is just like a text listing of a database. In each of the IE cookie files, the same data points are stored for a cookie as for Navigator, but the items are in a return-delimited list. The structure of these files is of no importance to scripting cookies, because all browsers utilize the same syntax for reading and writing cookies through the `document.cookie` property.

Note

As you experiment with browser's cookies, you will be tempted to look into the cookie file after a script writes some data to the cookie. The cookie file usually will not contain the newly written data, because in most browsers cookies are transferred to disk only when the user quits the browser; conversely, the cookie file is read into the browser's memory when it is launched. While you read, write, and delete cookies during a browser session, all activity is performed in memory (to speed up the process) to be saved later.

## A cookie record

Among the "fields" of each cookie record are the following (not necessarily in this order):

- ♦ Domain of the server that created the cookie
- ♦ Information on whether you need a secure HTTP connection to access the cookie
- ♦ Pathname of URL(s) capable of accessing the cookie
- ♦ Expiration date of the cookie
- ♦ Name of the cookie entry
- ♦ String data associated with the cookie entry

Notice that cookies are domain-specific. In other words, if one domain creates a cookie, another domain cannot access it through the browser's cookie mechanism behind your back. That reason is why it's generally safe to store what I call *throwaway passwords* (the username/password pairs required to access some free registration-required sites) in cookies. Moreover, sites that store passwords in a cookie usually do so as encrypted strings, making it more difficult for someone to hijack the cookie file from your unattended PC and figure out what your personal password scheme may be.

Cookies also have expiration dates. Because some browsers may allow no more than a fixed number of cookies (300 in NN), the cookie file can get pretty full over the years. Therefore, if a cookie needs to persist past the current browser session, it should have an expiration date established by the cookie writer. Browsers automatically clean out any expired cookies.

Not all cookies have to last beyond the current session, however. In fact, a scenario in which you use cookies temporarily while working your way through a Web site is quite typical. Many shopping sites employ one or more temporary cookie records to behave as the shopping cart for recording items you intend to purchase. These items are copied to the order form at checkout time. But after you submit the order form to the server, that client-side data has no particular value. As it turns out, if your script does not specify an expiration date, the browser keeps the cookie fresh in memory without writing it to the cookie file. When you quit the browser, that cookie data disappears as expected.

**document.cookie****JavaScript access**

Scripted access of cookies from JavaScript is limited to setting the cookie (with a number of optional parameters) and getting the cookie data (but with none of the parameters).

The original object model defines cookies as properties of documents, but this description is somewhat misleading. If you use the default path to set a cookie (that is, the current directory of the document whose script sets the cookie in the first place), all documents in that same server directory have read and write access to the cookie. A benefit of this arrangement is that if you have a scripted application that contains multiple documents, all documents served from the same directory can share the cookie data. NN and IE, however, impose a limit of 20 named cookie entries (that is, one name/value pair) for any domain. If your cookie requirements are extensive, you need to fashion ways of concatenating cookie data (I do this in the Decision Helper application in Chapter 55 on the CD-ROM).

**Saving cookies**

To write cookie data to the cookie file, you use a simple JavaScript assignment operator with the `document.cookie` property. But the formatting of the data is crucial to achieving success. Here is the syntax for assigning a value to a cookie (optional items are in brackets; placeholders for data you supply are in italics):

```
document.cookie = "cookieName=cookieData  
[; expires=timeInGMTString]  
[; path=pathName]  
[; domain=domainName]  
[; secure]"
```

Let's examine each of the properties individually.

**Name/Data**

Each cookie must have a name and a string value (even if that value is an empty string). Such name/value pairs are fairly common in HTML, but they look odd in an assignment statement. For example, if you want to save the string "Fred" to a cookie named "userName," the JavaScript statement is

```
document.cookie = "userName=Fred";
```

If the browser sees no existing cookie in the current domain with this name, it automatically creates the cookie entry for you; if the named cookie already exists, the browser replaces the old data with the new data. Retrieving the `document.cookie` property at this point yields the following string:

```
userName=Fred
```

You can omit all the other cookie-setting properties, in which case the browser uses default values, as explained in a following section. For temporary cookies (those that don't have to persist beyond the current browser session), the name/value pair is usually all you need.

The entire name/value pair must be a single string with no semicolons, commas, or character spaces. To take care of spaces between words, preprocess the value with the JavaScript `escape()` function, which URL-encodes the spaces as `%20` (and then be sure to `unescape()` the value to restore the human-readable spaces when you retrieve the cookie later).

You cannot save a JavaScript array or object to a cookie. But with the help of the `Array.join()` method, you can convert an array to a string; use `String.split()` to re-create the array after reading the cookie at a later time. These two methods are available in NN3+/Moz1+, IE4+, and Safari1+.

## Expires

Expiration dates, when supplied, must be passed as Greenwich Mean Time (GMT) strings (see Chapter 29 about time data). To calculate an expiration date based on today's date, use the JavaScript `Date` object as follows:

```
var exp = new Date();
var oneYearFromNow = exp.getTime() + (365 * 24 * 60 * 60 * 1000);
exp.setTime(oneYearFromNow);
```

Then convert the date to the accepted GMT string format:

```
document.cookie = "userName=Fred; expires=" + exp.toGMTString();
```

In the cookie file, the expiration date and time is stored as a numeric value (seconds) but, to set it, you need to supply the time in GMT format. You can delete a cookie before it expires by setting the named cookie's expiration date to a time and date earlier than the current time and date. The safest expiration parameter is

```
expires=Thu, 01-Jan-70 00:00:01 GMT
```

Omitting the expiration date signals the browser that this cookie is temporary. The browser never writes it to the cookie file and forgets it the next time you quit the browser.

## Path

For client-side cookies, the default path setting (the current directory) is usually the best choice. You can, of course, create a duplicate copy of a cookie with a separate path (and domain) so that the same data is available to a document located in another area of your site (or the Web).

## Domain

To help synchronize cookie data with a particular document (or group of documents), the browser matches the domain of the current document with the domain values of cookie entries in the cookie file. Therefore, if you were to display a list of all cookie data contained in a `document.cookie` property, you would get back all the name/value cookie pairs from the cookie file whose domain parameter matches that of the current document.

Unless you expect the document to be replicated in another server within your domain, you can usually omit the `domain` parameter when saving a cookie. Default behavior automatically supplies the domain of the current document to the cookie file entry. Be aware that a domain setting must have at least two periods, such as

```
.mcom.com
.hotwired.com
```

Or, you can write an entire URL to the domain, including the `http://` protocol.

## SECURE

If you omit the `SECURE` parameter when saving a cookie, you imply that the cookie data is accessible to any document or CGI program from your site that meets the other domain- and path-matching properties. For client-side scripting of cookies, you should omit this parameter when saving a cookie.

**document.cookie****Retrieving cookie data**

Cookie data retrieved via JavaScript is contained in one string, including the whole name-data pair. Even though the cookie file stores other parameters for each cookie, you can retrieve only the name-data pairs via JavaScript. Moreover, when two or more (up to a maximum of 20) cookies meet the current domain criteria, these cookies are also lumped into that string, delimited by a semicolon and space. For example, a `document.cookie` string may look like this:

```
userName=Fred; password=NikL2sPacU
```

In other words, you cannot treat named cookies as objects. Instead, you must parse the entire cookie string, extracting the data from the desired name-data pair.

When you know that you're dealing with only one cookie (and that no more will ever be added to the domain), you can customize the extraction based on known data, such as the cookie name. For example, with a cookie name that is seven characters long, you can extract the data with a statement such as this:

```
var data = unescape(document.cookie.substring(7,document.cookie.length));
```

The first parameter of the `substring()` method includes the equal sign to separate the name from the data.

A better approach is to create a general-purpose function that can work with single- or multiple-entry cookies. Here is one I use in some of my pages:

```
function getCookieData(labelName) {
    var labelLen = labelName.length;
    // read cookie property only once for speed
    var cookieData = document.cookie;
    var cLen = cookieData.length;
    var i = 0;
    var cEnd;
    while (i < cLen) {
        var j = i + labelLen;
        if (cookieData.substring(i,j) == labelName) {
            cEnd = cookieData.indexOf(";",j);
            if (cEnd == -1) {
                cEnd = cookieData.length;
            }
            return unescape(cookieData.substring(j+1, cEnd));
        }
        i++;
    }
    return "";
}
```

Calls to this function pass the label name of the desired cookie as a parameter. The function parses the entire cookie string, chipping away any mismatched entries (through the semicolons) until it finds the cookie name.

If all of this cookie code still makes your head hurt, you can turn to a set of functions devised by experienced JavaScripter and Web site designer Bill Dortch of hIdaho Design. His cookie functions provide generic access to cookies that you can use in all of your cookie-related pages. Listing 18-3 shows Bill's cookie functions, which include a variety of safety nets for date calculation bugs that appeared in some older versions of Netscape Navigator. Don't be put off by the length of the listing: Most of the lines are comments.

**Listing 18-3: Bill Dortch's Cookie Functions**

    <script type="text/javascript">
      //
      // Cookie Functions -- "Night of the Living Cookie" Version (25-Jul-96)
      //
      // Written by: Bill Dortch, hIdaho Design
      // The following functions are released to the public domain.
      //
      // This version takes a more aggressive approach to deleting
      // cookies. Previous versions set the expiration date to one
      // millisecond prior to the current time; however, this method
      // did not work in Netscape 2.02 (though it does in earlier and
      // later versions), resulting in "zombie" cookies that would not
      // die. DeleteCookie now sets the expiration date to the earliest
      // usable date (one second into 1970), and sets the cookie's value
      // to null for good measure.
      //
      // Also, this version adds optional path and domain parameters to
      // the DeleteCookie function. If you specify a path and/or domain
      // when creating (setting) a cookie**, you must specify the same
      // path/domain when deleting it, or deletion will not occur.
      //
      // The FixCookieDate function must now be called explicitly to
      // correct for the 2.x Mac date bug. This function should be
      // called *once* after a Date object is created and before it
      // is passed (as an expiration date) to SetCookie. Because the
      // Mac date bug affects all dates, not just those passed to
      // SetCookie, you might want to make it a habit to call
      // FixCookieDate any time you create a new Date object:
      //
      //   var theDate = new Date();
      //   FixCookieDate (theDate);
      //
      // Calling FixCookieDate has no effect on platforms other than
      // the Mac, so there is no need to determine the user's platform
      // prior to calling it.
      //
      // This version also incorporates several minor coding improvements.
      //
      // **Note that it is possible to set multiple cookies with the same
      // name but different (nested) paths. For example:
      //
      //   SetCookie ("color","red",null,"/outer");
      //   SetCookie ("color","blue",null,"/outer/inner");
      //
      // However, GetCookie cannot distinguish between these and will return
      // the first cookie that matches a given name. It is therefore
      // recommended that you *not* use the same name for cookies with
      // different paths. (Bear in mind that there is *always* a path
```

*Continued*

**document.cookie****Listing 18-3 (continued)**

```

// associated with a cookie; if you don't explicitly specify one,
// the path of the setting document is used.)
//
// Revision History:
//
// "Toss Your Cookies" Version (22-Mar-96)
//   - Added FixCookieDate() function to correct for Mac date bug
//
// "Second Helping" Version (21-Jan-96)
//   - Added path, domain and secure parameters to SetCookie
//   - Replaced home-rolled encode/decode functions with Netscape's
//     new (then) escape and unescape functions
//
// "Free Cookies" Version (December 95)
//
// For information on the significance of cookie parameters,
// and on cookies in general, please refer to the official cookie
// spec, at:
//
//   http://www.netscape.com/newsref/std/cookie_spec.html
//
//*****
// "Internal" function to return the decoded value of a cookie
//
function getCookieVal (offset) {
    var endstr = document.cookie.indexOf(";", offset);
    if (endstr == -1) {
        endstr = document.cookie.length;
    }
    return unescape(document.cookie.substring(offset, endstr));
}

//
// Function to correct for 2.x Mac date bug. Call this function to
// fix a date object prior to passing it to SetCookie.
// IMPORTANT: This function should only be called *once* for
// any given date object! See example at the end of this document.
//
function FixCookieDate (date) {
    var base = new Date(0);
    var skew = base.getTime(); // dawn of (Unix) time - should be 0
    if (skew > 0) { // Except on the Mac - ahead of its time
        date.setTime (date.getTime() - skew);
    }
}

//
// Function to return the value of the cookie specified by "name".
// name - String object containing the cookie name.
// returns - String object containing the cookie value, or null if
// the cookie does not exist.
//

```

```

function GetCookie (name) {
    var arg = name + "=";
    var alen = arg.length;
    var clen = document.cookie.length;
    var i = 0;
    while (i < clen) {
        var j = i + alen;
        if (document.cookie.substring(i, j) == arg) {
            return getCookieVal (j);
        }
        i = document.cookie.indexOf(" ", i) + 1;
        if (i == 0) {
            break;
        }
    }
    return null;
}

//
// Function to create or update a cookie.
// name - String object containing the cookie name.
// value - String object containing the cookie value. May contain
// any valid string characters.
// [expires] - Date object containing the expiration data of the
// cookie. If omitted or null, expires the cookie at the end of the
// current session.
// [path] - String object indicating the path for which the cookie is
// valid.
// If omitted or null, uses the path of the calling document.
// [domain] - String object indicating the domain for which the cookie
// is valid. If omitted or null, uses the domain of the calling
// document.
// [secure] - Boolean (true/false) value indicating whether cookie
// transmission requires a secure channel (HTTPS).
//
// The first two parameters are required. The others, if supplied, must
// be passed in the order listed above. To omit an unused optional
// field, use null as a place holder. For example, to call SetCookie
// using name, value and path, you would code:
//
//     SetCookie ("myCookieName", "myCookieValue", null, "/");
//
// Note that trailing omitted parameters do not require a placeholder.
//
// To set a secure cookie for path "/myPath", that expires after the
// current session, you might code:
//
//     SetCookie (myCookieVar, cookieValueVar, null, "/myPath", null,
//     true);
//
function SetCookie (name,value,expires,path,domain,secure) {
    document.cookie = name + "=" + escape (value) +
        ((expires) ? "; expires=" + expires.toGMTString() : "") +
        ((path) ? "; path=" + path : "") +
        ((domain) ? "; domain=" + domain : "") +
        ((secure) ? "; secure" : "");
}

```

*Continued*

## document.cookie

## Listing 18-3 (continued)

```

// Function to delete a cookie. (Sets expiration date to start of epoch)
// name - String object containing the cookie name
// path - String object containing the path of the cookie to delete.
// This MUST be the same as the path used to create the
// cookie, or null/omitted if
// no path was specified when creating the cookie.
// domain - String object containing the domain of the cookie to
// delete. This MUST be the same as the domain used to
// create the cookie, or null/omitted if no domain was
// specified when creating the cookie.
//
function DeleteCookie (name,path,domain) {
    if (GetCookie(name)) {
        document.cookie = name + "=" +
            ((path) ? "; path=" + path : "") +
            ((domain) ? "; domain=" + domain : "") +
            "; expires=Thu, 01-Jan-70 00:00:01 GMT";
    }
}

//
// Examples
//
var expdate = new Date ();
FixCookieDate (expdate); // Correct for Mac date bug (call only once)
expdate.setTime (expdate.getTime() + (24 * 60 * 60 * 1000)); // 24 hrs
SetCookie ("ccpath", "http://www.idaho.com/colorcenter/", expdate);
SetCookie ("ccname", "hIdaho Design ColorCenter", expdate);
SetCookie ("tempvar", "This is a temporary cookie.");
SetCookie ("ubiquitous", "This cookie will work anywhere in this
    domain",null,"/");
SetCookie ("paranoid", "This cookie requires secure
    communications",expdate,"/",null,true);
SetCookie ("goner", "This cookie must die!");
document.write (document.cookie + "<br>");
DeleteCookie ("goner");
document.write (document.cookie + "<br>");
document.write ("ccpath = " + GetCookie("ccpath") + "<br>");
document.write ("ccname = " + GetCookie("ccname") + "<br>");
document.write ("tempvar = " + GetCookie("tempvar") + "<br>");
</script>
</body>
</html>

```

**Extra batches**

You may design a site that needs more than 20 cookies for a given domain. For example, in a shopping site, you never know how many items a customer may load into the shopping cart cookie.

Because each named cookie stores plain text, you can create your own text-based data structures to accommodate multiple pieces of information per cookie. (But also watch out for a

**document.defaultView**

practical limit of 2,000 characters per name/value pair within the 4,000 character maximum for any domain's combined cookies.) The trick is determining a delimiter character that won't be used by any of the data in the cookie. In Decision Helper (in Chapter 55 on the CD-ROM), for example, I use a period to separate multiple integers stored in a cookie.

With the delimiter character established, you must then write functions that concatenate these “subcookies” into single cookie strings and extract them on the other side. It's a bit more work, but well worth the effort to have the power of persistent data on the client.

**Example**

Experiment with the last group of statements in Listing 18-3 to create, retrieve, and delete cookies. You can also experiment with The Evaluator by assigning a name/value pair string to `document.cookie`, and then examining the value of the `cookie` property.

**Related Items:** String object methods (Chapter 27).

**defaultCharset**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `defaultCharset` property reveals the character set used by the browser to render the current document. You can find possible values for this property at

<http://www.iana.org/assignments/character-sets>

Each browser and operating system has its own default character set. Values may also be set via a `<meta>` tag. The difference between the `defaultCharset` and `charset` properties is not clear, especially because both are read/write (although modifying the `defaultCharset` property has no visual effect on the page). However, if your scripts temporarily modify the `charset` property, you can use the `defaultCharset` property to return to the original character set:

```
document.charset = document.defaultCharset;
```

**Example**

Use The Evaluator (Chapter 13) to experiment with the `defaultCharset` property. To see the default setting applied to the page, enter the following statement into the top text box:

```
document.defaultCharset
```

**Related Items:** `charset`, `characterSet` properties.

**defaultView**

**Value:** window or frame object reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `defaultView` property returns a reference to the object serving as the “viewer” for the document. The viewer is responsible for rendering the document, and in NN6+ the object returned in the `defaultView` property is the window or frame object that contains the document. This W3C DOM Level 2 property provides access to computed CSS values being applied to any HTML element (via the `document.defaultView.getComputedStyle()` method, or more simply, the `window.getComputedStyle()` method).

**Related Items:** window and frame properties; `window.getComputedStyle()` method.

**document.designMode**

## designMode

**Value:** String.

Read/Write

**Compatibility:** WinIE5+, MacIE-, NN7.1, Moz1.4+, Safari-

The `designMode` property is applicable only when WinIE5+ technology is being used as a component in another application. The property controls whether the browser module is being used for HTML editing. Modifying the property from within a typical HTML page in the IE5+ browser has no effect. But on the Mozilla side, the property can be used to turn an `iframe` element's document object into an HTML editable document. Visit <http://www.mozilla.org/editor> for current details and examples.

## doctype

**Value:** `DocumentType` object reference.

Read-Only

**Compatibility:** WinIE-, MacIE5+, NN6+, Moz1+, Safari-

The `doctype` property comes from the W3C Core DOM and returns a `DocumentType` object — a representation of the DTD information for the document. The `DocumentType` object (if one is explicitly defined in the source code) is the first child node of the root document node (and is thus a sibling to the HTML element).

Table 18-2 shows the typical `DocumentType` object property list and values for a generic HTML page. Future DOM specifications will allow these properties to be read/write.

**Table 18-2: DocumentType Object in NN6+/Moz1+**

<i>Property</i>	<i>Value</i>
<code>entities</code>	<code>null</code>
<code>internalSubset</code>	<b>(empty)</b>
<code>name</code>	<code>html</code>
<code>notations</code>	<code>null</code>
<code>publicId</code>	<code>-//W3C//DTD XHTML 1.0 Transitional//EN</code>
<code>systemId</code>	<code>http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd</code>

**Related Items:** Node object (Chapter 14).

## documentElement

**Value:** HTML or XML element object reference.

Read-Only

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `documentElement` property returns a reference to the HTML (or XML) element object that contains all of the content of the current document. The naming of this property is a bit misleading, because the root document node is not an element, but its only child node is the HTML (or XML) element for the page. At best, you can think of this property as providing scripts with an “element face” to the `document` object and document node associated with the page currently loaded in the browser.

## Example

Use The Evaluator (Chapter 13) to examine the behavior of the `documentElement` property. In IE5+/W3C, enter the following statement into the top text field:

```
document.documentElement.tagName
```

The result is HTML, as expected.

**Related Items:** `ownerDocument` property (Chapter 15).

## domain

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

Security restrictions can get in the way of sites that have more than one server at their domain. Because some objects, especially the `location` object, prevent access to properties of other servers displayed in other frames, legitimate access to those properties are blocked. For example, it's not uncommon for popular sites to have their usual public access site on a server named something such as `www.popular.com`. If a page on that server includes a front end to a site search engine located at `search.popular.com`, visitors who use browsers with these security restrictions are denied access.

To guard against that eventuality, a script in documents from both servers can instruct the browser to think both servers are the same. In the preceding example, you would set the `document.domain` property in both documents to `popular.com`. Without specifically setting the property, the default value includes the server name as well, thus causing a mismatch between hostnames.

Before you start thinking that you can spoof your way into other servers, be aware that you can set the `document.domain` property only to servers with the same domain (following the "two-dot" rule) as the document doing the setting. Therefore, documents originating only from `xxx.popular.com` can set their `document.domain` properties to `popular.com` server.

**Related Items:** `window.open()` method; `window.location` object; security (Chapter 46 on the CD-ROM).

## embeds[]

**Value:** Array of embed element objects.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

Although now supplanted by the `<object>` tag, the `<embed>` tag used to be the markup that loaded data requiring a plug-in application to play or display. The `document.embeds` property is an array of embed element objects within the document:

```
var count = document.embeds.length;
```

For controlling those plug-ins in Navigator and Mozilla-based browsers, you can use the LiveConnect technology, described in Chapter 44 on the CD-ROM.

**Related Items:** embed element object (Chapter 40 on the CD-ROM).

**document.expando**

## expando

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

Microsoft calls any custom property that is not a native property of the `document` object an *expando* property. By default, most objects in recent generations of browsers allow scripts to add new properties of objects as a way to temporarily store data without explicitly defining global variables. For example, if you want to maintain an independent counter of how often a function is invoked, you can create a custom property of the `document` object and use it as the storage facility:

```
document.counter = 0;
```

IE4+ lets you control whether the `document` object is capable of accepting *expando* properties. The default value of the `document.expando` property is `true`, thus allowing custom properties. But the potential downside to this permissiveness, especially during the page construction phase, is that a misspelled native property name is gladly accepted by the `document` object. You may not be aware of why the title bar of the browser window doesn't change when you assign a new string to the `document.Title` property (which, in the case-sensitive world of JavaScript, is distinct from the native `document.title` property).

**Example**

Use The Evaluator (Chapter 13) to experiment with the `document.expando` property in IE4+. Begin by proving that the `document` object can normally accept custom properties. Type the following statement into the top text field:

```
document.spooky = "Boo!"
```

This property is now set and stays that way until the page is either reloaded or unloaded.

Now freeze the `document` object's properties with the following statement:

```
document.expando = false
```

If you try to add a new property, such as the following, you receive an error:

```
document.happy = "tra la"
```

Interestingly, even though `document.expando` is turned off, the first custom property is still accessible and modifiable.

**Related Items:** prototype property of custom objects (Chapter 33).

**fgColor**

(See `alinkColor`)

**fileCreatedDate****fileModifiedDate****fileSize****Value:** String, Integer (`fileSize`).

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

**document.fileCreatedDate**

These three IE-specific properties return information about the file that holds the current document. The first two properties (not implemented in MacIE) reveal the dates on which the current document's file was created and modified. For an unmodified file, its creation and modified dates are the same. The `fileSize` property reveals the number of bytes of the file.

Date values returned for the first two properties are formatted differently between IE4 and IE5+. The former provides a full readout of the day and date; the latter in a format similar to `mm/dd/yyyy`. Note, however, that the values contain only the date and not the time. In any case, you can use the values as the parameter to a new `Date()` constructor function. You can then use date calculations for such information as the number of days between the current day and the most recent modification.

Not all servers may provide the proper date or size information about a file or in a format that IE can interpret. Test your implementation on the deployment server to ensure compatibility.

Also, be aware that these properties can be read only for a file that is loaded in the browser. JavaScript by itself cannot get this information about files that are on the server but not loaded in the browser.

IE5.5+ exposes a property called `fileUpdatedDate`, but the property does not return any data. This property may be a phantom property left over from a prerelease version.

## Example

Listing 18-4 dynamically generates several pieces of content relating to the creation and modification dates of the file, as well as its size. More importantly, the listing demonstrates how to turn a value returned by the file date properties into a genuine date object that can be used for date calculations. In the case of Listing 18-4, the calculation is the number of full days between the creation date and the day someone views the file. Notice that the dynamically generated content is added very simply via the `innerText` properties of carefully located `span` elements in the body content.

### Listing 18-4: Displaying File Information for a Web Page

```
<html>
  <head>
    <title>fileCreatedDate and fileModifiedDate Properties</title>
    <script type="text/javascript">
      function fillInBlanks() {
        var created = document.fileCreatedDate;
        var modified = document.fileModifiedDate;
        document.getElementById("created").innerText = created;
        document.getElementById("modified").innerText = modified;
        var createdDate = new Date(created).getTime();
        var today = new Date().getTime();
        var diff = Math.floor((today - createdDate) / (1000*60*60*24));
        document.getElementById("diff").innerText = diff;
        document.getElementById("size").innerText = document.fileSize;
      }
    </script>
  </head>
  <body onload="fillInBlanks()">
```

*Continued*

**document.fileCreatedDate****Listing 18-4 (continued)**

```

<h1>fileCreatedDate and fileModifiedDate Properties</h1>
<hr />
<p>This file (<span id="size">&nbsp;</span> bytes) was created on <span
  id="created">&nbsp;</span> and most recently modified on <span
  id="modified">&nbsp;</span>.</p>
<p>It has been <span id="diff">&nbsp;</span> days since this file was
  created.</p>
</body>
</html>

```

**Related Items:** lastModified property.

**forms[]**

**Value:** Array.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

As I show in Chapter 21, which is dedicated to the form object, an HTML form (anything defined inside a `<form>...</form>` tag pair) is a JavaScript object unto itself. You can create a valid reference to a form according to its name (assigned via a form's name attribute). For example, if a document contains the following form definition

```

<form name="phoneData">
  input item definitions
</form>

```

your scripts can refer to the form object by name:

```
document.phoneData
```

However, a document object also tracks its forms in another way: as an array of form objects. The first item of a document.forms array is the form that loaded first (it was first from the top of the HTML code). If your document defines one form, the forms property is an array one entry in length; with three separate forms in the document, the array is three entries long.

Use standard array notation to reference a particular form from the document.forms array. For example, the first form in a document (the "zeroth" entry of the document.forms array) is referenced as

```
document.forms[0]
```

Any of the form object's properties or methods are available by appending the desired property or method name to the reference. For example, to retrieve the value of an input text field named homePhone from the second form of a document, the reference you use is

```
document.forms[1].homePhone.value
```

One advantage to using the document.forms property for addressing a form object or element instead of the actual form name is that you may be able to generate a library of generalizable scripts that know how to cycle through all available forms in a document and hunt for a form that has some special element and property. The following script fragment (part of a repeat loop described more fully in Chapter 31) uses a loop-counting variable (i) to help the script check all forms in a document:

```
for (var i = 0; i < document.forms.length; i++) {
  if (document.forms[i]. ... ) {
    statements
  }
}
```

One more variation on forms array references lets you substitute the name of a form (as a string) for the forms array index. For example, the form named `phoneData` can be referenced as

```
document.forms["phoneData"]
```

If you use a lot of care in assigning names to objects, you will likely prefer the `document.formName` style of referencing forms. In this book, you see both indexed array and form name style references. The advantage of using name references is that even if you redesign the page and change the order of forms in the document, references to the named forms will still be valid, whereas the index numbers of the forms will have changed. See also the discussion in Chapter 21 of the `form` object and how to pass a form's data to a function.

## Example

The document in Listing 18-5 is set up to display an alert dialog box that simulates navigation to a particular music site, based on the checked status of the “bluish” checkbox. The user input here is divided into two forms: one form with the checkbox and the other form with the button that does the navigation. A block of copy fills the space in between. Clicking the bottom button (in the second form) triggers the function that fetches the checked property of the “bluish” checkbox by using the `document.forms[i]` array as part of the address.

### Listing 18-5: A Simple Form Example

```
<html>
  <head>
    <title>document.forms example</title>
    <script type="text/javascript">
      function goMusic() {
        if (document.forms[0].bluish.checked) {
          alert("Now going to the Blues music area...");
        } else {
          alert("Now going to Rock music area...");
        }
      }
    </script>
  </head>
  <body>
    <form name="theBlues">
      <input type="checkbox" name="bluish" />Check here if you've got the
      blues.
    </form>
    <hr />
    M<br />
    o<br />
    r<br />
    e<br />
    <br />
    C<br />
    o<br />
```

*Continued*

**document.forms****Listing 18-5** (*continued*)

```
p<br />
y<br />
<hr />
<form name="visit">
  <input type="button" value="Visit music site" onclick="goMusic()" />
</form>
</body>
</html>
```

**Related Items:** form object (Chapter 21).

**frames[ ]**

**Value:** Array.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `document.frames` property is similar to the `window.frames` property, but its association with the document object may seem a bit illogical at times. The objects contained by the array returned from the property are window objects, which means they are the window objects of any frame elements (from a framesetting document) or `iframe` elements (from a plain HTML document) defined for the document. Distinguishing the window objects from the `iframe` element objects is important. Window objects have different properties and methods than the frame and `iframe` element objects. The latter's properties typically represent the attributes for those element's tags. If a document contains no `iframe` elements, the `document.frames` array length is zero.

While you can access an individual frame object via the typical array syntax (for example, `document.frames[0]`), you can also use alternate syntax that Microsoft provides for collections of objects. The index number can also be placed inside parentheses, as in

```
document.frames(0)
```

Moreover, if the frames have values assigned to their `name` attributes, you can use the name (in string form) as a parameter:

```
document.frames("contents")
```

And if the collection of frames has more than one frame with the same name, you must take special care. Using the duplicated name as a parameter forces the reference to return a collection of frame objects that share that name. Or, you can limit the returned value to a single instance of the duplicate-named frames by specifying an optional second parameter indicating the index. For example, if a document has two `iframe` elements with the name `contents`, a script could reference the second window object as

```
document.frames("contents", 1)
```

For the sake of cross-browser compatibility, my preference for referencing frame window objects is via the `window.frames` property.

### Example

See Listings 16-7 and 16-8 for examples of using the `frames` property with window objects. The listings work with IE4+ if you swap references to `window` with `document`.

**Related Items:** `window.frames` property.

`height`

`width`

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4+, Moz1+, Safari1+

The `height` and `width` properties provide the pixel dimensions of the content within the current window (or frame). If the document's content is smaller than the size of the browser's content region, the dimensions returned by these properties include the blank space to the right and/or bottom edges of the content area of the window. But if the content extends beyond the viewable edges of the content region, the dimensions include the unseen content as well. The corresponding measures in IE4+ are the `document.body.scrollHeight` and `document.body.scrollWidth` properties.

### Example

Use The Evaluator (Chapter 13) to examine the `height` and `width` properties of that document. Enter the following statement into the top text box and click the Evaluate button:

```
"height=" + document.height + "; width=" + document.width
```

Resize the window so that you see both vertical and horizontal scroll bars in the browser window and click the Evaluate button again. If either or both numbers get smaller, the values in the Results box are the exact size of the space occupied by the document. But if you expand the window to well beyond where the scroll bars are needed, the values extend to the number of pixels in each dimension of the window's content region.

**Related Items:** `document.body.scrollHeight`, `document.body.scrollWidth` properties.

`ids[]`

**Value:** Array.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

The NN4-specific `ids` property is used in the browser's alternative, JavaScript-based stylesheet syntax. Deployment of JavaScript stylesheets is exceedingly rare. In some ways, the `document.ids` property behaves similarly to the IE4+ `document.all` property, but `document.ids` cannot be used in regular scripts to access element objects.

**Related Items:** `tags` property.

`images[]`

**Value:** Array.

Read-Only

**Compatibility:** WinIE4+, MacIE3+, NN3+, Moz1+, Safari1+

With images treated as first-class objects beginning with NN3 and IE4, it's only natural for a document to maintain an array of all the image tags defined on the page (just as it does for links and anchors). The prime importance of having images as objects is that you can modify their content (the source file associated with the rectangular space of the image) on the fly. You can find details about the `image` object in Chapter 20.

**document.images**

Use image array references to pinpoint a specific image for retrieval of any image property or for assigning a new image file to its `src` property. Image arrays begin their index counts with 0: The first image in a document has the reference `document.images[0]`. And, as with any array object, you can find out how many images the array contains by checking the `length` property. For example:

```
var imageCount = document.images.length;
```

Images can also have names, so if you prefer, you can refer to the image object by its name, as in

```
var imageLoaded = document.imageName.complete;
```

or

```
var imageLoaded = document.images[imageName].complete;
```

The `document.images` array is a useful guide to knowing whether a browser supports swappable images. Any browser that treats an `img` element as an object always forms a `document.images` array in the page. If no images are defined in the page, the array is still there, but its `length` is zero. The array's existence, however, is the clue about image object compatibility. Because the `document.images` array evaluates to an array object when present, the expression can be used as a condition expression for branching to statements that involve image swapping:

```
if (document.images) {  
    // image swapping or precaching here  
}
```

Earlier browsers that don't have this property evaluate `document.images` as undefined and thus the condition is treated as a `false` value.

## Example

The `document.images` property is defined automatically as the browser builds the object model for a document that contains image objects. See the discussion about the Image object in Chapter 20 for reference examples.

**Related Items:** Image object (Chapter 20).

## implementation

**Value:** Object.

Read-Only

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The Core W3C DOM defines the `document.implementation` property as an avenue to let scripts find out what DOM features (that is, modules of the DOM standard) are implemented for the current environment. While the object returned by the property (a `DOMImplementation` object) has no properties, it has a method, `hasFeature()`, which lets scripts find out, for example, whether the environment supports HTML or just XML. The first parameter of the `hasFeature()` method is the feature in the form of a string. The second parameter is a string form of the version number. The method returns a Boolean value.

A section of the W3C DOM specification, called “Conformance,” governs the module names (the standard also allows browser-specific features to be tested via the `hasFeature()` method). Module names include strings such as `HTML`, `XML`, `MouseEvents`, and so on.

**document.lastModified**

Version numbering for W3C DOM modules corresponds to the W3C DOM level. Thus, the version for the XML DOM module in DOM Level 2 is known as 2.0. Note that versions refer to DOM modules and not, for instance, the separate HTML standard.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `document.implementation.hasFeature()` method. Enter the following statements one at a time into the top text field and examine the results:

```
document.implementation.hasFeature("HTML", "1.0")
document.implementation.hasFeature("HTML", "2.0")
document.implementation.hasFeature("HTML", "3.0")
document.implementation.hasFeature("CSS", "2.0")
document.implementation.hasFeature("CSS2", "2.0")
```

Feel free to try other values.

**lastModified**

**Value:** Date string.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Every disk file maintains a modified time stamp, and most (but not all) servers are configured to expose this information to a browser accessing a file. This information is available by reading the `document.lastModified` property. If your server supplies this information to the client, you can use the value of this property to present this information for readers of your Web page. The script automatically updates the value for you, rather than requiring you to hand-code the HTML line every time you modify the home page.

If the value returned to you displays itself as a date in 1969, it means that you are positioned somewhere west of GMT, or Greenwich Mean Time (some number of time zones west of GMT at 1 January 1970), and the server is not providing the proper data when it serves the file. Sometimes server configuration can fix the problem, but not always.

The returned value is not a date object (see Chapter 29) but rather a straight string consisting of time and date, as recorded by the document's file system. The format of the string varies from browser to browser and version to version. You can, however, usually convert the date string to a JavaScript date object and use the date object's methods to extract selected elements for recompilation into readable form. Listing 18-6 shows an example.

Even local file systems don't necessarily provide the correct data for every browser to interpret. But put that same file on a UNIX or Windows Web server, and the date appears correctly when accessed via the Net.

**Example**

Experiment with the `document.lastModified` property with Listing 18-6. But also be prepared for inaccurate readings if the file is located on some servers or local hard disks.

**document.lastModified****Listing 18-6: Putting a Time Stamp on a Page**

```

<html>
  <head>
    <title>Time Stamper</title>
  </head>
  <body>
    <center>
      <h1>GiantCo Home Page</h1>
    </center>
    <script type="text/javascript">
      update = new Date(document.lastModified);
      theMonth = update.getMonth() + 1;
      theDate = update.getDate();
      theYear = update.getFullYear();
      document.writeln("<I>Last updated:" + theMonth + "/" + theDate + "/" +
        theYear + "</I>");
    </script>
    <hr />
  </body>
</html>

```

As noted at great length in the `Date` object discussion in Chapter 29, you should be aware that date formats vary greatly from country to country. Some of these formats use a different order for date elements. When you hard-code a date format, it may take a form that is unfamiliar to other users of your page.

**Related Items:** `Date` object (Chapter 29).

**layers[]**

**Value:** Array.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

The `layer` object (see Chapter 39 on the CD-ROM) is the NN4 way of exposing positioned elements to the object model. Thus, the `document.layers` property is an array of positioned elements in the document. But due to the nonstandard way that NN4 implements positioned elements, not every positioned element is represented in the `document.layers` array. More deeply nested positioned elements must be referenced through a hierarchy of layers.

**Note**

The `Layer` object and `document.layers` property are orphaned in NN4, and their importance diminishes as the installed base of NN4 shrinks. The remaining discussion is included only for those Web authors who must support positioned elements in NN4. In NN6+, the layer is represented by any HTML element whose stylesheet definition includes a `position` attribute. References to such elements can be made through the `document.getElementById()` method or shortcuts described in Chapter 14.

A Netscape layer is a container for content that can be precisely positioned on the page. Layers can be defined with the NN4-specific `<layer>` tag or with W3C standard stylesheet positioning syntax, as explained in Chapter 39 on the CD-ROM. Each layer contains a `document` object—the true holder of the content displayed in that layer. Layers can be nested within each other, but a reference to `document.layers` reveals only the first level of layers defined in the document. Consider the following HTML skeleton.

```

<html>
<body>
<layer name="Europe">
  <layer name="Germany"></layer>
  <layer name="Netherlands"></layer>
</layer>
</body>
</html>

```

From the point of view of the primary document, there is one layer (Europe). Therefore, the length of the `document.layers` array is 1. But the Europe layer has a document, in which two more layers are nested. A reference to the array of those nested layers is

```
document.layers[1].document.layers
```

or

```
document.Europe.document.layers
```

The length of this nested array is two: The Germany and Netherlands layers. No property exists that reveals the entire set of nested arrays in a document, but you can create a `for` loop to crawl through all nested layers (shown in Listing 18-7).

## Example

Listing 18-7 demonstrates only for NN4 how to use the `document.layers` property to crawl through the entire set of nested layers in a document. Using reflexive calls to the `crawlLayers()` function, the script builds an indented list of layers in the same hierarchy as the objects themselves and displays the results in an alert dialog box. After you load this document (the script is triggered by the `onLoad` event handler), compare the alert dialog box contents against the structure of `<layer>` tags in the document.

### Listing 18-7: Crawling Through Nested Layers in NN4

```

<html>
<head>
  <title></title>
  <script type="text/javascript">
    var output = "";
    function crawlLayers(layerArray, indent) {
      for (var i = 0; i < layerArray.length; i++) {
        output += indent + layerArray[i].name + "\n";
        if (layerArray[i].document.layers.length) {
          var newLayerArray = layerArray[i].document.layers;
          crawlLayers(newLayerArray, indent + "  ");
        }
      }
      return output;
    }
    function revealLayers() {
      alert(crawlLayers(document.layers, ""));
    }
  </script>
</head>
<body onload="revealLayers()">
  <layer name="Europe">

```

*Continued*

**document.layers****Listing 18-7 (continued)**

```
<layer name="Germany">
</layer>
<layer name="Netherlands">
  <layer name="Amsterdam"></layer>
  <layer name="Rotterdam"></layer>
</layer>
<layer name="France">
</layer>
</layer>
<layer name="Africa">
  <layer name="South Africa">
</layer>
  <layer name="Ivory Coast">
</layer>
</layer>
</body>
</html>
```

**Related Items:** layer object (Chapter 39 on the CD-ROM).

**linkColor**

(See `alinkColor`)

**links[]**

**Value:** Array.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `document.links` property is similar to the `document.anchors` property, except that the objects maintained by the array are link objects — items created with `<a href="">` tags. Use the array references to pinpoint a specific link for retrieving any link property, such as the target window specified in the link's HTML definition.

Link arrays begin their index counts with 0: The first link in a document has the reference `document.links[0]`. And, as with any array object, you can find out how many entries the array has by checking the `length` property. For example:

```
var linkCount = document.links.length;
```

Entries in the `document.links` property are full-fledged location objects, which means you have the same properties available to each member of the `links[]` array as you do in the location object.

**Example**

The `document.links` property is defined automatically as the browser builds the object model for a document that contains link objects. You rarely access this property, except to determine the number of link objects in the document.

**Related Items:** link object; `document.anchors` property.

## location

### URL

**Value:** String.

Read/Write and Read-Only (see text)

**Compatibility:** WinIE3+, MacIE3+, NN3+, Moz1+, Safari1+

The fact that JavaScript frequently reuses the same terms in different contexts may be confusing to the language's newcomers. Such is the case with the `document.location` property. You may wonder how this property differs from the `location` object (see Chapter 17). In practice, many scripts also get the two confused when references don't include the `window` object. As a result, a new property name, `document.URL`, was introduced in NN3 and IE4 to take the place of `document.location`. You can still use `document.location`, but the term may eventually disappear from the object model vocabulary. To help you get into the future mindset, the rest of this discussion refers to this property as `document.URL`.

The remaining question is how the `window.location` object and `document.URL` property differ. The answer lies in their respective data types.

A `location` object, you may recall from Chapter 17, consists of a number of properties about the document currently loaded in a window or frame. Assigning a new URL to the `location` object (or `location.href` property) tells the browser to load the page from that URL into the frame. The `document.URL` property, on the other hand, is simply a string (read-only in Navigator, Mozilla, and Safari) that reveals the URL of the current document. The value may be important to your script, but the property does not have the "object power" of the `window.location` object. You cannot change (assign another value to) this property value because a document has only one URL: its location on the Net (or your hard disk) where the file exists, and what protocol is required to get it.

This may seem like a fine distinction, and it is. The reference you use (`window.location` object or `document.URL` property) depends on what you are trying to accomplish specifically with the script. If the script is changing the content of a window by loading a new URL, you have no choice but to assign a value to the `window.location` object. Similarly, if the script is concerned with the component parts of a URL, the properties of the `location` object provide the simplest avenue to that information. To retrieve the URL of a document in string form (whether it is in the current window or in another frame), you can use either the `document.URL` property or the `window.location.href` property.

### Example

HTML documents in Listings 18-8 through 18-10 create a test lab that enables you to experiment with viewing the `document.URL` property for different windows and frames in a multi-frame environment. Results are displayed in a table, with an additional listing of the `document.title` property to help you identify documents being referred to. The same security restrictions that apply to retrieving `window.location` object properties also apply to retrieving the `document.URL` property from another window or frame.

**document.location****Listing 18-8: A Simple Frameset for the URL Example**

```

<html>
  <head>
    <title>document.URL Reader</title>
  </head>
  <frameset rows="60%,40%">
    <frame name="Frame1" src="1st18-10.htm" />
    <frame name="Frame2" src="1st18-09.htm" />
  </frameset>
</html>

```

**Listing 18-9: Showing Location Information for Different Contexts**

```

<html>
  <head>
    <title>URL Property Reader</title>
    <script type="text/javascript">
      function fillTopFrame() {
        newURL=prompt("Enter the URL of a document to show in the top
          frame:", "");
        if (newURL != null && newURL != "") {
          top.frames[0].location = newURL;
        }
      }

      function showLoc(form,item) {
        var windName = item.value;
        var theRef = windName + ".document";
        form.dLoc.value = unescape(eval(theRef + ".URL"));
        form.dTitle.value = unescape(eval(theRef + ".title"));
      }
    </script>
  </head>
  <body>
    Click the "Open URL" button to enter the location of an HTML document to
    display in the upper frame of this window.
    <form>
      <input type="button" name="opener" value="Open URL..."
        onclick="fillTopFrame()" />
    </form>
    <hr />
    <form>
      Select a window or frame to view each document property values.
      <p><input type="radio" name="whichFrame" value="parent"
        onclick="showLoc(this.form,this)" />Parent window <input
        type="radio" name="whichFrame" value="top.frames[0]"
        onclick="showLoc(this.form,this)" />Upper frame <input type="radio"
        name="whichFrame" value="top.frames[1]"

```

```

        onclick="showLoc(this.form,this)" />This frame</p>
<table border="2">
  <tr>
    <td align="RIGHT">document.URL:</td>
    <td><textarea name="dLoc" rows="3" cols="30" wrap="soft">
      </textarea></td>
  </tr>
  <tr>
    <td align="RIGHT">document.title:</td>
    <td><textarea name="dTitle" rows="3" cols="30" wrap="soft">
      </textarea></td>
  </tr>
</table>
</form>
</body>
</html>

```

### Listing 18-10: A Placeholder Page for the URL Example

```

<html>
  <head>
    <title>Opening Placeholder</title>
  </head>
  <body>
    Initial place holder. Experiment with other URLs for this frame (see
    below).
  </body>
</html>

```

**Related Items:** location object; location.href, URLUnencoded properties.

## media

**Value:** String.

Read/Write

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `document.media` property indicates the output medium for which content is formatted. The property actually returns an empty string as of IE6, but the intention appears to be to provide a way to use scripting to set the equivalent of the CSS2 `@media` rule (one of the so-called “at” rules because of the at symbol). This stylesheet rule allows browsers to assign separate styles for each type of output device on which the page is rendered (for example, perhaps a different font for a printer versus the screen). In practice, however, this property is not modifiable in WinIE5.5 and WinIE6.

**Related Items:** None.

**document.mimeType****mimeType****Value:** String.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

Although this property is readable in WinIE5+, its value is not strictly speaking a MIME type, or at least not in traditional MIME format. Moreover, the results are inconsistent between WinIE5 and WinIE6. Perhaps this property will be of more use in an XML, rather than HTML, document environment. In any case, this property in no way exposes supported MIME types in the current browser.

**nameProp****Value:** String.

Read-Only

**Compatibility:** WinIE6+, MacIE-, NN-, Moz-, Safari-

The `nameProp` property returns a string containing the title of the document, which is the same as `document.title`. If the document doesn't have a title, `nameProp` contains an empty string.

**Related Items:** `title` property.**namespaces[]****Value:** Array of namespace objects.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

A namespace object can dynamically import an XML-based IE Element Behavior. The `namespaces` property returns an array of all namespace objects defined in the current document.

**Related Items:** None.**parentWindow****Value:** window object reference.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `document.parentWindow` property returns a reference to the `window` object containing the current document. The value is the same as any reference to the current window.

**Example**

To prove the `parentWindow` property points to the document's window, you can enter the following statement into the top text field of The Evaluator (Chapter 13):

```
document.parentWindow == self
```

This expression evaluates to `true` only if both references are of the same object.

**Related Items:** `window` object.**plugins[]****Value:** Array.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `document.plugins` property returns the same array of `embed` element objects that you get from the `document.embeds` property. This property appears to have been deprecated in favor of `document.embeds`.

**Related Items:** `document.embeds` property.

## protocol

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The IE-specific `document.protocol` property returns the plain-language version of the protocol that was used to access the current document. For example, if the file is accessed from a Web server, the property returns `Hypertext Transfer Protocol`. This property differs from the `location.protocol` property, which returns the portion of the URL that includes the often more cryptic protocol abbreviation (for example, `http:`). As a general rule, you want to hide all of this stuff from a Web application user.

### Example

If you use The Evaluator (Chapter 13) to test the `document.protocol` property, you will find that it displays `File Protocol` in the results because you are accessing the listing from a local hard disk or CD-ROM.

**Related Items:** `location.protocol` property.

## referrer

**Value:** String.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

When a link from one document leads to another, the second document can, under JavaScript control, reveal the URL of the document containing the link. The `document.referrer` property contains a string of that URL. This feature can be a useful tool for customizing the content of pages based on the previous location the user was visiting within your site. A referrer contains a value only when the user reaches the current page via a link. Any other method of navigation (such as through the history, bookmarks, or by manually entering a URL) sets this property to an empty string.

The `document.referrer` property usually returns an empty string unless the files are retrieved from a Web server. Also, early versions of WinIE never returned the correct referrer info.

### Example

This demonstration requires two documents (and for IE, you'll also need to access the documents from a Web server). The first document, in Listing 18-11, simply contains one line of text as a link to the second document. In the second document (see Listing 18-12), a script verifies the document from which the user came via a link. If the script knows about that link, it displays a message relevant to the experience the user had at the first document. Also try opening Listing 18-12 in a new browser window from the Open File command in the File menu to see how the script won't recognize the referrer.

**document.referrer****Listing 18-11: An Example Referrer Page**

```
<html>
  <head>
    <title>document.referrer Property 1</title>
  </head>
  <body>
    <h1><a href="1st18-12.htm">Visit my sister document</a></h1>
  </body>
</html>
```

---

**Listing 18-12: Determining the Referrer when a Page Is Visited through a Link**

```
<html>
  <head>
    <title>document.referrer Property 2</title>
  </head>
  <body>
    <h1>
      <script type="text/javascript">
        alert(document.referrer.length + " : " + document.referrer);
        if(document.referrer.length > 0 &&
            document.referrer.indexOf("1st18-11.htm") != -1) {
            document.write("How is my brother document?");
        } else {
            document.write("Hello, and thank you for stopping by.");
        }
      </script>
    </h1>
  </body>
</html>
```

---

**Related Items:** link object.

**scripts[]**

**Value:** Array.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The IE-specific `document.scripts` property returns an array of all script element objects in the current document. You can reference an individual script element object to read not only the properties it shares with all HTML element objects (see Chapter 15) but also script-specific properties, such as `defer`, `src`, and `htmlFor`. The actual scripting is accessible either through the `innerText` or `text` properties for any script element object.

While the `document.scripts` array is read-only, many properties of individual script element objects are modifiable. Adding or removing script elements impacts the length of the

`document.scripts` array. Don't forget, too, that if your scripts need to access a specific `script` element object, you can assign an `id` attribute to it and reference the element directly.

This property is an IE-specific convenience property that is the same as the W3C browser expression `document.getElementsByTagName("script")`, which returns an array of the same objects.

### Example

You can experiment with the `document.scripts` array in The Evaluator (Chapter 13). For example, you can see that only one `script` element object is in The Evaluator page if you enter the following statement into the top text field:

```
document.scripts.length
```

If you want to view all of the properties of that lone `script` element object, enter the following statement into the bottom text field:

```
document.scripts[0]
```

Among the properties are both `innerText` and `text`. If you assign an empty string to either property, the scripts are wiped out from the object model, but not from the browser. The scripts disappear because after the scripts loaded, they were cached outside of the object model. Therefore, if you enter the following statement into the top field:

```
document.scripts[0].text = ""
```

the script contents are gone from the object model, yet subsequent clicks of the Evaluate and List Properties buttons (which invoke functions of the `script` element object) still work.

**Related Items:** `script` element object (Chapter 36 on the CD-ROM).

## security

**Value:** String.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `security` property reveals information about a security certificate, if one is associated with the current document.

## selection

**Value:** Object.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `document.selection` property returns a `selection` object whose content is represented in the browser window as a body text selection. That selection can be explicitly performed by the user (by clicking and dragging across some text) or created under script control via the WinIE `TextRange` object (see Chapter 35). Because script action on a selection (for example, finding the next instance of selected text) is performed via the `TextRange` object, converting a selection to a `TextRange` object using the `document.selection.createRange()` method is common practice. See the `selection` object in Chapter 35 for more details.

**document.selection**

Be aware that you cannot script interaction with text selections through user interface elements, such as buttons. Clicking a button gives focus to the button and deselects the selection. Use other events, such as `document.onmouseup` to trigger actions on a selection.

**Example**

See Listings 15-30 and 15-39 in Chapter 15 to see the `document.selection` property in action for script-controlled copying and pasting (WinIE only).

**Related Items:** `selection`, `TextRange` objects.

**styleSheets[]**

**Value:** Array.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `document.styleSheets` array consists of references to all `style` element objects in the document. Not included in this array are stylesheets that are assigned to elements by way of the `style` attribute inside a tag or linked in via `link` elements. See Chapter 26 for details about the `styleSheet` object.

**Related Items:** `styleSheet` object (Chapter 26).

**tags[]**

**Value:** Array.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

The NN4-specific `tags` property is used in the browser's alternate, JavaScript-based stylesheet syntax. Deployment of JavaScript stylesheets is exceedingly rare. In some ways, the `document.tags` property behaves like the W3C DOM `document.getElementsByTagName()` method, but `document.tags` cannot be used in regular scripts to access element objects.

**Related Items:** `ids` property.

**title**

**Value:** String.

Read-Only and Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

A document's title is the text that appears between the `<title>...</title>` tag pair in an HTML document's Head portion. The title usually appears in the title bar of the browser window in a single-frame presentation. Only the title of the topmost framesetting document appears as the title of a multiframe window. Even so, the `title` property for an individual document within a frame is available via scripting. For example, if two frames are available (`UpperFrame` and `LowerFrame`), a script in the document occupying the `LowerFrame` frame can reference the `title` property of the other frame's document, such as this:

```
parent.UpperFrame.document.title
```

This property is read-only in browsers prior to IE4 and NN6+ but not all browsers allow scripts to change the text that appears in the browser window's title bar.

The `document.title` property is a holdover from the original document object model. HTML elements in recent browsers have an entirely different application of the `title` property (see Chapter 15). In modern browsers (IE4+/NN6+), you should address the document's title by way of the `title` element object directly.

**Related Items:** `history` object.

`document.captureEvents()`

## URL

(See `location`)

## URLUnencoded

**Value:** String.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `document.URL` property returns a URL-encoded string, meaning that non-alphanumeric characters in the URL are converted to URL-friendly characters (for example, a space becomes `%20`). You can always use the `unescape()` function on the value returned by the `document.URL` property, but the `URLUnencoded` property does that for you. If there are no URL-encoded characters in the URL, then both properties return identical strings.

**Related Items:** `document.URL` property.

## vlinkColor

(See `alinkColor`)

## width

(See `height`)

## Methods

### `captureEvents(eventTypeList)`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

In Navigator 4 only, the natural propagation of an event is downward from the `window` object, through the `document` object, and eventually reaching its target. For example, if you click a button, the `click` event first reaches the `window` object; then it goes to the `document` object; if the button is defined within a layer, the event also filters through that layer; eventually (in a split second) the event reaches the button, where an `onclick` event handler is ready to act on that click.

The NN4 mechanism allows `window`, `document`, and `layer` objects to intercept events and process them prior to reaching their intended targets (or preventing them from reaching their destinations entirely). But for an outer container to grab an event, your script must instruct it to capture the type of event your application is interested in preprocessing. If you want the `document` object to intercept all events of a particular type, use the `document.captureEvents()` method to turn that facility on.

**Note**

Event capture with different syntax has been standardized in the W3C DOM and is implemented in W3C browsers, such as NN6+ and Mozilla. See the `addEventListener()` method in Chapter 15 for the W3C counterpart to the NN4 `captureEvents()` method. Also, see Chapter 25 for more details on the combination of event capture and event bubbling in the W3C DOM.

The `document.captureEvents()` method takes one or more event types as parameters. An event type is a constant value built inside the NN4 `Event` object. One event type exists for every kind of event handler that you see in all of the `document` objects of NN4. The syntax

**document.captureEvents()**

consists of a reference to the `Event` object and the event name in all uppercase letters. For example, if you want the document to intercept all `click` events, the statement is

```
document.captureEvents(Event.CLICK);
```

For multiple events, add them as parameters, separated by the pipe (`|`) character:

```
document.captureEvents(Event.MOUSEDOWN | Event.KEYPRESS);
```

After the `document` object is set to capture an event type, it must have a function ready to deal with the event. For example, perhaps the function looks through all `Event.MOUSEDOWN` events and looks to see if the right mouse button is the one that triggers the event and what form element (if any) is the intended target. The goal is perhaps to display a pop-up menu (as a separate layer) for a right-click. If the click comes from the left mouse button, the event is routed to its intended target.

To associate a function with a particular event type captured by a `document` object, assign a function to the event. For example, to assign a custom `doClickEvent()` function to click events captured by the `document` object, use the following statement:

```
document.onclick = doClickEvent;
```

Notice that the function name is assigned only as a reference name, unlike an event handler within a tag. The function, itself, is like any function, but it has the added benefit of automatically receiving the event object as a parameter. To turn off event capture for one or more event types, use the `document.releaseEvent()` method. See Chapter 25 for details of working with NN4 events.

 **Note**

Capturing events at the `window`, `document`, or layer level in NN4 does not always work the way you may want, which is especially true if your page contains tables. For example, capturing mouse events has no effect in the Windows version of NN4 unless the cursor is atop a cell border. Event capture works most reliably when a scriptable object has an event handler defined for it (even if the handler is an empty string), and the element is the target of the event (for example, you are about to type into a text field). For all other elements, event capture may simply not be captured at the `document` or `window` level.

**Example**

See the example for the NN4 `window.captureEvents()` method in Listing 16-21 to see how to capture events on their way to other objects. In that example, you can substitute the `document` reference for the `window` reference to see how the document version of the method works just like the window version. If you understand the mechanism for windows, you understand it for documents. The same is true for the other NN4 event methods.

**Related Items:** `document.handleEvent()`, `document.releaseEvents()`, `document.routeEvent()` methods; parallel window object event methods.

**clear()**

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Ever since NN2, the `document.clear()` method was intended to clear the current document from the browser window. This method is quite impractical, because you typically need some further scripts to execute after you clear the document, but if the scripts are gone, nothing else happens.

## Fixing the Sticky Wait Cursor

From time to time, various browsers fail to restore the cursor to normal after `document.write()` and `document.close()` (and some other content-modifying scripts). The cursor stubbornly remains in the wait mode or the progress bar keeps spinning when, in truth, all processing has been completed. One, albeit ugly, workaround that I have found effective is to force an extra `document.close()` via a `javascript: pseudo-URL` (just adding another `document.close()` to your script doesn't do the trick). For use within a frameset, the `javascript: URL` must be directed to the top of the frameset hierarchy, while the `document.close()` is aimed at the frame that had its content changed. For example, if the change is made to a frame named `content`, create a function, such as the following:

```
function recloseDoc() {
    top.location.href =
        "javascript:void (parent.content.document.close())";
}
```

If you place this function in the framesetting document, scripts that modify the content frame can invoke this script after any operation that prevents the normal cursor from appearing.

In practice, the `document.clear()` method never did what it was supposed to do (and in earlier browsers easily caused browser crashes). I recommend against using `document.clear()`, including in preparation for generating a new page's content with `document.write()`. The `document.write()` method clears the original document from the window before adding new content. If you truly want to empty a window or frame, then use `document.write()` to write a blank HTML document or to load an empty HTML document from the server.

**Related Items:** `document.close()`, `document.write()`, `document.writeln()` methods.

## close()

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Whenever a layout stream is opened to a window via the `document.open()` method or either of the document writing methods (which also open the layout stream), you must close the stream after the document is written. This causes the `Layout:Complete` and `Done` messages to appear in the status line (although you may experience some bugs in the status message on some platforms). The document-closing step is very important to prepare the window for the next potential round of replenishment with new script-assembled HTML. If you don't close the document, subsequent writing is appended to the bottom of the document.

Some or all of the data specified for the window won't display properly until you invoke the `document.close()` method, especially when images are being drawn as part of the document stream. A common symptom is the momentary appearance and then disappearance of the document parts. If you see such behavior, look for a missing `document.close()` method after the last `document.write()` method.

## Example

Before you experiment with the `document.close()` method, be sure you understand the `document.write()` method described later in this chapter. After that, make a separate set of

**document.close()**

the three documents for that method's example (Listings 18-16 through 18-18 in a different directory or folder). In the `takePulse()` function listing, comment out the `document.close()` statement, as shown here:

```
msg += "<p>Make it a great day!</body></html>";
parent.frames[1].document.write(msg);
//parent.frames[1].document.close();
```

Now try the pages on your browser. You see that each click of the upper button appends text to the bottom frame, without first removing the previous text. The reason is that the previous layout stream was never closed. The document thinks that you're still writing to it. Also, without properly closing the stream, the last line of text may not appear in the most recently written batch.

**Related Items:** `document.open()`, `document.clear()`, `document.write()`, `document.writeln()` methods.

**createAttribute("attributeName")**

**Returns:** Attribute object reference.

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `document.createAttribute()` method generates an attribute node object (formally known as an `Attr` object in W3C DOM terminology) and returns a reference to the newly created object. Invoking the method assigns only the name of the attribute, so it is up to your script to assign a value to the object's `nodeValue` property and then plug the new attribute into an existing element via that element's `setAttributeNode()` method (described in Chapter 15). The following sequence generates an attribute that becomes an attribute of a table element:

```
var newAttr = document.createAttribute("width");
newAttr.nodeValue = "80%";
document.getElementById("myTable").setAttributeNode(newAttr);
```

Attributes do not always have to be attributes known to the HTML standard, because the method also works for XML elements, which have custom attributes.

**Example**

To create an attribute and inspect its properties, enter the following text into the top text box of The Evaluator (Chapter 13):

```
a = document.createAttribute("author")
```

Now enter `a` into the bottom text box to inspect the properties of an `Attr` object.

**Related Items:** `setAttributeNode()` method (Chapter 15).

**createComment("commentText")**

**Returns:** Comment object reference.

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `document.createComment()` method creates an instance of a comment node. Upon creation, the node is in memory and available to be inserted into the document via any node's `appendChild()` or `insertBefore()` method.

**Related Items:** `appendChild()` and `insertBefore()` methods.

**document.createElement()****createDocumentFragment()**

**Returns:** Document fragment object reference.

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `document.createDocumentFragment()` method creates an instance of an empty document fragment node. This node serves as a holder that can be used to assemble a sequence of nodes in memory. After creating and assembling nodes into the document fragment, the entire fragment can be inserted into the document tree.

A document fragment is particularly helpful when your scripts assemble an arbitrary sequence of element and text nodes. By providing a parent node for all content within, the fragment node supplies the necessary parent node context for W3C DOM node methods, such as `appendChild()` during the content assembly process. If you then append or insert the document fragment node to an element in the rendered document tree, the fragment wrapper disappears, leaving just its content in the desired location in the document. Therefore, a typical usage pattern for a document fragment is to begin by creating an empty fragment node (via the `createDocumentFragment()` method), populate it at will with newly created element and/or text nodes, and then use the appropriate node method on a document tree's element to append, insert, or replace using the fragment node as the source material.

**Related Items:** None.

**createElement("tagName")**

**Returns:** Element object reference.

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `document.createElement()` method generates an element object for whatever HTML (or XML) tag name you pass as the parameter. An object created in this manner is not officially part of the current document node tree because it has not yet been placed into the document. But this method is the way you begin assembling an element object that eventually gets inserted into the document.

The returned value is a reference to the object. Properties of that object include all properties (set to default values) that the browser's object model defines for that element object. Your scripts can then address the object via this reference to set the object's properties. Typically you do this before the object is inserted into the document, especially because otherwise read-only properties can be modified before the element is inserted into the document.

After the object is inserted into the document, the original reference (for example, a global variable used to store the value returned from the `createElement()` method) still points to the object, even while it is in the document and being displayed for the user. To demonstrate this effect, consider the following statements that create a simple paragraph element containing a text node:

```
var newText = document.createTextNode("Four score and seven years ago...");
var newElem = document.createElement("p");
newElem.id = "newestP";
newElem.appendChild(newText);
document.body.appendChild(newElem);
```

At this point, the new paragraph is visible in the document. But you can now modify, for example, the style of the paragraph by addressing either the element in the document object model or the variable that holds the reference to the object you created:

**document.createElement()**

```
newElem.style.fontSize = "20pt";
```

or

```
document.getElementById("newestP").style.fontSize = "20pt";
```

The two references are inextricably connected and always point to the exact same object. Therefore, if you want to use a script to generate a series of similar elements (for example, a bunch of `li` elements), then you can use `createElement()` to make the first one and set all properties that the items have in common. Then use `cloneNode()` to make a new copy, which you can then treat as a separate element (and probably assign unique IDs to each one).

When scripting in the W3C DOM environment, you may rely on `document.createElement()` frequently to generate new content for a page or portion thereof (unless you prefer to use the convenience `innerHTML` property to add content in the form of strings of HTML). In a strict W3C DOM environment, creating new elements is not a matter of assembling HTML strings, but rather creating genuine element (and text node) objects.

You may use this method to generate any HTML element in the supported browsers except IE4, which limits you to `area`, `img`, and `option` elements.

**Example**

Chapter 15 contains numerous examples of the `document.createElement()` method in concert with methods that add or replace content to a document. See Listings 15-10, 15-21, 15-22, 15-28, 15-29, and 15-31.

**Related Items:** `document.createTextNode()` method.

**createEvent("eventType")**

**Returns:** Event object reference.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `document.createEvent()` method creates an instance of a W3C DOM Event object of the specified event category. Upon creation, the generic event must be initialized as a particular event type, and any other relevant properties set for the event. After successfully initializing the event, you can fire it via a call to the `dispatchEvent()` method.

Event types recognized by NN6+/Moz are `KeyEvents`, `MouseEvents`, `MutationEvents`, and `UIEvents`. The process of initializing each of these event types requires its own series of parameters in the associated `initEvent()` method. See Chapter 25 for more details.

**Example**

Following is an example of how you might create an event, initialize it to a specific event type, and send it to a given element:

```
var evt = document.createEvent("MouseEvents");
evt.initEvent("mouseup", true, true);
document.getElementById("myButton").dispatchEvent(evt);
```

**Related Items:** `createEventObject()` method; W3C DOM event object (Chapter 25).

`document.createStyleSheet()`

## `createEventObject([eventObject])`

**Returns:** event object.

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The IE-specific `createEventObject()` method creates an event object, which can then be passed as a parameter to the `fireEvent()` method of any element object. The event object created by this event is just like an event object created by a user or system action.

An optional parameter lets you base the new event on an existing event object. In other words, the properties of the newly created event object pick up all the properties of the event object passed as a parameter, which lets you then modify properties of your choice. If you provide no parameter to the method, then you must fill the essential properties manually. For more about the properties of an event object, see Chapter 25.

### Example

See the discussion of the `fireEvent()` method in Chapter 15 for an example of the sequence to follow when creating an event to fire on an element.

**Related Items:** `createEvent()` method; `fireEvent()` method (Chapter 15); event object (Chapter 25).

## `createRange()`

**Returns:** Range object reference.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `document.createRange()` method creates an empty W3C DOM Range object with the boundary points of the range collapsed to the point before the first character of the rendered body text.

**Related Items:** Range object.

## `createStyleSheet(["URL" [, index]])`

**Returns:** `styleSheet` object reference.

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The IE-specific `createStyleSheet()` method creates a `styleSheet` object, a type of object that includes `style` element objects as well as stylesheets that are imported into a document via the `link` element. Thus you can dynamically load an external stylesheet even after a page has loaded.

Unlike the other “create” methods entering W3C DOM usage, the `createStyleSheet()` method not only creates the stylesheet, but it inserts the object into the document object model immediately. Thus, any stylesheet rules that belong (or are assigned to) that object take effect on the page right away. If you’d rather create a stylesheet and delay its deployment, you should use the `createElement()` method and element object assembly techniques.

If you don’t specify any parameters to the method in WinIE, an empty `styleSheet` object is created. It is assumed that you will then use `styleSheet` object methods, such as `addRule()` to add the details to the stylesheet. To link in an external stylesheet file, assign the file’s URL to the first parameter of the method. The newly imported stylesheet is appended to the end of

**document.createStyleSheet()**

the `document.styleSheets` array of `styleSheet` objects. An optional second parameter lets you specify precisely where in the sequence of stylesheet elements the newly linked stylesheet should be inserted. A stylesheet rule for any given selector is overridden by a stylesheet for the same selector that appears later in the sequence of stylesheets in a document.

**Example**

Listing 18-13 demonstrates adding an internal and external stylesheet to a document. For the internal addition, the `addStyle1()` function invokes `document.createStyleSheet()` and adds a rule governing the `p` elements of the page (not available for MacIE5). In the `addStyle2()` function, an external file is loaded. That file contains the following two style rules:

```
h2 {font-size:20pt; color:blue}
p {color:blue}
```

Notice that by specifying a position of zero for the imported stylesheet, the addition of the internal stylesheet always comes afterward in `styleSheet` object sequence. Thus, except when you deploy only the external stylesheet, the red text color of the `p` elements override the blue color of the external stylesheet. If you remove the second parameter of the `createStyleSheet()` method in `addStyle2()`, the external stylesheet is appended to the end of the list. If it is the last stylesheet to be added, the blue color prevails. Repeatedly clicking the buttons in this example continues to add the stylesheets to the document.

**Listing 18-13: Creating and Applying Stylesheets**

```
<html>
  <head>
    <title>document.createStyleSheet() Method</title>
    <script type="text/javascript">
      function addStyle1() {
        var newStyle = document.createStyleSheet();
        newStyle.addRule("P", "font-size:16pt; color:red");
      }

      function addStyle2() {
        var newStyle = document.createStyleSheet("1st18-13.css",0);
      }
    </script>
  </head>
  <body>
    <h1>document.createStyleSheet() Method</h1>
    <hr />
    <form>
      <input type="button" value="Add Internal"
        onclick="addStyle1()" />&nbsp;  <input type="button"
        value="Add External" onclick="addStyle2()" />
    </form>
    <h2>Section 1</h2>
    <p>Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do
      eiusmod tempor incididunt ut labore et dolore magna aliqua. Ut enim
      adminim veniam, quis nostrud exercitation ullamco laboris nisi ut
      aliquip ex ea commodo consequat.</p>
    <h2>Section 2</h2>
```

**document.createTextNode()**

```
<p>Duis aute irure dolor in reprehenderit involuptate velit esse cillum
dolore eu fugiat nulla pariatur. Excepteur sint occaecat cupidatat non
proident, sunt in culpa qui officia deserunt mollit anim id est
laborum.</p>
</body>
</html>
```

---

**Related Items:** `styleSheet` object (Chapter 26).

**createTextNode("text")**

**Returns:** Object.

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

A text node is a W3C DOM object that contains body text without any HTML (or XML) tags, but is usually contained by (meaning, is a child of) an HTML (or XML) element. Without the `innerText` convenience property for modifying the text of an element, the W3C DOM relies on the node hierarchy of a document (NN6+/Moz1+ exceeds the W3C DOM by providing an `innerHTML` property, which you can use to replace text in an element). To insert or replace text inside an HTML element in the W3C DOM way, you create the text node and then use methods of the parent element (for example, `appendChild()`, `insertBefore()`, and `replaceChild()`, all described in Chapter 15) to modify the document's content. To generate a fresh text node, use `document.createTextNode()`.

The sole parameter of the `createTextNode()` method is a string whose text becomes the `nodeValue` of the text node object returned by the method. You can also create an empty text node (passing an empty string) and assign a string to the `nodeValue` of the object later. As soon as the text node is present in the document object model, scripts can simply change the `nodeValue` property to modify text of an existing element. For more details on the role of text nodes in the W3C DOM, see Chapter 14.

## Example

Although Chapters 14 and 15 (Listing 15-21, for instance) provide numerous examples of the `createTextNode()` method at work, using The Evaluator (Chapter 13) is instructive to see just what the method generates in IE5+/W3C. You can use one of the built-in global variables of The Evaluator to hold a reference to a newly generated text node by entering the following statement into the top text field:

```
a = document.createTextNode("Hello")
```

The Results box shows that an object was created. Now, look at the properties of the object by typing `a` into the bottom text field. The precise listings of properties varies between IE5+ and W3C browsers, but the W3C DOM properties that they share in common indicate that the object is a node type 3 with a node name of `#text`. No parents, children, or siblings exist yet because the object created here is not part of the document hierarchy tree until it is explicitly added to the document.

To see how insertion works, enter the following statement into the top text field to append the text node to the `myP` paragraph:

```
document.getElementById("myP").appendChild(a)
```

**document.createTextNode()**

The word “Hello” appears at the end of the simple paragraph lower on the page. Now you can modify the text of that node either via the reference from the point of view of the containing p element or via the global variable reference for the newly created node:

```
document.getElementById("myP").lastChild.nodeValue = "Howdy"
```

or

```
a.nodeValue = "Howdy"
```

**Related Items:** document.createElement() method.

**createTreeWalker(*rootNode*, *whatToShow*, *filterFunction*, *entityRefExpansion*)**

**Returns:** TreeWalker object reference.

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1.4+, Safari-

The document.createTreeWalker() method creates an instance of a TreeWalker object that can be used to navigate the document tree. The first parameter to the method indicates the node in the document that is to serve as the root node of the tree. The second parameter is an integer constant that specifies one of several built-in filters for selecting nodes to be included in the tree. Following are the possible acceptable values for this parameter:

NodeFilter.SHOW_ALL	NodeFilter.SHOW_ATTRIBUTE
NodeFilter.SHOW_CDATA_SECTION	NodeFilter.SHOW_COMMENT
NodeFilter.SHOW_DOCUMENT	NodeFilter.SHOW_DOCUMENT_FRAGMENT
NodeFilter.SHOW_DOCUMENT_TYPE	NodeFilter.SHOW_ELEMENT
NodeFilter.SHOW_ENTITY	NodeFilter.SHOW_ENTITY_REFERENCE
NodeFilter.SHOW_NOTATION	NodeFilter.SHOW_PROCESSING_INSTRUCTION
NodeFilter.SHOW_TEXT	

The third parameter to the createNodeIterator() method is a reference to a filter function that can filter nodes even further than the *whatToShow* parameter. This function must accept a single node and return an integer value based upon one of the following constants:

NodeFilter.FILTER\_ACCEPT, NodeFilter.FILTER\_REJECT, or NodeFilter.FILTER\_SKIP.

The idea is that you code the function to perform a test on each node and return an indicator value that lets the node iterator know whether or not to include the node in the tree. Your function doesn't loop through nodes. The TreeWalker object mechanism repetitively invokes the function as needed to look for the presence of whatever characteristic you wish to use as a filter.

The final parameter to the method is a Boolean value that determines whether or not the content of entity reference nodes should be treated as hierarchical nodes. This parameter applies primarily to XML documents.

**Related Items:** TreeWalker object.

**elementFromPoint(*x*, *y*)**

**Returns:** Element object reference.

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

**document.elementFromPoint()**

The IE-specific `elementFromPoint()` method returns a reference to whatever element object occupies the point whose integer coordinates are supplied as parameters to the method. The coordinate plane is that of the document, whose top-left corner is at point 0,0. This coordinate plane can be very helpful in interactive designs that need to calculate collision detection between positioned objects or mouse events.

When more than one object occupies the same point (for example, one element is positioned atop another), the element with the highest z-index value is returned. A positioned element always wins when placed atop a normal body-level element. And if multiple overlapping positioned elements have the same z-index value (or none by default), the element that comes last in the source code order is returned for the coordinate that they share in common.

### Example

Listing 18-14 is a document that contains many different types of elements, each of which has an ID attribute assigned to it. The `onmouseover` event handler for the document object invokes a function that finds out which element the cursor is over when the event fires. Notice that the event coordinates are `event.clientX` and `event.clientY`, which use the same coordinate plane as the page for their point of reference. As you roll the mouse over every element, its ID appears on the page. Some elements, such as `br` and `tr`, occupy no space in the document, so you cannot get their IDs to appear. On a typical browser screen size, a positioned element rests atop one of the paragraph elements so that you can see how the `elementFromPoint()` method handles overlapping elements. If you scroll the page, the coordinates for the event and the page's elements stay in sync.

#### Listing 18-14: Tracking the Mouse as it Passes over Elements

```
<html>
  <head>
    <title>document.elementFromPoint() Method</title>
    <script type="text/javascript">
      function showElemUnderneath() {
        var elem = document.elementFromPoint(event.clientX, event.clientY);
        document.getElementById("mySpan").innerText = elem.id;
      }

      document.onmouseover = showElemUnderneath;
    </script>
  </head>
  <body id="myBody">
    <h1 id="header">document.elementFromPoint() Method</h1>
    <hr id="myHR" />
    <p id="instructions">Roll the mouse around the page. The coordinates
      of the mouse pointer are currently atop an element<br id="myBR" />
      whose ID is:<span id="mySpan" style="font-weight:bold"></span>.</p>
    <form id="myForm">
      <input id="myButton" type="button" value="Sample Button"
        onclick="" />&nbsp;
    </form>
    <table border="1" id="myTable">
      <tr id="tr1">
        <td id="td_A1">Cell A1</td>
        <td id="td_B1">Cell B1</td>
      </tr>
    </table>
  </body>
</html>
```

*Continued*

    </div>
</body>
</html>

```

**Related Items:** `event.clientX`, `event.clientY` properties; positioned objects (Chapter 39 on the CD-ROM).

**execCommand("commandName" [, UIFlag] [, param])**

**Returns:** Boolean.

**Compatibility:** WinIE4+, MacIE-, NN7.1, Moz1.4, Safari-

WinIE4+ includes a large set of commands that are outside of the methods defined for objects in the object model. These commands are also accessible to programmers who build an Internet Explorer ActiveX control into their applications. The `execCommand()` method is the JavaScript gateway to those commands. A series of related methods (`queryCommandEnable()` and others) also facilitate management of these commands.

The syntax for the `execCommand()` method requires at least one parameter, a string version of the command name. Command names are not case-sensitive. An optional second parameter is a Boolean flag to instruct the command to display any user interface artifacts that may be associated with the command. The default is `false`. For the third parameter, some commands require that an attribute value be passed for the command to work. For example, to set the font size of a text range, the syntax is

```
myRange.execCommand("FontSize", true, 5);
```

The `execCommand()` method returns Boolean `true` if the command is successful; `false` if not successful. Some commands can return values (for example, finding out the font name of a selection), but those are accessed through the `queryCommandValue()` method.

**document.execCommand()**

Most of these commands operate on body text selections that are `TextRange` objects. As described in Chapter 35, a `TextRange` object must be created under script control. But a `TextRange` object can be done in response to a user selecting some text in the document. Because a `TextRange` object is independent of the element hierarchy (indeed, a `TextRange` can spread across multiple nodes), it cannot respond to stylesheet specifications. Thus, many of the commands that can operate on a `TextRange` object have to do with formatting or modifying the text. For a list of commands that work exclusively on `TextRange` objects, see the `TextRange.execCommand()` method in Chapter 35.

While many of the commands intended for the `TextRange` also work when invoked from the document object, in this section the focus is on those commands that have scope over the entire document. Table 18-3 lists those few commands that work with the document. Also listed are many commands that work exclusively on text selections in the document, whether the selections are made manually by the user or with the help of the `TextRange` object (see Chapter 35).

---

**Table 18-3: document.execCommand() Commands**

---

<i>Command</i>	<i>Parameter</i>	<i>Description</i>
Refresh	None	Reloads the page.
SelectAll	None	Selects entire page content.
Unselect	None	Unselects any page selection.
BackColor	Color String	Encloses the current selection with a <code>font</code> element whose <code>style</code> attribute sets the <code>background-color</code> style to the parameter value.
CreateBookmark	Anchor String	Encloses the current selection (or text range) with an anchor element whose <code>name</code> attribute is set to the parameter value.
CreateLink	URL String	Encloses the current selection with an <code>a</code> element whose <code>href</code> attribute is set to the parameter value.
FontName	Font Face(s)	Encloses the current selection with a <code>font</code> element whose <code>face</code> attribute is set to the parameter value.
FontSize	Size String	Encloses the current selection with a <code>font</code> element whose <code>size</code> attribute is set to the parameter value.
FontColor	Color String	Encloses the current selection with a <code>font</code> element whose <code>color</code> attribute is set to the parameter value.
Indent	None	Indents the current selection.
JustifyCenter	None	Centers the current selection.
JustifyFull	None	Full-justifies the current selection.
JustifyLeft	None	Left-justifies the current selection.
JustifyRight	None	Right-justifies the current selection.
Outdent	None	Outdents the current selection.
RemoveFormat	None	Removes formatting for the current selection.
SelectAll	None	Selects all text of the document.
UnBookmark	None	Removes anchor tags that surround the current selection.
Unlink	None	Removes link tags that surround the current selection.
Unselect	None	Deselects the current selection anywhere in the document.

---

**document.execCommand()**

Mozilla 1.4 includes a feature that allows scripts to turn an `iframe` element's document object into an HTML editable document. Part of the scripting incorporates the `document.execCommand()` method. Visit <http://www.mozilla.org/editor> for current details and examples.

**Example**

You can find many examples of the `execCommand()` method for the `TextRange` object in Chapter 35. But you can try out the document-specific commands in The Evaluator (Chapter 13) if you like. Try each of the following statements in the top text box and click the Evaluate button:

```
document.execCommand("Refresh")
document.execCommand("SelectAll")
document.execCommand("Unselect")
```

All methods return `true` in the Results box.

Because any way you can evaluate a statement in The Evaluator forces a body selection to become deselected before the evaluation takes place, you can't experiment this way with the selection-oriented commands.

**Related Items:** `queryCommandEnabled()`, `queryCommandIndterm()`, `queryCommandState()`, `queryCommandSupported()`, `queryCommandText()`, `queryCommandValue()` methods.

**getElementById("elementID")**

**Returns:** Element object reference.

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `document.getElementById()` method is the W3C DOM syntax for retrieving a reference to any element in a document that has a unique identifier assigned to its `id` attribute. If the document contains more than one instance of an ID, the method returns a reference to the first element in source code order with that ID. Because this method is such an important avenue to writing references to objects that are to be modified under script control, you can see how important it is to assign unique IDs to elements.

This method's name is quite a finger twister for scripters, especially compared to the IE4+ convention of letting a reference to any element begin simply with the object's ID. However, the `getElementById()` method is the cross-browser way of acquiring an element's reference for W3C DOM-compatible browsers. When you type this method, be sure to use a lowercase "d" as the last character of the method name.

Unlike some other element-oriented methods (for example, `getElementsByTagName()`), which can be invoked on any element in a document, the `getElementById()` method works exclusively with the `document` object.

**Example**

You can find many examples of this method in use throughout this book, but you can take a closer look at how it works by experimenting in The Evaluator (Chapter 13). A number of elements in The Evaluator have IDs assigned to them, so that you can use the method to inspect the objects and their properties. Enter the following statements into both the top and bottom text fields of The Evaluator. Results from the top field are references to the objects; results from the bottom field are lists of properties for the particular object.

**document.getElementsByName()**

```
document.getElementById("myP")
document.getElementById("myEM")
document.getElementById("myTitle")
document.getElementById("myScript")
```

**Related Items:** `getElementsByTagName()` method (Chapter 15).

**getElementsByTagName("elementName")**

**Returns:** Array.

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `document.getElementsByTagName()` method returns an array of references to objects whose `name` attribute is assigned the element name passed as the method's attribute. Although NN6+/Moz1+ recognizes `name` attributes even for elements that don't have them by default, IE5+ does not. Therefore, for maximum cross-browser compatibility, use this method only to locate elements that have `name` attributes defined for them by default, such as form control elements. If the element does not exist in the document, the method returns an array of zero length.

For the most part, you are best served by using IDs on elements and the `getElementById()` method to unearth references to individual objects. But some elements, especially the `input` element of type `radio`, use the `name` attribute to group elements together. In that case, a call to `getElementsByTagName()` returns an array of all elements that share the name—facilitating perhaps a `for` loop that inspects the `checked` property of a radio button group. Thus, instead of using the old-fashioned (although entirely backward-compatible) approach by way of the containing form object

```
var buttonGroup = document.forms[0].radioGroupName;
```

you can go more directly:

```
var buttonGroup = document.getElementsByName(radioGroupName);
```

In the latter case, you operate independently of the containing form object's index number or name. This assumes, of course, that a group name is not shared elsewhere on the page.

## Example

Use The Evaluator (Chapter 13) to test out the `getElementsByTagName()` method. All form elements in the upper part of the page have names associated with them. Enter the following statements into the top text field and observe the results:

```
document.getElementsByName("output")
document.getElementsByName("speed").length
document.getElementsByName("speed")[0].value
```

You can also explore all of the properties of the text field by typing the following expression into the bottom field:

```
document.getElementsByName("speed")[0]
```

**Related Items:** `document.getElementById()`, `getElementsByTagName()` methods.

**document.getSelection()****getSelection()****Returns:** String.**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

Many Web browser users aren't aware that they can select and copy body text in a document for pasting into other application documents. Even so, NN4+ offers a scripted way of capturing the text selected by a user in a page. The `document.getSelection()` method returns the string of text selected by the user. If nothing is selected, an empty string is the result. Returned values consist only of the visible text on the page and not the underlying HTML or style of the text. This method generates JavaScript Console warning messages in Mozilla-based browsers, urging you to use the newer, more sophisticated `window.getSelection()` method instead.

The WinIE4+ equivalent involves the `document.selection` property, which returns an IE selection object. To derive the text from this object, you must create a `TextRange` object from it and then inspect the `text` property:

```
var selectedText = document.selection.createRange().text;
```

**Example**

The document in Listing 18-15 provides a cross-browser (but not MacIE5) solution to capturing text that a user selects in the page. Selected text is displayed in the `textarea`. The script uses browser detection and branching to accommodate the diverse ways of recognizing the event and reading the selected text.

**Listing 18-15: Retrieving Selected Text**

```
<html>
<head>
  <title>Getting Selected Text</title>
  <script type="text/javascript">
    var isNav4 = (navigator.appName == "Netscape" &&
      parseInt(navigator.appVersion) == 4);
    var isNav4Min = (navigator.appName == "Netscape" &&
      parseInt(navigator.appVersion) >= 4);
    var isIE4Min = (navigator.appName.indexOf("Microsoft") != -1 &&
      parseInt(navigator.appVersion) >= 4);

    function showSelection() {
      if (isNav4Min) {
        document.forms[0].selectedText.value = document.getSelection();
      } else if (isIE4Min) {
        if (document.selection) {
          document.forms[0].selectedText.value =
            document.selection.createRange().text;
          event.cancelBubble = true;
        }
      }
    }

    if (isNav4) {
      document.captureEvents(Event.MOUSEUP);
    }
  </script>
</head>
</html>
```

**document.open()**

```

    document.onmouseup = showSelection;
  </script>
</head>
<body>

    </textarea>
  </form>
</body>
</html>

```

---

**Related Items:** `document.selection` property.

**handleEvent(event)**

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

When you explicitly capture NN4 events in the window, document, or layer object (by invoking the `captureEvents()` method for that object), you can control where the events go after their initial capture. To let an event continue to its original target (for example, a button that is clicked by a user), you use the `routeEvent()` method. But if you want to redirect an event (or class of events) to a particular event handler elsewhere in the document, use the `handleEvent()` method.

See the discussion of the `handleEvent()` method for the window object in Chapter 16. The behavior of the `handleEvent()` method for all objects is the same.

**Related Items:** `document.captureEvents()`, `document.releaseEvents()`, `document.routeEvent()` methods; event object (Chapter 25).

**open(["mimeType"] [, "replace"])**

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Opening a document is different from opening a window. In the case of a window, you're creating a new object, both on the screen and in the browser's memory. Opening a document, on the other hand, tells the browser to get ready to accept some data for display in the window named or implied in the reference to the `document.open()` method. (For example, `parent.frames[1].document.open()` may refer to a different frame in a frameset, whereas `document.open()` implies the current window or frame.) Therefore, the method name may mislead newcomers because the `document.open()` method has nothing to do with loading documents from the Web server or hard disk. Rather, this method is a prelude to sending data to a window via the `document.write()` or `document.writeln()` methods. In a sense,

**document.open()**

the `document.open()` method merely opens the valve of a pipe; the other methods send the data down the pipe like a stream, and the `document.close()` method closes that valve as soon as the page's data has been sent in full.

The `document.open()` method is optional because a `document.write()` method that attempts to write to a closed document automatically clears the old document and opens the stream for a new one. Whether or not you use the `document.open()` method, be sure to use the `document.close()` method after all the writing has taken place.

An optional parameter to the `document.open()` method lets you specify the nature of the data being sent to the window. A MIME (Multipurpose Internet Mail Extension) type is a specification for transferring and representing multimedia data on the Internet (originally for mail transmission, but now applicable to all Internet data exchanges). You've seen MIME depictions in the list of helper applications in your browser's preferences settings. A pair of data type names separated by a slash represents a MIME type (such as `text/html` and `image/gif`). When you specify a MIME type as a parameter to the `document.open()` method, you're instructing the browser about the kind of data it is about to receive, so that it knows how to render the data. Common values that most browsers accept are

```
text/html
text/plain
image/gif
image/jpeg
image/xbm
```

If you omit the parameter, JavaScript assumes the most popular type, `text/html` — the kind of data you typically assemble in a script prior to writing to the window. The `text/html` type includes any images that the HTML references. Specifying any of the image types means that you have the raw binary representation of the image that you want to appear in the new document — possible, but unlikely.

Another possibility is to direct the output of a `write()` method to a plug-in. For the `mimeType` parameter, specify the plug-in's MIME type (for example, `application/x-director` for Shockwave). Again, the data you write to a plug-in must be in a form that it knows how to handle. The same mechanism also works for writing data directly to a helper application.

 **Note**

IE accepts only the `text/html` MIME type parameter.

NN4+/Moz1+ and IE5+ include a second, optional parameter to the method: `replace`. This parameter does for the `document.open()` method what the `replace()` method does for the `Location` object. For `document.open()`, it means that the new document you are about to write replaces the previous document in the window or frame from being recorded to that window or frame's history.

## Example

You can see an example of where the `document.open()` method fits in the scheme of dynamically creating content for another frame in the discussion of the `document.write()` method later in this chapter.

**Related Items:** `document.close()`, `document.clear()`, `document.write()`, `document.writeln()` methods.

**document.queryCommandEnabled()**

```

queryCommandEnabled("commandName")
queryCommandIndterm("commandName")
queryCommandCommandState("commandName")
queryCommandSupported("commandName")
queryCommandText("commandName")
queryCommandValue("commandName")

```

**Returns:** Various values.

**Compatibility:** WinIE4+, MacIE-, NN7.1, Moz1.4, Safari-

These six methods lend further support to the `execCommand()` method for `document` and `TextRange` objects in WinIE. If you choose to use the `execCommand()` method to achieve some stylistic change on a text selection, you can use some of these query methods to make sure the browser supports the desired command and to retrieve any returned values. Table 18-4 summarizes the purpose and returned values for each of the methods.

**Table 18-4: IE Query Commands**

<i>queryCommand</i>	<i>Returns</i>	<i>Description</i>
Enabled	Boolean	Reveals whether the document or TextRange object is in a suitable state to be invoked.
Indterm	Boolean	Reveals whether the command is in an indeterminate state.
CommandState	Boolean   null	Reveals whether the command has been completed ( <code>true</code> ), is still working ( <code>false</code> ), or is in an indeterminate state ( <code>null</code> ).
Supported	Boolean	Reveals whether the command is supported in the current browser.
Text	String	Returns any text that may be returned by a command.
Value	Varies	Returns whatever value (if any) is returned by a command.

Because the `execCommand()` method cannot be invoked on a page while it is still loading, any such invocations that may collide with the loading of a page should check with `queryCommandEnabled()` prior to invoking the command. Validating that the browser version running the script supports the desired command (especially for commands that have been introduced after IE4) is also a good idea. Therefore, you may want to wrap any command call with the following conditional structure:

```

if (document.queryCommandEnabled(commandName) &&
    document.queryCommandSupported(commandName)) {
    ...
}

```

When using a command to read information about a selection, use the `queryCommandText()` or `queryCommandValue()` methods to catch that information (recall that the `execCommand()` method itself returns a Boolean value regardless of the specific command invoked).

**document.queryCommandEnabled()****Example**

See the examples for these methods covered under the `TextRange` object in Chapter 35.

**Related Items:** `TextRange` object (Chapter 35); `execCommand()` method.

**recalc([allFlag])**

**Returns:** Nothing.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

IE5 introduced the concept of dynamic properties. With the help of the `setExpression()` method of all elements and the `expression()` stylesheet value, you can establish dependencies between object properties and potentially dynamic properties, such as a window's size or a draggable element's location. After those dependencies are established, the `document.recalc()` method causes those dependencies to be recalculated — usually in response to some user action, such as resizing a window or dragging an element.

The optional parameter is a Boolean value. The default value, `false`, means that the recalculations are performed only on expressions for which the browser has detected any change since the last recalculation. If you specify `true`, however, all expressions are recalculated whether they have changed or not.

Mozilla 1.4 includes a feature that allows scripts to turn an `iframe` element's document object into an HTML editable document. Part of the scripting incorporates the `document.execCommand()` and related methods. Visit <http://www.mozilla.org/editor> for current details and examples.

**Example**

You can see an example of `recalc()` in Listing 15-32 for the `setExpression()` method. In that example, the dependencies are between the current time and properties of standard element objects.

**Related Items:** `getExpression()`, `removeExpression()`, `setExpression()` methods (Chapter 15).

**releaseEvents(eventTypeList)**

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

If your NN4 scripts have enabled event capture for the document object (or window or layer, for that matter), you can turn off that capture with the `releaseEvents()` method. This method does not inhibit events from reaching their intended target. In fact, by releasing capture from a higher object, released events don't bother stopping at those higher objects anymore.

See the discussion of the `releaseEvents()` method for the window object in Chapter 16. The behavior of the `releaseEvents()` method for all objects is the same.

**Related Items:** `document.captureEvents()`, `document.routeEvent()` methods.

`document.write()`

## `routeEvent(event)`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

If you turn on NN4 event capturing in the `window`, `document`, or `layer` object (via their respective `captureEvents()` methods), the event handler you assign to those events really captures those events, preventing them from ever reaching their intended targets. For some page designs, this capturing is intentional, because it allows the higher-level object to handle all events of a particular type. But if your goal is to perform some preprocessing of events before they reach their destination, you need a way to pass that event along its regular path, which is what the `routeEvent()` method is for.

See the discussion of the `routeEvent()` method for the `window` object in Chapter 16. The behavior of the `routeEvent()` method for all objects is the same.

**Related Items:** `document.captureEvents()`, `document.releaseEvents()` methods.

```
write("string1" [, "string2" ... [, "stringn"]])  
writeln("string1" [, "string2" ... [, "stringn"]])
```

**Returns:** Boolean `true` if successful.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Both of these methods send text to a document for display in its window. The only difference between the two methods is that `document.writeln()` appends a carriage return to the end of the string it sends to the document. This carriage return is helpful for formatting source code when viewed through the browser's source view window. For new lines in rendered HTML that is generated by these methods, you must still write a `<br>` to insert a line break.

A common, incorrect conclusion that many JavaScript newcomers make is that these methods enable a script to modify the contents of an existing document, which is not true. As soon as a document has loaded into a window (or frame), the only fully backward-compatible text that you can modify without reloading or rewriting the entire page is the content of text and `textarea` objects. In IE4+, you can modify HTML and text via the `innerHTML`, `innerText`, `outerHTML`, and `outerText` properties of any element. For W3C DOM-compatible browsers, you can modify an element's text by setting its `nodeValue` or `innerHTML` properties; strict adherence to the W3C DOM requires creating and inserting or replacing new elements, as described in Chapter 15.

The two safest ways to use the `document.write()` and `document.writeln()` methods are to

- ♦ Write some or all of the page's content by way of scripts embedded in the document
- ♦ Send HTML code either to a new window or to a separate frame in a multiframe window

For the first case, you essentially interlace script segments within your HTML. The scripts run as the document loads, writing whatever scripted HTML content you like. This task is exactly what you did in `script1.htm` in Chapter 3. This task is also how you can have one page generate browser-specific HTML when a particular class of browser requires unique syntax.

In the latter case, a script can gather input from the user in one frame and then algorithmically determine the layout and content destined for another frame. The script assembles the HTML code for the other frame as a string variable (including all necessary HTML tags). Before the script can write anything to the frame, it can optionally open the layout stream

**document.write()**

(to close the current document in that frame) with the `parent.frameName.document.open()` method. In the next step, a `parent.frameName.document.write()` method pours the entire string into the other frame. Finally, a `parent.frameName.document.close()` method ensures that the total data stream is written to the window. Such a frame looks just the same as if it were created by a source document on the server rather than on the fly in memory. The document object of that window or frame is a full citizen as a standard document object. You can, therefore, even include scripts as part of the HTML specification for one of these temporary HTML pages.

After an HTML document (containing a script that is going to write via the `write()` or `writeln()` methods) loads completely, the page's incoming stream closes automatically. If you then attempt to apply a series of `document.write()` statements, the first `document.write()` method completely removes all vestiges of the original document. That includes all of its objects and scripted variable values. Therefore, if you try to assemble a new page with a series of `document.write()` statements, the script and variables from the original page will be gone before the second `document.write()` statement executes. To get around this potential problem, assemble the content for the new screen of content as one string variable and then pass that variable as the parameter to a single `document.write()` statement. Also be sure to include a `document.close()` statement in the next line of script.

Assembling HTML in a script to be written via the `document.write()` method often requires skill in concatenating string values and nesting strings. A number of JavaScript String object shortcuts facilitate the formatting of text with HTML tags (see Chapter 27 for details).

If you are writing to a different frame or window, you are free to use multiple `document.write()` statements if you like. Whether your script sends lots of small strings via multiple `document.write()` methods or assembles a larger string to be sent via one `document.write()` method depends partly on the situation and partly on your own scripting style. From a performance standpoint, a fairly standard procedure is to do more preliminary work in memory and place as few I/O (input/output) calls as possible. On the other hand, making a difficult-to-track mistake is easier in string concatenation when you assemble longer strings. My personal preference is to assemble longer strings, but you should use the system that's most comfortable for you.

You may see another little-known way of passing parameters to these methods. Instead of concatenating string values with the plus (+) operator, you can also bring string values together by separating them with commas. For example, the following two statements produce the same results:

```
document.write("Today is " + new Date());
document.write("Today is ",new Date());
```

Neither form is better than the other, so use the one that feels more comfortable to your existing programming style.

**Note**

Dynamically generating scripts requires an extra trick, especially in NN. The root of the problem is that if you try code, such as `document.write("<script></script>")`, the browser interprets the end script tag as the end of the script that is doing the writing. You have to trick the browser by separating the end tag into a couple of components. Escaping the forward slash also helps. For example, if you want to load a different `.js` file for each class of browser, the code looks similar to the following:

```
// variable 'browserVer' is a browser-specific string
// and 'page' is the HTML your script is accumulating
// for document.write()
page += "<script type='text/javascript' src='" +
    browseVer + ".js'><" + "\\script>";
```

**document.write()**

Using the `document.open()`, `document.write()`, and `document.close()` methods to display images in a document requires some small extra steps. First, any URL assignments that you write via `document.write()` must be complete (not relative) URL references. Alternatively, you can write the `<base>` tag for the dynamically generated page so that its `href` attribute value matches that of the file that is writing the page.

The other image trick is to be sure to specify `height` and `width` attributes for every image, scripted or otherwise. Document-rendering performance is improved on all platforms, because the values help the browser lay out elements even before their details are loaded.

In addition to the `document.write()` example that follows (see Listings 18-16 through 18-18), you can find fuller implementations that use this method to assemble images and bar charts in many of the applications in Chapters 48 through 57 on the CD-ROM. Because you can assemble any valid HTML as a string to be written to a window or frame, a customized, on-the-fly document can be as elaborate as the most complex HTML document that you can imagine.

**Example**

The example in Listings 18-16 through 18-18 demonstrates several important points about using the `document.write()` or `document.writeln()` methods for writing to another frame. First is the fact that you can write any HTML code to a frame, and the browser accepts it as if the source code came from an HTML file somewhere. In the example, I assemble a complete HTML document, including basic HTML tags for completeness.

**Listing 18-16: A Frameset for the Document Writing Example**

```
<html>
  <head>
    <title>Writin' to the doc</title>
  </head>
  <frameset rows="50%,50%">

</html>
```

*Continued*

**document.write****Listing 18-17 (continued)**

```

    }
    msg += "<br />Make it a great day!</body></html>";
    parent.Frame2.document.write(msg);
    parent.Frame2.document.close();
  }

  function getTitle() {
    alert("Lower frame document.title is now:" +
parent.Frame2.document.title);
  }
</script>
</head>
<body>
  Fill in a name, and select how that person feels today. Then click "Write
  To Below" to see the results in the bottom frame.
  <form>
    Enter your first name:<input type="text" name="yourName"
    value="Dave" />
    <p>How are you today? <input type="radio" name="how"
    value="I hope that feeling continues forever."
    checked="checked" />Swell <input type="radio" name="how"
    value="You may be on your way to feeling Swell" />Pretty Good
    <input type="radio" name="how"
    value="Things can only get better from here." />So-So</p>
    <p><input type="button" name="enter" value="Write To Below"
    onclick="takePulse(this.form)" /></p>
    <hr />
    <input type="button" name="peek" value="Check Lower Frame Title"
    onclick="getTitle()" />
  </form>
</body>
</html>

```

**Listing 18-18: A Placeholder Page for the Document Writing Example**

```

<html>
  <head>
    <title>Placeholder</title>
  </head>
  <body>
  </body>
</html>

```

It is important to note that this example customizes the content of the document based on user input. This customization makes the experience of working with your Web page feel far more interactive to the user —yet you're doing it without any CGI programs running on the server.

**document.onstop**

The second point I want to bring home is that the document created in the separate frame by the `document.write()` method is a genuine `document` object. In this example, for instance, the `<title>` tag of the written document changes if you redraw the lower frame after changing the entry of the name field in the upper frame. If you click the lower button after updating the bottom frame, you see that the `document.title` property has, indeed, changed to reflect the `<title>` tag written to the browser in the course of displaying the frame's page. The fact that you can artificially create full-fledged, JavaScript `document` objects on the fly represents one of the most important powers of serverless CGI scripting (for information delivery to the user) with JavaScript. You have much to take advantage of here if your imagination is up to the task.

Notice that you can easily modify Listing 18-17 to write the results to the same frame as the document containing the field and buttons. Instead of specifying the lower frame

```
parent.frames[1].document.open()
parent.frames[1].document.write(msg)
parent.frames[1].document.close()
```

the code simply can use

```
document.open()
document.write(msg)
document.close()
```

This code would replace the form document with the results and not require any frames in the first place. Because the code assembles all of the content for the new document into one variable value, that data survive the one `document.write()` method.

The frameset document (Listing 18-16) creates a blank frame by loading a blank document (Listing 18-18). An alternative I highly recommend is to have the framesetting document fill the frame with a blank document of its own creation. See the section titled “Blank frames” in Chapter 16 for further details about this technique for NN3+ and IE3+.

**Related Items:** `document.open()`; `document.close()`; `document.clear()` methods.

## Event handlers

### onselectionchange

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `onselectionchange` event can be triggered by numerous user actions, although all of those actions occur on elements that are under the influence of the WinIE5.5 edit mode.

**Related Items:** `oncontrolselect` event handler.

### onstop

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `onstop` event fires in WinIE5+ when the user clicks the browser's Stop button. Use this event handler to stop potentially runaway script execution on a page, because the Stop button does not otherwise control scripts after a page has loaded. If you are having a problem with a runaway repeat loop during development, you can temporarily use this event handler to let you stop the script for debugging.

**document.onstop****Example**

Listing 18-19 provides a simple example of an intentional infinitely looping script. In case you load this page into a browser other than IE5+, you can click the Halt Counter button to stop the looping. The Halt Counter button as well as the `onstop` event handler invokes the same function.

**Listing 18-19: Stopping a Script Using the `onstop` Event Handler**

```
<html>
  <head>
    <title>onStop Event Handler</title>
    <script type="text/javascript">
      var counter = 0;
      var timerID;
      function startCounter() {
        document.forms[0].display.value = ++counter;
        //clearTimeout(timerID)
        timerID = setTimeout("startCounter()", 10);
      }
      function haltCounter() {
        clearTimeout(timerID);
        counter = 0;
      }

      document.onstop = haltCounter;
    </script>
  </head>
  <body>
    <h1>onStop Event Handler</h1>
    <hr />
    <p>Click the browser's Stop button (in IE) to stop the script
    counter.</p>
    <form>
      <p><input type="text" name="display" /></p>
      <input type="button" value="Start Counter" onclick="startCounter()" />
      <input type="button" value="Halt Counter" onclick="haltCounter()" />
    </form>
  </body>
</html>
```

**Related Items:** Repeat loops (Chapter 31).

## body Element Object

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
alink	createControlRange()	onafterprint
background	createTextRange()	onbeforeprint
bgColor	doScroll()	onscroll
bgProperties		
bottomMargin		
leftMargin		
link		
noWrap		
rightMargin		
scroll		
scrollLeft		
scrollTop		
text		
topMargin		
vLink		

## Syntax

Accessing body element object properties or methods:

```
[window.] document.body.property | method([parameters])
```

## About this object

In object models that reveal HTML element objects, the `body` element object is the primary container of the content that visitors see on the page. The `body` contains all rendered HTML. This special place in the node hierarchy gives the `body` object some special powers, especially in the IE object model.

As if to signify the special relationship, both the IE and W3C object models provide the same shortcut reference to the `body` element: `document.body`. As a first-class HTML element object (as evidenced by the long lists of properties, methods, and event handlers covered in Chapter 15), you are also free to use other syntaxes to reach the `body` element.

You are certainly familiar with several `body` element attributes that govern body-wide content appearance, such as link colors (in three states) and background (color or image). But IE and NN/Mozilla (and the W3C so far) have some very different ideas about the `body` element's role in scripting documents. Many methods and properties that NN/Mozilla considers to be the domain of the window (for example, scrolling, inside window dimensions, and so forth), IE puts into the hands of the `body` element object. Therefore, while NN/Mozilla scrolls the window (and whatever it may contain), IE scrolls the `body` (inside whatever window it lives). And because the `body` element fills the entire viewable area of a browser window or frame, that

**document.body**

viewable rectangle is determined in IE by the body's `scrollHeight` and `scrollWidth` properties, whereas NN4+ features `window.innerHeight` and `window.innerWidth` properties. This distinction is important to point out because when you are scripting window- or document-wide appearance factors, you may have to look for properties and methods for the window or body element object, depending on your target browser(s).

**Note**

Use caution when referencing the `document.body` object while the page is loading. The object may not officially exist until the page has completely loaded. If you need to set some initial properties via scripting, do so in response to the `onload` event handler located in the `<body>` tag. Attempts at setting body element object properties in immediate scripts inside the `head` element may result in error messages about the object not being found.

## Properties

`aLink`  
`bgColor`  
`link`  
`text`  
`vLink`

**Value:** Hexadecimal triplet or color name string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `aLink`, `link`, and `vLink` properties are the new versions of the `document` properties `alinkColor`, `linkColor`, and `vlinkColor`. The `bgColor` is the same as the old `document.bgColor` property, while the `text` property is the new version of the `document.fgColor` property. These new properties are the scripted equivalents of the HTML attributes for the body element—the property names more closely align themselves with the HTML attributes than the old property names.

Link colors that are set via pseudo-class selectors in stylesheets (as `style` attributes of the body element) must be accessed via the `style` property for the body object. Over time, these properties will likely fall into disuse as stylesheets become more common.

## Example

You can modify Listing 18-1 for use with IE4+ and NN6+/Moz1+/W3C only by using the new property names instead. Replace all references to the `document` properties with their `document.body` equivalents. For example, the function would be reworked as the following (changes in boldface):

```
function showColorValues() {
    var result = "";
    result += "bgColor: " + newWindow.document.body.bgColor + "\n";
    result += "vLink: " + newWindow.document.body.vLink + "\n";
    result += "link: " + newWindow.document.body.link + "\n";
    document.forms[0].results.value = result;
}
```

**Related Items:** `document.alinkColor`, `document.bgColor`, `document.fgColor`, `document.linkColor`, `document.vlinkColor` properties.

## background

**Value:** URL string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `background` property lets you set or get the URL for the background image (if any) assigned to the `body` element. A `body` element's background image overlays the background color in case both attributes or properties are set. To remove an image from the document's background, set the `document.body.background` property to an empty string.

### Example

If you have a background image file named `images/logoBG.gif`, a script can set the background via the following statement:

```
document.body.background = "images/logoBG.gif";
```

To clear the background image:

```
document.body.background = "";
```

If a background color has been previously set, the color becomes visible after the image disappears.

**Related Items:** `body.backgroundColor`, `body.bgProperties` properties.

## bgColor

See `aLink`

## bgProperties

**Value:** String constant.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The IE-specific `bgProperties` property is an alternative way of adjusting whether the background image should remain fixed when the user scrolls the document or if it should scroll with the document. Initial settings for this behavior should be done via the `background-attachment` CSS attribute and modified under script control by way of the `body` element's `style.backgroundAttachment` property.

No matter which way you reference this property, the only allowable values are string constants `scroll` (the default) or `fixed`.

### Example

Both of the following statements change the default behavior of background image scrolling in IE4+:

```
document.body.bgProperties = "fixed";
```

or

```
document.body.style.backgroundAttachment = "fixed";
```

The added benefit of using the stylesheet version is that it also works in NN6+.

**Related Items:** `body.background` property.

**document.body.bottomMargin****bottomMargin****leftMargin****rightMargin****topMargin****Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The four IE-specific margin properties are alternatives to setting the corresponding four margin stylesheet attributes for the `body` element (`body.style.marginBottom`, and so on). Stylesheet margins represent blank space between the edge of an element's content and its next outermost container. In the case of the `body` element, that container is an invisible document container.

Of the four properties, only the one for the bottom margin may be confusing if the content does not fill the vertical space of a window or frame. The margin value is not automatically increased to accommodate the extra blank space.

Different versions and operating system implementations of IE4+ offer a variety of default integer values for these properties. But be aware that their values are not necessarily returned by these properties unless they are explicitly set in the IE-proprietary `body` element attributes of the same name. Therefore, even though a default `body` has a visible margin, the property does not return that default value except in MacIE, where the left and top margins may need to be factored into determining an inline element's position.

**Example**

Both of the following statements change the default left margin in IE4+:

```
document.body.leftMargin = 30;
```

or

```
document.body.style.marginLeft = 30;
```

**Related Items:** `style` object.

**leftMargin**(See `bottomMargin`)**link**(See `aLink`)**noWrap****Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `noWrap` property lets you modify the `body` element behavior normally set via the `nowrap` attribute. Because the property name is a negative, the Boolean logic needed to control it can get confusing.

The default behavior for a `body` element is for text to wrap within the width of the window or frame. This behavior occurs when the value of `noWrap` is its default value of `false`. By turning `noWrap` to `true`, a line of text continues to render past the right edge of the window or frame

**document.body.scrollLeft**

until the HTML contains a line break (or end of paragraph). If the text continues on past the right edge of the window, the window (or frame) gains a horizontal scroll bar (of course, not if a frame is set to not scroll).

By and large, users don't like to scroll in any direction if they don't have to. Unless you have a special need to keep single lines intact, let the default behavior rule the day.

**Example**

To change the word-wrapping behavior from the default, the statement is:

```
document.body.noWrap = true;
```

**Related Items:** None.

**rightMargin**

(See `bottomMargin`)

**scroll**

**Value:** Constant string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The IE-specific `scroll` property provides scripted access to the IE-specific `scroll` attribute of a body element. By default, an IE body element displays a vertical scroll bar even if the height of the content does not warrant it; a horizontal scroll bar appears only when the content is forced to be wider than the window or frame. You can make sure that both scroll bars are hidden by setting the `scroll` attribute to "no" or changing it via script. Possible values for this property are the constant strings `yes` and `no`.

Other than `frame` attributes and NN4+ signed scripts, other browsers do not provide facilities for turning off scroll bars under script control. You can generate a new window (via the `window.open()` method) and specify that its scroll bars be hidden.

**Example**

To change the scroll bar appearance from the default, the statement is:

```
document.body.scroll = "no";
```

**Related Items:** `window.scrollbars` property; `window.open()` method.

**scrollLeft****scrollTop**

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN7+, Moz1+, Safari-

Even though the `scrollLeft` and `scrollTop` properties of the `body` object are the same as those for generic HTML element objects, they play an important roll in determining the position of positioned elements (described more fully in Chapter 39 on the CD-ROM). Because the mouse event and element position properties tend to be relative to the visible content region of the browser window, you must take the scrolling values of the `document.body` object into account when assigning an absolute position. Values for both of these properties are integers representing pixels.

**document.body.scrollLeft****Example**

Listing 18-20 is the IE4+ (and NN7+/Moz1+) version of the original NN example for `pageXOffset` and `pageYOffset` properties (see Listing 16-13). Everything about these two examples is the same except for the syntax that retrieves the values indicating how much the document is scrolled in a window.

**Listing 18-20: Determining Scroll Values**

```

<html>
  <head>
    <title>Master of all Windows</title>
    <script type="text/javascript">
      function leftFrame() {
        var output = "<html><body><h3>Body Scroll Values</h3><hr />\n";
        output += "<form>body.scrollLeft:<input type='text' name='xOffset'
          size=4 /><br />\n";
        output += "body.scrollTop:<input type='text' name='yOffset'
          size=4 /><br />\n";
        output += "</form></body></html>";
        return output;
      }

      function rightFrame() {
        var output = "<html><head><script type='text/javascript'>\n";
        output += "function showOffsets() {\n";
        output += "parent.readout.document.forms[0].xOffset.value =
          document.body.scrollLeft\n";
        output += "parent.readout.document.forms[0].yOffset.value =
          document.body.scrollTop\n}\n";
        output += "document.onclick = showOffsets\n";
        output += "</script></head><body><h3>Content Page</h3>\n";
        output += "Scroll this frame and click on a table border to view page
          offset values.<br /><hr />\n";
        output += "<table border=5 width=800>";
        var oneRow = "<td>Cell 1</td><td>Cell 2</td><td>Cell 3</td><td>Cell 1
          4</td><td>Cell 5</td>";
        for (var i = 1; i <= 30; i++) {
          output += "<tr><td><b>Row " + i + "</b></td>" + oneRow +
            "</tr>";
        }
        output += "</table></body></html>";
        return output;
      }
    </script>
  </head>
  <frameset cols="30%,70%">
    <frame name="readout" src="javascript:parent.leftFrame()" />
    <frame name="display" src="javascript:parent.rightFrame()" />
  </frameset>
</html>

```

**Related Items:** `window.pageXOffset`, `window.pageYOffset` properties.

text

(See aLink)

topMargin

(See bottomMargin)

vLink

(See aLink)

## Methods

createControlRange()

**Returns:** Array.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

This method creates a control range in WinIE5+ browsers. Control ranges are used for control-based selection, as opposed to text-based selection made possible by text ranges. The method only applies to documents in edit mode. In regular document view mode, the `createControlRange()` method returns an empty array.

createTextRange()

**Returns:** Object.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The body element object is the most common object to use to generate a `TextRange` object in IE4+, especially when the text you are about to manipulate is part of the document's body text. The initial `TextRange` object returned from the `createTextRange()` method encompasses the entire body element's HTML and body text. Further action on the returned object is required to set the start and end point of the range. See Chapter 35's discussion of the `TextRange` object for more details.

## Example

See Listing 35-8 for an example of the `createTextRange()` method in action.

**Related Items:** `TextRange` object (Chapter 35).

doScroll(["scrollAction"])

**Returns:** Nothing.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

Use the `doScroll()` method to simulate user action on the scroll bars inside a window or frame that holds the current document. This method comes in handy if you are creating your own scroll bars in place of the standard system scroll bars. Scrolling is instantaneous, however, rather than with animation even if the `Display` control panel is set for animated scrolling. The parameter for this method is one of the string constant values shown in Table 18-5. In practice, occasionally the longer scroll action names more closely simulate an actual click on the scroll bar component, whereas the shortcut versions may scroll at a slightly different increment.

**document.body.doScroll()****Table 18-5: document.body.doScroll() Parameters**

<i>Long Parameter</i>	<i>Short Parameter</i>	<i>Scroll Action Simulates</i>
scrollbarDown	down	Clicking the down arrow.
scrollbarHThumb	n/a	Clicking the horizontal scroll bar thumb (no scrolling action).
scrollbarLeft	left	Clicking the left arrow.
scrollbarPageDown	pageDown	Clicking the page down area or pressing PgDn (default).
scrollbarPageLeft	pageLeft	Clicking the page left area.
scrollbarPageRight	pageRight	Clicking the page right area.
scrollbarPageUp	pageUp	Clicking the page up area or pressing PgUp.
scrollbarVThumb	n/a	Clicking the vertical scroll bar thumb (no scrolling action).

Unlike scrolling to a specific pixel location (by setting the body element's `scrollTop` and `scrollLeft` properties), the `doScroll()` method depends entirely on the spatial relationship between the body content and the window or frame size. Also, the `doScroll()` method triggers the `onscroll` event handler for the body element object.

Be aware that scripted modifications to body content can alter these spatial relationships. IE is prone to being sluggish in updating all of its internal dimensions after content has been altered. Should you attempt to invoke the `doScroll()` method after such a layout modification, the scroll may not be performed as expected. You may find the common trick of using `setTimeout()` to delay the invocation of the `doScroll()` method by a fraction of a second.

### Example

Use The Evaluator (Chapter 13) to experiment with the `doScroll()` method in IE5+. Size the browser window so that at least the vertical scroll bar is active (meaning it has a thumb region). Enter the following statement into the top text field and press Enter a few times to simulate clicking the PgDn key:

```
document.body.doScroll()
```

Return to the top of the page and now do the same for scrolling by the increment of the scroll bar down arrow:

```
document.body.doScroll("down")
```

You can also experiment with upward scrolling. Enter the desired statement in the top text field and leave the text cursor in the field. Manually scroll to the bottom of the page and then press Enter to activate the command.

**Related Items:** `body.scroll`, `body.scrollTop`, `body.scrollLeft` properties; `window.scroll()`, `window.scrollBy()`, `window.scrollTo()` methods.

## Event handlers

`onafterprint`

`onbeforeprint`

(See the `onafterprint` event handler for the window object, Chapter 16)

## onscroll

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `onscroll` event handler fires for the `body` element object as the result of manual scrolling of the document (via scroll bars or navigation keyboard keys) and scripted scrolling via the `doScroll()` method, `scrollIntoView()` method, or adjusting the `scrollTop` and/or `scrollLeft` properties of the `body` element object. For manual scrolling and scrolling by `doScroll()`, the event seems to fire twice in succession. Moreover, the `event.srcElement` property is `null`, even when the `body` element is handling the `onscroll` event handler.

### Example

Listing 18-21 is a highly artificial demonstration of what can be a useful tool for some page designs. Consider a document that occupies a window or frame, but one that you don't want scrolled, even by accident with one of the newer mouse wheels that are popular with Wintel PCs. If scrolling of the content would destroy the appearance or value of the content, then you want to make sure that the page always zips back to the top. The `onscroll` event handler in Listing 18-21 does just that. Notice that the event handler is set as a property of the `document.body` object after the page has loaded. Although the event handler can also be set as an attribute of the `<body>` tag, to assign it as a property requires the page to load first. Until then, the `document.body` object does not yet officially exist in the object model for this page.

#### Listing 18-21: Preventing a Page from Scrolling

```
<html>
  <head>
    <title>onscroll Event Handler</title>
    <script type="text/javascript">
      function zipBack() {
        window.scroll(0,0);
      }
      function init() {
        document.body.onscroll = zipBack;
      }
    </script>
  </head>
  <body onload="init()">
    <h1>onscroll Event Handler</h1>
    <hr />
    This page always zips back to the top if you try to scroll it.
    <p><iframe frameborder="0" scrolling="no" height="1000"
      src="bofright.htm"></iframe></p>
  </body>
</html>
```

**Related Items:** `body.scrollTop`, `body.scrollLeft` properties; `scrollIntoView()`, `body.doScroll()` methods.

## TreeWalker

## TreeWalker Object

<i>Property</i>	<i>Method</i>	<i>Event Handler</i>
currentNode	firstChild()	(None)
expandEntityReference	lastChild()	
filter	nextNode()	
root	nextSibling()	
whatToShow	parentNode()	
	previousNode()	
	previousSibling()	

## Syntax

Creating a `TreeWalker` object:

```
var treewalk = document.createTreeWalker(document, whatToShow, filterFunction,
entityRefExpansion);
```

Accessing `TreeWalker` object properties and methods:

```
TreeWalker.property | method([parameters])
```

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1+, Safari-

## About this object

The `TreeWalker` object serves as a container for a list of nodes that meet the criteria defined by the `document.createTreeWalker()` method, which is used to create the object. The list of nodes contained by a `TreeWalker` object conforms to the same hierarchical structure of the document from which they are referenced. The `TreeWalker` object provides a means of navigating through this list of nodes based upon their inherent tree-like structure.

You can think of the `TreeWalker` object as somewhat of an iterator object since its main purpose is to provide a means of stepping through nodes in a list. However, in this case the list is a hierarchical tree, as opposed to a linear list. The `TreeWalker` object maintains a pointer inside the list of nodes that always points to the “current node.” Whenever you navigate through the list using the `TreeWalker` object, the navigation is always relative to the pointer. For example, referencing the previous or next node via calls to the `previousNode()` or `nextNode()` methods depends upon the current position of the node pointer in the tree.

Use the `document.createTreeWalker()` method to create a `TreeWalker` object for a particular document. This method requires a user function that serves as a filter for nodes selected to be part of the tree. A reference to the function is the third parameter of the method call. The return value of this user function can be one of three constant values, which indicate the status of the current node: `NodeFilter.FILTER_ACCEPT`, `NodeFilter.FILTER_REJECT`, or `NodeFilter.FILTER_SKIP`. The difference between `NodeFilter.FILTER_REJECT` and `NodeFilter.FILTER_SKIP` is that descendants of skipped nodes may still qualify as part of

**TreeWalker.expandEntityReference**

the tree, while rejected nodes and their descendants are excluded altogether. Following is an example of a user function you could use to create a `TreeWalker` object:

```
function ratingAttrFilter(node) {
  if (node.hasAttribute("rating")) {
    return NodeFilter.FILTER_ACCEPT;
  }
  return NodeFilter.FILTER_REJECT;
}
```

In this example function, only nodes containing an attribute named `rating` are allowed through the filter, which means only those nodes will get added to the list (tree). With this function in place, you then call the `document.createTreeWalker()` method to create the `TreeWalker` object:

```
var myTreeWalker = document.createTreeWalker(document, NodeFilter.SHOW_ELEMENT,
  ratingAttrFilter, false);
```

Now that the `TreeWalker` object is created, you can use its properties and methods to access individual nodes and navigate through the list.

## Properties

### `currentNode`

**Value:** Node reference.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1+, Safari-

The `currentNode` property returns a reference to the current node, which sits at the location of the tree's node pointer. Although you can use the `currentNode` property to access the current node, you can also use it to set the current node.

### Example

To assign a node to the current position in the tree, just create an assignment statement using the `currentNode` property:

```
myTreeWalker.currentNode = document.getElementById("info");
```

**Related Item:** `root` property.

### `expandEntityReference`

#### `filter`

#### `root`

#### `whatToShow`

**Value:** See text.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1+, Safari-

These properties reflect the parameter values passed into the `document.createTreeWalker()` method upon the creation of the `TreeWalker` object.

**Related Item:** `document.createTreeWalker()` method.

**TreeWalker.firstChild()**

## Methods

firstChild()  
lastChild()  
nextSibling()  
parentNode()  
previousSibling()

**Returns:** Node reference.

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1+, Safari-

These methods return references to nodes within the hierarchy of the tree-like list of nodes contained by the `TreeWalker` object. There is a parent-child relationship among all of the nodes in the tree, and these functions are used to obtain node references based upon this relationship. The node pointer within the tree moves to the new node whenever you use one of these methods to navigate to a given node. This means you can access the new node as the current node after calling one of these navigation methods.

## Example

The following code shows how to obtain the tag name of the parent node of the current node in the `TreeWalker` object:

```
if (myTreeWalker.parentNode()) {  
    var parentTag = myTreeWalker.currentNode.tagName;  
}
```

**Related Items:** `nextNode()`, `previousNode()` methods.

nextNode()  
previousNode()

**Returns:** Node reference.

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1+, Safari-

The `nextNode()` and `previousNode()` methods navigate back and forth in the list of nodes contained by the `TreeWalker` object. It's important to note that these methods operate on the node list as if it has been flattened from a tree into a linear sequence of nodes. Both methods move the internal node pointer to the next or previous node, respectively.

## Example

The following code demonstrates both the node filter function and a typical function you could use to display (in a series of alert windows, perhaps for debugging purposes) the IDs of all elements inside the body that have `id` attributes assigned. The `nextNode()` method is called first to advance the `TreeWalker`'s node pointer to the first node of the collection, and then iteratively (inside a `do-while` construction) to obtain the next node that passes the filter's test.

**TreeWalker.nextNode()**

```
function idFilter(node) {
  if (node.hasAttribute("id")) {
    return NodeFilter.FILTER_ACCEPT;
  }
  return NodeFilter.FILTER_SKIP;
}

function showIds() {
  var tw =
  document.createTreeWalker(document.body, NodeFilter.SHOW_ELEMENT, idFilter,
  false);
  // make sure TreeWalker contains at least one node, and go to it if true
  if (tw.nextNode()) {
    do {
      alert(tw.currentNode.id);
    } while (tw.nextNode());
  }
}
```

**Related Items:** parentNode() method.

# Link and Anchor Objects

---

The Web is based on the notion that the world's information can be strung together by way of the *hyperlink*—the clickable hunk of text or image that enables an inquisitive reader to navigate to a further explanation or related material. Of all the document objects you work with in JavaScript, the link is the one that makes that connection. Anchors also provide guideposts to specific locations within documents.

As scriptable objects going back to the first scriptable browsers, links and anchors are comparatively simple devices. But this simplicity belies their significance in the entire scheme of the Web. Under script control, links can be far more powerful than mere tethers to locations on the Web.

In modern browsers (IE4+ and W3C-compatible browsers), the notion of separating links and anchors as similar yet distinctly different objects begins to fade. The association of the word “link” with objects is potentially confused by the newer browsers' recognition of the `link` element (see Chapter 36 on the CD-ROM), which has an entirely different purpose, as a scriptable object. Taking the place of the anchor and link objects is an HTML element object representing the element created by the `<a>` tag. As an element object, the `a` element assumes all of the properties, methods, and event handlers that accrue to all HTML element objects in modern object models. To begin making that transition, this chapter treats all three types of objects at once. If you develop pages that must be compatible with early scriptable browsers, pay special attention to the comments about properties and event handler compatibility.

## In This Chapter

Differences between link, anchor, and a element objects

Scripting a link to invoke a script function

Scripting a link to swap an image on mouse rollovers

### Syntax

Accessing link object properties:

```
(all) [window.]document.links[index].property
```

Accessing a element object properties:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

A little scripting history can help you to understand where the link and anchor objects came from and how the `a` element object evolved from them.

Using the terminology of the original object model, the anchor and link objects are both created in the object model from the `<a>` tag. What distinguishes a link from an anchor is the presence of the `href` attribute in the tag. Without an `href` attribute, the element is an anchor object, which (prior to version 4 browsers) has no properties, events, or event handlers associated with it. And even in NN4, the anchor object gains only four properties, all but one of which (`name`) disappear in NN6+/Moz1+.

A link, on the other hand, is much more alive as an object—all just because of the inclusion of an `href` attribute, which usually points to a URL to load into a window or frame. In fact, the majority of early object model properties for the link object are the same as those of the early `location` object—properties that reveal information about the URL assigned to the `href` attribute. The other vital part of the original link object—especially as distinct from an anchor object—is that a link can respond to events. Initially, event handlers were limited to just `onclick` and `onmouseover`. By NN4, additional mouse events and an `ondblclick` event joined the repertoire.

When object models treat HTML elements as objects, both the anchor and link objects are subsumed by the `a` element object. Even so, one important characteristic from the original object still holds true: all `a` element objects that behave as link objects (by virtue of the presence of an `href` attribute) are members of the `document.links` property array. Therefore, if your scripts need to inspect or modify properties of all link objects on a page, they can do so by way of a `for` loop through the array of link objects. This is true even if you script solely for modern browsers and want to, say, change a style attribute of all links (for example, changing their `style.textDecoration` property from `none` to `underline`). The fact that the same element can have different behaviors depending on the existence of one attribute makes me think of the `a` element object as potentially two different animals. Thus, you see references to link and anchor objects throughout this book when the distinction between the two is important.

Scripting newcomers are often confused about the purpose of the `target` attribute of an `a` element when they want a scripted link to act on a different frame or window. Under plain HTML, the `target` attribute points to the frame or window into which the new document (the one assigned to the `href` attribute) is to load, leaving the current window or frame intact. But if you intend to use event handlers to navigate (by setting the `location.href` property), the `target` attribute does not apply to the scripted action. Instead, assign the new URL to the `location.href` property of the desired frame or window. For example, if one frame contains a table of contents consisting entirely of links, the `onclick` event handlers of those links can load other pages into the `main` frame by assigning the URL to the `parent.main.location.href` property. You must also cancel the default behavior of any link, as described in the discussion of the generic `onclick` event handler in Chapter 15.

When you want a click of the link (whether the link consists of text or an image) to initiate an action without actually navigating to another URL, you can use a special technique—the `javascript: pseudo-URL`—to direct the URL to a JavaScript function. The URL `javascript: functionName()` is a valid parameter for the `href` attribute (and not just in the link object). Browsers that don't have JavaScript enabled do not respond to clicks on such a link.

a

If you don't want the link to do anything other than change the status bar in the `onmouseover` event handler, define an empty function and set the URL to that empty JavaScript function (such as `href="javascript:doNothing()"`). Starting with NN3 and IE4, you can also add a special `void` operator that guarantees that the called function does not trigger any true linking action (`href="javascript: void someFunction()"`). Specifying an empty string for the `href` attribute yields an FTP-like file listing for the client computer — an undesirable artifact. Don't forget, too, that if the URL leads to a type of file that initiates a browser helper application (for example, to play a RealAudio sound file) the helper app or plug-in loads and plays without changing the page in the browser window.

A single link can change the content of more than one frame at once with the help of JavaScript. If you want only JavaScript-enabled browsers to act on such links, use a `javascript: pseudo-URL` to invoke a function that changes the `location.href` properties of multiple frames. For example, consider the following function, which changes the content of two frames:

```
function navFrames(url1, url2) {
    parent.product.location.href = url1;
    parent.accessories.location.href = url2;
}
```

You can then have a `javascript: pseudo-URL` invoke this multipurpose function and pass the specifics for the link as parameters:

```
<a href="javascript: void navFrames('products/gizmo344.html',
'access/access344.html')">Deluxe Super Gizmo</a>
```

Or if you want one link to do something for everyone, but something extra for JavaScript-enabled browsers, you can combine the standard link behavior with an `onclick` event handler to take care of both situations:

```
function setAccessFrame(url) {
    parent.accessories.location.href = url;
}
...
<a href="products/gizmo344.html" target="product"
onclick="setAccessFrame('access/access344.html')">Deluxe Super Gizmo</a>
```

Notice here that the `target` attribute is necessary for the standard link behavior, while the script assigns a URL to a frame's `location.href` property.

One additional technique allows a single link tag to operate for both scriptable and nonscriptable browsers. For nonscriptable browsers, establish a genuine URL to navigate from the link. Then make sure that the link's `onclick` event handler evaluates to `return false`. At click time, a scriptable browser executes the event handler and ignores the `href` attribute; a nonscriptable browser ignores the event handler and follows the link. See the discussion of the generic `onclick` event handler in Chapter 15 for more details.

As you design your links, consider building `onmouseover` and `onmouseout` event handlers into your link definitions. The most common applications for these event handlers are as a means of adjusting the `window.status` property or swapping images. Thus, as a user rolls the mouse pointer atop a link, a descriptive label (perhaps more detailed or friendly than what the link text or image may indicate) appears in the status line at the bottom of the window. Whether a user notices the change down there is another issue, so don't rely on the status line as a medium for mission-critical communication. Image swaps, however, are more dramatic and enable a user to receive visual feedback that the mouse pointer is atop a particular button image. Thanks to the `onmousedown` event handler, you can even swap the image when the user presses down with the mouse button atop the link.

## Properties

### charset

**Value:** String.

Read/Write

**Compatibility:** WinIE6+, MacIE6+, NN6+, Moz1+, Safari1+

The `charset` property represents the HTML 4.0 `charset` attribute of an `a` element. It advises the browser of the character set used by the document to which the `href` attribute points. The value is a string of one of the character set codes from the registry found at <http://www.iana.org/assignments/character-sets>.

### coords

### shape

**Value:** Strings.

Read/Write

**Compatibility:** WinIE6+, MacIE6+, NN6+, Moz1+, Safari1+

HTML 4.0 provides specifications for `a` elements that accommodate different shapes (`rect`, `circle`, and `poly`) and coordinates when the link surrounds an image. Although the `coords` and `shape` properties are present for `a` element objects in all W3C DOM-compatible browsers, active support for the feature is not present in NN6.

### hash

### host

### hostname

### pathname

### port

### protocol

### search

**Value:** Strings.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

This large set of properties is identical to the same-named properties of the `location` object (see Chapter 17). All properties are components of the URL that is assigned to the link object's `href` attribute. Although none of these properties appear in the W3C DOM specification for the `a` element object, they survive in modern browsers for backward compatibility. If you want to script the change of the destination for a link, try modifying the value of the object's `href` property rather than individual components of the URL.

**Related Item:** `location` object.

### href

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `href` property (included in the W3C DOM) is the URL of the destination of an `a` element equipped to act as a link. URLs can be relative or absolute.

**a.href**

In W3C DOM-compatible browsers, you can turn an anchor object into a link object by assigning a value to the `href` property even if the `a` element has no `href` attribute in the HTML that loads from the server. Naturally, this conversion is temporary, and it lasts only as long as the page is loaded in the browser. When you assign a value to the `href` property of an `a` element that surrounds text, the text assumes the appearance of a link (either the default appearance or whatever style you assign to links).

**Related Item:** `location` object.

**hreflang**

**Value:** String.

Read/Write

**Compatibility:** WinIE6+, MacIE6+, NN6+, Moz1+, Safari1+

The `hreflang` property advises the browser (if the browser takes advantage of it) about the written language used for the content to which the `a` element's `href` attribute points. Values for this property must be in the form of the standard language codes (for example, `en-us` for U.S. English).

**Methods**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `Methods` property (note the uppercase “M”) represents the HTML 4.0 `methods` attribute for an `a` element. Values for this attribute and property serve as advisory instructions to the browser about which HTTP method(s) to use for accessing the destination document. This is a rare case in which an HTML 4.0 attribute is not echoed in the W3C DOM. In any case, while IE4+ supports the property, the IE browsers do nothing special with the information.

**mimeType**

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

This property is used to obtain the MIME type of the document linked to by the `a` element. The HTML 4.0 and W3C DOM specifications define a `type` attribute and `type` property instead of `mimeType`. The property is a read-only property, and therefore has no control over the MIME type of the destination document.

**Related Item:** `a.type` property.

**name**

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Although a `name` attribute is optional for an `a` element serving solely as a link object, it is required for an anchor object. This value is exposed to scripting via the `name` property. While it is unlikely you will need to change the value by scripting, you can use this property as a way to identify a link object from among the `document.links` arrays in a repeat loop. For example:

**a.rel**

```

for (var i = 0; i < document.links.length; i++) {
  if (document.links[i].name == "bottom" {
    // statements dealing with the link named "bottom"
  }
}

```

## nameProp

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The IE-specific `nameProp` property is a convenience property that retrieves the segment of the `href` to the right of the rightmost forward slash character of the URL. Most typically, this value is the name of the file from a URL. But if the URL also includes a port number, that number is returned as part of the `nameProp` value.

## protocolLong

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The IE-specific `protocolLong` property returns a verbose rendition of the `protocol` property as indicated in the `a` element's `href` attribute. For example, if the `href` attribute points to an `http:` protocol, the `protocolLong` property returns `HyperText Transfer Protocol`. Introduced in IE4, the `protocolLong` property is still present in IE5 but apparently is no longer supported.

## rel

## rev

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `rel` and `rev` properties define relationships in the forward and back directions with respect to the destination document of the `a` element. Browsers have yet to exploit most of the potential of these attributes and properties.

A long list of values are predefined for these properties, based on the corresponding attribute values specified in HTML 4.0. If the browser does nothing with a particular value, the value is ignored. You can string together multiple values in a space-delimited list inside a single string. Accepted values are as follows:

alternate	contents	index	start
appendix	copyright	next	stylesheet
bookmark	glossary	prev	subsection
chapter	help	section	

**a.target**

## target

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

An important property of the link object is the `target`. This value reflects the window name supplied to the `target` attribute in the `a` element.

You can temporarily change the target for a link. But, as with most transient object properties, the setting does not survive soft reloads. Rather than altering the target this way, you can safely force the target change by letting the `href` attribute call a `javascript: functionName()` pseudo-URL in which the function assigns a document to the desired `window.location`. If you have done extensive HTML authoring before, you will find it hard to break the habit of relying on the `target` attribute.

Further, if you develop XHTML pages that must validate with the strict DTD, you will not be able to include a `target` attribute in your `<a>` tags. Instead, use the page's `onload` event handler or the `a` element's `onclick` event handler to invoke a function that assigns the desired value to the `target` property.

**Related Item:** `document.links` property.

## text

**Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

Between the start and end tags of a link goes the text (or image) that is highlighted in the distinguishing link color of the document. Navigator 4 enables you to read that text with the `link.text` property. This property is read-only. For later browsers, use the IE4+ and/or W3C DOM syntax for reading the text node (`innerText`, `innerHTML`, or `nodeValue`) property of the `a` element.

Note

This property was not implemented in releases of Navigator 4 prior to version 4.02.

## type

**Value:** String.

Read/Write

**Compatibility:** WinIE6+, MacIE6+, NN6+, Moz1+, Safari1+

The `type` property represents the HTML 4.0 `type` attribute, which specifies the MIME type for the content of the destination document to which the element's `href` attribute points. This is primarily an advisory property for browsers that wish to, say, display different cursor styles based on the anticipated type of content at the other end of the link. Thus far, browsers do not take advantage of this feature. However, you can assign MIME type values to the attribute (for example, `video/mpeg`) and let scripts read those values for making style changes to the link text after the page loads. IE4+ also implements a similar property in the `mimeType` property.

**Related Item:** `a.mimeType` property.

a.x

urn

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `urn` property represents the IE-specific `URN` attribute, which enables authors to use a URN (Uniform Resource Name) for the destination of the `a` element. (See <http://www.ietf.org/rfc/rfc2141.txt> for information about URNs.) This property is not in common use.

x

y

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

Your Navigator 4 script can retrieve the `x` and `y` coordinates of a link object (the top-left corner of the rectangular space occupied by the linked text or image) via the `link.x` and `link.y` properties. With IE4+ and W3C DOM-compatible browsers, you can get the coordinates of a typical link via the `a` element's `offsetLeft` and `offsetTop` properties.

# Image, Area, and Map Objects

---

**F**or modern Web browsers, images and areas — those items created by the `<img>` and `<area>` tags — are first-class objects that you can script for enhanced interactivity. You can swap the image displayed in an `<img>` tag with other images, perhaps to show the highlighting of an icon button when the cursor rolls atop it. And with scriptable client-side area maps, pages can be smarter about how they respond to users' clicks on image regions.

One further benefit afforded scripters is that they can preload images into the browser's image cache as the page loads. With cached images, the user experiences no delay when the first swap occurs.

## Image and `img` Element Objects

For HTML element properties, methods, and event handlers, see Chapter 15.

### In This Chapter

How to precache images

Swapping images after a document loads

Creating interactive, client-side image maps

**img**

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>

y		

## Syntax

Creating an Image object:

```
imageName = new Image([pixelWidth, pixelHeight]);
```

Accessing img element and image object properties or methods:

```
(NN3+/IE4+) [window.]document.imageName.property | method([parameters])
(NN3+/IE4+) [window.]document.images[index].property | method([parameters])
(NN3+/IE4+) [window.]document.images["imageName"].property |
method([parameters])
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

## About this object

Before getting into detail about images as objects, it's important to understand the distinction between instances of the static `Image` object and `img` element objects. The former exist only in the browser's memory without showing anything to the user; the latter are the elements on the page generated via the `<img>` (or nonsanctioned, but accepted, `<image>`) tag. Scripts use `Image` objects to precache images for a page, but `Image` objects obviously have fewer applicable properties, methods, and event handlers because they are neither visible on the page nor influenced by tag attributes.

`img` elements have been in the HTML vocabulary since the earliest days, but Netscape Navigator 3 was the first to treat them like first-class objects along with the companion `Image` object for precaching images. All flavors of IE4+ treat `img` elements as true document objects. The primary advantage of treating `img` elements as objects is that scripts can change the image that occupies the `img` object's space on the page, even after the document has loaded and displayed an initial image. The key to this scriptability is the `src` property of an image.

In a typical scenario, a page loads with an initial image. That image's tags specify any of the extra attributes, such as `height` and `width` (which help speed the rendering of the page), and specify whether the image uses a client-side image map to make it interactive. (See the `area` object later in this chapter.) As the user spends time on the page, the image can then change (perhaps in response to user action or some timed event in the script), replacing the original image with a new one in the same space. In browsers prior to IE4 and NN6 that support the `img` element object, the `height` and `width` of the initial image that loads into the element establishes a fixed-sized rectangular space for the image. Attempts to fit an image of another size into that space forces the image to scale (up or down, as the case may be) to fit the rectangle. But in IE4+ and W3C-compatible browsers, a change in the image's size is reflected by an automatic reflow of the page content around the different size.

The benefit of the separate `Image` object is that a script can create a virtual image to hold a preloaded image. (The image is loaded into the image cache but the browser does not display the image.) The hope is that one or more unseen images will load into memory while the user is busy reading the page or waiting for the page to download. Then, in response to user action on the page, an image can change instantaneously rather than forcing the user to wait for the image to load on demand.

To preload an image, begin by assigning a new, empty image object to a global variable. The new image is created via the constructor function available to the `Image` object:

```
var imageVariable = new Image(width, height);
```

You help the browser allocate memory for the image if you provide the pixel height and width of the precached image as parameters to the constructor function. All that this statement does is create an object in memory whose properties are all empty. To force the browser to load the image into the cache, assign an image file URL to the object's `src` property:

```
var oneImage = new Image(55,68);
oneImage.src = "neatImage.gif";
```

As this image loads, you see the progress in the status bar just like any image. Later, assign the `src` property of this stored image to the `src` property of the `img` element object that appears on the page:

```
document.images["someImage"].src = oneImage.src;
```

Depending on the type and size of image, you will be amazed at the speedy response of this kind of loading. With small-palette graphics, the image displays instantaneously.

**img**

A popular user-interface technique is to change the appearance of an image that represents a clickable button when the user rolls the mouse pointer atop that art. This action assumes that a mouse event fires on an element associated with the object. Prior to IE4 and NN6, `img` element objects did not respond to mouse events on their own. The required technique was to encase the `img` element inside an `a` element. This allowed the events associated with rollovers (`onmouseover` and `onmouseout`) and a user click on the image to effect some change (usually to navigate to another page). Although IE4+, NN6+, and other W3C browsers provide these events directly for `img` element objects, you can guarantee your pages to be backward compatible if you continue to surround your images with `a` elements. You can see examples of these kinds of actions in Chapters 12 and 20.

Image rollovers are most commonly accomplished in two different image states: normal and highlighted. But you may want to increase the number of states to more closely simulate the way clickable buttons work in application programs. In some instances, a third state signifies that the button is switched on. For example, if you use rollovers in a frame for navigational purposes and the user clicks a button to navigate to the Products area, that button stays selected but in a different style than the rollover highlights. Some designers go one step further by providing a fourth state that appears briefly when the user mouses down an image. Each one of these states requires the download of yet another image, so you have to gauge the effect of the results against the delay in loading the page.

The speed with which image swapping takes place may lead you to consider using this approach for animation. Though this approach may be practical for brief bursts of animation, the many other ways of introducing animation to your Web page (such as via GIF89a-standard images, Flash animations, Java applets, and a variety of plug-ins) produce animation that offers better speed control. In fact, swapping preloaded JavaScript image objects for some cartoon-like animations may be too fast. You can build a delay mechanism around the `setInterval()` method, but the precise timing between frames varies with client processor performance.

All browsers that implement the `img` element object also implement the `document.images` array. You can (and should) use the availability of this array as a conditional switch before any script statements that work with the `img` element or `Image` object. The construction to use is as follows:

```
if (document.images) {
    // statements working with images as objects
}
```

Earlier browsers treat the absence of this array as the equivalent of `false` in the `if` clause's conditional statement.

Most of the properties discussed here mirror attributes of the `img` HTML element. For more details on the meanings and implications of attribute values on the rendered content, consult the HTML 4.01 specification (<http://www.w3.org/TR/REC-html401>) and Microsoft's extensions for IE (<http://msdn.microsoft.com/workshop/author/dhtml/reference/objects/img.asp>).

## Properties

**align**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `align` property defines how the image is oriented in relation to surrounding text content. It is a double-duty property because you can use it to control the vertical or horizontal alignment

depending on the value (and whether the image is influenced by a `float` style attribute). Values are string constants, as follows:

```
absbottom    middle
absmiddle    right
baseline     texttop
bottom       top
left
```

The default alignment for an image is `bottom`. Safari 1.0 responds only to `left` and `right`. Increasingly, element alignment is handed over to stylesheet control.

Listing 20-1 enables you to choose from the different `align` property values as they influence the layout of an image whose HTML is embedded inline with some other text. Resize the window to see different perspectives on word-wrapping on a page and their effects on the alignment choices. Not all browsers provide distinctive alignments for each choice, so experiment in multiple supported browsers.

### Listing 20-1: Testing an Image's align Property

```
<html>
  <head>
    <title>img align Property</title>
    <script type="text/javascript">
      function setAlignment(sel) {
        document.getElementById("myIMG").align =
          sel.options[sel.selectedIndex].value;
      }
    </script>
  </head>
  <body>
    <h1>img align Property</h1>
    <hr />
    <form>
      Choose the image alignment: <select onchange="setAlignment(this)">
        <option value="absbottom">absbottom</option>
        <option value="absmiddle">absmiddle</option>
        <option value="baseline">baseline</option>
        <option value="bottom" selected="selected">bottom</option>
        <option value="left">left</option>
        <option value="middle">middle</option>
        <option value="right">right</option>
        <option value="texttop">texttop</option>
        <option value="top">top</option>
      </select>
    </form>
    <hr />
    <p>Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do
      eiusmod tempor incididunt ut labore et dolore magna aliqua.  Ut
      enim adminim veniam, quis nostrud exercitation ullamco laboris nisi ut
      aliquip ex ea commodo consequat.</p>
  </body>
</html>
```

**Related Items:** `text-align`, `float` stylesheet attributes.

**img.alt****alt****Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `alt` property enables you to set or modify the text that the browser displays in the image's rectangular space (if height and width are specified in the tag) before the image downloads to the client. Also, if a browser has images turned off (or is incapable of displaying images), the `alt` text helps users identify what is normally displayed in that space. You can modify this `alt` text even after the page loads.

**Example**

Use The Evaluator (Chapter 13) to assign a string to the `alt` property of the `document.myIMG` image on the page. First, assign a nonexistent image to the `src` property to remove the existing image:

```
document.myIMG.src = "fred.gif"
```

Scroll down to the image, and you can see a space for the image. Now, assign a string to the `alt` property:

```
document.myIMG.src = "Fred\'s face"
```

The extra backslash is required to escape the apostrophe inside the string. Scroll down to see the new `alt` text in the image space.

**Related Item:** `title` property.**border****Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

The `border` property defines the thickness in pixels of a border around an image. Remember that if you wrap an image inside an `a` element to make use of the mouse events (for rollovers and such), be sure to set the `border=0` attribute of the `<img>` tag to prevent the browser from generating the usual link kind of border around the image. Even though the default value of the attribute is zero, surrounding the image with an `a` element or attaching the image to a client-side image map puts a border around the image.

**Example**

Feel free to experiment with the `document.myIMG.border` property for the image in The Evaluator (Chapter 13) by assigning different integer values to the property.

**Related Items:** `isMap`, `useMap` properties.**complete****Value:** Boolean.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari-

Sometimes you may want to make sure that an image is not still in the process of loading before allowing another process to take place. This situation is different from waiting for an image to load before triggering some other process (which you can do via the image object's `onload` event handler). To verify that the `img` object displays a completed image, check for the Boolean value of the `complete` property. To verify that a particular image file has loaded, first find out whether the `complete` property is `true`; then compare the `src` property against the desired filename.

**img.complete**

An image's `complete` property switches to `true` even if only the specified `lowsrc` image has finished loading. Do not rely on this property alone for determining whether the `src` image has loaded if both `src` and `lowsrc` attributes are specified in the `<img>` tag.

One of the best ways to use this property is in an `if` construction's conditional statement:

```
if (document.myImage.complete) {
    // statements that work with document.myImage
}
```

**Note**

The `complete` property is not reliable in Navigator 4 and some versions of Internet Explorer 4. For those browsers, the value returns `true` in all instances.

To experiment with the `image.complete` property, quit and relaunch your browser before loading Listing 20-2 (in case the images are in memory cache). As each image loads, click the “Is it loaded yet?” button to see the status of the `complete` property for the `image` object. The value is `false` until the loading finishes; then, the value becomes `true`. The arch image is the bigger of the two image files. You may have to quit and relaunch your browser between trials to clear the arch image from the cache (or empty the browser's memory cache). If you experience difficulty with this property in your scripts, try adding an `onload` event handler (even if it is empty, as in Listing 20-2) to your `<img>` tag.

**Listing 20-2: Scripting `image.complete`**

```
<html>
  <head>
    <title></title>
    <script type="text/javascript">
      function loadIt(theImage,form) {
        form.result.value = "";
        document.images[0].src = theImage;
      }
      function checkLoad(form) {
        form.result.value = document.images[0].complete;
      }
    </script>
  </head>
  <body>
    
    <form>
      <input type="button" value="Load keyboard"
        onclick="loadIt('cpu2.gif',this.form)" /> <input type="button"
        value="Load arch" onclick="loadIt('arch.gif',this.form)" />
      <p><input type="button" value="Is it loaded yet?"
        onclick="checkLoad(this.form)" /> <input type="text"
        name="result" /></p>
    </form>
  </body>
</html>
```

**Related Items:** `img.src`, `img.lowsrc`, `img.readyState` properties; `onload` event handler.

**img.dynsrc****dynsrc****Value:** URL string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `dynsrc` property is a URL to a video source file, which (in IE) you can play through an `img` element. You can turn a space devoted to a static image into a video viewer by assigning a URL of a valid video source (for example, an `.avi` or `.mpg` file) to the `dynsrc` property of the image element object. Unlike the `src` property of image objects, assigning a URL to the `dynsrc` property does not precache the video.

You may experience buggy behavior in various IE versions when you assign a value to an image's `dynsrc` property after the `img` element renders a `.gif` or `.jpg` image. In WinIE5, the status bar indicates that the video file is still downloading, even though the download is complete. Clicking the Stop button has no effect. WinIE5.5+ may not even load the video file, leaving a blank space on the page. MacIE5 changes between static and motion images with no problems, but playing the video file multiple times causes the `img` element to display black space beyond the element's rectangle. You can experience all this behavior in the example provided in Listing 20-3. None of these bugs is fatal, but they should discourage you from using the `img` element as a vehicle for video content.

To swap between still and video sources, simply empty the opposite property. Listing 20-3 shows a simplified example that swaps between one fixed image and one video image. This listing exhibits most of the bugs associated with changing between static image and video sources described a moment ago.

**Listing 20-3: Changing Between Still and Motion Images**

```
<html>
  <head>
    <title>img dynsrc Property</title>
    <script type="text/javascript">
      var trainImg = new Image(160,120);
      trainImg.src = "amtrak.jpg";
      trainImg.dynsrc = "amtrak.mpg";

      function setLoop() {
        var selector = document.forms[0].looper;
        document.getElementById("myIMG").loop =
          selector.options[selector.selectedIndex].value;
      }

      function setImage(type) {
        if (type == "jpg") {
          document.getElementById("myIMG").dynsrc = "";
          document.getElementById("myIMG").src = trainImg.src;
        } else {
          document.getElementById("myIMG").src = "";
          document.getElementById("myIMG").start = "fileopen";
          setLoop();
          document.getElementById("myIMG").dynsrc = trainImg.dynsrc;
        }
      }
    </script>
  </head>
```

**img.fileCreatedDate**

```

<body>
  <h1>img dynsrc Property</h1>
  <hr />
  <form>
    Choose image type: <input type="radio" name="imgGroup"
      checked="checked" onclick="setImage('jpg')" />Still <input
      type="radio" name="imgGroup" onclick="setImage('mpg')" />Video
    <p>Play video how many times after loading: <select name="looper"
      onchange="setLoop()">
      <option value="1" selected="selected">Once</option>
      <option value="2">Twice</option>
      <option value="-1">Continuously</option>
    </select></p>
  </form>
  <hr />
  
</body>
</html>

```

**Related Items:** `img.loop`, `img.start` properties.

**fileCreatedDate**

**fileModifiedDate**

**fileUpdatedDate**

**fileSize**

**Value:** String, Integer (`fileSize`).

Read-Only

**Compatibility:** WinIE4+, MacIE5+, NN-, Moz-, Safari-

These four IE-specific properties return information about the file displayed in the `img` element (whether still or motion image). Three of the properties reveal the dates on which the current image's file was created, modified, and updated. For an unmodified file, its creation and modified dates are the same. The updated date of an image is the date on which the image file was last uploaded to the server; the `fileUpdatedDate` property is only supported on WinIE5.5+ and MacIE5. The `fileSize` property reveals the number of bytes of the file.

Date values returned for the first two properties are formatted differently between IE4 and IE5. The former provides a full readout of the day and date; the latter returns a format similar to `mm/dd/yyyy`. Note, however, that the values contain only the date and not the time. In any case, you can use the values as the parameter to a new `Date()` constructor function. This enables you to then use date calculations for such information as the number of days between the current day and the most recent modification.

Not all servers provide the proper date or size information about a file or in a format that IE can interpret. Test your implementation on the deployment server to ensure compatibility.

Also, be aware that these properties can be read-only for a file that is loaded in the browser. JavaScript by itself cannot get this information about files on the server that are not loaded in the browser.

**Note**

All of these file-related properties are present in the Mac version of IE, but the values are empty.

**img.fileCreatedDate****Example**

These properties are similar to the same-named properties of the `document` object. You can see these properties in action in Listing 18-4. Make a copy of that listing, and supply an image before modifying the references from the `document` object to the image object to see how these properties work with the `img` element object.

**Related Items:** None.

**height****width**

**Value:** Integer.

Read/Write (see text)

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

The `height` and `width` properties return and (in later browsers) control the pixel height and width of an image object. The property is read-only in NN3 and NN4, but it is read/write in all newer browsers that support the `img` element object.

If you adjust the `height` property of an image, the browser automatically scales the image within the same proportions as the original. But adjusting the `width` property has no effect on the `height` property in most browser versions. Scaling of an image may cause unwanted pixelation in the image, so modify an image's size with extreme care.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `height` and `width` properties. Begin retrieving the default values by entering the following two statements into the top text box:

```
document.myIMG.height  
document.myIMG.width
```

Increase the height of the image from its default 90 to 180:

```
document.myIMG.height = 180
```

If you scroll down to the image, you see that the image has scaled in proportion. Next, exaggerate the width:

```
document.myIMG.width = 400
```

View the resulting image.

**Related Items:** `hspace`, `vspace` properties.

**href**

(See `src` property)

**hspace****vspace**

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

The `hspace` and `vspace` properties control the pixel width of a transparent margin surrounding an image. Specifically, `hspace` controls the margins at the left and right of the image; `vspace` controls the top and bottom margins. Images, by default, have margins of zero pixels.

## Example

Use The Evaluator (Chapter 13) to experiment with the `hspace` and `vspace` properties. Begin by noticing that the image near the bottom of the page has no margins specified for it and is flush left with the page. Now assign a horizontal margin spacing of 30 pixels:

```
document.myIMG.hspace = 30
```

The image has shifted to the right by 30 pixels. An invisible margin also exists to the right of the image.

**Related Items:** `height`, `width` properties.

## isMap

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `isMap` property enables you to set whether the image should act as a server-side image map. When set as a server-side image map, pixel coordinates of the click are passed as parameters to whatever link `href` surrounds the image. For client-side image maps, see the `useMap` property later in this chapter.

## Example

The image in The Evaluator page is not defined as an image map. Thus, if you type the following statement into the top text box, the property returns `false`:

```
document.myIMG.isMap
```

**Related Item:** `img.useMap` property.

## longDesc

**Value:** URL string.

Read/Write

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `longDesc` property is a URL of a file that is intended to provide a detailed description of the image associated with the `img` element. Version 6 browsers recognize this property, but do not do anything special with the information—whether specified by `script` or the `longdesc` attribute.

**Related Item:** `alt` property.

## loop

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `loop` property represents the number of times a video clip playing through the `img` element should run. After the video plays that number of times, only the first frame of the video appears in the image area. The default value is 1; but if you set the value to -1, the video plays continuously. Unfortunately, setting the property to 0 prior to assigning a URL to the `dynsrc` property does not prevent the movie from playing at least once (except on the Mac, as noted in the `dynsrc` property discussion earlier in this chapter).

## Example

See Listing 20-3 for the `dynsrc` property to see the `loop` property in action.

**Related Item:** `dynsrc` property.

**img.lowsrc**

lowsrc

lowSrc

**Value:** URL string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari-

For image files that take several seconds to load, recent browsers enable you to specify a lower-resolution image or some other quick-loading placeholder to stand in while the big image crawls to the browser. You assign this alternate image via the `lowsrc` attribute in the `<img>` tag. The attribute is reflected in the `lowsrc` property of an image object.

All compatible browsers recognize the all-lowercase version of this property. NN6 also recognizes an interCap “S” version of the property, `lowSrc`.

Be aware that if you assign a URL to the `lowsrc` attribute, the `complete` property switches to `true` and the `onLoad` event handler fires when the alternate file finishes loading: The browser does not wait for the main `src` file to load.

**Example**

See Listing 20-5 for the image object’s `onload` event handler to see how the source-related properties affect event processing.

**Related Items:** `img.src`, `img.complete` properties.

**mimeType****Value:** String.

Read-Only

**Compatibility:** WinIE6+, MacIE-, NN-, Moz-, Safari-

The `mimeType` property returns a plain-language description of the MIME type for the image, such as `JPEG Image` or `GIF Image`.

**Example**

You can use the `mimeType` property to determine the format of an image, as the following example demonstrates:

```
if (document.myIMG.mimeType.indexOf("JPEG") != -1) {
    // Carry out JPEG-specific processing
}
```

In this example, the `indexOf()` method is used to check for the presence of the phrase “JPEG” anywhere in the MIME type string. This works because the string returned in the `mimeType` property for JPEG images is “JPEG Image”.

**Related Items:** None.

**name****Value:** Identifier string.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `name` property returns the value assigned to the `name` attribute of an `img` element. Starting with IE4 and NN6, you can use the ID of the element (`id` attribute) to reference the `img` element object via `document.all` and `document.getElementById()`. But references in the form of `document.imageName` and `document.images[imageName]` must use only the value assigned to the `name` attribute.

**img.naturalHeight**

In some designs, it may be convenient to assign numerically sequenced names to `img` elements, such as `img1`, `img2`, and so on. As with any scriptable identifier, the name cannot begin with a numeric character. Rarely, if ever, will you need to change the name of an `img` element object.

**Example**

You can use The Evaluator (Chapter 13) to examine the value returned by the `name` property of the image on that page. Enter the following statement into the top text box:

```
document.myIMG.name
```

Of course, this is redundant because the name is part of the reference to the object.

**Related Item:** `id` property.

**nameProp**

**Value:** Filename string.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

Unlike the `src` property, which returns a complete URL in IE, the IE `nameProp` property returns only the filename exclusive of protocol and path. If your image-swapping script needs to read the name of the file currently assigned to the image (to determine which image to show next), the `nameProp` property makes it easier to get the actual filename without having to perform extensive parsing of the URL.

**Example**

You can use The Evaluator Sr. (Chapter 13) to compare the results of the `src` and `nameProp` properties in WinIE5+. Enter each of the following statements into the top text box:

```
document.myIMG.src  
document.myIMG.nameProp
```

**Related Item:** `img.src` property.

**naturalHeight****naturalWidth**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `naturalHeight` and `naturalWidth` properties return the unscaled height and width of the image, in pixels. These properties are useful in situations where script code or `img` element attributes have scaled an image and you wish to know the image's original size.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `naturalHeight` and `naturalWidth` properties. Begin retrieving the default values by entering the following statement into the top text box:

```
document.myIMG.width
```

Increase the width of the image from its default 120 to 200:

```
document.myIMG.width = 200
```

**img.naturalHeight**

If you scroll down to the image, you see that the image has scaled in proportion. You can now find out the natural width of the original image by taking a look at the `naturalWidth` property:

```
document.myIMG.naturalWidth
```

The Evaluator will reveal 120 as the natural image width even though the image is currently scaled to 200.

**Related Items:** `img.height`, `img.width` properties.

**protocol**

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE5+, NN-, Moz-, Safari-

The `protocol` property returns only the protocol portion of the complete URL returned by the `src` property. This allows your script, for example, to see if the image is sourced from a local hard drive or a Web server. Values returned are not the actual protocol strings; rather, they are descriptions thereof: `HyperText Transfer Protocol` or `File Protocol`.

**Example**

You can use The Evaluator Sr. (Chapter 13) to examine the `protocol` property of the image on the page. Enter the following statement into the top text box:

```
document.myIMG.protocol
```

**Related Items:** `img.src`, `img.nameProp` properties.

**src**

**Value:** URL string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

The `src` property is the gateway to precaching images (in instances of the `Image` object that are stored in memory) and performing image swapping (in `img` element objects). Assigning a URL to the `src` property of an image object in memory causes the browser to load the image into the browser's cache (provided the user has the cache turned on). Assigning a URL to the `src` property of an `img` element object causes the element to display the new image. To take advantage of this powerful combination, you preload alternate versions of swappable images into image objects in memory and then assign the `src` property of the image object to the `src` property of the desired `img` element object.

In NN3 and NN4 (all OS platforms) and MacIE3, the size of the image defined by the `img` element's attributes (or, if not specified, then calculated by the browser from the size of the incoming image) governs the rectangular space devoted to that image. An attempt to assign an image of a different size to that `img` element object causes the image to rescale to fit the rectangle (usually resulting in a distorted image). In all later browsers, however, the `img` element object resizes itself to accommodate the image, and the page content reflows around the new size.

Note that when you read the `src` property, it returns a fully formed URL of the image file including protocol and path. This often makes it inconvenient to let the name of the file guide your script to swap images with another image in a sequence of your choice. Some other mechanism (such as storing the current filename in a global variable) may be easier to work with (and see the WinIE5+ `nameProp` property).

## Example

In the following example (see Listing 20-4), you see a few applications of image objects. Of prime importance is a comparison of how precached and regular images feel to the user. As a bonus, you see an example of how to set a timer to automatically change the images displayed in an image object. This feature is a popular request among sites that display advertising banners or slide shows.

As the page loads, a global variable is handed an array of image objects. Entries of the array are assigned string names as index values ("desk1", "desk2", and so on). The intention is that these names ultimately will be used as addresses to the array entries. Each image object in the array has a URL assigned to it, which precaches the image.

The page (see Figure 20-1) includes two `img` elements: one that displays noncached images and one that displays cached images. Under each image is a `select` element that you can use to select one of four possible image files for each element. The `onchange` event handler for each `select` list invokes a different function to change the noncached (`loadIndividual()`) or cached (`loadCached()`) images. Both of these functions take as their single parameter a reference to the form that contains the `select` elements.

To cycle through images at five-second intervals, the `checkTimer()` function looks to see if the timer checkbox is checked. If so, the `selectedIndex` property of the cached image `select` control is copied and incremented (or reset to zero if the index is at the maximum value). The `select` element is adjusted, so you can now invoke the `loadCached()` function to read the currently selected item and set the image accordingly.

Figure 20-1: The image object demonstration page.

**img.src**

For some extra style points, the `<body>` tag includes an `onunload` event handler that invokes the `resetSelects()` function. This general-purpose function loops through all forms on the page and all elements within each form. For every `select` element, the `selectedIndex` property is reset to zero. Thus, if a user reloads the page, or returns to the page via the Back button, the images start in their original sequence. An `onload` event handler makes sure that the images are in sync with the `select` choices and the `checkTimer()` function is invoked with a five-second delay. Unless the timer checkbox is checked, however, the cached images don't cycle.

**Listing 20-4: A Scripted Image Object and Rotating Images**

```

<html>
  <head>
    <title>Image Object</title>
    <script type="text/javascript">
      // global declaration for 'desk' images array
      var imageDB;
      // pre-cache the 'desk' images
      if (document.images) {
        // list array index names for convenience
        var deskImages = new Array("desk1", "desk2", "desk3", "desk4");
        // build image array and pre-cache them
        imageDB = new Array(4);
        for (var i = 0; i < imageDB.length ; i++) {
          imageDB[deskImages[i]] = new Image(120,90);
          imageDB[deskImages[i]].src = deskImages[i] + ".gif";
        }
      }
      // change image of 'individual' image
      function loadIndividual(form) {
        if (document.images) {
          var gifName =
            form.individual.options[form.individual.selectedIndex].value;
          document.getElementById("thumbnail1").src = gifName + ".gif";
        }
      }
      // change image of 'cached' image
      function loadCached(form) {
        if (document.images) {
          var gifIndex =
            form.cached.options[form.cached.selectedIndex].value;
          document.getElementById("thumbnail2").src = imageDB[gifIndex].src;
        }
      }
      // if switched on, cycle 'cached' image to next in queue
      function checkTimer() {
        if (document.images && document.Timer.timerBox.checked) {
          var gifIndex = document.selections.cached.selectedIndex;
          if (++gifIndex > imageDB.length - 1) {
            gifIndex = 0;
          }
          document.selections.cached.selectedIndex = gifIndex;
          loadCached(document.selections);
          var timeoutID = setTimeout("checkTimer()",5000);
        }
      }
      // reset form controls to defaults on unload
      function resetSelects() {

```

```

        for (var i = 0; i < document.forms.length; i++) {
            for (var j = 0; j < document.forms[i].elements.length; j++) {
                if (document.forms[i].elements[j].type == "select-one") {
                    document.forms[i].elements[j].selectedIndex = 0;
                }
            }
        }
    }
}
// get things rolling
function init() {
    loadIndividual(document.selections);
    loadCached(document.selections);
    setTimeout("checkTimer()",5000);
}
</script>
</head>
<body onload="init()" onunload="resetSelects ()">
    <h1>Image Object</h1>
    <hr />
    <center>
        <table border="3" cellpadding="3">
            <tr>
                <th></th>
                <th>Individually Loaded</th>
                <th>Pre-cached</th>
            </tr>
            <tr>
                <td align="right"><b>Image:</b></td>
                <td></td>
                <td></td>
            </tr>
            <tr>
                <td align="right"><b>Select image:</b></td>
                <form name="selections">
                    <td><select name="individual"
                        onchange="loadIndividual(this.form)">
                        <option value="cpu1">Wires</option>
                        <option value="cpu2">Keyboard</option>
                        <option value="cpu3">Disks</option>
                        <option value="cpu4">Cables</option>
                    </select></td>
                    <td><select name="cached" onchange="loadCached(this.form)">

                        <option value="desk3">Lamp</option>
                        <option value="desk4">Erasers</option>
                    </select></td>
                </form>
            </tr>
        </table>
        <form name="Timer">
            <input type="checkbox" name="timerBox"
                onclick="checkTimer()" />Auto-cycle through pre-cached images
        </form>
    </center>
</body>
</html>

```

**img.src**

**Related Items:** `img.lowsrc`, `img.nameProp` properties.

**start**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `start` property works in conjunction with video clips viewed through the `img` element in IE4+. By default, a clip starts playing (except on the Macintosh) when the image file opens.

This follows the default setting of the `start` property: "fileopen". Another recognized value is "mouseover", which prevents the clip from running until the user rolls the mouse pointer atop the image.

**Related Items:** `img.dynsrc`, `img.loop` properties.

**useMap**

**Value:** Identifier string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `useMap` property represents the `usemap` attribute of an `img` element, pointing to the name assigned to the `area` element in the page (see Listing 20-7). This `area` element contains the details about the client-side image map (described later in this chapter). The value for the `useMap` property must include the hash mark that defines an internal HTML reference on the page. If you need to switch among two or more image maps for the same `img` element (for example, you swap images or the user is in a different mode), you can define multiple `map` elements each with a different name. Then change the value of the `useMap` property for the `img` element object to associate a different map with the image.

**Related Item:** `isMap` property.

**vspace**

(See `hspace`)

**width**

(See `height`)

**x****y**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

An NN4 script can retrieve the `x` and `y` coordinates of an `img` element (the top-left corner of the rectangular space occupied by the image) via the `x` and `y` properties. These properties are read-only. They were supplanted in NN6 via the `offsetLeft` and `offsetTop` properties of any element.

Even without Dynamic HTML, you can use the information from these properties to help scroll a NN4 document to a precise position (with the `window.scrollTo()` method) as a navigational aid in your page. Due to the different ways each operating system platform renders pages and the different sizes of browser windows, you can dynamically locate the position of an image (in other words, scroll the document) given the current client conditions.

## Example

If you want to scroll the document so that the link is a few pixels below the top of the window, use a statement such as this:

```
window.scrollTo(document.images[0].x, (document.images[0].y - 3));
```

**Related Items:** `img.offsetLeft`, `img.offsetTop` properties; `img.scrollIntoView()`, `window.scrollTo()` methods.

## Event handlers

`onabort`

`onerror`

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

Your scripts may need to be proactive when a user clicks the Stop button while an image loads or when a network or server problem causes the image transfer to fail. Use the `onabort` event handler to activate a function in the event of a user clicking the Stop button; use the `onerror` event handler for the unexpected transfer snafu.

In practice, these event handlers don't supply all the information you may like to have in a script, such as the filename of the image loading at the time. If such information is critical to your scripts, the scripts need to store the name of a currently loading image to a variable before they set the image's `src` property. You also don't know the nature of the error that triggers an error event. You can treat such problems by forcing a scripted page to reload or by navigating to an entirely different spot in your Web site.

## Example

Listing 20-5 includes an `onabort` event handler. If the images already exist in the cache, you must quit and relaunch the browser to try to stop the image from loading. In that example, I provide a reload option for the entire page. How you handle the exception depends a great deal on your page design. Do your best to smooth over any difficulties that users may encounter.

`onload`

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

An `img` object's `onload` event handler fires when one of three actions occurs: an image's `lowsrc` image finishes loading; in the absence of a `lowsrc` image specification, the `src` image finishes loading; or when each frame of an animated GIF (GIF89a format) appears.

It's important to understand that if you define a `lowsrc` file inside an `<img>` tag, the `img` object receives no further word about the `src` image having completed its loading. If this information is critical to your script, verify the current image file by checking the `src` property of the image object.

Be aware, too, that an `img` element's `onload` event handler may fire before the other elements on the page have completed loading. If the event handler function refers to other elements on the page, the function should verify the existence of other elements prior to addressing them.

**img.onload**

Quit and restart your browser to get the most from Listing 20-5. As the document first loads, the `lowsrc` image file (the picture of pencil erasers) loads ahead of the computer keyboard image. When the erasers are loaded, the `onload` event handler writes “done” to the text field even though the main image is not loaded yet. You can experiment further by loading the arch image. This image takes longer to load, so the `lowsrc` image (set on the fly, in this case) loads way ahead of it.

**Listing 20-5: The Image onload Event Handler**

```
<html>
  <head>
    <title></title>
    <script type="text/javascript">
      function loadIt(theImage,form) {
        if (document.images) {
          form.result.value = "";
          document.images[0].lowsrc = "desk1.gif";
          document.images[0].src = theImage;
        }
      }
      function checkLoad(form) {
        if (document.images) {
          form.result.value = document.images[0].complete;
        }
      }
      function signal() {
        if(confirm("You have stopped the image from loading. Do you want to
          try again?")) {
          location.reload();
        }
      }
    </script>
  </head>
  <body>
    
    <form>
      <input type="button" value="Load keyboard"
        onclick="loadIt('cpu2.gif',this.form)" /> <input type="button"
        value="Load arch" onclick="loadIt('arch.gif',this.form)" />
      <p><input type="button" value="Is it loaded yet?"
        onclick="checkLoad(this.form)" /> <input type="text"
        name="result" /> <input type="hidden" /></p>
    </form>
  </body>
</html>
```

---

**Related Items:** `img.src`, `img.lowsrc` properties.

## area Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>

## Syntax

Accessing area element object properties:

```
(NN3+/IE4+)    [window.]document.links[index].property
(IE4+)         [window.]document.all.elemID.property | method([parameters])
(IE4+)         [window.]document.all.MAPElemID.areas[index].property |
               method([parameters])
(IE5+/W3C)    [window.]document.getElementById("MAPElemID").areas[index].property
               |
               method([parameters])
(IE5+/W3C)    [window.]document.getElementById("elemID").property |
               method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

## About this object

Document object models treat an image map area object as one of the link (a element) objects in a document (see the anchor object in Chapter 19). When you think about it, such treatment is not illogical at all because clicking a map area generally leads the user to another document or anchor location in the same document — a hyperlinked reference.

Although the HTML definitions of links and map areas differ greatly, the earliest scriptable implementations of both kinds of objects had nearly the same properties and event handlers. Therefore, to read about the details for these items, refer to the discussion about the link object in Chapter 19. The one difference is that in NN3 and NN4, a map area object does not have the same full array of mouse event handlers — you can count upon having only the `onclick` (NN4+), `onmouseover`, and `onmouseout` event handlers for those browsers.

**area**

Starting with IE4, NN6, and W3C-compatible browsers, all `area` element attributes are accessible as scriptable properties. Moreover, you can change the makeup of client-side image map areas by way of the `map` element object. The `map` element object contains an array of `area` element objects nested inside. You can remove, modify, or add to the `area` elements inside the `map` element.

Client-side image maps are fun to work with, and they have been well documented in HTML references since Netscape Navigator 2 introduced the feature. Essentially, you define any number of areas within the image based on shape and coordinates. Many graphics tools can help you capture the coordinates of images that you need to enter into the `coords` attribute of the `<area>` tag.

**Tip**

If one gotcha exists that trips up most HTML authors, it's the tricky link between the `<img>` and `<map>` tags. You must assign a name to the `<map>`; in the `<img>` tag, the `usemap` attribute requires a hash symbol (`#`) and the map name. If you forget the hash symbol, you can't create a connection between the image and its map.

Listing 20-6 contains an example of a client-side image map that allows you to navigate through different geographical features of the Middle East. As you drag the mouse around an aerial image, certain regions cause the mouse pointer to change, indicating that there is a link associated with the region. Clicking a region results in an alert box indicating which region you clicked.

### Listing 20-6: A Simple Client-Side Image Map

```
<html>
  <head>
    <title></title>
    <script type="text/javascript">
      function show(msg) {
        window.status = msg;
        return true;
      }
      function go(where) {
        alert("We're going to " + where + "!");
      }
      function clearIt() {
        window.status = "";
        return true;
      }
    </script>
  </head>
  <body>
    <h1>Sinai and Vicinity</h1>
    
    <map id="sinai" name="sinai">
      <area href="javascript:go('Cairo')" coords="12,152,26,161"
        shape="rect" onmouseover="return show('Cairo')"
        onmouseout="return clearIt()" />
      <area href="javascript:go('the Nile River')"
        coords="1,155,6,162,0,175,3,201,61,232,109,227,167,238,274,239,292,
        220,307,220,319,230,319,217,298,213,282,217,267,233,198,228,154,227,
        107,221,71,225,21,199,19,165,0,149"

```

**area.coords**

```

shape="poly" onmouseover="return show('Nile River')"
onmouseout="return clearIt()" />
<area href="javascript:go('Israel')" coords="95,69,201,91"
shape="rect" onmouseover="return show('Israel')"
onmouseout="return clearIt()" />
<area href="javascript:go('Saudi Arabia')" coords="256,57,319,121"
shape="rect" onmouseover="return show('Saudi Arabia')"
onmouseout="return clearIt()" />
<area href="javascript:go('the Mediterranean Sea')"
coords="1,55,26,123" shape="rect"
onmouseover="return show('Mediterranean Sea')"
onmouseout="return clearIt()" />
<area href="javascript:go('the Mediterranean Sea')"
coords="27,56,104,103" shape="rect"
onmouseover="return show('Mediterranean Sea')"
onmouseout="return clearIt()" />
</map>
</body>
</html>

```

---

## Properties

### alt

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `alt` property represents the `alt` attribute of an `area`. Future browsers may implement this attribute to provide additional information about the link associated with the `area` element.

**Related Item:** `title` property.

### coords

### shape

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `coords` and `shape` properties control the location, size, and shape of the image hot spot governed by the `area` element. Shape values that you can use for this property control the format of the `coords` property values, as follows:

<i>Shape</i>	<i>Coordinates</i>	<i>Example</i>
circ	center-x, center-y, radius	"30, 30, 20"
circle	center-x, center-y, radius	"30, 30, 20"
poly	x1, y1, x2, y2,...	"0, 0, 0, 30, 15, 30, 0, 0"
polygon	x1, y1, x2, y2,...	"0, 0, 0, 30, 15, 30, 0, 0"
rect	left, top, right, bottom	"10, 20, 60, 40"
rectangle	left, top, right, bottom	"10, 20, 60, 40"

**area.coords**

The default shape for an area is a rectangle.

**Related Items:** None.

hash  
host  
hostname  
href  
pathname  
port  
protocol  
search  
target

(See corresponding properties of the link object in Chapter 19)

shape

(See coords)

## map Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
areas[] name		onscroll

### Syntax

Accessing map element object properties:

```
(IE4+)      [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
           method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

### About this object

The map element object is an invisible HTML container for all area elements, each of which defines a “hot” region for an image. Client-side image maps associate links (and targets) to rectangular, circular, or polygonal regions of the image.

By far, the most important properties of a map element object are the areas array and, to a lesser extent, its name. It is unlikely that you will change the name of a map. (It is better to define multiple map elements with different names, and then assign the desired name to an img element object’s useMap property.) But you can use the areas array to change the makeup of the area objects inside a given client-side map.

## Properties

areas[]

**Value:** Array of area element objects.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Use the `areas` array to iterate through all area element objects within a `map` element. While NN6 adheres closely to the document node structure of the W3C DOM, IE4+ provides more direct access to the area element objects nested inside a `map`. If you want to rewrite the area elements inside a `map`, you can clear out the old ones by setting the `length` property of the `areas` array to zero. Then assign area element objects to slots in the array to build that array.

Listing 20-7 demonstrates how to use scripting to replace the area element objects inside a `map` element. The scenario is that the page loads with one image of a computer keyboard. This image is linked to the `keyboardMap` client-side image map, which specifies details for three hot spots on the image. If you then switch the image displayed in that `img` element, scripts change the `useMap` property of the `img` element object to point to a second `map` that has specifications more suited to the desk lamp in the second image. Roll the mouse pointer atop the images, and view the URLs associated with each area in the status bar (for this example, the URLs do not lead to other pages).

Another button on the page, however, invokes the `makeAreas()` function (not working in MacIE5), which creates four new area element objects and (through DOM-specific pathways) adds those new area specifications to the image. If you roll the mouse atop the image after the function executes, you can see that the URLs now reflect those of the new areas. Also note the addition of a fourth area, whose status bar message appears in Figure 20-2.

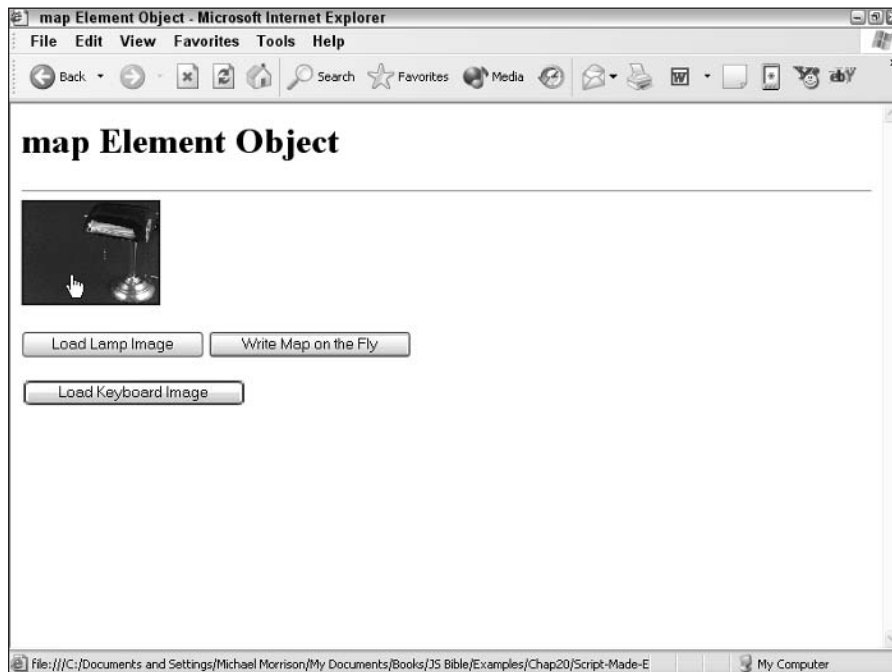

Figure 20-2: Scripts created a special client-side image map for the image.

## map.areas

## Listing 20-7: Modifying area Elements on the Fly

```

<html>
  <head>
    <title>map Element Object</title>
    <script type="text/javascript">
      // generate area elements on the fly
      function makeAreas() {
        document.getElementById("myIMG").src = "desk3.gif";
        // build area element objects
        var area1 = document.createElement("area");
        area1.href = "Script-Made-Shade.html";
        area1.shape = "polygon";
        area1.coords = "52,28,108,35,119,29,119,8,63,0,52,28";
        var area2 = document.createElement("area");
        area2.href = "Script-Made-Base.html";
        area2.shape = "rect";
        area2.coords = "75,65,117,87";
        var area3 = document.createElement("area");
        area3.href = "Script-Made-Chain.html";
        area3.shape = "polygon";
        area3.coords = "68,51,73,51,69,32,68,51";
        var area4 = document.createElement("area");
        area4.href = "Script-Made-Emptyness.html";
        area4.shape = "rect";
        area4.coords = "0,0,50,120";
        // stuff new elements into MAP child nodes
        var mapObj = document.getElementById("lamp_map");
        while (mapObj.childNodes.length) {
          mapObj.removeChild(mapObj.firstChild);
        }
        mapObj.appendChild(area1);
        mapObj.appendChild(area2);
        mapObj.appendChild(area3);
        mapObj.appendChild(area4);
        // workaround NN6 display bug
        document.getElementById("myIMG").style.display = "inline";
      }

      function changeToKeyboard() {
        document.getElementById("myIMG").src = "cpu2.gif";
        document.getElementById("myIMG").useMap = "#keyboardMap";
      }

      function changeToLamp() {
        document.getElementById("myIMG").src = "desk3.gif";
        document.getElementById("myIMG").useMap = "#lampMap";
      }
    </script>
  </head>
  <body>
    <h1>map Element Object</h1>
    <hr />
    
  </body>
</html>

```

**Related Items:** area element object.

# The Form and Related Objects

---

**P**rior to the advent of dynamic object models and automatic page reflow, the majority of scripting in an HTML document took place in and around forms. Even with all the new DHTML powers, forms remain the primary user interface elements of HTML documents because they enable users to input information and make choices in very familiar user interface elements, such as buttons, option lists, and so on. The challenge of scripting forms and form elements often involves getting object references just right. The references can get pretty long by the time you start pointing to the property of a form control element (which is part of a form, which is part of a document, which is part of a window or frame).

Expanded object models of W3C-compatible browsers include scriptable access to form-related elements that are part of the HTML 4.0 specification. One pair of elements, `fieldset` and `legend`, provides both contextual and visual containment of form controls in a document. Another element, `label`, provides context for text labels that usually appear adjacent to form controls. Although there is generally little need to script these objects, the browsers give you access to them just as they do for virtually every HTML element supported by the browser.

## The Form in the Object Hierarchy

Take another look at the JavaScript object hierarchy in the lowest common denominator object model (refer back to Figure 14-1). The `form` element object can contain a wide variety of form element objects (sometimes called *form controls*), which I cover in Chapters 22 through 24. In this chapter, however, I focus primarily on the container.

The good news on the compatibility front is that much of the client-side scripting works on all scriptable browsers. While you are free to use newer ways of addressing forms and their nested elements when your audience exclusively uses the newer browsers, it can serve you well to be comfortable with the “old-fashioned” reference syntax. Therefore, almost all example code in this and the next three chapters uses syntax that is compatible with the earliest scriptable browsers. Besides, the only significant additions to the defining points of the `form` object in newer browsers are those characteristics that all other HTML elements share.

### In This Chapter

The `form` object as a container of form controls

Processing form validations

`label`, `fieldset`, and `legend` element objects

## form

# form Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
acceptCharset	handleEvent()	onreset
action	reset()	onsubmit
autocomplete	submit()	
elements[]		
encoding		
enctype		
length		
method		
name		
target		

## Syntax

Accessing form object properties or methods:

```
(All)      [window.]document.formName.property | method([parameters])
(All)      [window.]document.forms[index].property | method([parameters])
(All)      [window.]document.forms["formName"].property | method([parameters])
(IE4+)     [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

## About this object

Forms and their elements are the most common two-way gateways between users and JavaScript scripts. A form control element provides the only way that users can enter textual information. Form controls also provide somewhat standardized and recognizable user interface elements for the user to make a selection from a predetermined set of choices. Sometimes those choices appear in the form of an on/off checkbox, in a set of mutually exclusive radio buttons, or as a selection from a list.

As you have seen in many Web sites, the form is the avenue for the user to enter information that is sent to the server housing the Web files. Just what the server does with this information depends on the CGI (Common Gateway Interface) programs running on the server. If your Web site runs on a server directly under your control (that is, it is *in-house* or *hosted* by a service), you have the freedom to set up all kinds of data-gathering or database search programs to interact with the user. But with some of the more consumer-oriented Internet service providers (ISPs), you may have no CGI support available—or, at best, a limited set of

popular but inflexible CGI programs available to all customers of the service. Custom databases or transactional services are rarely provided for this kind of Internet service.

Regardless of your Internet server status, you can find plenty of uses for JavaScript scripts in forms. For instance, rather than using data exchanges (and Internet bandwidth) to gather raw user input and report any input errors, a JavaScript-enhanced document can preprocess the information to make sure that it employs the format that your back-end database or other programs most easily process. All corrective interaction takes place in the browser, without one extra bit flowing across the Net. I devote all of Chapter 43 (on the CD-ROM) to these kinds of form data-validation techniques.

How you define a `form` element (independent of the user interface elements described in subsequent chapters) depends a great deal on how you plan to use the information from the form's controls. If you intend to use the `form` exclusively for JavaScript purposes (that is, no queries or postings going to the server), you do not need to use the `action`, `target`, and `method` attributes. But if your Web page will be feeding information or queries back to a server, you need to specify at least the `action` and `method` attributes. You need to also specify the `target` attribute if the resulting data from the server is to be displayed in a window other than the calling window and the `enctype` attribute if your form's scripts fashion the server-bound data in a MIME type other than in a plain ASCII stream.

## References to form control elements

For most client-side scripting, user interaction comes from the elements within a form; the `form` element object is merely a container for the various control elements. If your scripts perform any data validation checks on user entries prior to submission or other calculations, many statements have the `form` object as part of the reference to the element.

A complex HTML document can have multiple `form` objects. Each `<form>...</form>` tag pair defines one form. You don't receive any penalties (except for potential confusion on the part of someone reading your script) if you reuse a name for an element in each of a document's forms. For example, if each of three forms has a grouping of radio buttons with the name "choice," the object reference to each button ensures that JavaScript doesn't confuse them. The reference to the first button of each of those button groups is as follows:

```
document.forms[0].choice[0]
document.forms[1].choice[0]
document.forms[2].choice[0]
```

If you assign identifiers to `id` attributes, however, you should not reuse an identifier on the same page.

## Passing forms and elements to functions

When a form or form element contains an event handler that calls a function defined elsewhere in the document, you can use a couple of shortcuts to simplify the task of addressing the objects while the function does its work. Failure to grasp this concept not only causes you to write more code than you have to, but it also hopelessly loses you when you try to trace somebody else's code in his or her JavaScripted document. The watchword in event handler parameters is

`this`

**form**

which represents a reference to the current object that contains the event handler attribute. For example, consider the function and form definition in Listing 21-1. The entire user interface for this listing consists of form elements, as shown in Figure 21-1.

### Listing 21-1: Passing the form Object as a Parameter

```

<html>
  <head>
    <title>Beatle Picker</title>
    <script type="text/javascript">
      function processData(form) {
        for (var i = 0; i < form.Beatles.length; i++) {
          if (form.Beatles[i].checked) {
            break;
          }
        }
        var chosenBeatle = form.Beatles[i].value;
        var chosenSong = form.song.value;
        alert("Looking to see if " + chosenSong + " was written by " +
          chosenBeatle + "...");
      }

      function checkSong(songTitle) {
        var enteredSong = songTitle.value;
        alert("Making sure that " + enteredSong + " was recorded by the
          Beatles.");
      }
    </script>
  </head>
  <body>
    <form name="Abbey Road">
      Choose your favorite Beatle: <input type="radio" name="Beatles"
        value="John Lennon" checked="true" />John <input type="radio"
        name="Beatles" value="Paul McCartney" />Paul <input type="radio"
        name="Beatles" value="George Harrison" />George <input type="radio"
        name="Beatles" value="Ringo Starr" />Ringo
      <p>Enter the name of your favorite Beatles song:<br />
        <input type="text" name="song" value="Eleanor Rigby"
          onchange="checkSong(this)" /></p>
      <p><input type="button" name="process" value="Process Request..."
        onclick="processData(this.form)" /></p>
    </form>
  </body>
</html>

```

The `processData()` function, which needs to read and write properties of multiple form control elements, can reference the controls in two ways. One way is to have the `onClick` event handler (in the button element at the bottom of the document) call the `processData()` function and not pass any parameters. Inside the function, all references to objects (such as the radio buttons or the song field) must be complete references, such as

```
document.forms[0].song.value
```

to retrieve the value entered into the song field.

**Figure 21-1:** Controls pass different object references to functions in Listing 21-1.

A more efficient way is to send a reference to the `form` object as a parameter with the call to the function (as shown in Listing 21-1). By specifying `this.form` as the parameter, you tell JavaScript to send along everything it knows about the form from which the function is called. This works because `form` is a property of every form control element; the property is a reference to the form that contains the control. Therefore, `this.form` passes the value of the `form` property of the control.

At the function, the reference to the `form` object is assigned to a variable name (arbitrarily set to `form` here) that appears in parentheses after the function name. I use the parameter variable name `form` here because it represents an entire form. But you can use any valid variable name you like.

The reference to the form contains everything the browser needs to know to find that form within the document. Any statements in the function can therefore use the parameter value in place of the longer, more cumbersome reference to the form. Thus, here I can use `form` to take the place of `document.forms[0]` in any address. To get the value of the `song` field, the reference is:

```
form.song.value
```

Had I assigned the `form` object to a parameter variable called `sylvester`, the reference would have been:

```
sylvester.song.value
```

When a function parameter is a reference to an object, statements in the function can retrieve or set properties of that object as well as invoke the object's methods.

**form**

Another version of the `this` parameter passing style simply uses the word `this` as the parameter. Unlike `this.form`, which passes a reference to the entire form connected to a particular element, `this` passes a reference only to that one element. In Listing 21-1, you can add an event handler to the `song` field to do some validation of the entry (to make sure that the entry appears in a database array of Beatles' songs created elsewhere in the document). Therefore, you want to send only the `field` object to the function for analysis:

```
<input type="text" name="song" onchange="checkSong(this)" />
```

You then have to create a function to catch this call:

```
function checkSong(songTitle) {  
    var enteredSong = songTitle.value;  
    alert("Making sure that " + enteredSong + " was recorded by the Beatles.");  
}
```

Within this function, you can go straight to the heart — the `value` property of the field element — without a long reference.

One further extension of this methodology passes only a single property of a form control element as a parameter. In the last example, the `checkSong()` function needs only the `value` property of the field, so the event handler can pass `this.value` as a parameter. Because `this` refers to the very object in which the event handler appears, the `this.propertyName` syntax enables you to extract and pass along a single property:

```
<input type="text" name="song" onchange="checkSong(this.value)" />
```

A benefit of this way of passing form element data is that the function doesn't have to do as much work:

```
function checkSong(songTitle) {  
    alert("Making sure that " + songTitle + " was recorded by the Beatles.");  
}
```

Unlike passing object references (like the form and text field objects above), when you pass a property value (for example, `this.value`), the property's value is passed with no reference to the object from which it came. This suffices when the function just needs the value to do its job. However, if part of that job is to modify the object's property (for example, converting all text from a field to uppercase and redisplaying the converted text), the value passed to the function does not maintain a "live" connection with its object. To modify a property of the object that invokes an event handler function, you need to pass some object reference so that the function knows where to go to work on the object.

 **Tip**

Many programmers with experience in other languages expect parameters to be passed either by reference or by value, but not both ways. The rule of thumb in JavaScript, however, is fairly simple: object references are passed by reference; property values are passed by value.

Here are some guidelines to follow when deciding what kind of value to pass to an event handler function:

- ♦ Pass the entire form control object (`this`) when the function needs to make subsequent access to that same element (perhaps reading an object's `value` property, converting the value to all uppercase letters, and then writing the result back to the same object's `value` property).
- ♦ Pass only one property (`this.propertyName`) when the function needs read-only access to that property.

- ♦ Pass the entire form element object (`this.form`) for the function to access multiple elements inside a form (for example, a button click means that the function must retrieve a field's content).

Also be aware that you can submit multiple parameters (for example, `onclick="someFunction(this.form, this.name)"`) or even an entirely different object from the same form (for example, `onclick="someFunction(this.form.emailAddr.value)"`). Simply adjust your function's incoming parameters accordingly. (See Chapter 33 for more details about custom functions.)

## E-mailing forms

A common request among scripters is how to send a form via e-mail to the page's author. This includes the occasional desire to send "secret" e-mail to the author whenever someone visits the Web site. Let me address the privacy issue first.

A site visitor's e-mail address is valuable personal information that you should not retrieve without the visitor's permission or knowledge. That's one reason why Netscape plugged a privacy hole in Navigator 2 that allowed submitting a form to a `mailto:` URL without requesting permission from the user. You can use some workarounds for this in Navigator 3, but I do not condone surreptitiously lifting e-mail addresses and therefore choose not to publicize those workarounds here. Besides, the workarounds fail in newer browsers anyway.

Microsoft, on the other hand, went too far in preventing forms e-mailing in the earliest browser versions. While Netscape's browsers reveal to the user in an alert that an e-mail message bearing the user's e-mail address (as stored in the browser's preferences) will be sent upon approval, Internet Explorer 3 does not send form content via e-mail at all. Internet Explorer 4 sends form content as an attachment through Microsoft Outlook, but only after displaying a mail composition window to the user. Starting with IE5, the process is somewhat more fluid, but if the user doesn't have a compatible e-mail application installed as the default, the job fails. Due to the unreliable nature and occasionally awkward user interface of mailing a form via the `mailto:` URL, I do not recommend its use.

Many ISPs that host Web sites provide standard CGIs for forwarding forms to an e-mail address of your choice. Search the Web for "formmail service" to locate third-party suppliers of this feature if you don't have access to server programming for yourself.

The remaining discussion about mailing forms focuses primarily on NN2+ and IE5+ browsers and assumes an ideally configured e-mail program is installed. You should be aware that mailing forms in the following ways is controversial in some Web standards circles. As of this writing, the W3C HTML specification does not endorse these techniques specifically. Use these facilities judiciously and only after extensive testing on the client browsers you intend to support.

If you want to have forms submitted as e-mail messages, you must attend to three `<form>` tag attributes. The first is the `method` attribute. You must set it to `POST`. Next comes `enctype`. If you omit this attribute, the e-mail client sends the form data as an attachment consisting of escaped name-value pairs, as in this example:

```
name=Danny+Goodman&rank=Scripter+First+Class&serialNumber=042
```

But if you set the `enctype` attribute to `text/plain`, the form name-value pairs are placed in the body of the mail message in a more human-readable format:

```
name=Danny Goodman
rank=Scripter First Class
serialNumber=042
```

**form**

The last attribute of note is the `action` attribute, which is normally the spot to place a URL to another file or server CGI. Substitute the URL with the special `mailto:` URL followed by an optional parameter for the subject. Here is an example:

```
action="mailto:prez@whitehouse.gov?subject=Opinion%20Poll"
```

To sum up, the following example shows the complete `<form>` tag for e-mailing the form in Navigator:

```
<form name="entry"
      method="POST"
      enctype="text/plain"
      action="mailto:prez@whitehouse.gov?subject=Opinion Poll">
```

None of this requires any JavaScript at all. But seeing how you can use the attributes — and the fact that these attributes are exposed as properties of the `form` element object — you might see some extended possibilities for script control over forms.

## Changing form attributes

With the exception of IE3 (whose `form` object properties are read-only), all scriptable browsers expose `form` element attributes as modifiable properties. Therefore, you can change, say, the action of a form via a script in response to user interaction on your page. For example, you can have two different CGI programs invoked on your server depending on whether a form's checkbox is checked.

 **Tip**

The best opportunity to change the properties of a `form` element object is in a function invoked by the form's `onsubmit` event handler. The modifications are performed at the last instant prior to actual submission, leaving no room for user-induced glitches to get in the way.

## Buttons in forms

A common mistake that newcomers to scripting make is defining all clickable buttons as the submit type of input object (`<input type="submit">`). The Submit button does exactly what it says — it submits the form. If you don't set any `method` or `action` attributes of the `<form>` tag, the browser inserts its default values for you: `method=GET` and `action=pageURL`. When you submit a form with these attributes, the page reloads itself and resets all field values to their initial values.

Use a Submit button only when you want the button to actually submit the form. If you want a button for other types of action, use the button style (`<input type="button">`). A regular button can invoke a function that performs some internal actions and then invokes the `form` element object's `submit()` method to submit the form under script control.

## Redirection after submission

Undoubtedly, you have submitted a form to a site and seen a “Thank You” page come back from the server to verify that your submission was accepted. This is warm and fuzzy, if not logical, feedback for the submission action. It is not surprising that you would want to re-create that effect even if the submission is to a `mailto:` URL. Unfortunately, a problem gets in the way.

A common sense approach to the situation calls for a script to perform the submission (via the `form.submit()` method) and then navigate to another page that does the “Thank You.” Here is such a scenario from inside a function triggered by a click of a link surrounding a nice, graphical Submit button:

```
function doSubmit() {
    document.forms[0].submit();
    location.href = "thanks.html";
}
```

The problem is that when another statement executes immediately after the `form.submit()` method, the submission is canceled. In other words, the script does not wait for the submission to complete itself and verify to the browser that all is well (even though the browser appears to know how to track that information given the status bar feedback during submission). The point is, because JavaScript does not provide an event that is triggered by a successful submission, there is no sure-fire way to display your own “Thank You” page.

Don’t be tempted by the `window.setTimeout()` method to change the location after some number of milliseconds following the `form.submit()` method. You cannot predict how fast the network and/or server is for every visitor. If the submission does not complete before the timeout ends, the submission is still canceled—even if it is partially complete.

## Form element arrays

Starting with NN2 and IE4, document object models provide a feature that is beneficial to a lot of scripters. If you create a series of like-named objects, they automatically become an array of objects accessible via array syntax (see Chapter 7). This is particularly helpful when you create forms with columns and rows of fields, such as in an order form. By assigning the same name to all fields in a column, you can employ `for` loops to cycle through each row using the loop index as an array index.

As an example, the following code shows a typical function that calculates the total for an order form row (and calls another custom function to format the value):

```
function extendRows(form) {
    for (var i = 0; i < Qty.length; i++) {
        var rowSum = form.Qty[i].value * form.Price[i].value;
        form.Total[i].value = formatNum(rowSum,2);
    }
}
```

All fields in the Qty column are named `Qty`. The item in the first row has an array index value of zero and is addressed as `form.Qty[i]`.

## About `<input>` element objects

While this chapter focuses strictly on the `form` element as a container of controls, the next three chapters discuss different types of controls that nest inside a form. Many of these controls share the same HTML tag: `<input>`. Only the `type` attribute of the `<input>` tag determines whether the browser shows you a clickable button, a checkbox, a text field, or so on. The fact that one element has so many guises makes the system seem illogical at times to scripters.

An `input` element has some attributes (and corresponding scriptable object properties) that simply don’t apply to every type of form control. For example, while the `maxLength` property

**form**

of a text box makes perfect sense in limiting the number of characters that a user can type into it, the property has no bearing whatsoever on form controls that act as clickable buttons. Similarly, you can switch a radio button or checkbox on or off by adjusting the `checked` property; however, that property simply doesn't apply to a text box.

As the document object models have evolved, they have done so in an increasingly object-oriented way. The result in this form-oriented corner of the model is that all elements created via the `<input>` tag have a long list of characteristics that they all share by virtue of being types of `input` elements—they inherit the properties and methods that are defined for any `input` element. To try to limit the confusion, I divide the chapters in this book that deal with `input` elements along functional lines (clickable buttons in one chapter, text fields in the other), and only list and discuss those `input` element properties and methods that apply to the specific control type.

In the meantime, this chapter continues with details of the `form` element object.

## Properties

### `acceptCharset`

**Value:** String.

Read/Write

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `acceptCharset` property represents the `acceptcharset` attribute of the `form` element in HTML 4.0. The value is a list of one or more recognized character sets that the server receiving the form must support. For a list of registered character set names, see <http://www.iana.org/assignments/character-sets>.

**Related Items:** None.

### `action`

**Value:** URL string.

Read/Write (see text)

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `action` property (along with the `method` and `target` properties) primarily functions for HTML authors whose pages communicate with server-based CGI scripts. This property is the same as the value you assign to the `action` attribute of a `<form>` tag. The value is typically a URL on the server where queries or postings are sent for submission.

User input may affect how you want your page to access a server. For example, a checked box in your document may set a form's `action` property so that a CGI script on one server handles all the input, whereas an unchecked box means the form data goes to a different CGI script or a CGI script on an entirely different server. Or, one setting may direct the action to one `mailto:` address, whereas another setting sets the `action` property to a different `mailto:` address.

Although the specifications for all three related properties indicate that you can set them on the fly, such changes are ephemeral. A soft reload eradicates any settings you make to these properties, so you should make changes to these properties only in the same script function that submits the form (see `form.submit()` later in this chapter).

**Related Items:** `form.method`, `form.target`, `form.encoding` properties.

## autocomplete

**Value:** String.

Read/Write

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

Microsoft added a feature to forms with WinIE5 that allows the browser to supply hints for filling out form controls if the controls' names map to a set of single-line text controls defined via some additional attributes linked to the vCard XML schema. For details on implementing this browser feature, see [http://msdn.microsoft.com/workshop/author/forms/autocomplete\\_ovr.asp](http://msdn.microsoft.com/workshop/author/forms/autocomplete_ovr.asp). Values for the `autocomplete` property are your choice of two strings: `on` or `off`. In either case, the form element object does not report knowing about this property unless you set the `autocomplete` attribute in the form's tag.

**Related Items:** None.

## elements[]

**Value:** Array of form control elements.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Elements include all the user interface elements defined for a form: text fields, buttons, radio buttons, checkboxes, selection lists, and more. The `elements` property is an array of all form control items defined within the current form. For example, if a form defines three `<input>` items, the `elements` property for that form is an array consisting of three entries (one for each item in source code order). Each entry is a valid reference to that element; so, to extract properties or call methods for those elements, your script must dig deeper in the reference. Therefore, if the first element of a form is a text field and you want to extract the string currently showing in the field (a text element's `value` property), the reference looks like this:

```
document.forms[0].elements[0].value
```

Notice that this reference summons two array-oriented properties along the way: one for the document's `forms` property and one for the form's `elements` property.

In practice, I suggest you refer to form controls (and forms) by their names. This allows you the flexibility to move controls around the page as you fine-tune the design, and you don't have to worry about the source code order of the controls. The `elements` array comes in handy when you need to iterate through all of the controls within a form. If your script needs to loop through all elements of a form in search of particular kinds of elements, use the `type` property of every form object (NN3+, IE4+, and W3C) to identify which kind of object it is. The `type` property consists of the same string used in the `type` attribute of an `<input>` tag.

Overall, I prefer to generate meaningful names for each form control element and use those names in references throughout my scripts. The `elements` array helps with form control names, as well. Instead of a numeric index to the `elements` array, you can use the string name of the control element as the index. Thus, you can create a generic function that processes any number of form control elements, and simply pass the string name of the control as a parameter to the function. Then use that parameter as the `elements` array index value. For example:

```
function putVal(controlName, val) {  
    document.forms[0].elements[controlName].value = val;  
}
```

**form.elements**

If you want to modify the number of controls within a form, you should use the element and/or node management facilities of the browser(s) of your choice. For example, in IE4+ and W3C browsers, you can assemble the HTML string for an entirely new set of form controls and then assign that string to the `innerHTML` property of the `form` element object.

The document in Listing 21-2 demonstrates a practical use of the `elements` property. A form contains four fields and some other elements mixed in between (see Figure 21-2). The first part of the function that acts on these items repeats through all the elements in the form to find out which ones are text box objects and which text box objects are empty. Notice how I use the `type` property to separate text box objects from the rest, even when radio buttons appear amid the fields. If one field has nothing in it, I alert the user and use that same index value to place the insertion point at the field with the field's `focus()` method.

**Listing 21-2: Using the `form.elements` Array**

```
<html>
  <head>
    <title>Elements Array</title>
    <script type="text/javascript">
      function verifyIt() {
        var form = document.forms[0];
        for (i = 0; i < form.elements.length; i++) {
          if (form.elements[i].type == "text" &&
              form.elements[i].value == "") {
            alert("Please fill out all fields.");
            form.elements[i].focus();
            break;
          }
          // more tests
        }
        // more statements
      }
    </script>
  </head>
  <body>
    <form>
      Enter your first name:<input type="text" name="firstName" />
      <p>Enter your last name:<input type="text" name="lastName" /></p>
      <p><input type="radio" name="gender" />Male <input type="radio"
        name="gender" />Female</p>
      <p>Enter your address:<input type="text" name="address" /></p>
      <p>Enter your city:<input type="text" name="city" /></p>
      <p><input type="checkbox" name="retired" />I am retired</p>
    </form>
    <form>
      <input type="button" name="act" value="Verify" onclick="verifyIt()" />
    </form>
  </body>
</html>
```

**Related Items:** text, textarea, button, radio, checkbox, select objects.

**Figure 21-2:** The elements array helps find text fields for validation.

## encoding

### enctype

**Value:** MIME type string.

Read/Write (see text)

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

You can define a form to alert a server when the data you submit is in a MIME type. The `encoding` property reflects the setting of the `enctype` attribute in the form definition. The `enctype` property name is defined for form element objects in the W3C DOM (with `encoding` removed), but NN6+ provides both properties for backward and forward compatibility.

For `mailto:` URLs, I recommend setting this value (in the tag or via script) to `"text/plain"` to have the form contents placed in the mail message body. If the definition does not have an `enctype` attribute, this property is an empty string.

**Related Items:** `form.action`, `form.method` properties.

### length

**Value:** Integer.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `length` property of a form element object provides the same information as the `length` property of the form's `elements` array. The property provides a convenient, if not entirely logical, shortcut to retrieving the number of controls in a form.

**Related Items:** `form.elements` property.

**form.method**

## method

**Value:** String (GET or POST).

Read/Write (see text)

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

A form's `method` property is either the GET or POST value (not case-sensitive) assigned to the `method` attribute in a `<form>` definition. Terminology overlaps here a bit, so be careful to distinguish a form's method of transferring its data to a server from the object-oriented method (action or function) that all JavaScript forms have.

The `method` property is of primary importance to HTML documents that submit a form's data to a server-based CGI script because it determines the format used to convey this information. For example, to submit a form to a `mailto:` URL, the `method` property must be POST. Details of forms posting and CGI processing are beyond the scope of this book. Consult HTML or CGI documentation to determine which is the appropriate setting for this attribute in your Web server environment. If a form does not have a `method` attribute explicitly defined for it, the default value is GET.

**Related Items:** `form.action`, `form.target`, `form.encoding` properties.

## name

**Value:** Identifier string.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Assigning a name to a form via the `name` attribute is optional but highly recommended when your scripts need to reference a form or its elements. This attribute's value is retrievable as the `name` property of a form. You don't have much need to read this property unless you inspect another source's document for its form construction, as in:

```
var formName = parent.frameName.document.forms[0].name;
```

Moreover, because CGI programs frequently rely on the name of the form for validation purposes, it is unlikely you will need to change this property.

## target

**Value:** Identifier string.

Read/Write (see text)

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Whenever an HTML document submits a query to a server for processing, the server typically sends back an HTML page—whether it is a canned response or, more likely, a customized page based on the input provided by the user. You see this situation all the time when you perform a search at Web sites. In a multiframe or multiwindow environment, you may want to keep the form part of this transaction in view for the user but leave the responding page in a separate frame or window for viewing. The purpose of the `target` attribute of a `<form>` definition is to enable you to specify where the output from the server's query should be displayed.

The value of the `target` property is the name of the window or frame. For instance, if you define a `frameset` with three frames and assign the names `Frame1`, `Frame2`, and `Frame3` to them, you need to supply one of these names (as a quoted string) as the parameter of the `target` attribute of the `<form>` definition. Browsers also observe four special window names that you can use in the `<form>` definition: `_top`, `_parent`, `_self`, and `_blank`. To set the target as a separate subwindow opened via a script, use the window name from the `window.open()` method's second parameter and not the window object reference that the method returns.

**form.reset()**

If you code your page to validate according to strict XHTML, you won't be able to include a `target` attribute for a form. But you can still use a script to assign a value to the property without interfering with the validation.

**Related Items:** `form.action`, `form.method`, `form.encoding` properties.

## Methods

### `handleEvent(event)`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

See the discussion of the `window.handleEvent()` method in Chapter 16 for a description of this NN4-specific method.

### `reset()`

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

A common practice, especially with a long form, is to provide a button that enables the user to return all the form elements to their default settings. The standard Reset button (a separate object type described in Chapter 22) does that task just fine. But if you want to clear the form using script control, you must do so by invoking the `reset()` method for the form. More than likely, such a call is initiated from outside the form, perhaps from a function or graphical button. In such cases, make sure that the reference to the `reset()` method includes the complete reference to the form you want to reset—even if the page only has one form defined for it.

In Listing 21-3, I assign the act of resetting the form to the `href` attribute of a link object (that is attached to a graphic called `reset.jpg`). I use the `javascript: URL` to invoke the `reset()` method for the form directly (in other words, without doing it via function). Note that the form's action in this example is to a nonexistent URL. If you click the Submit icon, you receive an “unable to locate” error from the browser.

#### Listing 21-3: `form.reset()` and `form.submit()` Methods

```
<html>
  <head>
    <title>Registration Form</title>
  </head>
  <body>
    <form name="entries" method="POST"
      action="http://www.u.edu/pub/cgi-bin/register">
      Enter your first name:<input type="text" name="firstName" />
      <p>Enter your last name:<input type="text" name="lastName" /></p>
      <p>Enter your address:<input type="text" name="address" /></p>
      <p>Enter your city:<input type="text" name="city" /></p>
      <p><input type="radio" name="gender" checked="checked" />Male <input
        type="radio" name="gender" />Female</p>
      <p><input type="checkbox" name="retired" />I am retired</p>
    </form>
```

*Continued*

**form.reset()****Listing 21-3 (continued)**

```
<p><a href="javascript:document.forms[0].submit()"></a> <a
  href="javascript:document.forms[0].reset()"></a></p>
</body>
</html>
```

**Related Items:** onreset event handler; reset object.

**submit()**

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The most common way to send a form's data to a server's CGI program for processing is to have a user click a Submit button. The standard HTML Submit button is designed to send data from all named elements of a form according to the specifications listed in the `<form>` definition's attributes. But if you want to submit a form's data to a server automatically for a user, or want to use a graphical button for submission, you can accomplish the submission with the `form.submit()` method.

Invoking this method is almost the same as a user clicking a form's Submit button (except that the `onsubmit` event handler is not triggered). Therefore, you may have an image on your page that is a graphical submission button. If that image is surrounded by a link object, you can capture a mouse click on that image and trigger a function whose content includes a call to a form's `submit()` method (see Listing 21-3).

In a multiple-form HTML document, however, you must reference the proper form either by name or according to its position in a `document.forms` array. Always make sure that the reference you specify in your script points to the desired form before you submit any data to a server.

As a security and privacy precaution for people visiting your site, JavaScript ignores all `submit()` methods whose associated form actions are set to a `mailto:` URL. Many Web page designers would love to have secret e-mail addresses captured from visitors. Because such a capture can be considered an invasion of privacy, the power has been disabled since NN2.02. You can, however, still use an explicit Submit button object to mail a form to you from browsers. (See the section "E-mailing forms" earlier in this chapter.)

Because the `form.submit()` method does not trigger the form's `onsubmit` event handler, you must perform any presubmission processing and forms validation in the same script that ends with the `form.submit()` statement. You also do not want to interrupt the submission process after the script invokes the `form.submit()` method. Script statements inserted after one that invokes `form.submit()` — especially those that navigate to other pages or attempt a second submission — cause the first submission to cancel itself.

**Related Item:** `onsubmit` event handler.

## Event handlers

### onreset

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

Immediately before a Reset button returns a form to its default settings, JavaScript sends a reset event to the form. By including an `onreset` event handler in the form definition, you can trap that event before the reset takes place.

A friendly way of using this feature is to provide a safety net for a user who accidentally clicks the Reset button after filling out a form. The event handler can run a function that asks the user to confirm the action.

The `onreset` event handler employs a technique that surfaced with Navigator 3: The event handler must evaluate to return `true` for the event to continue to the browser. This may remind you of the way `onmouseover` and `onmouseout` event handlers work for links and image areas. This requirement is far more useful here because your function can control whether the reset operation ultimately proceeds to conclusion.

Listing 21-4 demonstrates one way to prevent accidental form resets or submissions. Using standard Reset and Submit buttons as interface elements, the `<form>` object definition includes both event handlers. Each event handler calls its own function that offers a choice for users. Notice how each event handler includes the word `return` and takes advantage of the Boolean values that come back from the `confirm()` method dialog boxes in both functions.

#### Listing 21-4: The `onreset` and `onsubmit` Event Handlers

```
<html>
  <head>
    <title>Submit and Reset Confirmation</title>
    <script type="text/javascript">
      function allowReset() {
        return window.confirm("Go ahead and clear the form?");
      }
      function allowSend() {
        return window.confirm("Go ahead and mail this info?");
      }
    </script>
  </head>
  <body>
    <form method="POST" enctype="text/plain"
      action="mailto:trash4@dannyg.com" onreset="return allowReset()"
      onsubmit="return allowSend()">
      Enter your first name:<input type="text" name="firstName" />
      <p>Enter your last name:<input type="text" name="lastName" /></p>
      <p>Enter your address:<input type="text" name="address" /></p>
      <p>Enter your city:<input type="text" name="city" /></p>
      <p><input type="radio" name="gender" checked="checked" />Male <input
        type="radio" name="gender" />Female</p>
      <p><input type="checkbox" name="retired" />I am retired</p>
      <p><input type="reset" /> <input type="submit" /></p>
    </form>
  </body>
</html>
```

**form.onsubmit****onsubmit**

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

No matter how a form's data is actually submitted (by a user clicking a Submit button or by a script invoking the `form.submit()` method), you may want your JavaScript-enabled HTML document to perform some data validation on the user input, especially with text fields, before the submission heads for the server. You have the option of doing such validation while the user enters data (see Chapter 43 on the CD-ROM) or in batch mode before sending the data to the server (or both). The place to trigger this last-ditch data validation is the form's `onsubmit` event handler. Note, however, that this event fires only from a genuine Submit-type `<input>` element and not from the form's `submit()` method.

When you define an `onsubmit` handler as an attribute of a `<form>` definition, JavaScript sends the `submit` event to the form just before it dashes off the data to the server. Therefore, any script or function that is the parameter of the `onsubmit` attribute executes before the data is actually submitted. Note that this event handler fires only in response to a genuine Submit-style button and not from a `form.submit()` method.

Any code executed for the `onsubmit` event handler must evaluate to an expression consisting of the word `return` plus a Boolean value. If the Boolean value is `true`, the submission executes as usual; if the value is `false`, no submission is made. Therefore, if your script performs some validation prior to submitting data, make sure that the event handler calls that validation function as part of a return statement (as shown in Listing 21-4).

Even after your `onsubmit` event handler traps a submission, JavaScript's security mechanism can present additional alerts to the user depending on the server location of the HTML document and the destination of the submission.

## fieldset and legend Element Objects

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>align</code> <code>form</code>		

### Syntax

Accessing `fieldset` or `legend` element object properties or methods:

```
(IE4+)      [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
           method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About these objects

The `fieldset` and `legend` elements go hand in hand to provide some visual context to a series of form controls within a form. Browsers that implement the `fieldset` element draw a rectangle around the document space occupied by the form controls nested inside the `fieldset` element (although MacIE5 drops the space into a debossed area on the page—a nice effect). The rectangle renders the full width of the body, unless its width is controlled by appropriate stylesheet properties (for example, `width`). To that rectangle is added a text label that is assigned via the `legend` element nested inside the `fieldset` element. (For MacIE5, the legend text is rendered just inside the debossed space.) None of this HTML-controlled grouping is necessary if you design a page layout that already provides graphical elements to group the form controls together.

Nesting the elements properly is essential to obtaining the desired browser rendering. A typical HTML sequence looks like the following:

```
<form>
<fieldset>
<legend>Legend Text</legend>
All your form controls and their labels go here.
</fieldset>
</form>
```

You can have more than one `fieldset` element inside a form. Each set has a rectangle drawn around it. This can help organize a long form into more easily digestible blocks of controls for users—yet the single form retains its integrity for submission to the server.

A `fieldset` element acts like any HTML container with respect to stylesheets and the inheritance thereof. For example, if you set the `color` style property of a `fieldset` element, the color affects the text of elements nested within; however, the color of the border drawn by the browser is unaffected. Assigning a color to the `fieldset` style's `border-color` property colors just the border and not the textual content of nested elements.

Note that the content of the `legend` element can be any HTML. Alternatively, you can assign a distinctive stylesheet rule to the `legend` element. If your scripts need to modify the text of the legend, you can accomplish this with the `innerText` (IE4+), `innerHTML` (IE4+, NN6+, Moz1+, Safari1+), or `nodeValue` (IE5+, W3C) properties of HTML element objects.

Only two element-specific properties are assigned to this object pair. The first is the `align` property of the `legend` object. This property matches the capabilities of the `align` attribute for the element as specified in the HTML 4.0 recommendation (albeit the property is deprecated in favor of stylesheet rules). MacIE5+ and WinIE5.5+ enable you to adjust this property on the fly (generally between your choices of “right” and “left”) to alter the location of the legend at the top of the `fieldset` rectangle.

Because these elements are children of a `form` element, it makes sense that the DOM Level 2 specification supplies the read-only `form` property to both of these objects. That property returns a reference to the `form` element object that encloses either element. The `form` property for the `fieldset` and `legend` objects is implemented in WinIE6, MacIE5, and W3C browsers.

**label**

# label Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
form htmlFor		

## Syntax

Accessing `label` element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

With the push in the HTML 4.0 specification to provide context-oriented tags for just about every bit of content on the page, the W3C HTML working group filled a gap with respect to text that usually hangs in front of or immediately after `input`, `select`, and `textarea` form control elements. You use these text chunks as labels for the items to describe the purpose of the control. The only `input` element that had an attribute for its label was the `button` input type. But even the newer `button` element did away with that.

A `label` element enables you to surround a control's label text with a contextual tag. In addition, one of the element's attributes — `for` — enables you to associate the label with a particular form control element. In the HTML, the `for` attribute is assigned the ID of the control with which the label is associated. A `label` element can be associated with a form control if the form control's tag is contained between the `label` element's start and end tags.

At first glance, browsers do nothing special (from a rendering point of view) for a `label` element. But for some kinds of elements, especially checkbox and radio input type elements, browsers help restore to users a vital user-interface convention: clicking the label is the same as clicking the control. For text elements, focus events are passed to the text input element associated with the label. In fact, all events that are directed at a label bubble upward to the form control associated with it. The following page fragment demonstrates how `fieldset`, `legend`, and `label` elements look in a form consisting of two radio buttons:

```
<form ...>
<fieldset id="form1set1">
<legend id="form1set1legend">Choose the Desired Performance</legend>
<input type="radio" name="speed" id="speed1" />
  <label for="speed1">Fastest (lower quality)</label><br />
<input type="radio" name="speed" id="speed2" />
  <label for="speed2">Slower (best quality)</label>
</fieldset>
</form>
```

**label.htmlFor**

Even so, a `label` and its associated form control element do not have to be adjacent to each other in the source code. For example, you can have a label in one cell of a table row with the form control in another cell (in the same or different row).

## Properties

### htmlFor

**Value:** Element object reference.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `htmlFor` property is the scripted equivalent of the `for` attribute of the `label` element. An acceptable value is a full reference to a form control element (`input`, `textarea`, or `select` element objects). It is highly unlikely that you would modify this property for an existing `label` element. However, if your script is creating a new `label` element (perhaps a replacement form), use this property to associate the label with a form control.

# Button Objects

---

**T**his chapter is devoted to those lovable buttons that invite users to initiate action and make choices with a single click of the mouse button. In this category fall the standard system-looking buttons with labels on them, as well as radio buttons and checkboxes. For such workhorses of the HTML form, these objects have a limited vocabulary of object-specific properties, methods, and event handlers.

I group together the button, submit, and reset objects for an important reason: They look alike yet they are intended for very different purposes. Knowing when to use which button is important — especially when to differentiate between the button and submit objects. Many a newcomer gets the two confused and winds up with scripting error headaches. That confusion won't happen to you by the time you finish this chapter.

## The button Element Object, and the Button, Submit, and Reset Input Objects

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
form	click()	onclick
name		onmousedown
type		onmouseup
value		

## Syntax

Accessing button object properties or methods:

```
(All) [window.]document.formName.buttonName.property
| method([parameters])
(All) [window.]document.formName.elements[index].property |
method([parameters])
```

### In This Chapter

Triggering action from a user's click of a button

Assigning hidden values to radio and checkbox buttons

Distinguishing between radio button families and their individual buttons

**document.formObject.buttonObject**

```
(All)      [window.]document.forms[index].buttonName.property |
method([parameters])
(All)      [window.]document.forms["formName"].buttonName.property |
method([parameters])
(All)      [window.]document.forms["formName"].elements[index].property |
method([parameters])
(IE4+)     [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About these objects

Button objects generate standard, pushbutton-style user interface elements on the page, depending on the operating system on which the particular browser runs. In the early days, the browsers called upon the operating systems to generate these standard interface elements. In more recent versions, the browsers define their own look, albeit frequently still different for each operating system. More recently, the appearance of a button may also be influenced by browser-specific customizations that browser makers put into their products. Even so, any computer user will recognize a button when the browser produces it on the page.

Starting with IE4 and NN6, you have two ways to put standard buttons into a page. The first, and completely backward-compatible way, is to use `input` elements nested inside a `form` container. But a new HTML element, the `button` element, provides a slightly different way of specifying a button in a page, including the option of putting a button outside of a `form` (presumably for some client-side script execution, independent of form submission). From an HTML point of view, the difference between the two concerns itself with the way the label of the button is specified. With an `input` element, the string assigned to the `value` attribute becomes the label of the button; but a `button` element is a container (meaning with an end tag), whose content becomes the button's label. You can still assign a value to the `value` attribute, which, if a form contains the button, gets submitted to the server, independent of the label text.

Always give careful thought to the label that you assign to a button. Because a button initiates some action, make sure that the verb in the label clearly defines what happens after you click it. Also, take cues from experienced user interface designers who craft operating system and commercial software buttons: Be concise. If you find your button labels going longer than two or three words, reconsider the design of your page so that the user can clearly understand the purpose of any button from a shorter label.

Browsers automatically display a button sized to accommodate the label text. But only browsers that support stylesheets (IE4+ and W3C) allow you to control more visual aspects of the button, such as size, label font, and coloration. And, as for the position of the button on the page, buttons, as in all in-line elements, appear where they occur in the source code. You can, of course, use element positioning of recent browsers (Chapter 39 on the CD-ROM) to make a button appear wherever you want it. But if your pages run on multiple operating systems and generations of browsers, be aware that the appearance (and size) of a button will not be identical on all screens. Check out the results on as many platforms as possible.

Buttons in the Windows environment follow their normal behavior in that they indicate the focus with highlighted button-label text (usually with a dotted rectangle). Some newer browsers running on other operating systems offer this kind of highlighting and selection as a user option. IE5 provides additional `input` element features that prevent buttons from receiving this kind of visible focus.

The lone `button` object event handler that works on all browser versions is one that responds to a user clicking the pointer atop the button: the `onclick` event handler. Virtually all action surrounding a `button` object comes from this event handler. You rarely need to extract property values or invoke the `click()` method. NN4 and IE4 add events for the components of a click: `mousedown` and `mouseup`; and IE4+ and W3C browsers provide a plethora of user-initiated events for buttons.

Two special variants of the `button` object are the *submit* and *reset* `button` objects. With their heritages going back to early incarnations of HTML, these two `button` types perform special operations on their own. The *submit*-style `button` automatically sends the data within the same form object to the URL listed in the `action` attribute of the `<form>` definition. The `method` attribute dictates the format in which the `button` sends the data. Therefore, you don't have to script this action if your HTML page is communicating with a CGI program on the server.

If the form's `action` attribute is set to a `mailto:` URL, you must provide the page visitor with a Submit `button` to carry out the action. Setting the form's `enctype` attribute to `text/plain` is also helpful so that the form data arrives in a more readable form than the normal encoded name-value pairs. See "E-mailing forms" in Chapter 21 for details about submitting form content via e-mail.

The partner of the Submit `button` is the Reset `button`. This `button`, too, has special powers. A click of this `button` type restores all elements within the form to their default values. That goes for text objects, radio `button` groups, checkboxes, and selection lists. The most common application of the `button` is to clear entry fields of the last data entered by the user.

All that distinguishes these three types of buttons from each other in the `<input>` tag or `<button>` tag is the parameter of the `type` attribute. For buttons not intended to send data to a server, use the "button" style (this is the default value for the `button` element). Reserve "submit" and "reset" for their special powers.

If you want an image to behave like a `button` in all scriptable browsers, consider either associating a link with an image (see the discussion on the link object in Chapter 19) or creating a client-side image map (see the area object discussion in Chapter 20). But for IE4+ and W3C browsers, you can use the `input` element with a `type` attribute set to `image` (discussed later in this chapter).

Probably the biggest mistake scripters make with these buttons is using a Submit `button` to do the work of a plain `button`. Because these two buttons look alike, and the `submit` type of `input` element has a longer tradition than the `button`, confusing the two is easy. But if all you want is to display a `button` that initiates client-side script execution, use a plain `button`. The Submit `button` attempts to submit the form. If no `action` attribute is set, then the page reloads, and all previous processing and field entries are erased. The plain `button` does its job quietly without reloading the page (unless the script intentionally does so).

## Properties

### form

**Value:** Form object reference.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

A property of every `input` element object is a reference to the `form` element that contains the control. This property can be very convenient in a script when you are dealing with one form control that is passed as a parameter to the function and you want to either access another control in the same form or invoke a method of the form. An event handler of any

**document.formObject.buttonObject.form**

`input` element can pass `this` as the parameter, and the function can still get access to the form without having to hard-wire the script to a particular form name or document layout.

**Related Items:** form object.

**name**

**Value:** Identifier string.

Read/Write (see text)

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

A button's name is fixed in the `input` or `button` element's `name` attribute and cannot be adjusted via scripting except in newer browsers. You may need to retrieve this property in a general-purpose function handler called by multiple buttons in a document. The function can test for a button name and perform the necessary statements for that button. If you change the name of the object, even a soft reload or window resize restores its original name.

**Related Items:** name property of all form elements.

**type**

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The precise value of the `type` property echoes the setting of the `type` attribute of the `<input>` or `<button>` tag that defines the object: `button`; `submit`; or `reset`.

**value**

**Value:** String.

Read/Write (see text)

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Both `input` and `button` elements have the `value` attribute, which is represented by the `value` property in the object model. But the purpose of the attribute/property in the two elements differs. For the `input` element, the `value` property represents the label displayed on the button. For a `button` element, however, the label text is created by the HTML text between the start and end tags for the `button` element. When the `input` element has a name value associated with it, the name-value pair is submitted along with the form.

If you do not assign a `value` attribute to a `reset` or `submit` style button, the browsers automatically assign the labels `Reset` and `Submit` without assigning a value. A `value` property can be any string, including multiple words.

You can modify this text on the fly in a script, but some cautions apply. Browsers prior to IE4 and NN6 do not resize the width of the button to accommodate a new name that is longer or shorter than the original. Moreover, any soft reload or resize of the window restores the original label. IE4+ and NN6+, however, resize the button and reflow the page to meet the new space needs; the new label survives a window resizing, but not a soft reload of the page. Finally, IE4 for the Mac allows you to set this property, but it doesn't really stick.

**Related Items:** `value` property of text object.

## Methods

### click()

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

A button's `click()` method simulates, via scripting, the human action of clicking that button. Unfortunately, the method is highly unreliable in browsers prior to IE4 and NN4.

**Related Items:** `onclick` event handler.

## Event handlers

### onclick

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Virtually all button action takes place in response to the `onclick` event handler. A *click* is defined as a press and release of the mouse button while the screen pointer rests atop the button. The event goes to the button only after the user releases the mouse button.

For a Submit button, you should probably omit the `onclick` event handler and allow the form's `onsubmit` event handler to take care of last-minute data entry validation before sending the form. By triggering validation with the `onsubmit` event handler, your scripts can cancel the submission if something is not right (see the `form` object discussion in Chapter 21).

Listing 22-1 demonstrates not only the `onclick` event handler of a button but also how you may need to extract a particular button's `name` or `value` properties from a general-purpose function that services multiple buttons. In this case, each button passes its own object as a parameter to the `displayTeam()` function. The function then displays the results in an alert dialog box. A real-world application would probably use a more complex `if...else` decision tree to perform more sophisticated actions based on the button clicked (or use a `switch` construction on the `btn.value` expression for IE4+ and W3C browsers).

### Listing 22-1: Three Buttons Sharing One Function

```
<html>
  <head>
    <title>Button Click</title>
    <script type="text/javascript">
      function displayTeam(btn) {
        if (btn.value == "Abbott") {
          alert("Abbott & Costello");
        }
        if (btn.value == "Rowan") {
          alert("Rowan & Martin");
        }
        if (btn.value == "Martin") {
          alert("Martin & Lewis");
        }
      }
    </script>
  </head>
```

*Continued*

**document.formObject.buttonObject.onclick****Listing 22-1 (continued)**

```

<body>
  Click on your favorite half of a popular comedy team:
  <form>
    <input type="button" value="Abbott" onclick="displayTeam(this)" />
    <input type="button" value="Rowan" onclick="displayTeam(this)" />
    <input type="button" value="Martin" onclick="displayTeam(this)" />
  </form>
</body>
</html>

```

**Related Items:** `button.onmousedown`, `button.onmouseup`, `form.onsubmit` event handlers.

**onmousedown****onmouseup**

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

More recent browsers have event handlers for the components of a click event: the `onmousedown` and `onmouseup` event handlers. These events fire in addition to the `onclick` event handler.

The system-level buttons provided by the operating system perform their change of appearance while a button is being pressed. Therefore, trapping for the components of a click action won't help you in changing the button's appearance via scripting. Remember that a user can roll the cursor off the button while the button is still down. When the cursor leaves the region of the button, the button's appearance returns to its unpressed look, but any setting you make with the `onmousedown` event handler won't undo itself with an `onmouseup` counterpart, even after the user releases the mouse button elsewhere. On the other hand, if you can pre-cache a click-on and click-off sound, you can use these events to fire the respective sounds in response to the mouse button action.

**Related Items:** `button.onclick` event handler.

## checkbox Input Object

method([parameters])
```

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

## About this object

Checkboxes have a very specific purpose in modern graphical user interfaces: to toggle between “on” and “off” settings. As with a checkbox on a printed form, a mark in the box indicates that the label text is true or should be included for the individual who made that mark. When the box is unchecked or empty, the text is false or should not be included. If two or more checkboxes are physically grouped together, they should have no interaction: Each is an independent setting (see the discussion on the radio object for interrelated buttons).

I make these user interface points at the outset because, in order to present a user interface in your HTML pages consistent with the user’s expectations based on exposure to other programs, you must use checkbox objects only for on/off choices that the user makes. Using a checkbox as an action button that, for example, navigates to another URL is not good form. Just as they do in a Windows or Mac dialog box, users make settings with checkboxes and radio buttons and initiate action by clicking a standard button or image map.

That’s not to say that a checkbox object cannot perform some limited action in response to a user’s click, but such actions are typically related to the context of the checkbox button’s label text. For example, in some Windows and Macintosh dialog boxes, turning on a checkbox may activate a bunch of otherwise inactive settings elsewhere in the same dialog box. IE4+ and W3C browsers allow disabling (dimming) or hiding form elements, so a checkbox may control those visible attributes of related controls. Or, in a two-frame window, a checkbox in one frame may control whether the viewer is an advanced user. If so, the content in the other frame may be more detailed. Toggling the checkbox changes the complexity level of a document showing in the other frame (using different URLs for each level). The bottom line, then, is that you should use checkboxes for toggling between on/off settings. Provide regular buttons for users to initiate processing.

In the `<input>` tag for a checkbox, you can preset the checkbox to be checked when the page appears. Add the constant `checked` attribute to the definition. If you omit this attribute, the default, unchecked appearance rules. As for the checkbox label text, its definition lies outside the `<input>` tag. If you look at the way checkboxes behave in HTML browsers, this location makes sense: The label is not an active part of the checkbox (as it typically is in Windows and Macintosh user interfaces, where clicking the label is the same as clicking the box).

**document.formObject.checkboxObject**

Naming a checkbox can be an important part of the object definition, depending on how you plan to use the information in your script or document. For forms whose content goes to a CGI program on the server, you must word the box name as needed for use by the CGI program, so that the program can parse the form data and extract the setting of the checkbox. For JavaScript client-side use, you can assign not only a name that describes the button, but also a value useful to your script for making `if...else` decisions or for assembling strings that are eventually displayed in a window or frame.

## Properties

### checked

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The simplest property of a checkbox reveals (or lets you set) whether or not a checkbox is checked. The value is `true` for a checked box and `false` for an unchecked box. To check a box via a script, simply assign `true` to the checkbox's `checked` property:

```
document.forms[0].boxName.checked = true;
```

Setting the `checked` property from a script does not trigger a `click` event for the checkbox object.

You may need an instance in which one checkbox automatically checks another checkbox elsewhere in the same or other form of the document. To accomplish this task, create an `onclick` event handler for the one checkbox and build a statement similar to the preceding one to set the other related checkbox to `true`. Don't get too carried away with this feature, however: For a group of interrelated, mutually exclusive choices, use a group of radio buttons instead.

If your page design requires that a checkbox be checked after the page loads, don't bother trying to script this checking action. Simply add the one-word `checked` attribute to the `<input>` tag. Because the `checked` property is a Boolean value, you can use its results as an argument for an `if` clause, as shown in the next example.

The simple example in Listing 22-2 passes a form object reference to the JavaScript function. The function, in turn, reads the `checked` value of the form's checkbox object (`checkThis.checked`) and uses its Boolean value as the test result for the `if...else` construction.

### Listing 22-2: The checked Property as a Conditional

```
<html>
  <head>
    <title>Checkbox Inspector</title>
    <script type="text/javascript">
      function inspectBox(form) {
        if (form.checkThis.checked) {
          alert("The box is checked.");
        } else {
          alert("The box is not checked at the moment.");
        }
      }
    </script>
  </head>
```

**document.formObject.checkboxObject.value**

```

<body>
  <form>
    <input type="checkbox" name="checkThis" />Check here
    <p><input type="button" name="boxChecker" value="Inspect Box"
      onclick="inspectBox(this.form)" /></p>
  </form>
</body>
</html>

```

---

**Related Items:** `defaultChecked`, `value` properties.

## defaultChecked

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

If you add the `checked` attribute to the `<input>` definition for a checkbox, the `defaultChecked` property for that object is `true`; otherwise, the property is `false`. Having access to this property enables your scripts to examine checkboxes to see if they have been adjusted (presumably by the user, if your script does not set properties).

The function in Listing 22-3 is designed to compare the current setting of a checkbox against its default value. The `if` construction compares the current status of the box against its default status. Both are Boolean values, so they can be compared against each other. If the current and default settings don't match, the function goes on to handle the case in which the current setting is other than the default.

### Listing 22-3: Examining the defaultChecked Property

```

function compareBrowser(thisBox) {
  if (thisBox.checked != thisBox.defaultChecked) {
    // statements about using a different set of HTML pages
  }
}

```

---

**Related Items:** `checked`, `value` properties.

## type

**Value:** String (checkbox).

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

Use the `type` property to help you identify a checkbox object from an unknown group of form elements.

**Related Items:** `form.elements` property.

## value

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

A checkbox object's `value` property is a string of any text that you want to associate with the box. Note that the checkbox's `value` property is not the label, as it is for a regular button, but

**document.formObject.checkboxObject.value**

hidden text associated with the checkbox. For instance, the label that you attach to a checkbox may not be worded in a way that is useful to your script. But if you place that useful wording in the `value` attribute of the checkbox tag, you can extract that string via the `value` property.

When a checkbox object's data is submitted to a CGI program, the `value` property is sent as part of the name-value pair if the box is checked (nothing about the checkbox is sent if the box is unchecked). If you omit the `value` attribute in your definition, the property always yields the string "on," which is submitted to a CGI program when the box is checked. From the JavaScript side, don't confuse this string with the on and off settings of the checkbox: Use the `checked` property to determine a checkbox's status.

The scenario for the skeleton HTML page in Listing 22-4 is a form with a checkbox whose selection determines which of two actions to follow for submission to the server. After the user clicks the Submit button, a JavaScript function examines the checkbox's `checked` property. If the property is `true` (the button is checked), the script sets the `action` property for the entire form to the content of the `value` property—thus influencing where the form goes on the server side. If you try this listing on your computer, the result you see varies widely with the browser version you use. For most browsers, you see some indication (an error alert or other screen notation) that a file with the name `primaryURL` or `alternateURL` doesn't exist. Unfortunately, WinIE5.5 does not display the name of the file that can't be opened. Try the example in another browser if you have one. The names and the error message come from the submission process for this demonstration.

**Listing 22-4: Adjusting a CGI Submission Action**

```
<html>
  <head>
    <title>Checkbox Submission</title>
    <script type="text/javascript">
      function setAction(form) {
        if (form.checkThis.checked) {
          form.action = form.checkThis.value;
        } else {
          form.action = "file://primaryURL";
        }
        return true;
      }
    </script>
  </head>
  <body>
    <form method="POST" action="">
      <input type="checkbox" name="checkThis"
        value="file://alternateURL" />Use alternate
      <p><input type="submit" name="boxChecker"
        onclick="return setAction(this.form)" /></p>
    </form>
  </body>
</html>
```

---

**Related Items:** `checked` property.

## Methods

### click()

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The intention of the `click()` method is to enact, via script, the physical act of clicking a checkbox (but without triggering the `onclick` event handler). However, your scripts are better served by setting the `checked` property so that you know exactly what the setting of the box is at any time.

**Related Items:** `checked` property; `onclick` event handler.

## Event handlers

### onclick

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Because users regularly click checkboxes, the objects have an event handler for the `click` event. Use this event handler only if you want your page (or variable values hidden from view) to respond in some way to the action of clicking a checkbox. Most user actions, as mentioned earlier, are initiated by clicking standard buttons rather than checkboxes, so be careful not to overuse event handlers in checkboxes.

The page in Listing 22-5 shows how to trap the click event in one checkbox to influence the visibility and display of other form controls. After you turn on the Monitor checkbox, a list of radio buttons for monitor sizes appears. Similarly, engaging the Communications checkbox makes two radio buttons visible. Your choice of radio button brings up one of two further choices within the same table cell (see Figure 22-1).

Figure 22-1: Clicking on button choices reveals additional relevant choices.

**document.formObject.checkboxObject.onclick**

Notice how the `toggle()` function was written as a generalizable function. This function can accept a reference to any checkbox object and any related span. If five more groups like this were added to the table, no additional functions would be needed.

In the `swap()` function, an application of a nested `if...else` shortcut construction is used to convert the Boolean values of the `checked` property to the strings needed for the `display` style property. The nesting is used to allow a single statement to take care of two conditions: the group of buttons to be controlled and the `checked` property of the button invoking the function. This function is not generalizable, because it contains explicit references to objects in the document. The `swap()` function can be made generalizable, but due to the special relationships between pairs of span elements (meaning one has to be hidden while the other is displayed in its place), the function would require more parameters to fill in the blanks where explicit references are needed.

**Listing 22-5: A Checkbox and an onclick Event Handler**

```
<html>
  <head>
    <title>Checkbox Event Handler</title>
    <style type="text/css">
      #monGroup {visibility:hidden}
      #comGroup {visibility:hidden}
    </style>
    <script type="text/javascript">
      // toggle visibility of a main group spans
      function toggle(chkbox, group) {
        var visSetting = (chkbox.checked) ? "visible" : "hidden";
        document.getElementById(group).style.visibility = visSetting;
      }
      // swap display of communications sub group spans
      function swap(radBtn, group) {
        var modemsVisSetting = (group == "modems") ? ((radBtn.checked) ?
          "" : "none") : "none";
        var netwksVisSetting = (group == "netwks") ? ((radBtn.checked) ?
          "" : "none") : "none";
        document.getElementById("modems").style.display = modemsVisSetting;
        document.getElementById("netwks").style.display = netwksVisSetting;
      }
    </script>
  </head>
  <body>
    <form>
      <h3>Check all accessories for your computer:</h3>
      <table border="2" cellpadding="5">
        <tr>
          <td><input type="checkbox" name="monitor"
            onclick="toggle(this, 'monGroup')" />Monitor</td>
          <td><span id="monGroup"><input type="radio"
            name="monitorType" />15" <input type="radio"
            name="monitorType" />17" <input type="radio"
            name="monitorType" />21" <input type="radio"
            name="monitorType" />&gt;21"</span></td>
        </tr>
      </table>
    </form>
  </body>
</html>
```

**document.formObject.radioObject**

```

<tr>
  <td><input type="checkbox" name="comms"
    onclick="toggle(this, 'comGroup')" />Communications</td>
  <td><span id="comGroup"><p><input type="radio" name="commType"
    onclick="swap(this, 'modems')" />Modem <input type="radio"
    name="commType" onclick="swap(this, 'netwks')" />Network</p>
    <p><span id="modems" style="display:none"><input type="radio"
    name="modemType" />&lt;56kbps <input type="radio"
    name="modemType" />56kbps <input type="radio"
    name="modemType" />ISDN (any speed) <input type="radio"
    name="modemType" />Cable</span> <span id="netwks"
    style="display:none"><input type="radio"
    name="netwkType" />Ethernet 10Mbps (10-Base T) <input
    type="radio" name="netwkType" />Ethernet 100Mbps (10/100)
    <input type="radio" name="netwkType" />T1 or
    greater</span> &nbsp;  </p></span></td>
</tr>
</table>
</form>
</body>
</html>

```

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

**document.formObject.radioObject**

## About this object

A radio button object is an unusual one within the body of JavaScript applications. In every other case of form control elements, one object equals one visual element on the screen. But a radio object actually consists of a group of radio buttons. Because of the nature of radio buttons — a mutually exclusive choice among two or more selections — a group always has multiple visual elements. All buttons in the group share the same name — which is how the browser knows to group buttons together and to let the clicking of a button deselect any other selected button within the group. Beyond that, however, each button can have unique properties, such as its `value` or `checked` property.

Use JavaScript array syntax to access information about an individual button within the button group. Look at the following example of defining a button group and see how to reference each button. This button group lets the user select a favorite member of the Three Stooges:

```
<form>
<b>Select your favorite Stooge:</b><br />
<input type="radio" name="stooges" value="Moe Howard" checked="checked" />Moe
<input type="radio" name="stooges" value="Larry Fine" />Larry
<input type="radio" name="stooges" value="Curly Howard" />Curly
<input type="radio" name="stooges" value="Shemp Howard" />Shemp
</form>
```

After this group displays on the page, the first radio button is preselected for the user. Only one property of a radio button object (`length`) applies to all members of the group. However, the other properties apply to individual buttons within the group. To access any button, use an array index value as part of the button group name. For example:

```
firstBtnValue = document.forms[0].stooges[0].value; // "Moe Howard"
secondBtnValue = document.forms[0].stooges[1].value; // "Larry Fine"
```

Any time you access the `checked`, `defaultChecked`, `type`, or `value` property, you must point to a specific button within the group according to its order in the array (or, in IE4+/W3C, each button can also have a unique ID). The order of buttons in the group depends on the sequence in which the individual buttons are defined in the HTML document. In other words, to uncover the currently selected radio button, your script has to iterate through all radio buttons in the radio group. Examples of this come later in the discussion of this object.

Supplying a `value` attribute to a radio button can be very important in your script. Although the text label for a button is defined outside the `<input>` tag, the `value` attribute lets you store any string in the button's hip pocket. In the earlier example, the radio button labels were just first names, whereas the `value` properties were set in the definition to the full names of the actors. The values could have been anything that the script needed, such as birth dates, shoe sizes, URLs, or the first names again (because a script has no way to retrieve the labels except through `innerHTML` or `node` property access in more modern browsers). The point is that the `value` attribute should contain whatever string the script needs to derive from the selection made by the user. The `value` attribute contents are also what is sent to a CGI program on a server in a submit action for the form.

How you decide to orient a group of buttons on the screen is entirely up to your design and the real estate available within your document. You can string them in a horizontal row (as shown earlier), place `<br />` tags after each one to form a column, or do so after every other button to form a double column. Numeric order within the array is determined only by the order in which the buttons are defined in the source code, not by where they appear. To determine which radio button of a group is checked before doing processing based on that

**document.formObject.radioObject.checked**

choice, you need to construct a repeat loop to cycle through the buttons in the group (shown in the next example). For each button, your script examines the checked property.

## Properties

### checked

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Only one radio button in a group can be highlighted (checked) at a time (the browser takes care of highlighting and unhighlighting buttons in a group for you). That one button's checked property is set to true, whereas all others in the group are set to false.

Beginning with version 3 browsers, you can safely set the checked property of a radio button. By setting the checked property of one button in a group to true, all other buttons automatically uncheck themselves.

Listing 22-6 uses a repeat loop in a function to look through all buttons in the Stooges group in search of the checked button. After the loop finds the one whose checked property is true, it returns the value of the index. In one instance, that index value is used to extract the value property for display in the alert dialog box; in the other instance, the value helps determine which button in the group is next in line to have its checked property set to true.

### Listing 22-6: Finding the Selected Button in a Radio Group

```
<html>
  <head>
    <title>Extracting Highlighted Radio Button</title>
    <script type="text/javascript">
      function getSelectedButton(buttonGroup){
        for (var i = 0; i < buttonGroup.length; i++) {
          if (buttonGroup[i].checked) {
            return i;
          }
        }
        return 0;
      }
      function fullName(form) {
        var i = getSelectedButton(form.stooges);
        alert("You chose " + form.stooges[i].value + ".");
      }
      function cycle(form) {
        var i = getSelectedButton(form.stooges);
        if (i+1 == form.stooges.length) {
          form.stooges[0].checked = true;
        } else {
          form.stooges[i+1].checked = true;
        }
      }
    </script>
  </head>
```

*Continued*

**document.formObject.radioObject.checked****Listing 22-6 (continued)**

```

<body>
  <form>
    <b>Select your favorite Stooge:</b>
    <p><input type="radio" name="stooges" value="Moe Howard"
      checked="checked" />Moe <input type="radio" name="stooges"
      value="Larry Fine" />Larry <input type="radio" name="stooges"
      value="Curly Howard" />Curly <input type="radio" name="stooges"
      value="Shemp Howard" />Shemp</p>
    <p><input type="button" name="Viewer" value="View Full Name..."
      onclick="fullName(this.form)" /></p>
    <p><input type="button" name="Cycler" value="Cycle Buttons"
      onclick="cycle(this.form)" /></p>
  </form>
</body>
</html>

```

**Related Items:** defaultChecked property.

**defaultChecked**

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

If you add the `checked` attribute to the `<input>` definition for a radio button, the `defaultChecked` property for that object is `true`; otherwise, the property is `false`. Having access to this property enables your scripts to examine individual radio buttons to see if they have been adjusted (presumably by the user, if your script does not perform automatic clicking).

In the script fragment of Listing 22-7, a function is passed a reference to a form containing the Stooges radio buttons. The goal is to see, in as general a way as possible (supplying the radio group name where needed), if the user changed the default setting. Looping through each of the radio buttons, you look for the one whose `checked` attribute is set in the `<input>` definition. With that index value (`i`) in hand, you then look to see if that entry is still checked. If not (notice the `!` negation operator), you display an alert dialog box about the change.

**Listing 22-7: Has a Radio Button Changed?**

```

function groupChanged(form) {
  for (var i = 0; i < form.stooges.length; i++) {
    if (form.stooges[i].defaultChecked) {
      if (!form.stooges[i].checked) {
        alert("This radio group has been changed.");
      }
    }
  }
}

```

**Related Items:** checked, value properties.

## length

**Value:** Integer.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

A radio button group has *length*—the number of individual radio buttons defined for that group. Attempting to retrieve the length of an individual button yields a `null` value. The `length` property is valuable for establishing the maximum range of values in a repeat loop that must cycle through every button within that group. If you specify the `length` property to fill that value (rather than hard-wiring the value), the loop construction will be easier to maintain—as you make changes to the number of buttons in the group during page construction, the loop adjusts to the changes automatically.

**Related Items:** None.

## name

**Value:** Identifier string.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `name` property, while associated with an entire radio button group, can be read only from individual buttons in the group, such as

```
btnGroupName = document.forms[0].groupName[2].name;
```

In that sense, each radio button element in a group inherits the name of the group. Your scripts have little need to extract the `name` property of a button or group. More often than not, you will hard-wire a button group's name into your script to extract other properties of individual buttons. Getting the `name` property of an object whose name you know is obviously redundant. But understanding the place of radio button group names in the scheme of JavaScript objects is important for all scripters.

**Related Items:** `value` property.

## type

**Value:** String (`radio`).

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

Use the `type` property to help identify a radio object from an unknown group of form elements.

**Related Items:** `form.elements` property.

## value

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

As described earlier in this chapter for the checkbox object, the `value` property contains arbitrary information that you assign when mapping out the `<input>` definition for an individual radio button. Using this property is a handy shortcut to correlating a radio button label with detailed or related information of interest to your script or CGI program on a server. If you like, the `value` property can contain the same text as the label.

**Related Items:** `name` property.

**document.formObject.radioObject.click()**

## Methods

`click()`

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The intention of the `click()` method is to enact, via a script, the physical act of clicking a radio button. However, you better serve your scripts by setting the `checked` properties of all buttons in a group so that you know exactly what the setting of the group is at any time.

**Related Items:** `checked` property; `onclick` event handler.

## Event handlers

`onclick`

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Radio buttons, more than any user interface element available in HTML, are intended for use in making choices that other objects, such as submit or standard buttons, act upon later. You may see cases in Windows or Mac programs in which highlighting a radio button — at most — activates or brings into view additional, related settings (see Listing 22-5).

I strongly advise you not to use scripting handlers that perform significant actions at the click of any radio button. At best, you may want to use knowledge about a user's clicking of a radio button to adjust a global variable or `document.cookie` setting that influences subsequent processing. Be aware, however, that if you script such a hidden action for one radio button in a group, you must also script similar actions for others in the same group. That way, if a user changes the setting back to a previous condition, the global variable is reset to the way it was. JavaScript, however, tends to run fast enough so that a batch operation can make such adjustments after the user clicks a more action-oriented button.

Every time a user clicks one of the radio buttons in Listing 22-8, he or she sets a global variable to `true` or `false`, depending on whether the person is a Shemp lover. This action is independent of the action that is taking place if the user clicks on the View Full Name button. An `onunload` event handler in the `<body>` definition triggers a function that displays a message to Shemp lovers just before the page clears (click the browser's Reload button to leave the current page prior to reloading). Here I use an initialize function triggered by `onload` so that the current radio button selection sets the global value upon a reload.

### Listing 22-8: An `onclick` Event Handler for Radio Buttons

```
<html>
  <head>
    <title>Radio Button onClick Handler</title>
    <script type="text/javascript">
      var ShempOPhile = false
      function initValue() {
        ShempOPhile = document.forms[0].stooges[3].checked;
      }
    </script>
  </head>
</html>
```

**document.formObject.imageObject**

```

function fullName(form) {
    for (var i = 0; i < form.stooges.length; i++) {
        if (form.stooges[i].checked) {
            break;
        }
    }
    alert("You chose " + form.stooges[i].value + ".");
}
function setShemp(setting) {
    ShempOPhile = setting;
}
function exitMsg() {
    if (ShempOPhile) {
        alert("You like SHEMP?");
    }
}
</script>
</head>
<body onload="initValue()" onunload="exitMsg()">
  <form>
    <b>Select your favorite Stooge:</b>
    <p><input type="radio" name="stooges" value="Moe Howard"
      checked="checked" onclick="setShemp(false)" />Moe <input
      type="radio" name="stooges" value="Larry Fine"
      onclick="setShemp(false)" />Larry <input type="radio"
      name="stooges" value="Curly Howard"
      onclick="setShemp(false)" />Curly <input type="radio"
      name="stooges" value="Shemp Howard"
      onclick="setShemp(true)" />Shemp</p>
    <p><input type="button" name="Viewer" value="View Full Name..."
      onclick="fullName(this.form)" /></p>
  </form>
</body>
</html>

```

## image Input Object

† See Button object.

**document.formObject.imageObject**

## Syntax

Accessing image input object properties or methods:

```
(All)      [window.]document.formName.imageName.property |
method([parameters])
(All)      [window.]document.formName.elements[index].property |
method([parameters])
(All)      [window.]document.forms[index].imageName.property |
method([parameters])
(All)      [window.]document.forms["formName"].imageName.property |
method([parameters])
(All)      [window.]document.forms["formName"].elements[index].property |
method([parameters])
(IE4+)     [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

Browsers with fuller document object models include the `image` input element among scriptable objects. The `image` input object most closely resembles the `button` input object but replaces the `value` property (which defines the label for the button) with the `src` property, which defines the URL for the image that is to be displayed in the form control. This is a much simpler way to define a clickable image icon, for example, than the way required for compatibility with older browsers: wrapping an `img` element inside an `a` element so that you can use the `a` element's event handlers.

Although this element loads a regular Web image in the document, you have virtually no control over the image, which the `img` element provides. Be sure the rendering is as you predict.

## Properties

### complete

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `complete` property works as it does for an `img` element, reporting `true` if the image has finished loading. Otherwise the property returns `false`. Interestingly, there is no `onload` event handler for this object.

**Related Items:** `image.complete` property.

### src

**Value:** URL string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Like the `img` element object, the `image` input element's `src` property controls the URL of the image being displayed in the element. The property can be used for image swapping in a form control, just as it is for a regular `img` element. Because the `image` input element has all necessary mouse event handlers available (for example, `onmouseover`, `onmouseout`, `onmousedown`) you can script rollovers, click-downs, or any other user interface technique that you feel is appropriate for your buttons and images. To adapt code written for link-wrapped images,

**document.formObject.imageObject.type**

move the event handlers from the `a` element to the `image` input element, and make sure the name of the `image` input element is the same as your old `img` element.

Older browsers load images into an `image` input element, but no event handlers are recognized.

**Related Items:** `image.src` property.

**type**

**Value:** String (`image`).

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Use the `type` property to help you identify an image input object from an unknown group of form elements.

**Related Items:** `form.elements` property.

# Text-Related Form Objects

---

The document object model for forms includes four text-related user interface objects—`text`, `password`, and `hidden` `input` element objects, plus the `textarea` element object. All four of these objects are used for entry, display, or temporary storage of text data. While all of these objects can have text placed in them by default as the page loads, scripts can also modify the contents of these objects. Importantly, all but the hidden objects retain their user- or script-modified content during a soft reload (for example, clicking the Reload button); hidden objects revert to their default values on all reloads.

A more obvious difference between the hidden object and the rest is that its invisibility removes it from the realm of user events and actions. Therefore, the range of scripted possibilities is much smaller for the hidden object.

The persistence of text and `textarea` object data through reloads (and window resizes) makes these objects prime targets for off-screen storage of data that may otherwise be stored temporarily in a cookie. If you create a frame with no size (for example, you set the `cols` or `rows` values of a `<frameset>` tag to let all visible frames occupy 100 percent of the space and assign the rest—`*`—to the hidden frame), you can populate the frame with fields that act as shopping cart information or other data holders. Therefore, if users have cookies turned off or don't usually respond affirmatively to cookie requests, your application can still make use of temporary client storage. The field contents may survive unloading of the page, but whether this happens and for how many navigations away from the page the contents last depends on the visitor's cache settings. If the user quits the browser or closes the browser window, the field entry is lost.

(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

## About this object

The text input object is the primary medium for capturing single-line, user-entered text. By default, browsers tend to display entered text in a monospaced font (usually Courier or a derivative) so that you can easily specify the width (`size`) of a field based on the anticipated number of characters that a user may put into the field. Until you get to IE4+ and W3C-compatible browsers, the font is a fixed size and always is left-aligned in the field. In those later browsers, stylesheets can control the font characteristics of a text field. If your design requires multiple lines of text, use the `textarea` object that comes later in this chapter.

Before the W3C DOM allowed dynamic modification of body content, a common practice was to use text objects to display results of a script calculation or other processing. Such fields may stand alone on a page or be part of a table.

Also prior to the W3C DOM, these fields could not be made fully write-protected, so it was easy to understand how a novice user may have become confused after he or she caused the text pointer or selection to activate a field used exclusively for output, simply by tabbing through a page.

Text object methods and event handlers use terminology that may be known to Windows users but not to Macintosh users. A field is said to have *focus* whenever the user clicks or tabs into the field. When a field has focus, either the text insertion pointer flashes, or any text in the field may be selected. Only one text object on a page can have focus at a time. The inverse user action — clicking or tabbing away from a text object — is called a *blur*. Clicking another object, whether it is another field or a button of any kind, causes a field that currently has focus to blur.

If you don't want the contents of a field to be changed by the user, you have three possibilities — depending on the vintage of browsers you need to support: forcing the field to lose focus; disabling the field; or setting the field's `readOnly` property.

The tactic that is completely backward compatible uses the following event handler in a field you want to protect:

```
onfocus="this.blur()"
```

Starting with IE4 and NN6, the object model provides a `disabled` property for form controls. Setting the property to `true` leaves the element visible on the page, but the user cannot access the control. The same browsers provide a `readOnly` property, which doesn't dim the field, but prevents typing in the field.

## Text fields and events

Focus and blur also interact with other possible user actions to a text object: selecting and changing. *Selecting* occurs when the user clicks and drags across any text in the field; *changing* occurs when the user makes any alteration to the content of the field and then either tabs or clicks away from that field.

When you design event handlers for fields, be aware that a user's interaction with a field may trigger more than one event with a single action. For instance, clicking a field to select text may trigger both a `focus` and `select` event. If you have conflicting actions in the `onfocus` and `onselect` event handlers, your scripts can do some weird things to the user's experience with your page. Displaying alert dialog boxes, for instance, also triggers `blur` events, so a field that has both an `onselect` handler (which displays the alert) and an `onblur` handler gets a nasty interaction from the two.

As a result, be very judicious with the number of event handlers you specify in any text object definition. If possible, pick one user action that you want to use to initiate some JavaScript code execution and deploy it consistently on the page. Not all fields require event handlers — only those you want to perform some action as the result of user activity in that field.

Many newcomers also become confused by the behavior of the `change` event. To prevent this event from being sent to the field for every character the user types, any change to a field is determined only *after* the field loses focus by the user's clicking or tabbing away from it. At that point, instead of a `blur` event being sent to the field, only a `change` event is sent, triggering an `onchange` event handler if one is defined for the field. This extra burden of having to click or tab away from a field may entice you to shift any `onchange` event handler tasks to a separate button that the user must click to initiate action on the field contents.

**document.formObject.textObject**

Starting with version 4 browsers, text fields also have event handlers for keyboard actions, namely `onkeydown`, `onkeypress`, and `onkeyup`. With these event handlers, you can intercept keystrokes before the characters reach the text field. Thus, you can use keyboard events to prevent anything but numbers from being entered into a text box while the user types the characters.

To extract the current content of a text object, summon the property `document.formName.fieldName.value`. After you have the string value, you can use JavaScript's string object methods to parse or otherwise massage that text as needed for your script. If the field entry is a number and you need to pass that value to methods requiring numbers, you have to convert the text to a number with the help of the `parseInt()` or `parseFloat()` global functions.

## Text Boxes and the Enter/Return Key

Early browsers established a convention that continues to this day. When a form consists of only one text box, a press of the Enter/Return key acts the same as clicking a Submit button for the form. You have probably experienced this many times when entering a value into a single search field of a form. Press the Enter/Return key, and the search request goes off to the server.

The flip side is that if the form contains more than one text box, the Enter/Return key does no submission from any of the text boxes (IE for the Mac and Safari are exceptions: they submit no matter how many text boxes there are). But with the advent of keyboard events, you can script this action (or the invocation of a client-side script) into any text boxes of the form you like. To make it work with all flavors of browsers capable of keyboard events requires a small conversion function that extracts the DOM-specific desired code from the keystroke. The following listing shows a sample page that demonstrates how to implement a function that inspects each keystroke from a text field and initiates processing if the key pressed is the Enter/Return key:

```
<html>
  <head>
    <title>Enter/Return Event Trigger</title>
    <script type="text/javascript">
      // Event object processor for NN4, IE4+, NN6
      function isEnterKey(evt) {
        evt = (evt) ? evt : (window.event) ? window.event : "";
        var theKey;
        if (evt) {
          theKey = (evt.which) ? evt.which : evt.keyCode;
        }
        return (theKey == 13);
      }

      function processOnEnter(fld, evt) {
        if (isEnterKey(evt)) {
          alert("Ready to do some work with the form.");
          return false;
        }
        return true;
      }
    </script>
  </head>
```

```
<body>
  <h1>Enter/Return Event Trigger</h1>
  <hr />
  <form onsubmit="return false">
    Field 1: <input type="text" name="field1"
      onkeydown="return processOnEnter(this, event)" />
    Field 2: <input
      type="text" name="field2"
      onkeydown="return processOnEnter(this, event)" />
    Field 3: <input
      type="text" name="field3"
      onkeydown="return processOnEnter(this, event)" />
  </form>
</body>
</html>
```

Notice that to accommodate the NN4+ and W3C event models, a reference to the `event` object must be passed as a parameter to the processing function. For more details on event handling, see Chapter 25.

## Properties

### `defaultValue`

**Value:** String.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Though your users and your scripts are free to muck with the contents of a `text` object by assigning strings to the `value` property, you can always extract (and thus restore, if necessary) the string assigned to the text object in its `<input>` definition. The `defaultValue` property yields the string parameter of the `value` attribute.

#### Note

Listings 23-1, 23-2, and 23-3 feature a form with only one `text` input element. The rules of HTML forms say that such a form submits itself if the user presses the Enter key whenever the field has focus. Such a submission to a form whose action is undefined causes the page to reload, thus stopping any scripts that are running at the time. `form` elements for these example listings contain an `onsubmit` event handler that both blocks the submission and attempts to trigger the text box `onchange` event handler to run the demonstration script. In some browsers, such as MacIE5, you may have to press the Tab key or click outside of the text box to trigger the `onchange` event handler after you enter a new value.

Listing 23-1 has a simple form with a single field that has a default value set in its tag. A function (`resetField()`) restores the contents of the page's lone field to the value assigned to it in the `<input>` definition. For a single-field page such as this, defining a `type="reset"` button or calling `form.reset()` works the same way because such buttons reestablish default values of all elements of a form. But if you want to reset only a subset of fields in a form, follow the example button and function in Listing 23-1.

**Listing 23-1: Resetting a Text Object to Default Value**

```

<html>
  <head>
    <title>Text Object DefaultValue</title>
    <script type="text/javascript">
      function upperMe(field) {
        field.value = field.value.toUpperCase();
      }
      function resetField(form) {
        form.converter.value = form.converter.defaultValue;
      }
    </script>
  </head>
  <body>
    <form onsubmit="window.focus(); return false">
      Enter lowercase letters for conversion to uppercase: <input
        type="text" name="converter" value="sample"
        onchange="upperMe(this)" /> <input type="button" value="Reset Field"
        onclick="resetField(this.form)" />
    </form>
  </body>
</html>

```

**Related Items:** value property.

**form**

**Value:** Form object reference.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

A property of every input element object is a reference to the form element that contains the control. This property can be very convenient in a script when you are dealing with one form control that is passed as a parameter to the function and you want to either access another control in the same form or invoke a method of the form. An event handler of any input element can pass *this* as the parameter, and the function can still get access to the form without having to hard-wire the script to a particular form name or document layout.

The following function fragment receives a reference to a text element as the parameter. The text element reference is needed to decide which branch to follow; then the form is submitted.

```

function setAction(fld) {
  if (fld.value.indexOf("@") != -1) {
    fld.form.action = "mailto:" + fld.value;
  } else {
    fld.form.action = "cgi-bin/normal.pl";
  }
  fld.form.submit();
}

```

Notice how this function doesn't have to worry about the form reference, because its job is to work with whatever form encloses the text field that triggers this function.

**Related Items:** form object.

**document.formObject.textObject.name**

## maxLength

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `maxLength` property controls the maximum number of characters allowed to be typed into the field. There is no interaction between the `maxLength` and `size` properties. This value is normally set initially via the `maxLength` attribute of the `input` element.

Use The Evaluator (Chapter 13) to experiment with the `maxLength` property. The top text field has no default value, but you can temporarily set it to only a few characters and see how it affects entering new values:

```
document.forms[0].input.maxLength = 3;
```

Try typing this into the field to see the results of the change. To restore the default value, reload the page.

**Related Items:** `size` property.

## name

**Value:** Identifier string.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Text object names are important for two reasons. First, if your HTML page submits information to CGI scripts, the input device passes the name of the text object along with the data to help the server program identify the data being supplied by the form. Second, you can use a text object's name in its reference within JavaScript coding. If you assign distinctive, meaningful names to your fields, these names will help you read and debug your JavaScript listings (and will help others follow your scripting tactics).

Be as descriptive about your text object names as you can. Borrowing text from the field's on-page label may help you mentally map a scripted reference to a physical field on the page. Like all JavaScript object names, text object names must begin with a letter and be followed by any number of letters or numbers. Avoid punctuation symbols with the exception of the very safe underscore character.

Although I urge you to use distinctive names for all objects you define in a document, you can make a case for assigning the same name to a series of interrelated fields—and JavaScript is ready to help. Within a single form, any reused name for the same object type is placed in an indexed array for that name. For example, if you define three fields with the name `entry`, the following statements retrieve the `value` property for each field:

```
data = document.forms[0].entry[0].value;  
data = document.forms[0].entry[1].value;  
data = document.forms[0].entry[2].value;
```

This construction may be useful if you want to cycle through all of a form's related fields to determine which ones are blank. Elsewhere, your script probably needs to know what kind of information each field is supposed to receive, so that it can process the data intelligently. I don't often recommend reusing object names, but you should be aware of how the object model handles them in case you need this construction. See "Form element arrays" in Chapter 21 for more details.

Consult Listing 23-2 later in this chapter, where I use the text object's name, `converter`, as part of the reference when assigning a value to the field. To extract the name of a text object,

**document.formObject.textObject.name**

you can use the property reference. Therefore, assuming that your script doesn't know the name of the first object in the first form of a document, the statement is

```
var objectName = document.forms[0].elements[0].name;
```

**Related Items:** `form.elements` property; all other form element objects' name property.

**readOnly**

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

To display text in a text field yet prevent users from modifying it, newer browsers offer the `readOnly` property (and tag attribute). When set to `true`, the property prevents users from changing or removing the content of the text field. Unlike a disabled text field, a read-only text field looks just like an editable one.

For older browsers, you can partially simulate this behavior by including the following event handler in the `input` element:

```
onfocus="this.blur()"
```

The event handler approach is not foolproof, however, in that quick-fingered users may be able to change a field before the event handler completes its task. For NN4, you can also trap for any keyboard events and prevent them from putting characters in the field.

Use The Evaluator (Chapter 13) to set the bottom text box to be read-only. Begin by typing anything you want in the bottom text box. Then enter the following statement into the top text box:

```
document.forms[0].inspector.readOnly = true;
```

While existing text in the box is selectable (and therefore can be copied into the clipboard), it cannot be modified or removed.

**Related Items:** `disabled` property.

**size**

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Unless otherwise directed, a text box is rendered to accommodate approximately 20 characters of text for the font family and size assigned to the element's stylesheet. You can adjust this under script control (in case the `size` attribute of the tag wasn't enough) via the `size` property, whose value is measured in characters (not pixels). Be forewarned, however, that browsers don't always make completely accurate estimates of the space required to display a set number of characters. If you are setting the `maxLength` attribute of a text box, making the `size` one or two characters larger is often a safe bet.

Resize the bottom text box of The Evaluator (Chapter 13) by entering the following statements into the top text box:

```
document.forms[0].inspector.size = 20;  
document.forms[0].inspector.size = 400;
```

Reload the page to return the size back to normal (or set the value to 80).

**Related Items:** `maxLength` property.

**document.formObject.textObject.value**

## type

**Value:** String (text).

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

Use the `type` property to help you identify a text input object from an unknown group of form elements.

**Related Items:** `form.elements` property.

## value

**Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

A text object's `value` property is the two-way gateway to the content of the field. A reference to an object's `value` property returns the string currently showing in the field. Note that all values coming from a text object are string values. If your field prompts a user to enter a number, your script may have to perform data conversion to the number-as-string value ("42" instead of plain, old 42) before a script can perform math operations on it. JavaScript tries to be as automatic about this data conversion as possible and follows some rules about it (see Chapter 27). If you see an error message that says a value is not a number (for a math operation), the value is still a string.

Your script places text of its own into a field for display to the user by assigning a string to the `value` property of a text object. Use the simple assignment operator. For example:

```
document.forms[0].ZIP.value = "90210";
```

JavaScript is more forgiving about data types when assigning values to a text object. JavaScript does its best to convert a value to a string on its way to a text object display. Even Boolean values get converted to their string equivalents `true` or `false`. Scripts can place numeric values into fields without a hitch. But remember that if a script later retrieves these values from the text object, they will come back as strings. About the only values that don't get converted are objects. They typically show up in text boxes as `[object]` or, in some browsers, a more descriptive label for the object.

Storing arrays in a field requires special processing. You need to use the `array.join()` method to convert an array into a string. Each array entry is delimited by a character you establish in the `array.join()` method. Later you can use the `string.split()` method to turn this delimited string into an array.

As a demonstration of how to retrieve and assign values to a text object, Listing 23-2 shows how the action in an `onchange` event handler is triggered. Enter any lowercase letters into the field and click out of the field. I pass a reference to the entire form object as a parameter to the event handler. The function extracts the value, converts it to uppercase (using one of the JavaScript string object methods), and assigns it back to the same field in that form.

### Listing 23-2: Getting and Setting a Text Object's Value

```
<html>
  <head>
    <title>Text Object Value</title>
    <script type="text/javascript">
```

*Continued*

**document.formObject.textObject.value****Listing 23-2 (continued)**

```
function upperMe(form) {
    inputStr = form.converter.value;
    form.converter.value = inputStr.toUpperCase();
}
</script>
</head>
<body>
  <form onsubmit="window.focus(); return false">
    Enter lowercase letters for conversion to uppercase: <input
      type="text" name="converter" value="sample"
      onchange="upperMe(this.form)" />
  </form>
</body>
</html>
```

I also show two other ways to accomplish the same task, each one more efficient than the previous example. Both utilize the shortcut object reference to get at the heart of the text object. Listing 23-3 passes the text object — contained in the `this` reference — to the function handler. Because that text object contains a complete reference to it (out of sight, but there just the same), you can access the `value` property of that object and assign a string to that object's `value` property in a simple assignment statement.

**Listing 23-3: Passing a Text Object (as this) to the Function**

```
<html>
  <head>
    <title>Text Object Value</title>
    <script type="text/javascript">
      function upperMe(field) {
        field.value = field.value.toUpperCase();
      }
    </script>
  </head>
  <body>
    <form onsubmit="window.focus(); return false">
      Enter lowercase letters for conversion to uppercase: <input
        type="text" name="converter" value="sample"
        onchange="upperMe(this)" />
    </form>
  </body>
</html>
```

Yet another way is to deal with the field values directly in an embedded event handler — instead of calling an external function (which is easier to maintain because all scripts are grouped together in the Head). With the function removed from the document, the event handler attribute of the `<input>` tag changes to do all the work:

```
<input type="text" name="converter" value="sample"
  onchange="this.value = this.value.toUpperCase()" />
```

`document.formObject.textObject.focus()`

The right-hand side of the assignment expression extracts the current contents of the field and (with the help of the `toUpperCase()` method of the string object) converts the original string to all uppercase letters. The result of this operation is assigned to the `value` property of the field.

The application of the `this` keyword in the previous examples may be confusing at first, but these examples represent the range of ways in which you can use such references effectively. Using `this` by itself as a parameter to an object's event handler refers only to that single object—a text object in Listing 23-3. If you want to pass along a broader scope of objects that contain the current object, use the `this` keyword along with the outer object layer that you want. In Listing 23-2, I sent a reference to the entire form along by specifying `this.form`—meaning the form that contains “this” object, which is being defined in the line of HTML code.

At the other end of the scale, you can use similar-looking syntax to specify a particular property of the `this` object. Thus, in the last example, I zeroed in on just the `value` property of the current object being defined—`this.value`. Although the formats of `this.form` and `this.value` appear the same, the fact that one is a reference to an object and the other just a value can influence the way your functions work. When you pass a reference to an object, the function can read and modify properties of that object (as well as invoke its functions); but when the parameter passed to a function is just a property value, you cannot modify that value without building a complete reference to the object and its value.

**Related Items:** `form.defaultValue` property.

## Methods

### `blur()`

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Just as a camera lens blurs when it goes out of focus, a text object blurs when it loses focus—when someone clicks or tabs out of the field. Under script control, `blur()` deselects whatever may be selected in the field, and the text insertion pointer leaves the field. The pointer does not proceed to the next field in tabbing order, as it does if you perform a blur by tabbing out of the field manually.

The following statement invokes the `blur()` method on a text box named `vanishText`:

```
document.forms[0].vanishText.blur();
```

**Related Items:** `focus()` method; `onblur` event handler.

### `focus()`

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

For a text object, having focus means that the text insertion pointer is flashing in that text object's field (having focus means something different for buttons in a Windows environment). Giving a field focus is like opening it up for human editing.

Setting the focus of a field containing text does not let you place the cursor at any specified location in the field. The cursor usually appears at the beginning of the text (although in WinIE4+, you can use the `TextRange` object to position the cursor wherever you want in the field, as shown in Chapter 35 on the CD-ROM). To prepare a field for entry to remove the existing text, use both the `focus()` and `select()` methods.

**document.formObject.textObject.focus()**

See Listing 23-4 for an example of an application of the `focus()` method in concert with the `select()` method.

**Related Items:** `select()` method; `onfocus` event handler.

**select()**

**Returns:** Nothing.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Selecting a field under script control means selecting all text within the text object. A typical application is one in which an entry validation script detects a mistake on the part of the user. After alerting the user to the mistake (via a `window.alert()` dialog box), the script finishes its task by selecting the text of the field in question. Not only does this action draw the user's eye to the field needing attention (especially important if the validation code is checking multiple fields), but it also keeps the old text there for the user to examine for potential problems. With the text selected, the next key the user presses erases the former entry.

Trying to select a text object's contents with a click of a button is problematic. One problem is that a click of the button brings the document's focus to the button, which disrupts the selection process. For more ensured selection, the script should invoke both the `focus()` and the `select()` methods for the field, in that order. No penalty exists for issuing both methods, and the extra insurance of the second method provides a more consistent user experience with the page.

Some versions of WinIE are known to exhibit anomalous (meaning buggy) behavior when using the technique of focusing and selecting a text field after the appearance of an alert dialog box. The fix is not elegant, but it works: inserting an artificial delay via the `setTimeout()` method before invoking a separate function that focuses and selects the field. Better-behaved browsers accept the workaround with no penalty.

Selecting a text object via script does *not* trigger the same `onselect` event handler for that object as the one that triggers if a user manually selects text in the field. Therefore, no event handler script is executed when a user invokes the `select()` method.

A click of the Verify button in Listing 23-4 performs a validation on the contents of the text box, making sure the entry consists of all numbers. All work is controlled by the `checkNumeric()` function, which receives a reference to the field needing inspection as a parameter. Because of the way the delayed call to the `doSelection()` function has to be configured, various parts of what will become a valid reference to the form are extracted from the field's and form's properties. If the validation (performed in the `isNumber()` function) fails, the `setSelection()` method is invoked after an artificial delay of zero milliseconds. As goofy as this sounds, this method is all that IE needs to recover from the display and closure of the alert dialog box. Because the first parameter of the `setTimeout()` method must be a string, the example assembles a string invocation of the `setSelection()` function via string versions of the form and field names. All that the `setSelection()` function does is focus and select the field whose reference is passed as a parameter. This function is now generalizable to work with multiple text boxes in a more complex form.

**Listing 23-4: Selecting a Field**

```
<html>
  <head>
    <title>Text Object Select/Focus</title>
```

**document.formObject.textObject.onafterupdate**

```

<script type="text/javascript">
// general purpose function to see if a suspected numeric input is a
// number
function isNumber(inputStr) {
    for (var i = 0; i < inputStr.length; i++) {
        var oneChar = inputStr.charAt(i);
        if (oneChar < "0" || oneChar > "9") {
            alert("Please make sure entries are numbers only.");
            return false;
        }
    }
    return true;
}

function checkNumeric(fld) {
    var inputStr = fld.value;
    var fldName = fld.name;
    var formName = fld.form.name;
    if (isNumber(inputStr)) {
        // statements if true
    } else {
        setTimeout("doSelection(document." + formName + ". " + fldName +
            ")", 0);
    }
}

function doSelection(fld) {
    fld.focus();
    fld.select();
}
</script>
</head>
<body>
    <form name="entryForm" onsubmit="return false">
        Enter any positive integer: <input type="text" name="numeric" />
        <p><input type="button" value="Verify"
            onclick="checkNumeric(this.form.numeric)" /></p>
    </form>
</body>
</html>

```

**Related Items:** focus() method; onselect event handler.

## Event handlers

onafterupdate  
onbeforeupdate  
onerrorupdate

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

If you are using WinIE data binding on a text element, the element is subject to three possible events in the course of retrieving updated data. The onbeforeupdate and onafterupdate events fire immediately before and after (respectively) the update takes place. If an error occurs in the retrieval of data from the database, the onerrorupdate event fires.

**document.formObject.textObject.onafterupdate**

All three events may be used for advisory purposes. For example, an `onafterupdate` event handler may temporarily change the font characteristics of the element to signify the arrival of fresh data. Or an `onerrorupdate` event handler may fill the field with hyphens because no valid data exists for the field. These events apply only to `input` elements of type text (meaning not password or hidden types).

**Related Items:** `dataFld`, `dataSrc` properties (Chapter 15).

`onblur`  
`onfocus`  
`onselect`

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

All three of these event handlers should be used only after you have a firm understanding of the interrelationships of the events that reach text objects. You must use extreme care and conduct lots of user testing before including more than one of these three event handlers in a text object. Because some events cannot occur without triggering others either immediately before or after (for example, an `onfocus` occurs immediately before an `onselect` if the field did not have focus before), whatever actions you script for these events should be as distinct as possible to avoid interference or overlap.

 **Note**

The `onselect` event handler does not work in Windows versions of NN through Version 4.

In particular, be careful about displaying modal dialog boxes (for example, `window.alert()` dialog boxes) in response to the `onfocus` event handler. Because the text field loses focus when the alert displays and then regains focus after the alert is closed, you can get yourself into a loop that is difficult to break out of. If you get trapped in this manner, try the keyboard shortcut for reloading the page (`Ctrl+R` or `⌘-R`) repeatedly as you keep closing the dialog box window.

A question often arises about whether data-entry validation should be triggered by the `onblur` or `onchange` event handler. An `onblur` validation cannot be fooled, whereas an `onchange` one can be (the user simply doesn't change the bad entry as he or she tabs out of the field). What I don't like about the `onblur` way is it can cause a frustrating experience for a user who wants to tab through a field now and come back to it later (assuming your validation requires data be entered into the field before submission). As in Chapter 43's discussion (on the CD-ROM) about form data validation, I recommend using `onchange` event handlers to trigger immediate data checking and then using another last-minute check in a function called by the form's `onsubmit` event handler.

To demonstrate one of these event handlers, Listing 23-5 shows how you may use the window's status bar as a prompt message area after a user activates any field of a form. When the user tabs to or clicks on a field, the prompt message associated with that field appears in the status bar. In Figure 23-1, the user has tabbed to the second text box, which caused the status bar message to display a prompt for the field.

**Listing 23-5: The onfocus Event Handler**

```
<html>
  <head>
    <title>onfocus Event Handler</title>
    <script type="text/javascript">
      function prompt(msg) {
        window.status = "Please enter your " + msg + ".";
      }
    </script>
  </head>
  <body>
    <form>
      Enter your first name:<input type="text" name="firstName"
      onfocus="prompt('first name')" />
      <p>Enter your last name:<input type="text" name="lastName"
      onfocus="prompt('last name')" /></p>
      <p>Enter your address:<input type="text" name="address"
      onfocus="prompt('address')" /></p>
      <p>Enter your city:<input type="text" name="city"
      onfocus="prompt('city')" /></p>
    </form>
  </body>
</html>
```

**Figure 23-1:** An onfocus event handler triggers a status bar display.

**document.formObject.textObject.onchange****onchange**

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Of all the event handlers for a text object, you will probably use the `onchange` handler the most in your forms (see Listing 23-6). This event is the one I prefer for triggering the validation of whatever entry the user just typed in the field. The potential hazard of trying to do only a batch-mode data validation of all entries before submitting an entire form is that the user's mental focus is away from the entry of a given field as well. When you immediately validate an entry, the user is already thinking about the information category in question. See Chapter 43 on the CD-ROM for more about data-entry validation.

**Note**

In NN4 (only), if you have both `onchange` and any keyboard event handlers defined for the same text field tag, the `onchange` event handlers are ignored. This is not true for IE4+, NN6+, and other W3C browsers, where all events fire.

**Listing 23-6: Data Validation via an onchange Event Handler**

```
<html>
  <head>
    <title>Text Object Select/Focus</title>
    <script type="text/javascript">
      // general purpose function to see if a suspected numeric input is a
      // number
      function isNumber(inputStr) {
        for (var i = 0; i < inputStr.length; i++) {
          var oneChar = inputStr.substring(i, i + 1);
          if (oneChar < "0" || oneChar > "9") {
            alert("Please make sure entries are numbers only.");
            return false;
          }
        }
        return true;
      }

      function checkIt(form) {
        inputStr = form.numeric.value;
        if (isNumber(inputStr)) {
          // statements if true
        } else {
          form.numeric.focus();
          form.numeric.select();
        }
      }
    </script>
  </head>
  <body onsubmit="checkIt(this); return false">
    <form>
      Enter any positive integer: <input type="text" name="numeric"
        onchange="checkIt(this.form)" />
    </form>
  </body>
</html>
```

*document.formObject.hiddenObject*

## password Input Object

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
See "Text Input Object"		

### Syntax

See "Text Input Object"

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

### About this object

A password-style field looks like a text object, but when the user types something into the field, only asterisks or bullets (depending on your operating system) appear in the field. For the sake of security, any password exchanges should be handled by a server-side program (CGI, Java servlet, and so on).

Scripts can treat a password object exactly like a text `input` object. This may lead a scripter to capture a user's Web site password for storage in the `document.cookie` of the client machine. A password object value property is returned in plain language, so that such a captured password would be stored in the cookie file the same way. Because a client machine's cookie file can be examined on the local computer (perhaps by a snoop during lunch hour), plain-language storage of passwords is a potential security risk. Instead, develop a scripted encryption algorithm for your page for reading and writing the password in the cookie. Most password-protected sites, however, usually have a server program (CGI, for example) encrypt the password prior to sending it back to the cookie.

See the text object discussion for the behavior of password object's properties, methods, and event handlers. The `type` property for this object returns `password`.

## hidden Input Object

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
See "Text Input Object"		

### Syntax

See "Text Input Object"

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

**document.formObject.hiddenObject**

## About this object

A hidden object is a simple string holder within a form object whose contents are not visible to the user of your Web page. Despite the long list of properties, methods, and event handlers that this input element type inherits by virtue of being an input element, you will be doing little with a `hidden` element beyond reading and writing its `value` property.

The `hidden` object plays a vital role in applications that rely on CGI programs on the server. Very often, the server has data that it needs to convey to itself the next time the client makes a submission (for example, a user ID captured at the application's login page). A CGI program can generate an HTML page with the necessary data hidden from the user but located in a field transmitted to the server at submit time.

Along the same lines, a page for a server application may present a user-friendly interface that makes data-entry easy for the user. But on the server end, the database or other application requires that the data be in a more esoteric format. A script located in the page generated for the user can use the `onsubmit` event handler to perform the last-minute assembly of user-friendly data into database-friendly data in a hidden field. When the CGI program receives the request from the client, it passes along the hidden field value to the database.

I am not a fan of the `hidden` object for use on client-side-only JavaScript applications. If I want to deliver with my JavaScript-enabled pages some default data collections or values, I do so in JavaScript variables and arrays as part of the script.

Because scripted changes to the contents of a hidden field are fragile (for example, a soft reload erases the changes), the only place you should consider making such changes is in the same script that submits a form to a CGI program or in a function triggered by an `onsubmit` event handler. In effect, you're just using the hidden fields as holding pens for the scripted data to be submitted. For more persistent storage, use the `document.cookie` property or genuine text fields in hidden frames, even if just for the duration of the visit to the page.

For information about the properties of the `hidden` object, consult the earlier listing for the text input object. The `type` property for this object returns `hidden`.

## textarea Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>

## Syntax

Accessing textarea element object properties or methods:

```
(All)      [window.]document.formName.textareaName.property |
method([parameters])
(All)      [window.]document.formName.elements[index].property |
method([parameters])
(All)      [window.]document.forms[index].textareaName.property |
method([parameters])
(All)      [window.]document.forms["formName"].textareaName.property |
method([parameters])
(All)      [window.]document.forms["formName"].elements[index].property |
method([parameters])
(IE4+)     [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

## About this object

Although not in the same HTML syntax family as other `<input>` elements of a form, a `textarea` object is indeed a form input element, providing multiple-line text input facilities. Although some browsers let you put a `textarea` element anywhere in a document, it really should be contained by a `form` element.

A `textarea` object closely resembles a text object, except for attributes that define its physical appearance on the page. Because the intended use of a `textarea` object is for multiple-line text input, the attributes include specifications for height (number of rows) and width (number of columns in the monospaced font). No matter what size you specify, the browser displays a `textarea` with horizontal and vertical scrollbars in older browsers; more recent browsers tend to be smarter about displaying scrollbars only when needed (although there are exceptions). Text entered in the `textarea` wraps within the visible rectangle of the field if you set the `wrap` attribute to `virtual` or `physical` in NN and `soft` or `hard` in IE; otherwise the text scrolls for a significant distance horizontally (the horizontal scrollbar appears when wrapping has the default off setting). This field is, indeed, a primitive text field by GUI computing standards in that font specifications made possible in newer browsers by way of stylesheets apply to all text in the box.

Use The Evaluator Sr. (Chapter 13) to play with the `cols` and `rows` property settings for the Results `textarea` on that page. Shrink the width of the `textarea` by entering the following statement into the top text box:

```
document.forms[0].output.cols = 30;
```

And make the `textarea` one row deeper:

```
document.forms[0].output.rows++;
```

All properties, methods, and event handlers of text objects apply to the `textarea` object. They all behave exactly the same way (except, of course, for the `type` property, which is `textarea`). Therefore, refer to the previous listings for the text object for scripting details for those items. Some additional properties that are unique to the `textarea` object are discussed next.

## textarea

## Carriage returns inside textareas

The three classes of operating systems supported by Netscape Navigator — Windows, Macintosh, and UNIX — do not agree about what constitutes a carriage return character in a text string. This discrepancy carries over to the `textarea` object and its contents on these platforms.

After a user enters text and uses Enter/Return on the keyboard, one or more unseen characters are inserted into the string. In the parlance of JavaScript's literal string characters, the carriage return consists of some combination of the newline (`\n`) and return (`\r`) character. The following table shows the characters inserted into the string for each operating system category.

<i>Operating System</i>	<i>Character String</i>
Windows	<code>\r\n</code>
Macintosh	<code>\r</code>
UNIX	<code>\n</code>

This tidbit is valuable if you need to remove carriage returns from a `textarea` for processing in a CGI or local script. The problem is that you obviously need to perform platform-specific operations on each. For the situation in which you must preserve the carriage return locations, but your server-side database cannot accept the carriage return values, I suggest you use the `string.escape()` method to URL-encode the string. The return character is converted to `%0D` and the newline character is converted to `%0A`. Of course these characters occupy extra character spaces in your database, so these additions must be accounted for in your database design.

As far as writing carriage returns into textareas, the situation is a bit easier. From NN3 and IE4 onward, if you specify any one of the combinations in the preceding table, all platforms know how to automatically convert the data to the form native to the operating system. Therefore, you can set the value of a `textarea` object to `1\r\n2\r\n3` in all platforms, and a columnar list of the numbers 1, 2, and 3 will appear in those fields. Or, if you URL-encoded the text for saving to a database, you can unescape that character string before setting the `textarea` value, and no matter what platform the visitor has, the carriage returns are rendered correctly. Upon reading those values again by script, you can see that the carriage returns are in the form of the platform (shown in the previous table).

## Properties

`cols`

`rows`

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The displayed size of a `textarea` element is defined by its `cols` and `rows` attributes, which are represented in the object model by the `cols` and `rows` properties, respectively. Values for these properties are integers. For `cols`, the number represents the number of characters that

**textarea.createTextRange()**

can be displayed without horizontal scrolling of the textarea; for `rows`, the number is the number of lines of text that can be displayed without vertical scrolling.

**Related Items:** `wrap` property.

**wrap**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `wrap` property represents the `wrap` attribute, which, surprisingly, is not a W3C-sanctioned attribute as of HTML 4.01. In any case, IE4+ lets you adjust the property by scripting. Allowable string values are `soft`, `hard`, and `off`. The browser adds soft returns (the default in IE) to word-wrap the content, but no carriage return characters are actually inserted into the text. A setting for `hard` returns means that carriage return characters are added to the text (and would be submitted with the value to a server CGI). With `wrap` set to `off`, text continues to extend beyond the right edge of the textarea until the user manually presses the Enter/Return key.

**Related Items:** `cols` property.

## Methods

**createTextRange()**

**Returns:** `TextRange` object.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `createTextRange()` method for a `textarea` operates just as the `document.createTextRange()` method, except that the range consists of text inside the `textarea` element, apart from the regular body content. This version of the `TextRange` object comes in handy when you want a script to control the location of the text insertion pointer inside a `textarea` element for the user.

See the example for the `TextRange.move()` method in Chapter 5 to see how to control the text insertion pointer inside a `textarea` element.

**Related Items:** `TextRange` object (Chapter 35 on the CD-ROM).

# Select, Option, and FileUpload Objects

---

**S**election lists — whether in the form of pop-up menus or scrolling lists — are space-saving form elements in HTML pages. They enable designers to present a lot of information in a comparatively small space. At the same time, users are familiar with the interface elements from working in their own operating systems' preference dialog boxes and application windows.

However, selection lists are more difficult to script, especially in older browsers, because the objects themselves are complicated entities. Scripts find all the real data associated with the form control in `option` elements that are nested inside `select` elements. As you can see throughout this chapter, backward-compatible references necessary to extract information from a `select` element object and its `option` objects can get pretty long. The results, however, are worth the effort.

The other object covered in this chapter, the `fileUpload` input object, is frequently misunderstood as being more powerful than it actually is. It is, alas, not the great file transfer elixir desired by many page authors.

## select Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>formt</code>	<code>add()</code>	<code>onchange</code>
<code>length</code>	<code>options[i].add()</code>	
<code>multiple</code>	<code>item()</code>

method([parameters])
(IE4+)     [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

## About this object

`select` element objects are perhaps the most visually interesting user interface elements among the standard built-in objects. In one format, they appear on the page as pop-up lists; in another format, they appear as scrolling list boxes. Pop-up lists, in particular, offer efficient use of page real estate for presenting a list of choices for the user. Moreover, only the choice selected by the user shows on the page, minimizing the clutter of unneeded verbiage.

Compared with other JavaScript objects, `select` objects are difficult to script — mostly because of the complexity of data that goes into a list of items. What the user sees as a `select` element on the page consists of both that element and `option` elements that contain the actual choices from which the user makes a selection. Some properties that are of value to scripters belong to the `select` object, while others belong to the nested `option` objects. For example, you can extract the number (`index`) of the currently selected option in the list — a property of the entire `select` object. To get the displayed text of the selected option, however, you must zero in further to extract the `text` property of a single option among all options defined for the object.

When you define a `select` object within a form, the construction of the `<select>...</select>` tag pair is easy to inadvertently mess up. First, most attributes that define the entire object — such as `name`, `size`, and event handlers — are attributes of the opening `<select>` tag. Between the end of the opening tag and the closing `</select>` tag are additional tags for each option to be displayed in the list. The following object definition creates a selection pop-up list containing three color choices:

```
<form>
<select name="RGBColors" onchange="changeColor(this)">
  <option selected="selected">Red</option>
  <option>Green</option>
  <option>Blue</option>
</select>
</form>
```

The indented formatting of the tags in the HTML document is not critical. I indent the lines of options merely for the sake of readability.

**select**

By default, a `select` element is rendered as a pop-up list. To make it appear as a scrolled list, assign an integer value greater than 1 to the `size` attribute to specify how many options should be visible in the list without scrolling—how tall the list’s box should be, measured in lines. Because scrollbars in GUI environments tend to require a fair amount of space to display a minimum set of clickable areas (including sliding “thumbs”), you should set list-box style sizes to no less than 4. If that makes the list box too tall for your page design, consider using a pop-up menu instead.

Significant differences exist in the way each GUI platform presents pop-up menus. Because each browser sometimes relies on the operating system to display its native pop-up menu style (and sometimes the browser designers go their own way), considerable differences exist among the OS and browser platforms in the size of a given pop-up menu. What fits nicely within a standard window width of one OS may not fit in the window of another OS in a different browser. In other words, you cannot rely on any `select` object having a precise dimension on a page (in case you’re trying to align a `select` object with an image).

In list-box form, you can set a `select` object to accept multiple, noncontiguous selections. Users typically accomplish such selections by holding down a modifier key (the Shift, Ctrl, or ⌘ key, depending on the operating system) while clicking additional options. To switch on this capability for a `select` object, include the `multiple` attribute constant in the definition.

For each entry in a list, your `<select>` tag definition must include an `<option>` tag plus the text as you want it to appear in the list. If you want a pop-up list to show a default selection when the page loads, you must attach a `selected` attribute to that item’s `<option>` tag. Without this attribute, the default item may be empty or the first item, depending on the browser. (I go more in depth about this in the `option` object discussion later in this chapter.) You can also assign a string to each `option`’s `value` attribute. As with radio buttons, this value can be text other than the wording displayed in the list. In essence, your script can act on that “hidden” value rather than on the displayed text, such as letting a plain-language `select` listing actually refer to a complex URL. This string value is also the value sent to a CGI program (as part of the name-value pair) when the user submits the `select` object’s form.

One behavioral aspect of the `select` object may influence your page design. The `onchange` event handler triggers immediately when a user makes a new selection in a pop-up list. If you prefer to delay any action until the user makes other settings in the form, omit an `onchange` event handler in the `select` object—but be sure to create a button that enables users to initiate an action governed by those user settings.

## Modifying select options (NN3+, IE4+)

Script control gives you considerable flexibility in modifying the contents and selection of a `select` object. These powers are available only in NN3+ or IE4+ (I discuss a W3C approach a bit later in the chapter). Some of this flexibility is rather straightforward, such as changing the `selectObj.options[i].text` property to alter the display of a single-option entry. The situation gets tricky, though, when the number of options in the `select` object changes. Your choices include

- ♦ Removing an individual option (and thus collapsing the list)
- ♦ Reducing an existing list to a fewer number of options
- ♦ Removing all options
- ♦ Adding new options to a `select` object

**select**

To remove an option from the list, set the specific option to `null`. For example, if a list contains five items and you want to eliminate the third item altogether (reducing the list to four items), the syntax (from the `select` object reference) for doing that task is this:

```
selectObj.options[2] = null;
```

After this statement, `selectObj.options.length` equals 4.

In another scenario, suppose that a `select` object has five options in it and you want to replace it with one having only three options. You first must hard-code the `length` property to 3:

```
selectObj.options.length = 3;
```

Then, set individual `text` and `value` properties for index values 0 through 2.

Perhaps you want to start building a new list of contents by completely deleting the original list (without harming the `select` object). To accomplish this, set the `length` to 0:

```
selectObj.options.length = 0;
```

From here, you have to create new options (as you do when you want to expand a list from, say, three to seven options). The mechanism for creating a new option involves an object constructor: `new Option()`. This constructor accepts up to four parameters, which enable you to specify the equivalent of an `<option>` tag's attributes:

- ♦ Text to be displayed in the option
- ♦ Contents of the option's `value` property
- ♦ Whether the item is the `defaultSelected` option (Boolean)
- ♦ Whether the item is selected (Boolean)

You can set any (or none) of these items as part of the constructor and return to other statements to set their properties. I suggest setting the first two parameters (leave the others blank) and then setting the `selected` property separately. The following is an example of a statement that creates a new, fifth entry, in a `select` object and sets both its displayed text and `value` properties:

```
selectObj.options[4] = new Option("Yahoo", "http://www.yahoo.com");
```

To demonstrate all of these techniques, Listing 24-1 enables you to change the text of a `select` object—first by adjusting the text properties in the same number of options and then by creating an entirely new set of options. Radio button `onclick` event handlers trigger functions for making these changes—rare examples of when radio buttons can logically initiate visible action.

**Listing 24-1: Modifying select Options**

```
<html>
<head>
  <title>Changing Options On The Fly</title>
  <script type="text/javascript" language="JavaScript">
    // flag to reload page for older NNs
    var isPreNN6 = (navigator.appName == "Netscape" &&
      parseInt(navigator.appVersion) <= 4);
```

```
// initialize color list arrays
plainList = new Array(6);
hardList = new Array(6);
plainList[0] = "cyan";
hardList[0] = "#00FFFF";
plainList[1] = "magenta";
hardList[1] = "#FF00FF";
plainList[2] = "yellow";
hardList[2] = "#FFFF00";
plainList[3] = "lightgoldenrodyellow";
hardList[3] = "#FAFAD2";
plainList[4] = "salmon";
hardList[4] = "#FA8072";
plainList[5] = "dodgerblue";
hardList[5] = "#1E90FF";

// change color language set
function setLang(which) {
    var listObj = document.forms[0].colors;
    // filter out old browsers
    if (listObj.type) {
        // find out if it's 3 or 6 entries
        var listLength = listObj.length;
        // save selected index
        var currSelected = listObj.selectedIndex;
        // replace individual existing entries
        for (var i = 0; i < listLength; i++) {
            if (which == "plain") {
                listObj.options[i].text = plainList[i];
            } else {
                listObj.options[i].text = hardList[i];
            }
        }
        if (isPreNN6) {
            history.go(0);
        } else {
            listObj.selectedIndex = currSelected;
        }
    }
}

// create entirely new options list
function setCount(choice) {
    var listObj = document.forms[0].colors;
    // filter out old browsers
    if (listObj.type) {
        // get language setting
        var lang = (document.forms[0].geekLevel[0].checked) ?
            "plain" : "hard";
        // empty options from list
        listObj.length = 0;
        // create new option object for each entry
        for (var i = 0; i < choice.value; i++) {
            if (lang == "plain") {
                listObj.options[i] = new Option(plainList[i]);
            } else {
                listObj.options[i] = new Option(hardList[i]);
            }
        }
    }
}
```

*Continued*

## select

## Listing 24-1 (continued)

```

    }
    }
    listObj.options[0].selected = true;
    if (isPreNN6) {
        history.go(0);
    }
}
</script>
</head>
<body>
<h1>Flying Select Options</h1>
<form>
    Choose a palette size: <input type="radio" name="paletteSize"
    value="3" onclick="setCount(this)" checked="checked" />Three <input
    type="radio" name="paletteSize" value="6"
    onclick="setCount(this)" />Six
    <p>Choose geek level: <input type="radio" name="geekLevel" value=""
    onclick="setLang('plain')" checked="checked" />Plain-language
    <input type="radio" name="geekLevel" value=""
    onclick="setLang('hard')" />Gimme hex-triplets!</p>
    <p>Select a color: <select name="colors">
        <option selected="selected">cyan</option>
        <option>magenta</option>
        <option>yellow</option>
    </select></p>
</form>
</body>
</html>

```

In an effort to make this code easily maintainable, the color choice lists (one in plain language, the other in hexadecimal triplet color specifications) are established as two separate arrays. Repeat loops in both large functions can work with these arrays no matter how big they get.

The first two radio buttons (see Figure 24-1) trigger the `setLang()` function. This function's first task is to extract a reference to the `select` object to make additional references shorter (just `listObj`). Then by way of the `length` property, you find out how many items are currently displayed in the list because you just want to replace as many items as are already there. In the repeat loop, you set the `text` property of the existing `select` options to corresponding entries in either of the two array listings.

In the second pair of radio buttons, each button stores a value indicating how many items should be displayed when the user clicks the button. This number is picked up by the `setCount()` function and is used in the repeat loop as a maximum counting point. In the meantime, the function finds the selected language radio button and zeros out the `select` object entirely. Options are rebuilt from scratch using the new `Option()` constructor for each option. The parameters are the corresponding display text entries from the arrays. Because none of these new options have other properties set (such as which one should be selected by default), the function sets that property of the first item in the list.

**Figure 24-1:** Radio button choices alter the contents of the `select` object on the fly.

Notice that both functions call `history.go(0)` for NN3 and NN4 browsers after setting up their `select` objects. The purpose of this call is to give these earlier Navigator versions an opportunity to resize the `select` object to accommodate the contents of the list. The difference in size here is especially noticeable when you switch from the six-color, plain-language list to any other list. Without resizing, some long items are not readable. IE4+ and NN6+, on the other hand, automatically redraw the page to the newly sized form element.

## Modifying select options (IE4+)

Microsoft offers another way to modify `select` element options for IE4+, but the technique involves two proprietary methods of the `options` array property of the `select` object. Because I cover all other ways of modifying the `select` element in this section, I cover the IE way of doing things here as well.

The two `options` array methods are `add()` and `remove()`. The `add()` method takes one required parameter and one optional parameter. The required parameter is a reference to an option element object that your script creates in another statement (using the `document.createElement()` method). If you omit the second parameter to `add()`, the new option element is appended to the current collection of items. But you can also specify an index value as the second parameter. The index points to the position in the `options` array where the new item is to be inserted.

Listing 24-2 shows how to modify the two main functions from Listing 24-1 using the IE approach exclusively (changes and additions appear in bold). The script assumes that only IE browsers ever load the page (in other words, there is no filtering for browser brand here).

**select**

When replacing one set of options with another, there are two approaches demonstrated. In the first (the `setLang()` function), the replacements have the same number of items, so the length of existing options provides a counter and index value for the `remove()` and `add()` methods. But when the number of items may change (as in the `setCount()` function), a tight loop removes all items before they are added back via the `add()` method without a second parameter (items are appended to the list). The approach shown in Listing 24-2 has no specific benefit over that of Listing 24-1.

**Listing 24-2: Modifying select Options (IE4+)**

```
// change color language set
function setLang(which) {
    var listObj = document.forms[0].colors;
    var newOpt;
    // filter out old IE browsers
    if (listObj.type) {
        // find out if it's 3 or 6 entries
        var listLength = listObj.length;
        // save selected index
        var currSelected = listObj.selectedIndex;
        // replace individual existing entries
        for (var i = 0; i < listLength; i++) {
            newOpt = document.createElement("option");
            newOpt.text = (which == "plain") ? plainList[i] : hardList[i];
            listObj.options.remove(i);
            listObj.options.add(newOpt, i);
        }
        listObj.selectedIndex = currSelected;
    }
}

// create entirely new options list
function setCount(choice) {
    var listObj = document.forms[0].colors;
    var newOpt;
    // filter out old browsers
    if (listObj.type) {
        // get language setting
        var lang = (document.forms[0].geekLevel[0].checked) ? "plain" : "hard";
        // empty options from list
        while (listObj.options.length) {
            listObj.options.remove(0);
        }
        // create new option object for each entry
        for (var i = 0; i < choice.value; i++) {
            newOpt = document.createElement("option");
            newOpt.text = (lang == "plain") ? plainList[i] : hardList[i];
            listObj.options.add(newOpt);
        }
        listObj.options[0].selected = true;
    }
}
```

## Modifying select options (W3C DOM)

Yet another approach is possible in browsers that closely adhere to the W3C DOM Level 2 standard. In NN6+, Moz1+, and Safari1+, for example, you can use the `add()` and `remove()` methods of the `select` element object. They work very much like the same-named methods for the `options` array in IE4+, but these are methods of the `select` element object itself. The other main difference between the two syntaxes is that the `add()` method does not use the index value as the second parameter but rather a reference to the `option` element object before which the new option is inserted. The second parameter is required, so to simply append the new item at the end of the current list, supply `null` as the parameter. Listing 24-3 shows the W3C-compatible version of the `select` element modification scripts shown in Listings 24-1 and 24-2. I highlight source code lines in bold that exhibit differences between the IE4+ and W3C DOM versions.

### Listing 24-3: Modifying select Options (W3C)

```
// change color language set
function setLang(which) {
    var listObj = document.forms[0].colors;
    var newOpt;
    // filter out old IE browsers
    if (listObj.type) {
        // find out if it's 3 or 6 entries
        var listLength = listObj.length;
        // save selected index
        var currSelected = listObj.selectedIndex;
        // replace individual existing entries
        for (var i = 0; i < listLength; i++) {
            newOpt = document.createElement("option");
            newOpt.text = (which == "plain") ? plainList[i] : hardList[i];
            listObj.remove(i);
            listObj.add(newOpt, listObj.options[i]);
        }
        listObj.selectedIndex = currSelected;
    }
}

// create entirely new options list
function setCount(choice) {
    var listObj = document.forms[0].colors;
    var newOpt;
    // filter out old browsers
    if (listObj.type) {
        // get language setting
        var lang = (document.forms[0].geekLevel[0].checked) ? "plain" : "hard";
        // empty options from list
        while (listObj.options.length) {
            listObj.remove(0);
        }
        // create new option object for each entry
        for (var i = 0; i < choice.value; i++) {
            newOpt = document.createElement("option");
```

*Continued*

**select****Listing 24-3 (continued)**

```

        newOpt.text = (lang == "plain") ? plainList[i] : hardList[i];
        listObj.add(newOpt, null);
    }
    listObj.options[0].selected = true;
}
}

```

As with the IE4 version, the W3C version offers no specific benefit over the original, backward-compatible approach. Choose the most modern one that fits the types of browsers you need to support with your page.

## Properties

### length

**Value:** Integer.

Read/Write (see text)

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Like all JavaScript arrays, the `options` array has a `length` property of its own. But rather than having to reference the `options` array to determine its length, the `select` object has its own `length` property that you use to find out how many items are in the list. This value is the number of options in the object. A `select` object with three choices in it has a `length` property value of 3.

In NN3+ and IE4+, you can adjust this value downward after the document loads. This is one way to decrease the number of options in a list. Setting the value to 0 causes the `select` object to empty but not disappear.

See Listing 24-1 for an illustration of the way you use the `length` property to help determine how often to cycle through the repeat loop in search of selected items. Because the loop counter, `i`, must start at 0, the counting continues until the loop counter is one less than the actual length value (which starts its count with 1).

**Related Item:** `options` property.

### multiple

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `multiple` property represents the `multiple` attribute setting for a `select` element object. If the value is `true`, the element accepts multiple selections by the user (for example, Ctrl+clicking in Windows). If you want to convert a pop-up list into a multiple `select` pick list, you must also adjust the `size` property to direct the browser to render a set number of visible choices in the list.

The following statement toggles between single and multiple selections on a `select` element object whose `size` attribute is set to a value greater than 1:

```
document.forms[0].mySelect.multiple = !document.forms[0].mySelect.multiple;
```

**Related Item:** `size` property.

## options[ *index*]

**Value:** Array of option element objects.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

You typically don't summon this property by itself. Rather, it is part of a reference to a specific option's properties (or methods in later browsers) within the entire `select` object. In other words, the `options` property is a kind of gateway to more specific properties, such as the value assigned to a single option within the list.

In newer browsers (IE4+ and W3C), you can reference individual options as separate HTML element objects. These references do not require the reference to the containing `form` or `select` element objects. For backward compatibility, however, I recommend you stick with the long references through the `select` objects.

I list the next several properties here in the `select` object discussion because they are backward-compatible with all browsers, including browsers that don't treat the `option` element as a distinct object. Be aware that all properties shown here that include `options [index]` as part of their references are also properties of the `option` element object in IE4+ and W3C browsers.

See Listings 24-1 through 24-3 for examples of how the `options` array references information about the options inside a `select` element.

**Related Items:** All `options[index].property` items.

## options[ *index*].defaultSelected

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

If your `select` object definition includes one option that features the `selected` attribute, that option's `defaultSelected` property is set to `true`. The `defaultSelected` property for all other options is `false`. If you define a `select` object that allows multiple selections (and whose `size` attribute is greater than 1), however, you can define the `selected` attribute for more than one option definition. When the page loads, all items with that attribute are preselected for the user (even in noncontiguous groups).

The following statement preserves a Boolean value if the first option of the select list is the default selected item:

```
var zeroIsDefault = document.forms[0].listName.options[0].defaultSelected;
```

**Related Item:** `options[index].selected` property.

## options[ *index*].index

**Value:** Integer.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN6+, Moz1+, Safari1+

The `index` value of any single option in a `select` object likely is a redundant value in your scripting. Because you cannot access the option without knowing the `index` anyway (in brackets as part of the `options[index]` array reference), you have little need to extract the `index` value. The value is a property of the item just the same.

The following statement assigns the `index` integer of the first option of a `select` element named `listName` to a variable named `itemIndex`.

```
var itemIndex = document.forms[0].listName.options[0].index;
```

**Related Item:** `options` property.

**select.options[index].selected**

## options[ index ].selected

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

As mentioned earlier in the discussion of this object, better ways exist for determining which option a user selects from a list than looping through all options and examining the `selected` property. An exception to that “rule” occurs when you set up a list box to enable multiple selections. In this situation, the `selectedIndex` property returns an integer of only the topmost item selected. Therefore, your script needs to look at the `true` or `false` values of the `selected` property for each option in the list and determine what to do with the text or value data.

To accumulate a list of all items selected by the user, the `seeList()` function in Listing 24-4 systematically examines the `options[index].selected` property of each item in the list. The text of each item whose `selected` property is `true` is appended to the list. I add the “\n” inline carriage returns and spaces to make the list in the alert dialog box look nice and indented. If you assign other values to the `value` attributes of each option, the script can extract the `options[index].value` property to collect those values instead.

**Listing 24-4: Cycling through a Multiple-Selection List**

```

<html>
  <head>
    <title>Accessories List</title>
    <script type="text/javascript">
      function seeList(form) {
        var result = "";
        for (var i = 0; i < form.acList.length; i++) {
          if (form.acList.options[i].selected) {
            result += "\n  " + form.acList.options[i].text;
          }
        }
        alert("You have selected:" + result);
      }
    </script>
  </head>
  <body>
    <form>
      <p>Control/Command-click on all accessories you use: <select
        name="acList" size="9" multiple="multiple">
          <option selected="selected">Color Monitor</option>
          <option>Modem</option>
          <option>Scanner</option>
          <option>Laser Printer</option>
          <option>Tape Backup</option>
          <option>MO Drive</option>
          <option>Video Camera</option>
        </select></p>
      <p><input type="button" value="View Summary..."
        onclick="seeList(this.form)" /></p>
    </form>
  </body>
</html>

```

**Related Items:** options[ index ].text, options[ index ].value, selectedIndex properties.

**select.options[index].value****options[ index ].text****Value:** String.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The `text` property of an option is the text of the item as it appears in the list. If you can pass that wording along with your script to perform appropriate tasks, this property is the one you want to extract for further processing. But if your processing requires other strings associated with each option, assign a `value` attribute in the definition and extract the `options[ index ].value` property (see Listing 24-6).

To demonstrate the `text` property of an option, Listing 24-5 applies the text from a selected option to the `document.backgroundColor` property of a document in the current window. The color names are part of the collection built into all scriptable browsers; fortunately, the values are case-insensitive so that you can capitalize the color names displayed and assign them to the property.

**Listing 24-5: Using the options[index].text Property**

```
<html>
  <head>
    <title>Color Changer 1</title>
    <script type="text/javascript">
      function seeColor(form) {
        var newColor =
          (form.colorsList.options[form.colorsList.selectedIndex].text);
        document.backgroundColor = newColor;
      }
    </script>
  </head>
  <body>
    <form>
      <p>Choose a background color: <select name="colorsList">
        <option selected="selected">Gray</option>
        <option>Lime</option>
        <option>Ivory</option>
        <option>Red</option>
      </select></p>
      <p><input type="button" value="Change It"
        onclick="seeColor(this.form)" /></p>
    </form>
  </body>
</html>
```

**Related Item:** `options[index].value` property.**options[ index ].value****Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

In many instances, the words in the options list appear in a form that is convenient for the document's users but inconvenient for the scripts behind the page. Rather than set up an elaborate lookup routine to match the `selectedIndex` or `options[ index ].text` values with

**select.options[index].value**

the values your script needs, you can easily store those values in the `value` attribute of each `<option>` definition of the `select` object. You can then extract those values as needed.

You can store any string expression in the `value` attributes. That includes URLs, object properties, or even entire page descriptions that you want to send to a `parent.frames[index].document.write()` method.

Starting with IE4 and W3C browsers, the `select` element object itself has a `value` property that returns the `value` property of the selected option. But for backward compatibility, be sure to use the longer approach shown in the example in Listing 24-6.

Listing 24-6 requires the option text that the user sees to be in familiar, multiple-word form. But to set the color using the browser's built-in color palette, you must use the one-word form. Those one-word values are stored in the `value` attributes of each `<option>` definition. The function then reads the `value` property, assigning it to the `bgColor` of the current document. If you prefer to use the hexadecimal triplet form of color specifications, those values are assigned to the `value` attributes (`<option value="#e9967a">Dark Salmon`).

### Listing 24-6: Using the options[index].value Property

```
<html>
  <head>
    <title>Color Changer 2</title>
    <script type="text/javascript">
      function seeColor(form) {
        var newColor =
          (form.colorsList.options[form.colorsList.selectedIndex].value);
        document.bgColor = newColor;
      }
    </script>
  </head>
  <body>
    <form>
      <p>Choose a background color: <select name="colorsList">
        <option selected="selected" value="cornflowerblue">
          Cornflower Blue</option>
        <option value="darksalmon">Dark Salmon</option>
        <option value="lightgoldenrodyellow">
          Light Goldenrod Yellow</option>
        <option value="seagreen">Sea Green</option>
      </select></p>
      <p><input type="button" value="Change It"
        onclick="seeColor(this.form)" /></p>
    </form>
  </body>
</html>
```

**Related Item:** `options[index].text` property.

**select.selectedIndex**

## selectedIndex

**Value:** Integer.

Read/Write

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

When a user clicks a choice in a selection list, the `selectedIndex` property changes to a zero-based number corresponding to that item in the list. The first item has a value of 0. This information is valuable to a script that needs to extract the value or text of a selected item for further processing.

You can use this information as a shortcut to getting at a selected option's properties. To examine a `select` object's `selected` property, rather than cycling through every option in a repeat loop, use the object's `selectedIndex` property to fill in the index value for the reference to the selected item. The wording gets kind of long; but from an execution standpoint, this methodology is much more efficient. Note, however, that when the `select` object is a multiple-style, the `selectedIndex` property value reflects the index of only the topmost item selected in the list.

To script the selection of a particular item, assign an integer value to the `select` element object's `selectedIndex` property, as shown in Listings 24-1 through 24-3.

In the `inspect()` function of Listing 24-7, notice that the value inside the `options` property index brackets is a reference to the object's `selectedIndex` property. Because this property always returns an integer value, it fulfills the needs of the index value for the `options` property. Therefore, if you select Green in the pop-up menu, `form.colorsList.selectedIndex` returns a value of 1; that reduces the rest of the reference to `form.colorsList.options[1].text`, which equals "Green."

### Listing 24-7: Using the selectedIndex Property

```
<html>
  <head>
    <title>Select Inspector</title>
    <script type="text/javascript">
      function inspect(form) {
        alert(form.colorsList.options[form.colorsList.selectedIndex].text);
      }
    </script>
  </head>
  <body>
    <form>
      <p><select name="colorsList">
        <option selected="selected">Red</option>
        <option value="Plants">Green</option>
        <option>Blue</option>
      </select></p>
      <p><input type="button" value="Show Selection"
        onclick="inspect(this.form)" /></p>
    </form>
  </body>
</html>
```

**Related Item:** `options` property.

**select.size****size****Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `size` property represents the `size` attribute setting for a `select` element object. You can modify the integer value of this property to change the number of options that are visible in a pick list without having to scroll.

The following statement uses the `size` property to set the number of visible items to 5:

```
document.forms[0].mySelect.size = 5;
```

**Related Item:** `multiple` property.**type****Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

Use the `type` property to help you identify a `select` object from an unknown group of form elements. The precise string returned for this property depends on whether the `select` object is defined as a single- (`select-one`) or multiple- (`select-multiple`) type.

**Related Item:** `form.elements` property.**value****Value:** String.

Read/Write (see text)

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The more recent browsers (and the W3C DOM) provide a `value` property for the `select` element object. This property returns the string assigned to the `value` attribute (or `value` property) of the currently selected `option` element. If you do not assign a string to the attribute or property, the `value` property returns an empty string. For these browser generations, you can use this shortcut reference to the `select` element object's `value` property instead of the longer version that requires a reference to the `selectedIndex` property and the `options` array of the element object.

The `seeColor()` function in Listing 24-6 that accesses the chosen value the long way can be simplified for newer browsers only with the following construction:

```
function seeColor(form) {
    document.bgColor = form.colorsList.value;
}
```

**Related Item:** `options[index].value` property.**Methods**`add(newOptionElementRef[, index])``add(newOptionElementRef, optionElementRef)``remove(index)`**Returns:** Nothing.**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

These methods represent the W3C approach to adding and removing option elements from a selection. The first parameter to each of the `add()` methods is the new `option` element object to be added to the selection. The second parameters differ due to variances in IE and

**select.onChange**

other W3C browsers. The first version of `add()` is the IE version, which allows you to specify an optional index position for the new option; the option is placed just before the index position or it is appended to the end of the selection list if no index is provided. The W3C approach is represented by the second `add()` method, which requires an `option` object reference as the second parameter. This reference is to an option already in the selection list; the new option is added just before the option or it is appended to the end of the selection list if `null` is passed as the second parameter.

The `remove()` method requires the index of the option to be removed, and simply removes the option from the selection list.

```
options[index].add(elementRef[, index])
options[index].remove()
```

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

These two IE-specific methods belong to the `options` array property of a `select` element object. See the discussion at the opening of the `select` element object earlier in this chapter to see how to use these methods and their counterparts in other browser versions and object models.

```
item(index)
namedItem("optionID")
```

**Returns:** `option` element reference.

**Compatibility:** WinIE5+, MacIE5+, NN-, Moz-, Safari-

The `item()` and `namedItem()` methods are IE-specific convenience methods that access `option` element objects nested inside a `select` object. In a sense, they provide shortcuts to referencing nested options without having to use the `options` array property and the indexing within that array.

The parameter for the `item()` method is an index integer value. For example, the following two statements refer to the same `option` element object:

```
document.forms[0].mySelect.options[2]
document.forms[0].mySelect.item(2)
```

If your script knows the ID of an `option` element, it can use the `namedItem()` method, supplying the string version of the ID as the parameter, to return a reference to that `option` element.

The following statement assigns an `option` element reference to a variable:

```
var oneOption = document.forms[0].mySelect.namedItem("option3_2");
```

**Related Item:** `options` property.

## Event handlers

### onChange

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

As a user clicks a new choice in a `select` object, the object receives a `change` event that the `onChange` event handler can capture. In examples earlier in this section (Listings 24-6 and 24-7, for example), the action is handed over to a separate button. This design may make sense in

**select.onChange**

some circumstances, especially when you use multiple `select` lists or any list box. (Typically, clicking a list box item does not trigger any action that the user sees.) But for most pop-up menus, triggering the action when the user makes a choice is desirable.

To bring a pop-up menu to life, add an `onChange` event handler to the `<select>` definition. If the user makes the same choice as previously selected, the `onChange` event handler is not triggered. In this case, you can still trigger an action via the `onclick` event handler; but this event works for the `select` object only in IE4+ and W3C browsers.

Listing 24-8 is a version of Listing 24-6 that invokes all action as the result of a user making a selection from the pop-up menu. The `onChange` event handler in the `<select>` tag replaces the action button. For this application — when you desire a direct response to user input — an appropriate method is to have the action triggered from the pop-up menu rather than by a separate action button.

Notice two other important changes. First, the `select` element now contains a blank first option. When a user visits the page, nothing is selected yet, so you should present a blank option to encourage the user to make a selection. The function also makes sure that the user selects one of the color-valued items before it attempts to change the background color.

Second, the `body` element contains an `onunload` event handler that resets the form. The purpose behind this is that if the user navigates to another page and uses the Back button to return to the page, the script-adjusted background color does not persist. I recommend you return the `select` element to its original setting. Unfortunately, the reset does not stick to the form in IE4 and IE5 for Windows (although this problem appears to be repaired in IE5.5+). Another way to approach this issue is to use the `onload` event handler to invoke `seeColor()`, passing as a parameter a reference to the `select` element. Thus, if the `select` element choice persists, the background color is adjusted accordingly after the page loads.

### Listing 24-8: Triggering a Color Change from a Pop-Up Menu

```
<html>
  <head>
    <title>Color Changer 2</title>
    <script type="text/javascript">
      function seeColor(list) {
        var newColor = (list.options[list.selectedIndex].value);
        if (newColor) {
          document.bgColor = newColor;
        }
      }
    </script>
  </head>
  <body onunload="document.forms[0].reset()">
    <form>
      <p>Choose a background color: <select name="colorsList"
        onchange="seeColor(this)">
        <option selected="selected" value=""></option>
        <option value="cornflowerblue">Cornflower Blue</option>
        <option value="darksalmon">Dark Salmon</option>
        <option value="lightgoldenrodyellow">
          Light Goldenrod Yellow</option>
        <option value="seagreen">Sea Green</option>
      </select></p>
    </form>
  </body>
</html>
```

### Syntax

Accessing option object properties:

```
(All)      [window.]document.formName.selectName.options[index].property |
           method([parameters])
(All)      [window.]document.formName.elements[index].options[index].property
           |
           method([parameters])
(All)      [window.]document.forms[index].selectName.options[index].property
           |
           method([parameters])
(All)      [window.]document.forms["formName"].selectName.options[index].property |
           method([parameters])
(All)      [window.]document.forms["formName"].elements[index].options[index].
           property | method([parameters])
(IE4+)     [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
           method([parameters])
(W3C)      [window.]document.forms[index].selectName.item(index).property |
           method([parameters])
(W3C)      [window.]document.forms["formName"].selectName.namedItem(elemID).
           property | method([parameters])
```

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

### About this object

option elements are nested inside select elements. Each option represents an item in the list of choices presented by the select element. Properties of the option element object let scripts inspect whether a particular option is currently selected or is the default selection. Other properties enable you to get or set the hidden value associated with the option as well as the visible text. For more details about the interaction between the select and option element objects, see the discussion about the select object earlier in this chapter as well as the discussion of the properties and methods associated with the options array returned by the select object's options property.

**option**

I discuss all backward-compatible `option` object properties (`defaultSelected`, `selected`, `text`, and `value`) among the `options` property descriptions in the `select` object section. The only items listed in this section are those that are unique to the `option` element object defined in newer browsers.

In NN3+ and IE4+, there is a provision for creating a new `option` object via an `Option` object constructor function. The syntax is as follows:

```
var newOption = new Option("text", "value");
```

Here, `text` is the string that is displayed for the item in the list, and `value` is the string assigned to the `value` property of the new option. This new `option` object is not added to a `select` object until you assign it to a slot in the `options` array of the `select` object. You can see an example of this approach to modifying options in Listing 24-1.

## Properties

### label

**Value:** String.

Read/Write

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `label` property corresponds to the HTML 4.01 `label` attribute of an `option` element. This attribute (and property) enables you to assign alternate text for an option. In MacIE5, any string assigned to the `label` attribute or corresponding property overrides the display of text found between the start and end tags of the `option` element. Therefore, you can assign content to both the attribute and tag, but only browsers adhering to the HTML 4.01 standard for this element display the value assigned to the label. Although the `label` property is implemented in NN6, the browser does not modify the option item's text to reflect the property's setting.

The following statement modifies the text that appears as the selected text in a pop-up list:

```
document.forms[0].mySelect.options[3].label = "Widget 9000";
```

If this option is the currently selected one, the text on the pop-up list at rest changes to the new label.

**Related Item:** `text` property.

## optgroup Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<ul style="list-style-type: none"> <li>formt</li> <li>label</li> </ul>		

†See "Text Input Object" (Chapter 23).

## Syntax

Accessing `optgroup` object properties:

```
(IE)           [window.]document.all.elemID.property | method([parameters])
(W3C)         [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

## About this object

An `optgroup` element in the HTML 4.01 specification enables authors to group options into subgroups within a `select` list. The label assigned to the `optgroup` element is rendered in the list as a non-selectable item, usually differentiated from the selectable items by some alternate display. In W3C browsers, `optgroup` items by default are shown in bold italic, while all `option` elements nested within an `optgroup` are indented but with normal font characteristics.

Browsers not recognizing this element ignore it. All options are presented as if the `optgroup` elements are not there.

## Properties

### label

**Value:** String.

Read/Write

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `label` property corresponds to the HTML 4.01 `label` attribute of an `optgroup` element. This attribute (and property) enables you to assign text to the label that encompasses a group of nested `option` elements in the pop-up list display.

#### Note

MacIE5 exhibits a bug that prevents scripts from assigning values to the last `optgroup` element inside a `select` element.

I present Listing 24-9 in the hope that Microsoft and Netscape will eventually eradicate the bugs that afflict their current implementations of the `label` property. When the feature works as intended, Listing 24-9 demonstrates how a script can alter the text of option group labels. This page is an enhanced version of the background color setters used in other examples of this chapter. Be aware that several versions of IE do not alter the last `optgroup` element's label, and NN6+ achieves only a partial change to the text displayed in the `select` element.

### Listing 24-9: Modifying `optgroup` Element Labels

```
<html>
  <head>
    <title>Color Changer 3</title>
    <script type="text/javascript">
      var regularLabels = ["Reds", "Greens", "Blues"];
      var naturalLabels = ["Apples", "Leaves", "Sea"];
    </script>
  </head>
</html>
```

*Continued*

**optgroup.label****Listing 24-9 (continued)**

```

function setRegularLabels(list) {
    var optGrps = list.getElementsByTagName("optgroup");
    for (var i = 0; i < optGrps.length; i++) {
        optGrps[i].label = regularLabels[i];
    }
}
function setNaturalLabels(list) {
    var optGrps = list.getElementsByTagName("optgroup");
    for (var i = 0; i < optGrps.length; i++) {
        optGrps[i].label = naturalLabels[i];
    }
}
function seeColor(list) {
    var newColor = (list.options[list.selectedIndex].value);
    if (newColor) {
        document.bgColor = newColor;
    }
}
</script>
</head>
<body onload="document.forms[0].reset()">
<form>
<p>Choose a background color: <select name="colorsList"
onchange="seeColor(this)">
<optgroup id="optGrp1" label="Reds">
<option value="#fff999">Light Red</option>
<option value="#ff3366">Medium Red</option>
<option value="#ff0000">Bright Red</option>
<option value="#660000">Dark Red</option>
</optgroup>
<optgroup id="optGrp2" label="Greens">
<option value="#ccff66">Light Green</option>
<option value="#99ff33">Medium Green</option>
<option value="#00ff00">Bright Green</option>
<option value="#006600">Dark Green</option>
</optgroup>
<optgroup id="optGrp3" label="Blues">
<option value="#ccffff">Light Blue</option>
<option value="#66ccff">Medium Blue</option>
<option value="#0000ff">Bright Blue</option>
<option value="#000066">Dark Blue</option>
</optgroup>
</select></p>
<p><input type="radio" name="labels" checked="checked"

### Syntax

Accessing file input element object properties:

```
(NN3+/IE4+) [window.]document.formName.inputName.property |
method([parameters])
(NN3+/IE4+) [window.]document.formName.elements[index].property |
method([parameters])
(NN3+/IE4+) [window.]document.forms[index].inputName.property |
method([parameters])
(NN3+/IE4+) [window.]document.forms["formName"].inputName.property |
method([parameters])
(NN3+/IE4+) [window.]document.forms["formName"].elements[index].property |
method([parameters])
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

### About this object

Some Web sites enable you to upload files from the client to the server, typically by using a form-style submission to a CGI program on the server. The `input` element whose `type` is set to "file" (also known as a `fileUpload` object) is merely a user interface that enables users to specify which file on their PC they want to upload. Without a server process capable of receiving the file, the `file` input element does nothing. Moreover, you must also set two `form` element attributes as follows:

```
method="POST"
enctype="multipart/form-data"
```

This element displays a field and a Browse button. The Browse button leads to an Open File dialog box (in the local operating system's interface vernacular) where a user can select a file.

**document.formObject.fileInputObject**

After you make a selection, the filename (or pathname, depending on the operating system) appears in the `file` input element's field. The `value` property of the object returns the filename.

You do not have to script much for this object on the client side. The `value` property, for example, is read-only in earlier browsers; in addition, a form cannot surreptitiously upload a file to the server without the user's knowledge or consent.

Listing 24-10 helps you see what the `file` input element looks like in an example page.

**Listing 24-10: file Input Element**

```
<html>
  <head>
    <title>FileUpload Object</title>
  </head>
  <body>
    <form method="POST" action="yourCGIURL" enctype="multipart/form-data">
      File to be uploaded: <input type="file" size="40" name="fileToGo" />
      <p><input type="button" value="View Value"
        onclick="alert(this.form.fileToGo.value)" /></p>
    </form>
  </body>
</html>
```

In a true production environment, a Submit button and a URL to your CGI process are specified for the `action` attribute of the `<form>` tag.

# Event Objects

---

**P**rior to version 4 browsers, user and system actions — events — were captured predominantly by event handlers defined as attributes inside HTML tags. For instance, when a user clicked a button, the `click` event triggered the `onclick` event handler in the tag. That handler may invoke a separate function or perform some inline JavaScript script. Even so, the events themselves were rather dumb: Either an event occurred or it didn't. Where an event occurred (that is, the screen coordinates of the pointer at the moment the mouse button was clicked) and other pertinent event tidbits (for example, whether a keyboard modifier key was pressed at the same time) were not part of the equation. Until version 4 browsers, that is.

While remaining fully backward-compatible with the event handler mechanism of old, version 4 browsers had the first event model that turned events into first-class objects whose properties automatically carry a lot of relevant information about the event when it occurs. These properties are fully exposed to scripts, allowing pages to respond more intelligently about what the user does with the page and its elements.

Another new aspect of version 4 event models was the notion of “event propagation.” It was possible to have an event processed by an object higher up the element containment hierarchy whenever it made sense to have multiple objects share one event handler. That the event being processed carried along with it information about the intended target, plus other golden information nuggets, made it possible for event handler functions to be smart about processing the event without requiring an event handler call to pass all kinds of target-specific information.

Unfortunately, the joy of this newly found power is tempered by the forces of object model incompatibility. No fewer than three event object models are in use today: the one initiated by, and unique to, NN4 (whose importance diminishes with each passing day as users migrate to other, newer browsers); the IE4+ model; and the model adopted by the W3C DOM Level 2 as implemented in NN6+/Moz1+/Safari1+. Many of these distinctions are addressed in the overviews of the object models in Chapter 15. In this chapter, you find out more about the actual event objects that contain all the “goodies.” Where possible, cross-browser concerns are addressed.

## Why “Events”?

Graphical user interfaces are more difficult to program than the “old-fashioned” command-line interface. With a command-line or menu-driven system, users were intentionally restricted in the

### In This Chapter

The “life” of an event object

Event support in different browser generations

Retrieving information from an event

types of actions they could take at any given moment. The world was very modal, primarily as a convenience to programmers who led users through rigid program structures.

That all changed in a graphical user interface, such as Windows, MacOS, XWindow System, and all others derived from the pioneering work of the Xerox Star system. The challenge for programmers is that a good user interface in this realm must make it possible for users to perform all kinds of actions at any given moment: roll the mouse, click a button, type a key, select text, choose a pull-down menu item, and so on. To accommodate this, a program (or, better yet, the operating system) must be on the lookout for any possible activity coming from all input ports, whether it be the mouse, keyboard, or network connection.

A common methodology to accomplish this at the operating system level is to look for any kind of event, whether it comes from user action or some machine-generated activity. The operating system or program then looks up how it should process each kind of event. Such events, however, must have some smarts about them so that the program knows what and where on the screen the event is.

## What an event knows (and when it knows it)

Although the way to reference an event object varies a bit among the three event models, the one concept they all share is that an event object is created the instant the event action occurs. For instance, if you click a button, an event object is created in the browser's memory. As the object is created, the browser assigns values to the object's properties — properties that reflect numerous characteristics of that specific event. For a `click` event, that information includes the coordinates of the click and which mouse button was used to generate the event. To be even more helpful, the browser does some quick calculations to determine that the coordinates of the `click` event coincide with the rectangular space of a button element on the screen. Therefore, the event object has as one of its properties a reference to the “screen thing” that you clicked on.

Most event object properties (all of them in some event models) are read-only, because an event object is like a snapshot of an event action. If the event model were to allow modification of event properties, performing both potentially useful and potentially unfriendly actions would be possible. For example, how frustrating would it be to a user to attempt to type into a text box only to have a keystroke modified after the actual key press and then have a totally different character appear in the text box? On the other hand, perhaps it may be useful in some situations to make sure that anything typed into a text box is converted to uppercase characters, no matter what is typed. Each event model brings its own philosophy to the table in this regard. For example, the IE4+ event model allows keyboard character events to be modified by script; the NN4 and W3C DOM event models do not.

Perhaps the most important aspect of an event object to keep in mind is that it exists only as long as scripts process the event. An event can trigger an event handler — usually a function. That function, of course, can invoke other functions. As long as statements are still executing in response to the event handler, the event object and all its properties are still “alive” and available to your scripts. But after the last script statement runs, the event object reverts to an empty object.

The reason an event object has such a brief life is that there can be only one event object at a time. In other words, no matter how complex your event handler functions are or how rapidly events fire, they are executed serially (for experienced programmers: there is one execution thread). The operating system buffers events that start to bunch up on each other. Except in rare cases in which the buffer gets full and events are not recorded, event handlers are executed in the order in which the events occur.

## The static Event object

Up to this point, the discussion has been about the event object (with a lowercase “e”), which is one instance of an event, with all the properties associated with that specific event action. In the NN4 and W3C DOM event models, there is also a static `Event` object (with an uppercase “E”). In the W3C DOM event model are additional subcategories of the `Event` object. These subcategories are all covered later in this chapter, but they are introduced here to draw the contrast between the event and `Event` objects. The former, as you’ve seen, is a transient object with details about a specific event action; the latter serves primarily as a holder of event-related constant values that scripts can use. The static `Event` object is always available to scripts inside any window or frame. If you want to see a list of all `Event` object properties in NN4 and NN6+, use The Evaluator (Chapter 13): enter `Event` into the bottom text box (also check out the `KeyEvent` object in NN6+).

The static `Event` object also turns out to be the object from which event objects are cloned. Thus, the static `Event` object has a number of properties and methods that apply to (are inherited by) the event objects created by event actions. These relationships are more important in the W3C DOM event model, which builds upon the DOM’s object-oriented tendencies to implement the event model.

## Event Propagation

Prior to version 4 browsers, an event fired on an object. If an event handler was defined for that event and that object, the handler executed; if there was no event handler, the event just disappeared into the ether. Newer browsers, however, send events on a longer ride, causing them to propagate through the document object models. As you know by now, three propagation models exist, one for each of the event models in use today: NN4, IE4+, and W3C DOM as implemented in NN6+/Moz1+/Safari1+. Conceptually, the NN4 and IE4+ propagation models are diametrically opposite each other — any NN4 event propagates inward toward the target, whereas an IE event starts at the target and propagates outward. But the W3C DOM model manages to implement both models simultaneously, albeit with all new syntax so as not to step on the older models.

At the root of all three models is the notion that every event has a target. For user-initiated actions, this is fairly obvious. If you click a button or type in a text box, that button is the target of your mouse-related event; the text box is the target of your keyboard event. System-generated events are not so obvious, such as the `onload` event after a page finishes loading. In all event models, this event fires on the `window` object. What distinguishes the event propagation models is how an event reaches its target, and what, if anything, happens to the event after it finishes executing the event handler associated with the target.

### NN4-only event propagation

Although the installed base of NN4 has largely given way to newer browsers, its propagation model initiated some concepts that are found in the modern W3C DOM event propagation model. The name for the model is *event capture*.

In NN4, all events propagate from the top of the document object hierarchy (starting with the `window` object) downward to the target object. For example, if you click a button in a form, the `click` event passes through the `window` and `document` (and, if available, `layer`) objects before reaching the button (the `form` object is not part of the propagation path). This propagation happens instantaneously, so that there is no performance penalty by this extra journey.

The event that passes through the `window`, `document`, and `layer` objects is a fully formed event object, complete with all properties relevant to that event action. Therefore, if the event were processed at the window level, one of the event object's properties is a reference to the target object, so that the event handler scripts at the window level can find out information, such as the name of the button, and even get a reference to its enclosing form.

By default, event capture is turned off. To instruct the `window`, `document`, or `layer` object levels to process that passing click object requires turning on event capture for the `window`, `document`, and/or `layer` object.

### Enabling NN4 event capture

All three objects just mentioned—`window`, `document`, and `layer`—have a `captureEvents()` method. You use this method to enable event capture at any of those object levels. The method requires one or more parameters, which are the event types (as supplied by `Event` object constants) that the object should capture, while letting all others pass untouched. For example, if you want the `window` object to capture all `keypress` events, you include the following statement in a script that executes as the page loads:

```
window.captureEvents(Event.KEYPRESS);
```

Defining event handlers in the intended targets is also a good idea, even if they are empty (for example, `onkeypress=""`) to help NN4 generate the event in the first place. If you want the `window` to capture multiple event types, string the event type constants together, separated by the pipe character:

```
window.captureEvents(Event.KEYPRESS | Event.CLICK);
```

Now you must assign an action to the event at the window's level for each event type. More than likely, you have defined functions to execute for the event. Assign a function reference to the event handler by setting the handler property of the `window` object:

```
window.onkeypress = processKeyEvent;  
window.onclick = processClickEvent;
```

Hereafter, if a user clicks a button or types into a field inside that window, the events are processed by their respective window-level event handler functions.

### Turning off event capture

As soon as you enable event capture for a particular event type in a document, that capture remains in effect until the page unloads or you specifically disable the capture. You can turn off event capture for each event via the `window`, `document`, or `layer` `releaseEvents()` method. The `releaseEvents()` method takes the same kind of parameters—`Event` object type constants—as the `captureEvents()` method.

The act of releasing an event type simply means that events go directly to their intended targets without stopping elsewhere for processing, even if an event handler for the higher-level object is still defined. And because you can release individual event types based on parameters set for the `releaseEvents()` method, other events being captured are not affected by the release of others.

To demonstrate not only the `captureEvents()` and `releaseEvents()` methods, but other event model techniques, I present a series of several versions of the same document. Each successive version implements an added feature to help you experience the numerous interactions among events and event handling methods. The document merely contains a few buttons, plus some switches to enable and disable various methods being demonstrated in the section. A `layer` object is also thrown into the mixture because a lot of impetus for capturing and modifying event handling comes from application of layers in a document.

Listing 25-1 is the first example, which shows the basic event capture and release from the outermost document level. A checkbox lets you enable or disable the document-level capture of `click` events (all checkboxes in these examples use `onmousedown` event handlers to avoid getting in the way of tracing `click` events). Because all `click` events are being captured by the outermost document, even clicks to the layer's buttons get trapped by the outermost document when `captureEvents()` is set.

### Listing 25-1: Event Capture and Release

```
<html>
  <head>
    <title></title>
    <script type="text/javascript">
      function setDocCapture(enable) {
        if (!enable) {
          document.captureEvents(Event.CLICK);
        } else {
          document.releaseEvents(Event.CLICK);
        }
      }
      function doMainClick(e) {
        if (e.target.type == "button") {
          alert("Captured in top document");
        }
      }
      document.captureEvents(Event.CLICK);
      document.onclick=doMainClick;
    </script>
  </head>
  <body>
    <b>Basic document-level capture of Event.CLICK</b>
    <hr />
    <form>
      <input type="checkbox" onmousedown="setDocCapture(this.checked)"
        checked="checked" />Enable Document Capture
    <hr />
    <input type="button" value="Button 'main1'" name="main1"
      onclick="alert('Event finally reached Button:' + this.name)" />
    </form>
    <layer id="layer1" left="200" top="150" bgcolor="coral">
      <form>
        <br />
        <p><input type="button" value="Button 'layerButton1'"
          name="layerButton1"
          onclick="alert('Event finally reached Button:' + this.name)" />
        </p>
        <p><input type="button" value="Button 'layerButton2'"
          name="layerButton2"
          onclick="alert('Event finally reached Button:' + this.name)" />
        </p>
      </form>
    </layer>
  </body>
</html>
```

With document-level event capture turned on (the default), all `click` events are trapped by the document's `onclick` event handler property, a function that alerts the user that the event was captured by the top document. Because all `click` events for buttons are trapped there, even `click` events of the layer's buttons are trapped at the top. But if you turn off event capture, the events reach their intended targets.

**Note**

If the logic of the `setDocCapture()` function seems backward to you, recall that when the `onmousedown` event fires on the checkbox, its state is the opposite of what it is being changed to.

In Listing 25-2, I add some code (shown in boldface) that lets the `layer` object capture `click` events whenever the outer document event capture is turned off. Inside the `<layer>` tag, a script sets the layer to capture `click` events. Therefore, if you disable the outer document capture, the `click` event goes straight to the `main1` button and to the layer event capture. Event capture in the `layer` object prevents the events from ever reaching the buttons in the layer, unless you disable event capture for both the document and the layer.

### Listing 25-2: Document and Layer Event Capture and Release

```
<html>
  <head>
    <title></title>
    <script type="text/javascript">
      function setDocCapture(enable) {
        if (!enable) {
          document.captureEvents(Event.CLICK);
        } else {
          document.releaseEvents(Event.CLICK);
        }
      }
      function setLayerCapture(enable) {
        if (!enable) {
          document.layer1.captureEvents(Event.CLICK);
        } else {
          document.layer1.releaseEvents(Event.CLICK);
        }
      }
      function doMainClick(e) {
        if (e.target.type == "button") {
          alert("Captured in top document");
        }
      }
      document.captureEvents(Event.CLICK);
      document.onclick=doMainClick;
    </script>
  </head>
  <body>
    <b>Document-level and/or Layer-level capture of Event.CLICK</b>
    <hr />
    <form>
      <input type="checkbox" onmousedown="setDocCapture(this.checked)"
        checked="checked" />Enable Document Capture
      <input type="checkbox" onmousedown="setLayerCapture(this.checked)"
        checked="checked" />Enable Layer Capture
    <hr />
  </body>
</html>
```

```

        <input type="button" value="Button 'main1'" name="main1"
            onclick="alert('Event finally reached Button:' + this.name)" />
    </form>
    <layer id="layer1" left="200" top="150" bgcolor="coral">
        <script type="text/javascript">
            function doLayerClick(e) {
                if (e.target.type == "button") {
                    alert("Captured in layer1");
                }
            }
            layer1.captureEvents(Event.CLICK);
            layer1.onclick=doLayerClick;
        </script>
    </form>
    &#160;layer1<br />
    <p><input type="button" value="Button 'layerButton1'"
        name="layerButton1"
        onclick="alert('Event finally reached Button:' + this.name)" />
    </p>
    <p><input type="button" value="Button 'layerButton2'"
        name="layerButton2"
        onclick="alert('Event finally reached Button:' + this.name)" />
    </p>
</form>
</layer>
</body>
</html>

```

## Passing events toward their targets

If you capture a particular event type, your script may need to perform some limited processing on that event before letting it reach its intended target. For example, perhaps you want to do something special if a user clicks an element with the Shift meta key pressed. In that case, the function that handles the event at the document level inspects the event's `modifiers` property to determine if the Shift key was pressed at the time of the event. If the Shift key was not pressed, you want the event to continue on its way to the element that the user clicked.

To let an event pass through the object hierarchy to its target, you use the `routeEvent()` method, passing as a parameter the event object being handled in the current function. A `routeEvent()` method does not guarantee that the event will reach its intended destination, because another object in between may have event capturing for that event type turned on and will intercept the event. That object, too, can let the event pass through with its own `routeEvent()` method.

Listing 25-3 demonstrates event routing by adding onto the document being built in previous examples. While the clickable button objects are the same, additional powers are added to the document and layer function handlers that process events that come their way. For each of these event-capturing objects, you have additional checkbox settings to allow or disallow events from passing through after each level has processed them.

The default settings for the checkboxes are like the ones in Listing 25-2, where event capture (for the `click` event) is set for both the document and layer objects. Clicking any button causes the document object's event handler to process and none other. But if you then enable the checkbox that lets the event continue, you find that click events on the layer buttons cause alerts to display from both the document and layer object event handler functions. If you then also let events continue from the layer object, a click on the button displays a third

alert, showing that the event has reached the buttons. Because the `main1` button is not in the `layer`, none of the `layer` object event handling settings affect its behavior.

### Listing 25-3: Capture, Release, and Route Events

```
<html>
  <head>
    <title></title>
    <script type="text/javascript">
      function setDocCapture(enable) {
        if (!enable) {
          document.captureEvents(Event.CLICK);
        } else {
          document.releaseEvents(Event.CLICK);
          document.forms[0].setDocRte.checked = false;
          docRoute = false;
        }
      }
      function setLayerCapture(enable) {
        if (!enable) {
          document.layer1.captureEvents(Event.CLICK);
        } else {
          document.layer1.releaseEvents(Event.CLICK);
          document.forms[0].setLyrRte.checked = false;
          layerRoute = false;
        }
      }
      var docRoute = false;
      var layerRoute = false;
      function setDocRoute(enable) {
        docRoute = !enable;
      }
      function setLayerRoute(enable) {
        layerRoute = !enable;
      }
      function doMainClick(e) {
        if (e.target.type == "button") {
          alert("Captured in top document");
          if (docRoute) {
            routeEvent(e);
          }
        }
      }
      document.captureEvents(Event.CLICK);
      document.onclick=doMainClick;

</html>

```

In some cases, your scripts need to know if an event that is passed onward by the `routeEvent()` method activated a function that returns a value. This knowledge is especially valuable if your event must return a `true` or `false` value to let an object know if it should proceed with its default behavior (for example, whether a link should activate its `href` attribute URL or cancel after the event handler evaluates to return `true` or return `false`). When a function is invoked by the action of a `routeEvent()` method, the return value of the destination function is passed back to the `routeEvent()` method. That value, in turn, can be returned to the object that originally captured the event.

### Event traffic cop

The last scenario is one in which a higher-level object captures an event and directs the event to a particular object elsewhere in the hierarchy. For example, you could have a document-level event handler function direct every `click` event whose `modifiers` property indicates that the Alt key was pressed to a Help button object whose own `onclick` event handler displays a help panel (perhaps shows an otherwise hidden layer).

You can redirect an event to any object via the `handleEvent()` method. This method works differently from the others described in this chapter, because the object reference of this

method is the reference of the object to handle the event (with the event object being passed as a parameter, such as the other methods). As long as the target object has an event handler defined for that event, it will process the event as if it had received the event directly from the system (even though the event object's target property may be some other object entirely).

To demonstrate how this event redirection works, Listing 25-4 includes the final additions to the document being built so far in this chapter. The listing includes mechanisms that allow all click events to be sent directly to the second button in the layer (`layerButton2`). The previous interaction with document and layer event capture and routing is still intact, although you cannot have event routing and redirection on at the same time.

The best way to see event redirection at work is to enable both document and layer event capture (the default settings). When you click the `main1` button, the event reaches only as far as the document-level capture handler. But if you then turn on the “Send event to ‘layerButton2’” checkbox associated with the document level, a click of the `main1` button reaches both the document-level event handler and `layerButton2`, even though the `main1` button is not anywhere near the layer button in the document object hierarchy. Click other checkboxes to work with the interaction of event capturing, routing, and redirection.

#### Listing 25-4: Redirecting Events

```
<html>
  <head>
    <title></title>
    <script type="text/javascript">
      function setDocCapture(enable) {
        if (!enable) {
          document.captureEvents(Event.CLICK);
        } else {
          document.releaseEvents(Event.CLICK);
          document.forms[0].setDocRte.checked = false;
          docRoute = false;
        }
      }
      function setLayerCapture(enable) {
        if (!enable) {
          document.layer1.captureEvents(Event.CLICK);
        } else {
          document.layer1.releaseEvents(Event.CLICK);
          document.forms[0].setLyrRte.checked = false;
          layerRoute = false;
        }
      }
      var docRoute = false;
      var layerRoute = false;
      function setDocRoute(enable) {
        docRoute = !enable;
        document.forms[0].setDocShortCircuit.checked = false;
        docShortCircuit = false;
      }
      function setLayerRoute(enable) {
        layerRoute = !enable;
      }
    </script>
  </head>

      onclick="alert('Event finally reached Button:' + this.name)" />
    </p>
  </form>
</layer>
</body>
</html>

```

## IE4+ event propagation

IE's event propagation model is called *event bubbling*, in which events “bubble” upward from the target object through the HTML element containment hierarchy. It's important to distinguish between the old-fashioned document object hierarchy (followed in the NN4 event capture model) and the more modern notion of HTML element containment — a concept that carries to the W3C DOM as well.

A good way to demonstrate the effect of event bubbling — a behavior that is turned on by default — is to populate a simple document with lots of event handlers to see which ones fire and in what order. Listing 25-5 has `onclick` event handlers defined for a button inside a form, the form itself, and other elements and objects all the way up the hierarchy out to the window.

## Listing 25-5: Event Bubbling Demonstration

```

<html onclick="alert('Event is now at the HTML element.')">
  <head>
    <title>Event Bubbles</title>
    <script type="text/javascript">

```

```

function init() {
window.onclick = winEvent
  document.onclick = docEvent;
  document.body.onclick = docBodEvent;
}
function winEvent() {
  alert("Event is now at the window object level.");
}
function docEvent() {
  alert("Event is now at the document object level.");
}
function docBodEvent() {
  alert("Event is now at the BODY element.");
}
</script>
</head>
<body onload="init()">
  <h1>Event Bubbles</h1>
  <hr />
  <form onclick="alert('Event is now at the FORM element.')">
    <input type="button" value="Button 'main1'" name="main1"
      onclick="alert('Event started at Button: ' + this.name)" />
  </form>
</body>
</html>

```

You can try this listing in IE4+ and even NN6+ or Safari, because W3C DOM browsers also observe event bubbling. But you will notice differences in the precise propagation among WinIE4+, MacIE4+, and W3C DOM browsers. But first, notice that after you click the button in Listing 25-5, the event first fires at the target: the button. Then the event bubbles upward through the HTML containment to fire at the enclosing `form` element; next to the enclosing `body` element; and so on. Where the differences occur are after the `body` element. Table 25-1 shows the objects for which event handlers are defined in Listing 25-5 and which objects have the `click` event bubble to them in the three classes of browsers.

**Table 25-1: Event Bubbling Variations for Listing 25-5**

<i>Event Handler Location</i>	<i>WinIE4+</i>	<i>MacIE4+</i>	<i>NN6+/Moz1+/Safari</i>
button	yes	yes	yes
form	yes	yes	yes
body	yes	yes	yes
HTML	yes	no	yes
document	yes	yes	yes
window	no	no	yes

Despite the discrepancies in Table 25-1, events do bubble through the most likely HTML containers that come to mind. The object level with the most global scope and that works in all browser categories shown in the table is the `document` object.

## Preventing IE event bubbling

Because bubbling occurs by default, there are times when you may prefer to prevent an event from bubbling up the hierarchy. For example, if you have one handler at the `document` level whose job is to deal with the `click` event from a related series of buttons, any other object that receives `click` events will allow those events to bubble upward to the `document` level unless the bubbling is cancelled. Having the event bubble up could conflict with the document-level event handler.

Each event object in IE has a property called `cancelBubble`. The default value of this property is `false`, which means that the event bubbles to the next outermost container that has an event handler for that event. But if, in the execution of an event handler, that property is set to `true`, the processing of that handler finishes its job, but the event does not bubble up any higher. Therefore, to stop an event from bubbling beyond the current event handler, include the following statement somewhere in the handler function:

```
event.cancelBubble = true;
```

You can prove this to yourself by modifying the page in Listing 25-5 to cancel bubbling at any level. For example, if you change the event handler of the `form` element to include a statement that cancels bubbling, the event goes no further than the `form` in IE (the syntax is different for NN6+/Moz1+, as discussed later):

```
<form onclick="alert('Event is now at the form element.');"
  event.cancelBubble=true">
```

## Preventing IE event default action

In the days when events were almost always bound to elements by way of attributes in tags, the technique to block the event's default action was to make sure the event handler evaluated to return `false`. This is how, for instance, a `form` element's `onsubmit` event handler could prevent the form from carrying out the submission if client-side form validation failed.

To enhance that capability—especially when events are bound by other means, such as object element properties—IE's event object includes a `returnValue` property. Assign `false` to this property in the event handler function to block the element's default action to the event:

```
event.returnValue = false;
```

This way of blocking default actions in IE is often more effective than the old `return false` technique.

## Redirecting events

Starting with IE5.5, you can redirect an event to another element, but with some limitations. The mechanism that makes this possible is the `fireEvent()` method of all HTML element objects (see Chapter 15). This method isn't so much redirecting an event as causing a brand-new event to be fired. But you can pass most of the properties of the original event object with the new event by specifying a reference to the old event object as the optional second parameter to the `fireEvent()` method.

The big limitation in this technique, however, is that the reference to the target element gets lost in this hand-off to the new event. The `srcElement` property of the old event gets overwritten with a reference to the object that is the target of the call to `fireEvent()`. For example, consider the following `onclick` event handler function for a button inside a `form` element:

```
function buttonEvent() {
    event.cancelBubble = true;
    document.body.fireEvent("onclick", event);
}
```

By cancelling event bubbling, the event does not propagate upward to the enclosing form element. Instead, the event is explicitly redirected to the `body` element, passing the current event object as the second parameter. When the event handler function for the `body` element runs, its event object has information about the original event, such as the mouse button used for the click and the coordinates. But the `event.srcElement` property points to the `document.body` object. As the event bubbles upward from the `body` element, the `srcElement` property continues to point to the `document.body` object. You can see this at work in Listing 25-6 for IE5.5+.

### Listing 25-6: Cancelling and Redirecting Events in IE5.5+

```
<html onclick="revealEvent('HTML', event)">
<head>
  <title>Event Cancelling & Redirecting</title>
  <script type="text/javascript">
    // display alert with event object info
    function revealEvent(elem, evt) {
      var msg = "Event (from " + evt.srcElement.tagName + " at ";
      msg += event.clientX + "," + event.clientY + ") is now at the ";
      msg += elem + " element.";
      alert(msg);
    }
    function init() {
      document.onclick = docEvent;
      document.body.onclick = docBodEvent;
    }
    function docEvent() {
      revealEvent("document", event);
    }
    function docBodEvent() {
      revealEvent("BODY", event);
    }
    function buttonEvent(form) {
      revealEvent("BUTTON", event);
      // cancel if checked (IE4+)
      event.cancelBubble = form.bubbleCancelState.checked;
      // redirect if checked (IE5.5+)
      if (form.redirect.checked) {
        document.body.fireEvent("onclick", event);
      }
    }
  </script>
</head>
<body onload="init()">
  <h1>Event Cancelling & Redirecting</h1>
  <hr />
  <form onclick="revealEvent('FORM', event)">
    <p><button name="main1" onclick="buttonEvent(this.form)">Button
      'main1'</button></p>
```

*Continued*

**Listing 25-6 (continued)**

```

    <p><input type="checkbox" name="bubbleCancelState"
      onclick="event.cancelBubble=true" />Cancel Bubbling at BUTTON<br />
      <input type="checkbox" name="redirect"
      onclick="event.cancelBubble=true" /> Redirect Event to BODY</p>
  </form>
</body>
</html>

```

Listing 25-6 is a modified version of Listing 25-5. Major additions are enhanced event handlers at each level so that you can see the tag name of the event that is regarded as the `srcElement` of the event as well as the coordinates of the `click` event. With both checkboxes unchecked, events bubble upward from the button, and the `button` element is then shown to be the original target all the way up the bubble hierarchy. If you check the Cancel Bubbling checkbox, the event goes no further than the `button` element, because that's where event bubbling is turned off. If you then check the Redirect Event to body checkbox, the original event is cancelled at the `button` level, but a new event is fired at the `body` element. But notice that by passing the old event object as the second parameter, the click location properties of the old event are applied to the new event directed at the `body`. This event then continues to bubble upward from the `body`.

As a side note, if you uncheck the Cancel Bubbling checkbox but leave the Redirect Event box checked, you can see how the redirection is observed at the end of the `button`'s event handler, and something special goes on. The original event is held aside by the browser while the redirected event bubbles upward. As soon as that event-processing branch finishes, the original bubbling propagation carries on with the `form`. Notice, though, that the event object still knows that it was targeted at the `button` element, and the other properties are intact. This means that for a time, two event objects were in the browser's memory, but only one is "active" at a time. While the redirected event is propagating, the `window.event` object refers to that event object only.

## Applying event capture

WinIE 5 and later also provide a kind of event capture, which overrides all other event propagation. Intended primarily for temporary capture of mouse events, it is controlled not through the event object but via the `setCapture()` and `releaseCapture()` methods of all HTML element objects (described in Chapter 15).

When you engage capture mode, all mouse events are directed to the element object that invoked the `setCapture()` method, regardless of the actual target of the event. This action facilitates such activities as element dragging so that mouse events that might fire outside of the intended target (for example, when dragging the cursor too fast for the animation to track) continue to go to the target. When the drag mode is no longer needed, invoke the `releaseCapture()` method to allow mouse events to propagate normally.

## W3C event propagation

Yielding to arguments in favor of both NN4's event capture and IE's event bubbling, the W3C DOM group managed to assemble an event model that employs both propagation systems. Although forced to use new syntax so as not to conflict with older browsers, the W3C DOM propagation model works like the NN4 one for capture and like IE4+ for bubbling. In other

words, an event bubbles by default, but you can also turn on event capture if you want. Thus, an event first trickles down the element containment hierarchy to the target; then it bubbles up through the reverse path.

Event bubbling is on by default, just as in IE4+. To enable capture, you must apply a W3C DOM event listener to an object at some higher container. Use the `addEventListener()` method (see Chapter 15) for any visible HTML element or node. One of the parameters of the `addEventListener()` method determines whether the event listener function should be triggered while the event is bubbling or is captured.

Listing 25-7 is a simplified example that demonstrates how a `click` event aimed at a button can be both captured and allowed to bubble. Most event handling functions are assigned inside the `init()` function. Borrowing code from Listing 25-5, event handlers are assigned to the `window`, `document`, and `body` objects as property assignments. These are automatically treated as bubble-type event listeners. Next, two objects—the `document` and a `form`—are given capture-type event listeners for the `click` event. The `document` object event listener invokes the same function as the bubble-type event handler (the `alert` text includes some asterisks to remind you that it is the same `alert` being displayed in both the capture and bubble phases of the event). For the `form` object, however, the capture-type event listener is directed to one function, while a bubble-type listener for the same object is directed at a separate function. In other words, the `form` object invokes one function as the event trickles down to the target and another function when the event starts bubbling back up. Many of the event handler functions dynamically read the `eventPhase` property of the event object to reveal which phase of event propagation is in force at the instance the event handler is invoked (although an apparent bug reports the incorrect phase at the `document` object during event capture).

### Listing 25-7: NN6+ Event Capture and Bubble

```
<html>
  <head>
    <title>W3C DOM Event Propagation</title>
    <script type="text/javascript">
      function init() {
        // using old syntax to assign bubble-type event handlers
        window.onclick = winEvent;
        document.onclick = docEvent;
        document.body.onclick = docBodEvent;
        // turn on click event capture for document and form objects
        document.addEventListener("click", docEvent, true);
        document.forms[0].addEventListener("click", formCaptureEvent, true);
        // set event listener for bubble
        document.forms[0].addEventListener("click", formBubbleEvent, false);
      }
      function winEvent(evt) {
        alert("Event is now at the window object level (" +
          getPhase(evt) + ").");
      }
      function docEvent(evt) {
        alert("Event is now at the **document** object level (" +
          getPhase(evt) + ").");
      }
    </script>
  </head>
</html>
```

*Continued*

## Listing 25-7 (continued)

```

function docBodEvent(evt) {
    alert("Event is now at the BODY level (" + getPhase(evt) + ").");
}
function formCaptureEvent(evt) {
    alert("This alert triggered by FORM only on CAPTURE.");
}
function formBubbleEvent(evt) {
    alert("This alert triggered by FORM only on BUBBLE.");
}
// reveal event phase of current event object
function getPhase(evt) {
    switch (evt.eventPhase) {
        case 1:
            return "CAPTURING";
            break;
        case 2:
            return "AT TARGET";
            break;
        case 3:
            return "BUBBLING";
            break;
        default:
            return "";
    }
}
</script>
</head>
<body onload="init()">
<h1>W3C DOM Event Propagation</h1>
<hr />
<form>
    <input type="button" value="Button 'main1'" name="main1"
        onclick="alert('Event is now at the button object level (' +
            getPhase(event) + ').')" />
</form>
</body>
</html>

```

If you want to remove event capture after it has been enabled, use the `removeEventListener()` method on the same object as the event listener that was originally added (see Chapter 15). And, because multiple event listeners can be attached to the same object, specify the exact same three parameters to the `removeEventListener()` method as applied to the `addEventListener()` method.

### Preventing W3C event bubbling or capture

Corresponding to the `cancelBubble` property of the IE4+ event object is an event object method in the W3C DOM. The method that prevents propagation in any event phase is the `stopPropagation()` method. Invoke this method anywhere within an event listener handler function. The current function executes to completion, but the event propagates no further.

Listing 25-8 extends the example of Listing 25-7 to include two checkboxes that let you stop propagation type at the `form` element in your choice of the capture or bubble phase.

### Listing 25-8: Preventing Bubble and Capture

```
<html>
<head>
  <title>W3C DOM Event Propagation</title>
  <script type="text/javascript">
    function init() {
      // using old syntax to assign bubble-type event handlers
      window.onclick = winEvent;
      document.onclick = docEvent;
      document.body.onclick = docBodEvent;
      // turn on click event capture for two objects
      document.addEventListener("click", docEvent, true);
      document.forms[0].addEventListener("click", formCaptureEvent, true);
      // set event listener for bubble
      document.forms[0].addEventListener("click", formBubbleEvent, false);
    }
    function winEvent(evt) {
      if (evt.target.type == "button") {
        alert("Event is now at the window object level (" +
          getPhase(evt) + ").");
      }
    }
    function docEvent(evt) {
      if (evt.target.type == "button") {
        alert("Event is now at the **document** object level (" +
          getPhase(evt) + ").");
      }
    }
    function docBodEvent(evt) {
      if (evt.target.type == "button") {
        alert("Event is now at the BODY level (" + getPhase(evt) + ").");
      }
    }
    function formCaptureEvent(evt) {
      if (evt.target.type == "button") {
        alert("This alert triggered by FORM only on CAPTURE.");
        if (document.forms[0].stopAllProp.checked) {
          evt.stopPropagation();
        }
      }
    }
    function formBubbleEvent(evt) {
      if (evt.target.type == "button") {
        alert("This alert triggered by FORM only on BUBBLE.");
        if (document.forms[0].stopDuringBubble.checked) {
          evt.preventDefault();
        }
      }
    }
  }
</script>
</head>
<body>

## Listing 25-8 (continued)

```

// reveal event phase of current event object
function getPhase(evt) {
    switch (evt.eventPhase) {
        case 1:
            return "CAPTURING";
            break;
        case 2:
            return "AT TARGET";
            break;
        case 3:
            return "BUBBLING";
            break;
        default:
            return "";
    }
}
</script>
</head>
<body onload="init()">
<h1>W3C DOM Event Propagation</h1>
<hr />
<form>
    <input type="checkbox" name="stopAllProp" />Stop all propagation at
    FORM<br />
    <input type="checkbox" name="stopDuringBubble" />Prevent bubbling past
    FORM
<hr />
    <input type="button" value="Button 'main1'" name="main1"
    onclick="alert('Event is now at the button object level (' +
    getPhase(event) + ').')" />
</form>
</body>
</html>

```

In addition to the W3C DOM `stopPropagation()` method, NN6+, Moz1+, and Safari also support IE's `cancelBubble` property for syntactical convenience.

### Preventing W3C event default action

The W3C DOM counterpart to IE's `returnValue` property is the event object's `preventDefault()` method. Invoke this method in an event handler function when you wish to block the element's default action to the event:

```
evt.preventDefault();
```

### Redirecting W3C DOM events

The mechanism for sending an event to an object outside the normal propagation pattern in W3C is similar to that of IE4+, although with different syntax. In place of the IE4+ `fireEvent()` method, NN6+/Moz1+/Safari uses the W3C DOM `dispatchEvent()` method. The sole parameter of the method is an event object, such as the current event object. Listing 25-9 is the same

as the IE4+ Listing 25-6, but with just a few modifications to run in the W3C event model. Notice that the `dispatchEvent()` method passes the current event object as its sole parameter.

### Listing 25-9: Cancelling and Redirecting Events in the W3C DOM

```
<html onclick="revealEvent('HTML', event)">
  <head>
    <title>Event Cancelling & Redirecting</title>
    <script type="text/javascript">
      // display alert with event object info
      function revealEvent(elem, evt) {
        var msg = "Event (from " + evt.target.tagName + " at ";
        msg += evt.clientX + "," + evt.clientY + ") is now at the ";
        msg += elem + " element.";
        alert(msg);
      }
      function init() {
        document.onclick = docEvent;
        document.body.onclick = docBodEvent;
      }
      function docEvent(evt) {
        revealEvent("document", evt);
      }
      function docBodEvent(evt) {
        revealEvent("BODY", evt);
      }
      function buttonEvent(form, evt) {
        revealEvent("BUTTON", evt);
        // redirect if checked
        if (form.redirect.checked) {
          document.body.dispatchEvent(evt);
        }
        // cancel if checked
        if (form.bubbleCancelState.checked) {
          evt.stopPropagation();
        }
      }
    </script>
  </head>
  <body onload="init()">
    <h1>Event Cancelling & Redirecting</h1>
    <hr />
    <form onclick="revealEvent('FORM', event)">
      <p><button name="main1" onclick="buttonEvent(this.form, event)">Button
        'main1'</button></p>
      <p><input type="checkbox" name="bubbleCancelState"
        onclick="event.stopPropagation()" />Cancel Bubbling at BUTTON<br />
        <input type="checkbox" name="redirect"
        onclick="event.stopPropagation()" /> Redirect Event to BODY</p>
    </form>
  </body>
</html>
```

## Referencing the event object

While there may be essentially three different event object models in today's browsers, the way your scripts access those objects is divided into two camps: the IE way and the W3C (NN4+/Moz1+/Safari1+) way. I start with the simpler, IE way.

### IE4+ event object references

In IE4+, the `event` object is accessible as a property of the `window` object:

```
window.event
```

But, as you are well aware, the `window` part of references is optional, so your scripts can treat the `event` object as if it were a global reference:

```
event.propertyName
```

Thus, any statement in an event handler function can access the `event` object without any special preparation or initializations.

### W3C event object references

The situation is a bit more complicated in the W3C event model. In some cases you must explicitly pass the event object as a parameter to an event handler function, while in other cases, the event object is delivered as a parameter automatically. The difference depends on how the event handler function is bound to the object.

Using the original way of binding event handlers to objects — via an attribute in the element's tag — you must specify the event object as a parameter by passing `event` as a parameter, as in `onclick="doSomething(event)"`

This is the only time in the W3C model that you see an explicit reference to the `event` (lowercase “e”) object as if it were a global reference. This reference does not work in any other context — only as a parameter to an event handler function. If you have multiple parameters, the `event` reference can go in any order, but I tend to put it last:

```
onclick="doSomething(this, event)"
```

The function definition that is bound to the element should therefore have a parameter variable in place to “catch” the event object parameter:

```
function doSomething(widget, evt) {...}
```

You have no restrictions on how you name this parameter variable. In some examples of this book, you may see the variable assigned as `event` or, more commonly, `evt`. When working with cross-browser scripts, avoid using `event` as a parameter variable name so as not to interfere with IE's `event` property.

Other ways of binding event handler functions to objects — via property assignments and the W3C DOM `addEventListener()` method — assign references of those handlers to the desired objects in the document, as in either of the following:

```
document.forms[0].someButton.onclick = doSomething;  
document.getElementById("myButton").addEventListener("click", doSomething,  
    false);
```

Event binding through these approaches prevents explicit passage of your own parameters to the invoked functions. But W3C browsers automatically pass as the sole parameter a

reference to the event object created in response to the user or system action that triggered the event. This means that your functions should “receive” the passed event object in a parameter variable:

```
function doSomething(evt) {...}
```

Recall that the `event` object contains a reference to the object that was the target of the event. From that, you can access any properties of that object, such as the `form` object that contains a form control object.

You can see the way the `event` object is passed as a parameter in Listing 25-9. For all event handlers that are assigned by reference (both to an event handler property of an object and to an `addEventListener()` method call), the functions have a parameter variable in place to act as a reference to the event object for statements within the function. If you need to invoke other functions from there, you can pass the `event` object reference further along as needed. The `event` object retains its properties as long as the chain of execution triggered by the event action continues.

## event Object Compatibility

Despite the incompatible ways that W3C DOM and IE event objects arrive at an event handler function, you can easily stuff the object into one variable that both browser types can use. For example, the following function fragment receives a W3C DOM event object but also accommodates the IE event object:

```
function doSomething(evt) {
    evt = (evt) ? evt : ((window.event) ? window.event : null);
    if (evt) {
        // browser has an event to process
        ...
    }
}
```

If an event object arrives as a parameter, it continues to be available as `evt`; but if not, the function makes sure that a `window.event` object is available and assigns it to the `evt` variable; finally, if the browser doesn’t know about an event object, the `evt` variable is made `null`. Processing continues only if `evt` contains an event object.

That’s the easy part. The madness comes in the details: reading properties of the event object when the property names can vary widely across the three event object models. Sections later in this chapter provide details of each property and method of all three event object models, but seeing an overview of the property terminology on a comparative basis is helpful. Table 25-2 lists the common information bits and actions you are likely to want from an event object and the property or method names used in the three event object models.

**Table 25-2: Common event Object Properties and Methods**

<i>Property/Action</i>	<i>NN4</i>	<i>IE4+</i>	<i>W3C DOM</i>

Y coordinate on screen	screenY	screenY	screenY
Mouse button	which	button	button
Keyboard key	which	keyCode	keyCode
Shift key pressed	modifiers	shiftKey	shiftKey
Alt key pressed	modifiers	altKey	altKey
Ctrl key pressed	modifiers	ctrlKey	ctrlKey
Previous Element	n/a	fromElement	relatedTarget
Next Element	n/a	toElement	relatedTarget
Cancel bubbling	n/a	cancelBubble	preventBubble()
Prevent default action	return false	returnValue	preventDefault()

<sup>†</sup>Value can be derived through calculations with other properties.

As you can see in Table 25-2, properties for the IE4+ and NN6+/W3C event objects have a lot in common. This is good news, given that the installed base of NN4 users has diminished dramatically thanks to newer browsers. The primary incompatibility is how to reference the element that is the intended target of the event. This, too, can be branched in your code to achieve a common variable that references the element. For example, embedded within the previous function fragment can be a statement, such as the following:

```
var elem = (evt.target) ? evt.target : evt.srcElement;
```

Each event model has additional properties that are not shared by the other. Details about these are covered in the rest of this chapter.

## Dueling Event Models

Despite the sometimes widely divergent ways event object models treat their properties, accommodating a wide range of browsers for event manipulation is not difficult. In this section, you see two scripts that examine important event properties. The first script reveals which, if any, modifier keys are held down during an event; the second script extracts the codes for both mouse buttons and keyboard keys. Both scripts work with all browsers that have event objects, including NN4. If your audience no longer uses NN4, you can eliminate the code branches that support it.

## Cross-platform modifier key check

Listing 25-10 demonstrates branching techniques for examining the modifier key(s) being held down while an event fires. You can find details of the event object properties, such as `modifiers` and `altKey`, later in this chapter. To see the page in action, click a link, type into a text box, and click a button while holding down any combination of modifier keys (the link is all that works in Safari 1.0). A series of four checkboxes representing the four modifier keys is at the bottom. As you click or type, the checkbox(es) of the pressed modifier key(s) become checked.

### Listing 25-10: Checking Events for Modifier Keys

```
<html>
  <head>
    <title>Event Modifiers</title>
    <script type="text/javascript">
      function checkMods(evt) {
        evt = (evt) ? evt : ((window.event) ? window.event : null);
        if (evt) {
          var elem = (evt.target) ? evt.target : evt.srcElement;
          var form = document.output;
          if (evt.modifiers) {
            form.modifier[0].checked = evt.modifiers & Event.ALT_MASK;
            form.modifier[1].checked = evt.modifiers & Event.CONTROL_MASK;
            form.modifier[2].checked = evt.modifiers & Event.SHIFT_MASK;
            form.modifier[3].checked = evt.modifiers & Event.META_MASK;
          } else {
            form.modifier[0].checked = evt.altKey;
            form.modifier[1].checked = evt.ctrlKey;
            form.modifier[2].checked = evt.shiftKey;
            form.modifier[3].checked = false;
          }
        }
        return false;
      }
    </script>
  </head>
  <body>
    <h1>Event Modifiers</h1>
    <hr />
    <p>Hold one or more modifier keys and click on <a
      href="javascript:void(0)" onmousedown="return checkMods(event)">this
      link</a> to see which keys you are holding.</p>
    <form name="output">
      <p>Enter some text with uppercase and lowercase letters: <input
        type="text" size="40" onkeyup="checkMods(event)" /></p>
      <p><input type="button" value="Click Here With Modifier Keys"
        onclick="checkMods(event)" /></p>
      <p><input type="checkbox" name="modifier" />Alt <input type="checkbox"
        name="modifier" />Control <input type="checkbox"
        name="modifier" />Shift <input type="checkbox"
        name="modifier" />Meta</p>
    </form>
  </body>
</html>
```

Because all three event handlers call the same `checkMods()` function, branching is needed only in this function. Notice, though, that branching is done by object detection, rather than `navigator.userAgent` detection. This method makes the most sense for this example, because the scripts rely on the existence of particular objects and properties for their proper execution. For NN4, the event object is passed as a parameter (`evt`) whose `modifiers` property is Bitwise ANDed with an `Event` object constant for each modifier key. For IE4+ and NN6+/W3C, the script checks the event object property for each of three modifiers.

## Cross-platform key capture

To demonstrate keyboard events in both browsers, Listing 25-11 captures the key character being typed into a text box, as well as the mouse button used to click a button. As with Listing 25-10, NN4 has a very different way of getting this information compared to IE4+ and NN6+/W3C. In this arena, however, NN6+ continues to support the NN4 syntax as well, so you can use the old or new syntax as you like. Whereas NN4 combines the features of key character code and mouse button into one event object property (depending on the event type), newer browsers have entirely separate properties for these values. Listing 25-11 is written such that NN6+ follows the NN4 syntax path, but even if the NN4 syntax should disappear in a future NN version, the browser would follow the new syntax path without blinking an eye.

### Listing 25-11: Checking Events for Key and Mouse Button Pressed

```
<html>
  <head>
    <title>Button and Key Properties</title>
    <script type="text/javascript">
      function checkWhich(evt) {
        evt = (evt) ? evt : ((window.event) ? window.event : null);
        if (evt) {
          var thingPressed = "";
          var elem = (evt.target) ? evt.target : evt.srcElement;
          if (elem.type == "textarea") {
            thingPressed = (evt.charCode) ? evt.charCode :
              ((evt.which) ? evt.which : evt.keyCode);
          } else if (elem.type == "button") {
            thingPressed = (typeof evt.button != "undefined") ? evt.button :
              ((typeof evt.which != "undefined") ? evt.which : "n/a");
          }
          window.status = thingPressed;
        }
        return false;
      }
    </script>
  </head>
  <body>
    <h1>Button and Key Properties</h1>
    (results in the status bar)
    <hr />
    <form>
      <p>Mouse down atop this <input type="button" value="Button"
        onmousedown="checkWhich(event)" /> with either mouse button (if you
        have more than one).</p>
    </form>
  </body>
</html>
```

```

        <p>Enter some text with uppercase and lowercase letters: <textarea
            cols="40" rows="4" onkeypress="checkWhich(event)"
            wrap="virtual"></textarea></p>
    </form>
</body>
</html>

```

The codes displayed for the keyboard event are equivalent to the ASCII values of character keys. If you need the codes of other keys, the `onkeydown` and `onkeyup` event handlers provide Unicode values for any key that you press on the keyboard. See the `charCode` and `keyCode` property listings for event objects later in this chapter for more details.

## Event Types

Although browsers prior to version 4 did not have an accessible event object, this is a good time to summarize the evolution of what in today's browsers is known as the `type` property. The `type` property reveals the kind of event that generates an event object (the event handler name minus the "on"). Object models in IE4+ and NN6+/W3C provide event handlers for virtually every HTML element, so that it's possible, for example, to define an `onclick` event handler for not only a clickable button but also a `p` or even an arbitrary `span` element. We'll come back to the current crop of browsers in a moment. But first, in case you must write scripts that work on older browsers, you need to know which elements in those browsers support which event handlers. This knowledge will help you determine a common denominator of event handlers to implement in your pages, based on the browsers you anticipate will be accessing the pages.

### Older browsers

Earlier browsers tended to limit the number of event handlers for any particular element to just those that made sense for the kind of element it was. Even so, many scripters wanted more event handlers on more objects. But until that became a reality in IE4+ and NN6+/W3C, authors had to know the limits of the object models. Table 25-3 shows the event handlers available for objects within three generations of early browsers. Each column represents the version in which the event type was introduced. For example, the `window` object started out with four event types and gained three more when NN4 was released. In contrast, the `area` object was exposed as an object for the first time in NN3, which is where the first event types for that object are listed.

**Table 25-3: Event Types through the Early Ages**

<i>Object</i>	<i>NN2/IE3</i>	<i>NN3</i>	<i>NN4</i>
window	blur		dragdrop
	focus		move
	load		resize
	unload		
layer			blur
			focus

*Continued*

**Table 25-3** (continued)

<i>Object</i>	<i>NN2/IE3</i>	<i>NN3</i>	<i>NN4</i>
			load
			mouseout
			mouseover
			mouseup
link	click	mouseout	dblclick
	mouseover		mousedown
			onmouseup
area		mouseout	click
		mouseover	
image		abort	
		error	
		load	
Form text, textarea, password	submit	reset	
	blur		keydown
	change		keypress
	focus		keyup
	select		
all buttons	click		mousedown
			mouseup
select	blur		
	change		
	focus		
fileUpload		blur	
		focus	
		select	

With the exception of the NN4 layer object, all objects shown in Table 25-3 have survived into the newer browsers, so that you can use these event handlers with confidence. Again, keep in mind that of the browsers listed in Table 25-3, only NN4 has an event object of any kind exposed to scripts.

## Event types in IE4+ and NN6+/W3C

By now you should have at least scanned the list of event handlers defined for elements in common, as shown in Chapter 15. This list of event types is enormous. A sizable number of the event types are unique to IE4, IE5, and IE5.5/6, and in some cases, just the Windows version at that.

If you compose pages for both IE4+ and NN6+/W3C, however, you need to know which event types these browser families and generations have in common. Event types for

**(NN4) eventObject**

NN6+/Moz1+/Safari are based primarily on the W3C DOM Level 2 specification, although they also include keyboard events, which are not formally part of the Level 2 specification. Table 25-4 lists a common denominator of event types for modern browsers and the objects that support them. As you can see, many of these event types and corresponding objects go way back to the beginning. The biggest change is that mouse events are available for any visible element. While not as long as the IE event list, the event types in Table 25-4 are the basic set you should get to know for all browsers.

**Table 25-4: IE4+ and W3C DOM Event Types in Common**

<i>Event type</i>	<i>Applicable Elements</i>
abort	object
blur	window, button, <b>text</b> , <b>password</b> , label, select, textarea
change	<b>text</b> , <b>password</b> , textarea, select
click	<b>All elements</b>
error	window, frameset, object
focus	window, button, <b>text</b> , <b>password</b> , label, select, textarea
keydown	<b>text</b> , <b>password</b> , textarea
keypress	<b>text</b> , <b>password</b> , textarea
keyup	<b>text</b> , <b>password</b> , textarea
load	window, frameset, object
mousedown	<b>All elements</b>
mousemove	<b>All elements</b>
mouseout	<b>All elements</b>
mouseover	<b>All elements</b>
mouseup	<b>All elements</b>
reset	form
resize	window
scroll	window
select	<b>text</b> , <b>password</b> , textarea
submit	form
unload	window, frameset

## Syntax

Accessing NN4 event object properties:

```
eventObject.property
```

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

## About this object

Most of the details about this object were covered in the comparative event object discussions earlier in this chapter. As the NN4 browser continues to dissipate from the user-installed base, this object and its details will become less important.

## Properties

**data**

**Value:** Array of strings.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

A `dragdrop` event contains information about the URL string being dragged to the browser window. Because dragging multiple items to a window is possible (for example, many icons representing URLs on some operating systems), the value of the property is an array of strings, with each string containing a single URL (including `file://` URLs for computer files).

URL information such as this is deemed to be private data, so it is exposed only to signed scripts after the user has granted permission to read browser data. If you want your signed script to capture this information without loading the URL into the window, the event handler must evaluate to return `false`.

## Example

The page in Listing 25-12 contains little more than a `textarea` in which the URLs of dragged items are listed. To run this script without signing the scripts, turn on codebase principals, as directed in Chapter 46 on the CD-ROM.

To experiment with this listing, load the page and drag any desktop icons that represent files, applications, or folders to the window. Select multiple items and drag them all at once. Because the `ondragdrop` event handler evaluates to return `false`, the files are not loaded into the window. If you want merely to look at the URL and allow only some to process, you

**(NN4) eventObject.layerX**

would generate an `if...else` construction to return `true` or `false` to the event handler as needed. A value of `return true` allows the normal processing of the `dragdrop` event to take place after your event handler function has completed its processing.

**Listing 25-12: Obtaining URLs of a dragdrop Event's data Property**

```
<html>
  <head>
    <title>Drag and Drop</title>
    <script type="text/javascript">
      function handleDrag(evt) {
        netscape.security.PrivilegeManager.enablePrivilege(
          "UniversalBrowserRead");
        var URLArray = evt.data;
        netscape.security.PrivilegeManager.disablePrivilege(
          "UniversalBrowserRead");
        if (URLArray) {
          document.forms[0].output.value = URLArray.join("\n");

layerX

layerY

pageX

pageY

screenX

screenY

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

For many (but not all) mouse-related events, the NN4 event object contains a lot of information about the coordinates of the pointer when the event occurred. In the most complex case, a click in a `layer` object has three distinct pairs of horizontal and vertical ( $x$  and  $y$ ) coordinate values relative to the layer, the page, and the entire screen. If no layers are specified for a document, the layer and page coordinate systems are identical. Note that these values are

**(NN4) *eventObject.layerX***

merely geographical in nature and do not, by themselves, contain any information about the object being clicked (information held by the *eventObject.target* property).

These mouse coordinate properties are set only with specific events. In the case of a link object, the `click` and all four mouse events pack these values into the event object. For buttons, however, only the mouse events (`mousedown` and `mouseup`) receive these coordinates.

Each of the two window event types (`move` and `resize`) uses one of these property pairs to convey the results of the user action involved. For example, when the user resizes a window, the `resize` event stuffs the *eventObject.layerX* and *eventObject.layerY* properties with the inner width and height (that is, the content area) of the browser window (you can also use the optional *eventObject.width* and *eventObject.height* property names if you prefer). When the user moves the window, the *eventObject.screenX* and *eventObject.screenY* properties contain the screen coordinates of the top-left corner of the entire browser application window.

**Example**

You can see the effects of the coordinate systems and associated properties with the page in Listing 25-13. Part of the page contains a three-field readout of the layer-, page-, and screen-level properties. Two clickable objects are provided so that you can see the differences between an object not in any layer and an object residing within a layer. The object not confined by a layer has the same coordinates for the layer and the page in the event object properties.

Additional readouts display the event object coordinates for resizing and moving a window. If you maximize the window under Windows, the Navigator browser's top-left corner is actually out of sight, four pixels up and to the left. That's why the `screenX` and `screenY` values are both -4.

**Listing 25-13: NN4 Event Coordinate Properties**

```

**Related Items:** window and layer object move and resize methods.

**(NN4) eventObject.modifiers**

## modifiers

**Value:** Constant.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

The `modifiers` property of the NN4 event object refers to the modifier keys that can be pressed while clicking or typing. Modifier keys are Alt (also the Option key on the Macintosh keyboard), Ctrl, Shift, and what is known as a meta key (for example, the Command key,  $\mathfrak{C}$ , on the Macintosh keyboard). You can use this property to find out if one or more modifier keys were pressed at the time the event occurred.

Values for these keys are integer values designed in such a way that any combination of keys generates a unique value. Fortunately, you don't have to know anything about these values, because the event model supplies some plain-language constants (properties of a global `Event` object always available behind the scenes) that a script can apply to the property value passed with the object. The constant names consist of the key name (all uppercase), followed by an underscore and the uppercase word `MASK`. For example, if the Alt key is pressed by itself or in concert with other modifier keys, you can use the bitwise and operator (`&`) and the `Event.ALT_MASK` constant to test for the presence of the Alt key in the property value:

```
function handleMyEvent(evt) {
    if (evt.modifiers & Event.ALT_MASK) {
        //statements for Alt key handling
    }
}
```

Modifiers are not available with every event. You can capture them with `mousedown` and `mouseup` events in buttons and links. The only `click` event offering modifiers is with button objects. Keyboard events in text objects also include these modifiers. But be aware that accelerated keyboard combinations (for example, `Ctrl+Q`/ $\mathfrak{C}$ -`Q` for Quit) are not trappable by JavaScript event mechanisms because they are reserved for the browser's own menu shortcuts.

**Example**

See Listing 25-10 earlier in this chapter to see (in a cross-browser way) how the modifier keys are read for NN4.

## target

**Value:** Object reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

Every event has a property containing a reference to the object that was clicked, typed into, or otherwise acted upon. Most commonly, this property is examined when you set up a page to trap for events at the window, document, or layer level, as described earlier in this chapter. The `target` property lets you better identify the intended destination of the event while handling all processing for that type of event in one place. With a reference to the target object at hand in this property, your scripts can extract and/or set properties of the object directly.

(IE) event

## type

**Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

An event object's `type` is the name of the event that generated the event object. An event name is the same as the event handler's name, without the "on" prefix. Therefore, if a button's `onclick` event handler is triggered by a user's click, then the event type is `click` (all lowercase). If you create a multipurpose function for handling events, you can extract the `eventObject.type` property to help the function decide how to handle the current event. This sounds like a good job for the `switch` control structure (see Chapter 31).

## which

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

The value of the `which` property depends on the event type: a mouse button indicator for mouse events and a character key code for keyboard events.

For a mouse-related event, the `eventObject.which` property contains either a 1 for the left (primary) mouse button or a 3 for the right (secondary) mouse button. Most Macintosh computers have only a one-button mouse, so exercise care in designing pages that rely on the second mouse button. Even on Windows and other platforms, you must program an object's `onmousedown` event handler to return `false` for the secondary button to be registered instead of a browser pop-up menu appearing onscreen.

Keyboard events generate the ISO-Latin character code for the key that has been pressed. This value is an integer between 0 and 255. If your script needs to look at the actual character being typed, rather than the key code, use the `String.fromCharCode()` method (see Chapter 27) to make the conversion. If you have difficulty obtaining character codes from keyboard events, try using the `onkeydown` and `onkeyup` events rather than `onkeypress`. In either case, the function keys do not present character codes.

## Example

See Listing 25-10 for an example of using the `eventObject.which` property.

## Syntax

Accessing IE4+ event object properties:

```
[window.]event.property
```

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

## About this object

The IE4+ event object is a property of the `window` object. Its basic operation is covered earlier in this chapter.

You can see a little of what the event object is about with the help of The Evaluator (see Chapter 13). If you type `event` into the bottom text box, you can examine the properties of the event object for the event that triggers the function that displays the event object properties. If you press the Enter key in the text box, you see properties of the `keypress` event that caused the internal script to run; click the List Properties button to see the properties of the `click` event fired at the button. Hold down some of the modifier keys while clicking to see how this affects some of the properties.

As you review the properties for the event object, make special note of the compatibility rating for each property. The list of properties for this object has grown over the evolution of the IE4+ event object model. Also, most properties are listed here as being read-only, which they were in IE4. But for IE5+, these properties are also Read/Write if the event is created artificially via methods, such as IE5.5+'s `document.createEventObject()` method. Event objects that are created by user or system action have very few properties that can be modified on the fly (to prevent your scripts from altering user actions). Notice, too, that some properties are the same as for the W3C DOM event object, as revealed in the compatibility ratings.

## Properties

`altKey`

`ctrlKey`

`shiftKey`

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

When an event object is created in response to a user or system action, these three properties are set based on whether their corresponding keys were being held down at the time — a Shift-click, for example. If the key was held down, the property is assigned a value of `true`; otherwise the value is `false`.

Most commonly, you use expressions consisting of this property as `if` construction condition statements. Because these are Boolean values, you can combine multiple properties in a single condition. For example, if you have a branch of a function that is to execute only if the event occurred with both the Shift and Control keys held down, the condition looks as the following:

```
if (event.shiftKey && event.ctrlKey) {  
    // statements to execute  
}
```

Conversely, you can take a more user-friendly approach to provide special processing if the user holds down any one of the three modifier keys:

```
if (event.shiftKey || event.ctrlKey || event.altKey) {  
    // statements to execute  
}
```

**(IE) event.altKey**

The rationale behind this approach is to offer perhaps some shortcut operation for users, but not force them to memorize a specific modifier key combination.

**Example**

See Listing 25-10, where the values of these three properties are used to set the checked properties of corresponding checkboxes for a variety of event types.

**Related Items:** altLeft, ctrlLeft, shiftLeft properties.

altLeft  
ctrlLeft  
shiftLeft

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

Some versions of Windows allow events to be modified by only the left-hand Alt, Ctrl, and Shift keys when using IE5.5+. For these modifiers to be recorded by the event object, focus must be on the document (body), and not in any form control. If the left-key version is false and the regular version is true, then your script knows that the right-hand key had been held down during the event.

**Related Items:** altKey, ctrlKey, shiftKey properties.

behaviorCookie  
behaviorPart

**Value:** Integer.

Read-Only

**Compatibility:** WinIE6+, MacIE-, NN-, Moz-, Safari-

These two properties are related to a Windows technology that Microsoft calls *rendering behaviors*. Unlike the behaviors discussed under the addBehavior() method in Chapter 15, rendering behaviors are written in C++ and provide services for custom drawing on your Web page. For more details, consult the document “Implementing Rendering Behaviors” at <http://msdn.microsoft.com/workshop/browser/editing/imprendbehav.asp>.

bookmarks  
boundElements  
dataFld  
qualifier  
reason  
recordset

**Value:** See text.

Read-Only

**Compatibility:** WinIE6+, MacIE-, NN-, Moz-, Safari-

This group of event object properties is tied to using Data Binding in Windows versions of IE4+. Extensive details of Data Binding lie outside the scope of this book, but Table 25-5 provides a summary of these event object properties within that context (much of the terminology is used in Data Binding, but doesn't affect other scripting). For more details, search for ActiveX Data Objects (ADO) at <http://msdn.microsoft.com/workshop/>.

(IE) `event.button`**Table 25-5: ADO-Related event Object Properties**

<i>Property</i>	<i>Value</i>	<i>First Implemented</i>	<i>Description</i>
<code>bookmarks</code>	Array	IE4	Array of ADO bookmarks (saved positions) for records within a recordset associated with the object that received the event.
<code>boundElements</code>	Array	IE5	Array of element references for all elements bound to the same data set that was touched by the current event.
<code>dataFld</code>	String	IE5	Name of the data source column that is bound to a table cell that receives a <code>cellchange</code> event.
<code>qualifier</code>	String	IE5	Name of the data member associated with a data source that receives a data-related event. Available only if the data source object (DSO) allows multiple-named data members or a <code>qualifier</code> has been explicitly set via the <code>datasrc</code> attribute of the bound element. Read-write in IE5+.
<code>reason</code>	Integer	IE4	Set only from <code>onDataSetComplete</code> event, provides the result code of the data set loading (0=successful; 1=transfer aborted; 2=other error).
<code>recordset</code>	Object	IE4	Reference to the current recordset in a data source object.

## button

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `button` property reveals which button or buttons were pressed to activate a mouse event. If no mouse button is pressed to generate an event, this property is zero. But integers 1 through 7 reveal single and multiple button presses, including three-button mice when they are recognized by the operating system. Integer values correspond to buttons according to the following scheme:

<i>Value</i>	<i>Description</i>
0	No button
1	Left (primary) button
2	Right button
3	Left and right buttons together
4	Middle button

*Continued*

**(IE) event.button**

<i>Value</i>	<i>Description</i>
5	Left and middle buttons together
6	Right and middle buttons together
7	Left, middle, and right buttons together

Mouse buttons other than the primary one are easier to look for in `mousedown` or `mouseup` events rather than `onclick` events. Be aware that as the user works toward pressing multiple buttons, each press fires a `mousedown` event. Therefore, if the user presses the left button first, the `mousedown` event fires, with the `event.button` property bearing the 1 value; as soon as the right button is pressed, the `mousedown` event fires again, but this time with an `event.button` value of 3. If your script intends to perform special action with both buttons pressed, it should ignore and not perform any action for a single mouse button, because that one-button event will very likely fire in the process, disturbing the intended action.

Exercise caution when scripting the `event.button` property for both IE4+ and NN6+/W3C. The W3C DOM event model defines different button values for mouse buttons (0, 1, and 2 for left, middle, and right) and no values for multiple buttons.

**Example**

See Listing 25-11, where the `event.button` property is revealed in the status bar. Try pressing individual mouse buttons on, for example, the screen button. Then try combinations, watching the results very closely in the status bar.

**Related Items:** None.

**cancelBubble**

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `cancelBubble` property (which sounds more as if it should be a method name) determines whether the current `event` object bubbles up any higher in the element containment hierarchy of the document. By default, this property is `false`, meaning that if the event is supposed to bubble, it will do so automatically.

To prevent event bubbling for the current event, set the property to `true` anywhere within the event handler function. As an alternative, you can cancel bubbling directly in an element's event handler attribute, as in the following:

```
onclick="doButtonClick(this); event.cancelBubble = true"
```

Canceling event bubbling works only for the current event. The very next event to fire will have bubbling enabled (provided the event bubbles).

**Example**

See Listing 25-6 to see the `cancelBubble` property in action. Even though that listing has some features that apply to IE5.5+, the bubble cancelling demonstration works all the way back to IE4.

**Related Items:** `returnValue` property.

`clientX`  
`clientY`  
`offsetX`  
`offsetY`  
`screenX`  
`screenY`  
`x`  
`y`

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

An IE `event` object provides coordinates for an event in as many as four coordinate spaces: the element itself, the parent element of the event's target, the viewable area of the browser window, and the entire video screen. Unfortunately, misleading values can be returned by some of the properties that correspond to these coordinate spaces, as discussed in this section. Note that no properties provide the explicit position of an event relative to the entire page, in case the user has scrolled the window.

Starting with the innermost space—that of the element that is the target of the event—the `offsetX` and `offsetY` properties should provide pixel coordinates within the target element. This is how, for example, you could determine the click point on an image, regardless of whether the image is embedded in the `body` or floating around in a positioned `div`. Windows versions through IE6 produce the correct values in most cases. But for some elements that are child elements of the `body` element, the vertical (`y`) value may be relative to the viewable window, rather than just the element itself. You can see an example of this when you work with Listing 25-14 and click the `h1` or `p` elements near the top of the page. This problem does not affect MacIE, but there is another problem on Mac versions: If the page is scrolled away from its normal original position, the scrolled values are subtracted from the `clientX` and `clientY` values. This is an incompatibility bug, and you must take this error into account if you need click coordinates inside an element for a potentially scrolled page. This error correction must be done only for the Mac, because Windows works okay.

Extending scope to the offset parent element of the event's target, the `x` and `y` properties in IE5+ for Windows should return the coordinates for the event relative to the target's offset parent element (the element that can be found via the `offsetParent` property). For most non-positioned elements, these values are the same as the `clientX` and `clientY` properties because, as discussed in a moment, the offset parent element has a zero offset with *its* parent, the `body`. Observe an important caution about the `x` and `y` properties: In WinIE4 and through MacIE5, the properties do not take into account any offset parent locations other than the `body`. Even in WinIE5+, this property can give false readings in some circumstances. By and large, these two properties should not be used.

The next set of coordinates, `clientX` and `clientY`, are relative to the visible document area of the browser window. When the document is scrolled all the way to the top (or the document doesn't scroll at all), these coordinates are the same as the coordinates on the entire page. But because the page can scroll “underneath” the viewable window, the coordinates on the page can change if the page scrolls. Also, in the Windows versions of IE, you can actually register mouse events that are up to 2 pixels outside of the `body` element, which seems weird, but true. Therefore, in WinIE, if you click the background of the `body`, the event

**(IE) event.clientX**

fires on the `body` element, but the `clientX/clientY` values will be 2 pixels greater than `offsetX/offsetY` (they're equal in MacIE). Despite this slight discrepancy, you should rely on the `clientX` and `clientY` properties if you are trying to get the coordinates of an event that may be in a positioned element, but have those coordinates relative to the entire viewable window, rather than just the positioning context.

Taking the page's scrolling into account for an event coordinate is often important. After all, unless you generate a fixed-size window for a user, you don't know how the browser window will be oriented. If you're looking for a click within a specific region of the page, you must take page scrolling into account. The scrolling factor can be retrieved from the `document.body.scrollLeft` and `document.body.scrollTop` properties. When reading the `clientX` and `clientY` properties, be sure to add the corresponding scroll properties to get the position on the page:

```
var coordX = event.clientX + document.body.scrollLeft;
var coordY = event.clientY + document.body.scrollTop;
```

Do this in your production work without fail.

Finally, the `screenX` and `screenY` properties return the pixel coordinates of the event on the entire video screen. These properties may be more useful if IE provided more window dimension properties. In any case, because mouse events fire only when the cursor is somewhere in the content region of the browser window, don't expect to get screen values of anywhere outside this region.

If these descriptions seem confusing to you, you are not alone. Throw in a few bugs, and it may seem like quite a mess. But think how you may use event coordinates in scripts. By and large, you want to know one of two types of mouse event coordinates: within the element itself and within the page. Use the `offsetX/offsetY` properties for the former; use `clientX/clientY` (plus the scroll property values) for the latter.

Although the coordinate properties are used primarily for mouse events, there is a little quirk that may let you determine if the user has resized the window via the maximize icon in the title bar (on the Mac, this is called the zoom box) or the resize handle at the bottom-right corner of the screen. Mouse event coordinates are recorded in the `event` object for a `resize` event. In the case of the maximize icon, the `clientY` coordinate is a negative value (above the client space) and the `clientX` coordinate is within about 45 pixels of the previous width of the window (`document.body.clientWidth`). This, of course, happens after the window has resized, so it is not a way to prevent window resizing.

## Example

Listing 25-14 provides readings of all event coordinate properties in an interactive way. An `onmousedown` event handler triggers all event handling, and you can click the mouse anywhere on the page to see what happens. You see the tag of the element targeted by the mouse event to help you visualize how some of the coordinate properties are determined. An image is encased inside a positioned `div` element to help you see what happens to some of the properties when the event is targeted inside a positioned element.

    </table>
</form>
<div id="display" style="position:relative; left:100">
    
</div>
</body>
</html>

```

Here are some tasks to try with the page that loads from Listing 25-14 to help you understand the relationships among the various pairs of coordinate properties:

1. Click the dot above the “i” on the “Click Here” button label. The target element is the button (input) element, whose `offsetParent` is a table cell element. The `offsetY` value is very low because you are near the top of the element’s own coordinate space. The client coordinates (and `x` and `y`), however, are relative to the viewable area in the window. If your browser window is maximized in Windows, the `screenX` and `clientX` values will be the same; the difference between `screenY` and `clientY` is the height of all the window chrome above the content region. With the window not scrolled at all, the client coordinates are the same with and without scrolling taken into account.
2. Jot down the various coordinate values and then scroll the page down slightly (clicking the scrollbar fires an event) and click the dot on the button again. The `clientY` value shrinks because the page has moved upward relative to the viewable area, making the measure between the top of the area smaller with respect to the button. The Windows version does the right thing with the offset properties, by continuing to return values relative to the element’s own coordinate space; the Mac, unfortunately, subtracts the scrolled amount from the offset properties.
3. Click the large image. The client properties perform as expected for both Windows and Mac, as do the screen properties. For Windows, the `x` and `y` properties correctly return the event coordinates relative to the `img` element’s `offsetParent`, which is the `div` element that surrounds it. Note, however, that the browser “sees” the `div` as starting

**(IE) event.dataTransfer**

10 pixels to the left of the image. In WinIE5.5+, you can click within those 10 transparent pixels to the left of the image to click the `div` element. This padding is inserted automatically and impacts the coordinates of the `x` and `y` properties. A more reliable measure of the event inside the image is the offset properties. The same is true in the Macintosh version, as long as the page isn't scrolled, in which case the scroll, just as in Step 2, affects the values above.

4. Click the top `hr` element under the heading. It may take a couple of tries to actually hit the element (you've made it when the `hr` element shows up in the `srcElement` box). This is to reinforce the way the client properties provide coordinates within the element itself (again, except on the Mac when the page is scrolled). Clicking at the very left end of the rule, you eventually find the 0,0 coordinate.

Finally, if you are a Windows user, here are two examples to try to see some of the unexpected behavior of coordinate properties.

1. With the page not scrolled, click anywhere along the right side of the page, away from any text so that the `body` element is `srcElement`. Because the `body` element theoretically fills the entire content region of the browser window, all coordinate pairs except for the screen coordinates should be the same. But offset properties are 2 pixels less than all the others. By and large, this difference won't matter in your scripts, but you should be aware of this potential discrepancy if precise positioning is important. For inexplicable reasons, the offset properties are measured in a space that is inset 2 pixels from the left and top of the window. This is not the case in the Macintosh version, where all value pairs are the same from the `body` perspective.
2. Click the text of the `h1` or `p` elements (just above and below the long horizontal rule at the top of the page). In theory, the offset properties should be relative to the rectangles occupied by these elements (they're block elements, after all). But instead, they're measured in the same space as the client properties (plus the 2 pixels). This unexpected behavior doesn't have anything to do with the cursor being a text cursor, because if you click inside any of the text box elements, their offset properties are properly relative to their own rectangles. This problem does not afflict the Macintosh version.

Many of these properties are also in the W3C DOM and are therefore supported in W3C DOM browsers. Unsupported properties display their values as `undefined` when you run Listing 25-14 in those browsers.

You can see further examples of important event coordinate properties in action in the discussion of dragging elements around the IE page in Chapter 39 on the CD-ROM.

**Related Items:** `fromElement`, `toElement` properties.

## dataTransfer

**Value:** Object.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `dataTransfer` property is a reference to a WinIE-only object called the `dataTransfer` object. Use this object in drag-and-drop operations (that is, with drag-and-drop-related events) to control not only the data that gets transferred from the source to the target but also to control the look of the cursor along the way.

Table 25-6 lists the properties and methods of the `dataTransfer` object.

## (IE) event.dataTransfer

**Table 25-6: dataTransfer object Properties and Methods**

<i>Property/Method</i>	<i>Returns</i>	<i>Description</i>
<code>dropEffect</code>	String	An element that is a potential recipient of a drop action can use the <code>ondragenter</code> , <code>ondragover</code> , or <code>ondrop</code> event handler to set the cursor style to be displayed when the cursor is atop the element. Before this can work, the source element's <code>ondragstart</code> event handler must assign a value to the <code>event.effectAllowed</code> property. Possible string values for both properties are <code>copy</code> , <code>link</code> , <code>move</code> , or <code>none</code> . These properties correspond to the Windows system cursors for the operations users typically do with files and in other documents. You must also cancel the default action (meaning set <code>event.returnValue</code> to <code>false</code> ) for all of these drop element event handlers: <code>ondragenter</code> , <code>ondragover</code> , and <code>ondrop</code> .
<code>effectAllowed</code>	String	Set in response to an <code>ondragstart</code> event of the source element, this property determines which kind of drag-and-drop action will be taking place. Possible string values are <code>copy</code> , <code>link</code> , <code>move</code> , or <code>none</code> . This property value must match the <code>dropEffect</code> property value for the target element's event object. Also, cancel the default action (meaning, set <code>event.returnValue</code> to <code>false</code> ) in the <code>ondragstart</code> event handler.
<code>clearData([format])</code>	Nothing	Removes data in the clipboard. If no format parameters are supplied, all data are cleared. Data formats can be one or more of the following strings: <code>Text</code> , <code>URL</code> , <code>File</code> , <code>HTML</code> , <code>Image</code> .
<code>getData(format)</code>	String	Retrieves data of the specified format from the clipboard. The format is one of the following strings: <code>Text</code> , <code>URL</code> , <code>File</code> , <code>HTML</code> , <code>Image</code> . The clipboard is not emptied after you get the data, so that it can be retrieved in several sequential operations.
<code>setData(format, data)</code>	Boolean	Stores string data in the clipboard. The format is one of the following strings: <code>Text</code> , <code>URL</code> , <code>File</code> , <code>HTML</code> , <code>Image</code> . For non-text data formats, the data must be a string that specifies the path or URL to the content. Returns <code>true</code> if the transfer to the clipboard is successful.

The `dataTransfer` object acts as a conduit and controller of data that your scripts need to transfer from one element to another in response to a user's drag-and-drop action. You need to adhere to a well-defined sequence of actions triggered by a handful of event handlers. This means that the object is invoked on different instances of the event object as different events fire in the process of dragging and dropping.

The sequence begins at the source element, where an `ondragstart` event handler typically assigns a value to the `dropEffect` property and uses the `getData()` method to explicitly

**(IE) event.fromElement**

capture whatever data it is about the source object that gets transferred to the eventual target. For example, if you drag an image, the information being transferred may simply be the URL of the image—data that is extractable from the `event.srcElement.src` property of that event (the `src` property of the image, that is).

At the target element(s), three event handlers must be defined: `ondragenter`, `ondragover`, and `ondrop`. Most commonly, the first two event handlers do nothing more than mark the element for a particular `dropEffect` (which must match the `effectAllowed` set at the source during the drag's start) and set `event.returnValue` to `false` so that the cursor displays the desired cursor. These actions are also carried out in the `ondrop` event handler, but that is also the handler that does the processing of the destination action at the target element. This is when the `dataTransfer` object's `getData()` method is invoked to pick up the data that has been “stored” away by `getData()` at the start of the drag. If you also want to make sure that the data is not picked up accidentally by another event, invoke the `clearData()` method to remove that data from memory.

Note that the style of dragging being discussed here is not the kind in which you see the source element actually moving on the screen (although you could script it that way). The intention is to treat drag-and-drop operations just as Windows does in, say, the Windows Explorer window or on the Desktop. To the user, the draggable component becomes encapsulated in the cursor. That's why the properties of the `dataTransfer` object control the appearance of the cursor at the drop point as a way of conveying to the user the type of action that will occur with the impending drop.

## Example

An extensive example of the `dataTransfer` property in action can be found in Listing 15-37 in the section for the `ondrag` event handler.

**Related Items:** `ondragend`, `ondragenter`, `ondragleave`, `ondragover`, `ondragstart`, `ondrop` event handlers.

## fromElement toElement

**Value:** Element object.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `fromElement` and `toElement` properties allow an element to uncover where the cursor rolled in from or has rolled out to. These properties extend the power of the `onmouseover` and `onmouseout` event handlers by expanding their scope to outside the current element (usually to an adjacent element).

When the `onmouseover` event fires on an element, the cursor had to be over some other element just beforehand. The `fromElement` property holds a reference to that element. Conversely, when the `onmouseout` event fires, the cursor is already over some other element. The `toElement` property holds a reference to that element.

## Example

Listing 25-15 provides an example of how the `fromElement` and `toElement` properties can reveal the life of the cursor action before and after it rolls into an element. When you roll the cursor to the center box (a table cell), its `onmouseover` event handler displays the text from the table cell from which the cursor arrived.

**(IE) event.fromElement****Listing 25-15: Using the toElement and fromElement Properties**

```

<html>
  <head>
    <title>fromElement and toElement Properties</title>
    <style type="text/css">
      .direction {background-color:#00FFFF; width:100; height:50;
      text-align:center}
      #main {background-color:#FF6666; text-align:center}
    </style>
    <script type="text/javascript">
      function showArrival() {
        var direction = (event.fromElement.innerText) ?
          event.fromElement.innerText : "parts unknown";
        status = "Arrived from: " + direction;
      }
      function showDeparture() {
        var direction = (event.toElement.innerText) ?
          event.toElement.innerText : "parts unknown";
        status = "Departed to: " + direction;
      }
    </script>
  </head>
  <body>
    <h1>fromElement and toElement Properties</h1>
    <hr />
    <p>Roll the mouse to the center box and look for arrival information in
      the status bar. Roll the mouse away from the center box and look for
      departure information in the status bar.</p>
    <table cellpadding="0" cellspacing="5">
      <tr>
        <td></td>
        <td class="direction">North</td>
      </tr>
      <tr>
        <td class="direction">West</td>
        <td id="main" onmouseover="showArrival()"
          onmouseout="showDeparture()">Roll</td>
        <td class="direction">East</td>
      </tr>
      <tr>
        <td></td>
        <td class="direction">South</td>
      </tr>
    </table>
  </body>
</html>

```

This is a good example to experiment with in the browser, because it also reveals a potential limitation. The element registered as the `toElement` or `fromElement` must fire a mouse event to register itself with the browser. If not, the next element in the sequence that registers itself is the one acknowledged by these properties. For example, if you roll the mouse into the center box and then extremely quickly roll the cursor to the bottom of the page, you may bypass the South box entirely. The text that appears in the status bar is actually the inner text of the

**(IE) event.keyCode**

body element, which is the element that caught the first mouse event to register itself as the `toElement` for the center table cell.

**Related Items:** `srcElement` property.

## keyCode

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

For keyboard events, the `keyCode` property returns an integer corresponding to the Unicode value of the character (for `onkeypress` events) or the keyboard character key (for `onkeydown` and `onkeyup` events). There is a significant distinction between these numbering code systems.

If you want the Unicode values (the same as ASCII values for the Latin character set) for the key that a user pressed, get the `keyCode` property from the `onkeypress` event handler. For example, a lowercase “a” returns 97, while an uppercase “A” returns 65. Non-character keys, such as arrows, page navigation, and function keys, return a `null` value for the `keyCode` property during `onkeypress` events. In other words, the `keyCode` property for `onkeypress` events is more like a character code than a key code.

To capture the exact keyboard key that the user presses, use either the `onkeydown` or `onkeyup` event handler. For these events, the `event` object captures a numeric code associated with a particular key on the keyboard. For the character keys, this varies with the language assigned as the system language. Importantly, there is no distinction between uppercase or lowercase: The “A” key on the Latin keyboard returns a value of 65, regardless of the state of the Shift key. At the same time, however, the press of the Shift key fired its own `onkeydown` and `onkeyup` events, setting the `keyCode` value to 16. Other non-character keys — arrows, page navigation, function, and similar — have their own codes as well. This gets very detailed, including special key codes for the numeric keyboard keys that are different from their corresponding numbers along the top row of the alphanumeric keyboard.

Be sure to see the extensive section on keyboard events in Chapter 15 for examples of how to apply the `keyCode` property in applications.

## Example

Listing 25-16 provides an additional play area to view the `keyCode` property for all three keyboard events while you type into a `textarea`. You can use this page later as an authoring tool to grab the precise codes for keyboard keys you may not be familiar with.

### Listing 25-16: Displaying keyCode Property Values

```
<html>
  <head>
    <title>keyCode Property</title>
    <style type="text/css">
      td {text-align:center}
    </style>
    <script type="text/javascript">
      function showCode(which) {
        document.forms[0].elements[which].value = event.keyCode
      }
    </script>
  </head>
  <body>
    <div style="border: 1px solid black; padding: 5px; width: fit-content; margin: auto;">
      <input type="text" value="Enter a character here" />
    </div>
  </body>
</html>
```

*Continued*

**(IE) event.keyCode****Listing 25-16 (continued)**

```

function clearEm() {
    for (var i = 1; i < document.forms[0].elements.length; i++) {
        document.forms[0].elements[i].value = ""
    }
}
</script>
</head>
<body>
<h1>keyCode Property</h1>
<hr />
<form>
  <p><textarea name="scratchpad" cols="40" rows="5" wrap="hard"
    onkeydown="clearEm(); showCode('down')" onkeyup="showCode('up')"
    onkeypress="showCode('press')">
    </textarea></p>
  <table cellpadding="5">
    <tr>
      <th>Event</th>
      <th>event.keyCode</th>
    </tr>
    <tr>
      <td>onKeyDown:</td>
      <td><input type="text" name="down" size="3" /></td>
    </tr>
    <tr>
      <td>onKeyPress:</td>
      <td><input type="text" name="press" size="3" /></td>
    </tr>
    <tr>
      <td>onKeyUp:</td>
      <td><input type="text" name="up" size="3" /></td>
    </tr>
  </table>
</form>
</body>
</html>

```

The following are some specific tasks to try with the page to examine key codes (if you are not using a browser set for English and a Latin-based keyboard, your results may vary):

1. Enter a lowercase “a”. Notice how the `onkeypress` event handler shows the code to be 97, which is the Unicode (and ASCII) value for the first of the lowercase letters of the Latin alphabet. But the other two events record just the key’s code: 65.
2. Type an uppercase “A” via the Shift key. If you watch closely, you see that the Shift key, itself, generates the code 16 for the `onkeydown` and `onkeyup` events. But the character key then shows the value 65 for all three events, because the ASCII value of the uppercase letter happens to match the keyboard key code for that letter.
3. Press and release the Down Arrow key (be sure the cursor still flashes in the `textarea`, because that’s where the keyboard events are being monitored). As a non-character key, it does not fire an `onkeypress` event. But it does fire the other events, and assigns 40 as the code for this key.

(IE) event.repeat

4. Poke around with other non-character keys. Some may produce dialog boxes or menus, but their key codes are recorded nonetheless. Note that not all keys on a Macintosh keyboard register with MacIE.

**Related Items:** onkeydown, onkeypress, onkeyup event handlers.

## nextPage

**Value:** String.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `nextPage` property is applicable only if your WinIE5.5+ page uses a `TemplatePrinter` behavior. Values of this property are one of the following strings: `left`, `right`, or an empty string. For more information about the `TemplatePrinter` behavior for WinIE5.5+, see

<http://msdn.microsoft.com/workshop/browser/hosting/printpreview/reference/behaviors/TemplatePrinter.asp>

## propertyName

**Value:** String.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `propertyName` property is filled only after an `onpropertychange` event fires.

If a script modifies a property, the `onpropertychange` event handler fires, and the string name of the property is stuffed into the `event.propertyName` property. If the property happens to be a property of the `style` object associated with the element, the `propertyName` is the full property reference, as in `style.backgroundColor`.

## Example

See Listing 15-46 in the section about the `onpropertychange` event handler for an example of the values returned by this property.

**Related Items:** `onpropertychange` event handler (Chapter 15).

## repeat

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `repeat` property reveals for `onkeydown` events only whether the key is in repeat mode (as determined by the Keyboard control panel settings in the system). With this information, you can prevent the automatic triggering of repeat mode from causing multiple characters from being recognized by the browser. This property can come in handy if users may be physically challenged and may occasionally and accidentally hold down a key too long. The following script fragment in an `onkeydown` event handler for a text box or `textarea` prevents multiple characters from appearing even if the system goes into repeat mode:

```
if (event.repeat) {
    event.returnValue = false;
}
```

By disabling the default action while in repeat mode, no further characters reach the text box until repeat mode goes away (meaning, with the press of another key).

**Related Items:** `onkeydown` event handler.

**(IE) event.returnValue**

## returnValue

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

While IE4+ continues to honor the original way of preventing default action for an event handler (that is, having the last statement of the event handler evaluate to `return false`), the IE4+ event model provides a property that lets the cancellation of default action take place entirely within a function invoked by an event handler. By default, the `returnValue` property of the event object is `true`, meaning that the element processes the event after the scripted handler completes its job, just as if the script weren't there. Normal processing, for example, is displaying a typed character, navigating to a link's `href` URL upon being clicked, or submitting a form after the Submit button is clicked.

But you don't always want the default action to occur. For example, consider a text box that is supposed to allow only numbers to be typed in it. The `onkeypress` event handler can invoke a function that inspects each typed character. If the character is not a numeric character, it should not reach the text box for display. The following validation function may be invoked from the `onkeypress` event handler of just such a text box:

```
function checkIt() {
    var charCode = event.keyCode;
    if (charCode < 48 || charCode > 57) {
        alert("Please make sure entries are numerals only.");
        event.returnValue = false;
    }
}
```

By using this event handler, the errant character won't appear in the text box.

Note that this property is not a substitute for the `return` statement of a function. If you need a value to be returned to the invoking statement, you can use a `return` statement in addition to setting the `event.returnValue` property.

**Example**

You can find several examples of the `returnValue` property at work in Chapter 15 and Chapter 1. Look at Listings 15-30, 15-33, 15-36, 15-37, 15-38, and 15-45. Moreover, many of the other examples in Chapter 15 can substitute the `returnValue` property way of cancelling the default action if the scripts were to be run exclusively on IE4+.

**Related Items:** `return` statement (Chapter 33).

## saveType

**Value:** String.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `saveType` property is assigned a value only when an `oncontentsave` event is bound to a WinIE DHTML behavior (`.htc`). For more information about behaviors, see

<http://msdn.microsoft.com/workshop/author/behaviors/overview.asp>

**Related Items:** `addBehavior()` method.

## srcElement

**Value:** Element object reference.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `srcElement` property is a reference to the HTML element object that is the original target of the event. Because an event may bubble up through the element containment hierarchy and be processed at any level along the way, having a property that points back to the element from which the event originated is comforting. After you have a reference to that element, you can read or write any properties that belong to that element or invoke any of its methods.

## Example

As a simplified demonstration of the power of the `srcElement` property, Listing 25-17 has but two event handlers defined for the `body` element, each invoking a single function. The idea is that the `onmousedown` and `onmouseup` events will bubble up from whatever their targets are, and the event handler functions will find out which element is the target and modify the color style of that element.

An extra flair is added to the script in that each function also checks the `className` property of the target element. If the `className` is `bold`—a class name shared by three `span` elements in the paragraph—the stylesheet rule for that class is modified so that all items share the same color. Your scripts can do even more in the way of filtering objects that arrive at the functions to perform special operations on certain objects or groups of objects.

Notice that the scripts don't have to know anything about the objects on the page to address each clicked one individually. That's because the `srcElement` property provides all of the specificity needed for acting on the target element.

### Listing 25-17: Using the `srcElement` Property

```
<html>
  <head>
    <title>srcElement Property</title>
    <style type="text/css">
      .bold {font-weight:bold}
      .ital {font-style:italic}
    </style>
    <script type="text/javascript">
      function highlight() {
        var elem = event.srcElement;
        if (elem.className == "bold") {
          document.styleSheets[0].rules[0].style.color = "red";
        } else {
          elem.style.color = "#FFCC00";
        }
      }
      function restore() {
        var elem = event.srcElement;
        if (elem.className == "bold") {
          document.styleSheets[0].rules[0].style.color = "";
        } else {
          elem.style.color = "";
        }
      }
    </script>
  </head>
```

*Continued*

**(IE) event.srcElement****Listing 25-17 (continued)**

```

<body onmousedown="highlight()" onmouseup="restore()">
  <h1>srcElement Property</h1>
  <hr />
  <p>One event handler...</p>
  <ul>
    <li>Can</li>
    <li>Cover</li>
    <li>Many</li>
    <li>Objects</li>
  </ul>
  <p>Lorem ipsum dolor sit amet, consectetur adipiscing elit, <span
  class="bold">sed do</span> eiusmod tempor incididunt <span
  class="ital">ut labore et</span> dolore magna aliqua. Ut enim adminim
  veniam, <span class="bold">quis nostrud exercitation</span> ullamco
  laboris nisi ut aliquip ex ea <span class="bold">commodo
  consequat</span>.</p>
</body>
</html>

```

**Related Items:** `fromElement`, `toElement` properties.

**srcFilter**

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

According to Microsoft, the `srcFilter` property should return a string of the filter that was applied to trigger an `onfilterchange` event handler. While the property exists in the event object, its value is always `null`, at least through WinIE6.

**Related Items:** `onfilterchange` event handler; `style.filter` object.

**srcUrn**

**Value:** String.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

If an event is fired in a WinIE behavior attached to an element, and the behavior has a URN identifier defined for it, the `srcUrn` property returns the string from the URN identifier. For more information about behaviors, see

<http://msdn.microsoft.com/workshop/author/behaviors/overview.asp>

**Related Items:** `addBehavior()` method.

**toElement**

(See `fromElement`)

**type**

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

**(NN6/Moz/Safari) eventObject**

You can find out what kind of event fired to create the current `event` object by way of the `type` property. The value is a string version of the event name — just the name of the event without the “on” prefix that is normally associated with event names in IE. This property can be helpful when you designate one event handler function to process different kinds of events. For example, both the `onmousedown` and `onclick` event handlers for an object can invoke one function. Inside the function, a branch is written for whether the `type` comes in as `mousedown` or `click`, with different processing for each event type. That is not to endorse such event handler function sharing, but for you to be aware of this power should your script constructions find the property helpful.

This property and its values are fully compatible with the NN4 and W3C/NN6+ event models.

**Example**

Use The Evaluator (Chapter 13) to see values returned by the `type` property. Enter the following object name into the bottom text box and press Enter/Return:

```
event
```

If necessary, scroll the Results box to view the `type` property, which should read `keypress`. Now click the List Properties button. The `type` changes to `click`. The reason for these types is that the `event` object whose properties are being shown here is the event that triggers the function to show the properties. From the text box, an `onkeypress` event handler triggers that process; from the button, an `onclick` event handler does the job.

**Related Items:** All event handlers (Chapter 15).

**wheelData**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `wheelData` property returns an integer indicating which direction the mouse wheel was rolled for an `onmousewheel` event. The values returned are typically either 120 or -120, with a positive value indicating that the mouse wheel was rolled toward the screen and a negative value indicating that the wheel was rolled the opposite direction.

## Syntax

Accessing NN6+ event object properties and methods:

```
eventObject.property | method([parameters])
```

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

## About this object

Although it is based largely on the event object as defined by the W3C DOM Level 2, the NN6+/Moz event object also carries forward several characteristics from the NN4 event object. A few properties are continued primarily for backward compatibility. But because future Mozilla development will likely forego the peculiarities of the NN4 DOM and event models, you should ignore these items (as highlighted below). Wherever possible, look forward and embrace the W3C DOM aspects of the event model. Safari, for example, implements a lot of the W3C DOM event model, but excludes all old NN4 properties.

Although the NN6+ event model provides a bubbling event propagation model just as IE4+, the incompatibility of referencing event objects between the event models is still there. In the W3C DOM (as in NN4), an event object is explicitly passed as a parameter to event handler (or, rather, event listener) functions. But after you have a browser-specific event object assigned to a variable inside a function, a few important properties have the same names

**(NN6/Moz/Safari) eventObject.altKey**

between the IE4+ and W3C DOM event models. If Microsoft adopts more of the W3C DOM event model in future versions of IE, the compatibility situation should improve.

The event object discussed in this section is the instance of an event that is created as the result of a user or system event action. The W3C DOM includes an additional static `Event` object. Many of the properties of the static `Event` object are inherited by the event instances, so the detailed coverage of those shared properties is in this section because it is the event object you'll be scripting for the most part.

In many code fragments in the following detail sections, you will see references that begin with the `evt` reference. This assumes that the statement(s) resides inside a function that has assigned the incoming event object to the `evt` parameter variable:

```
function myFunction(evt) {...}
```

As shown earlier in this chapter, you can equalize W3C DOM and IE4+ event object references when it is practical to do so because the scripts work on identical (or similar) event object properties.

## Properties

`altKey`

`ctrlKey`

`metaKey`

`shiftKey`

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

When an event object is created in response to a user or system action, these four properties are set based on whether their corresponding keys were being held down at the time—a Shift-click, for example. If the key was held down, the property is assigned a value of `true`; otherwise the value is `false`. The `metaKey` property corresponds to the Command key on the Macintosh keyboard but does not register for the Windows key on Wintel computers.

Most commonly, you use expressions consisting of this property as `if` construction condition statements. Because these are Boolean values, you can combine multiple properties in a single condition. For example, if you have a branch of a function that is to execute only if the event occurred with both the Shift and Control keys held down, the condition looks as the following:

```
if (evt.shiftKey && evt.ctrlKey) {  
    // statements to execute  
}
```

Conversely, you can take a more user-friendly approach to provide special processing if the user holds down any one of the four modifier keys:

```
if (evt.shiftKey || evt.ctrlKey || evt.metaKey || evt.altKey) {  
    // statements to execute  
}
```

The rationale behind this approach is to offer perhaps some shortcut operation for users, but not force them to memorize a specific modifier key combination.

(NN6/Moz/Safari) *eventObject.altKey*

## Example

See Listing 25-10, where the values of these properties are used to set the checked properties of corresponding checkboxes for a variety of event types.

**Related Items:** None.

## bubbles

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

Not every event bubbles. For example, an `onsubmit` event propagates no further than the form object with which the event is associated. Events that do not bubble have their event object's `bubbles` property set to `false`; all others have the property set to `true`. You use this property in the rare circumstance of a single event handler function processing a wide variety of events. You may want to perform special operations only on events that can bubble and handle the others without special treatment. For this branch, you can use the property in an `if` condition statement:

```
if (evt.bubbles) {
    // special processing for bubble-able events
}
```

You do not have to branch, however, just to cancel bubbling. A non-propagating event doesn't mind if you tell it not to propagate.

**Related Items:** `cancelBubble` property.

## button

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `button` property reveals the button that was pressed to activate the mouse event. In the W3C DOM, the left (primary) button returns a value of 0. If the mouse is a three-button mouse, the middle button returns 1. The right button (on any multibutton mouse) returns a value of 2. Note that Safari elects to follow the IE button-numbering convention, where the primary mouse button has a code of 1.

Mouse buttons other than the primary one are easier to look for in `mousedown` or `mouseup` events, rather than `onclick` events. In the case of a user pressing multiple buttons, only the most recent button is registered.

Exercise caution when scripting the `button` property across browsers. The respective event models define different button values for mouse buttons.

## Example

See Listing 25-11, where the `button` property is revealed in the status bar. Try pressing individual mouse buttons on, say, the screen button.

**Related Items:** None.

## cancelable

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

**(NN6/Moz/Safari) eventObject.charCode**

If an event is cancelable, then its default action can be prevented from occurring with the help of a script. While most events are cancelable, some are not. The cancelable property lets you inquire about a particular event object to see if its event type is `cancelable`. Values for the property are Booleans. You may want to perform special operations only on events that are cancelable and handle the others without special treatment. For this branch, you can use the property in an `if` condition statement:

```
if (evt.cancelable) {  
    // special processing for cancelable events  
}
```

You do not have to branch, however, just to prevent an event's default action. A non-cancelable event doesn't mind if you tell it to prevent the default action.

**Related Items:** `preventDefault()` method.

## cancelBubble

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `cancelBubble` property is a rare instance of an IE4+ event property being implemented in NN6+/Moz/Safari even though the property is not defined in the W3C DOM. The property operates the same as in IE4+ in that it determines whether the current event object bubbles up any higher in the element containment hierarchy of the document. By default, this property is `false`, meaning that if the event is supposed to bubble, it will do so automatically.

To prevent event bubbling for the current event, set the property to `true` anywhere within the event handler function. As an alternative, you can cancel bubbling directly in an element's event handler attribute, as in the following:

```
onclick="doButtonClick(this); event.cancelBubble = true"
```

Canceling event bubbling works only for the current event. The very next event to fire will have bubbling enabled (provided the event bubbles).

If you are trying to migrate your code as much as possible to the W3C DOM, use the `stopPropagation()` method instead of `cancelBubble`. For cross-browser compatibility, however, `cancelBubble` is a safe bet.

## Example

See Listing 25-6 to see the `cancelBubble` property in action in an IE environment. Even though that listing has some features that apply to WinIE5.5+, the bubble cancelling demonstration works all the way back to IE4.

**Related Items:** `stopPropagation()` method.

## charCode

### keyCode

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The W3C DOM event object model clearly distinguishes between the Unicode character attached to the alphanumeric keys of the keyboard and the code attached to each of the keyboard keys (regardless of its character). To inspect the character of a key, use the

**(NN6/Moz/Safari) `eventObject.charCode`**

`onkeypress` event to create the event object, and then look at the event object's `charCode` property. This is the property that returns 97 for “a” and 65 for “A” because it’s concerned with the character associated with the key action. This property’s value is zero for `onkeydown` and `onkeyup` events.

In contrast, the `keyCode` property is filled with a non-zero value only from `onkeydown` and `onkeyup` events (`onkeypress` sets the property to zero) when alphanumeric keys are pressed; for most other non-character keys, all three events fill the `keyCode` property. Through this property you can look for non-character keys, such as arrows, page navigation, and function keys. For the character keys, there is no distinction between uppercase or lowercase: The “A” key on the Latin keyboard returns a value of 65, regardless of the state of the Shift key. At the same time, however, the press of the Shift key fires its own `onkeydown` and `onkeyup` events, setting the `keyCode` value to 16. Other non-character keys — arrows, page navigation, function, and similar — have their own codes as well. This gets very detailed, including special key codes for the numeric keyboard keys that are different from their corresponding numbers along the top row of the alphanumeric keyboard.

**Note**

Safari 1.0 does not support the `charCode` property. Instead, the `keyCode` property returns the ASCII values of alphanumeric keyboard keys — and no non-character keys for any keyboard event.

Be sure to see the extensive section on keyboard events in Chapter 15 for examples of how to apply the `keyCode` property in applications.

**Example**

Listing 25-18 provides a play area to view the `charCode` and `keyCode` properties for all three keyboard events while you type into a `textarea`. You can use this later as an authoring tool to grab the precise codes for keyboard keys you may not be familiar with.

**Listing 25-18: Displaying `charCode` and `keyCode` Property Values**

```
<html>
  <head>
    <title>charCode and keyCode Properties</title>
    <style type="text/css">
      td {text-align:center}
    </style>
    <script type="text/javascript">
      function showCode(which, evt) {
        document.forms[0].elements[which + "Char"].value = evt.charCode;
        document.forms[0].elements[which + "Key"].value = evt.keyCode;
      }
      function clearEm() {
        for (var i = 1; i < document.forms[0].elements.length; i++) {
          document.forms[0].elements[i].value = "";
        }
      }
    </script>
  </head>
  <body>
    <h1>charCode and keyCode Properties</h1>
    <hr />
```

```

<form>
  <p><textarea name="scratchpad" cols="40" rows="5" wrap="hard"
    onkeydown="clearEm(); showCode('down', event)"
    onkeyup="showCode('up', event)"
    onkeypress="showCode('press', event)"></textarea></p>
  <table cellpadding="5">
    <tr>
      <th>Event</th>
      <th>event.charCode</th>
      <th>event.keyCode</th>
    </tr>
    <tr>
      <td>onKeyDown:</td>
      <td><input type="text" name="downChar" size="3" /></td>
      <td><input type="text" name="downKey" size="3" /></td>
    </tr>
    <tr>
      <td>onKeyPress:</td>
      <td><input type="text" name="pressChar" size="3" /></td>
      <td><input type="text" name="pressKey" size="3" /></td>
    </tr>
    <tr>
      <td>onKeyUp:</td>
      <td><input type="text" name="upChar" size="3" /></td>
      <td><input type="text" name="upKey" size="3" /></td>
    </tr>
  </table>
</form>
</body>
</html>

```

Here are some specific tasks to try with the page in NN6+/Moz1+ to examine key codes (if you are not using a browser set for English and a Latin-based keyboard, your results may vary):

1. Enter a lowercase “a”. Notice how the `onkeypress` event handler shows the `charCode` to be 97, which is the Unicode (and ASCII) value for the first of the lowercase letters of the Latin alphabet. But the other two event types record just the key’s code: 65.
2. Type an uppercase “A” via the Shift key. If you watch closely, you see that the Shift key, itself, generates the key code 16 for the `onkeydown` and `onkeyup` events. But the character key then shows the value 65 for all three events (until you release the Shift key), because the ASCII value of the uppercase letter happens to match the keyboard key code for that letter.
3. Press and release the Down Arrow key (be sure the cursor still flashes in the `textarea`, because that’s where the keyboard events are being monitored). As a non-character key, all three events stuff a value into the `keyCode` property, but zero into `charCode`. The `keyCode` value for this key is 40.
4. Poke around with other non-character keys. Some may produce dialog boxes or menus, but their key codes are recorded nonetheless.

**Related Items:** `onkeydown`, `onkeypress`, `onkeyup` event handlers.

**(NN6/Moz/Safari) *eventObject*.clientX**

clientX  
clientY  
layerX  
layerY  
pageX  
pageY  
screenX  
screenY

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The W3C DOM *event* object borrows mouse coordinate properties from both the NN4 and IE4+ event models. If you have worked with event coordinates in these other browsers, you have nothing new to learn for W3C DOM-compatible browsers.

Like the IE4+ *event* object, the W3C DOM *event* object's *clientX* and *clientY* properties are the coordinates within the viewable content region of the window. These values are relative to the window space, not the document. But unlike IE4+, you don't have to calculate the position of the coordinates within the document because another pair of NN/Moz/Safari properties, *pageX* and *pageY*, provide that information automatically. If the page has not scrolled, the values of the client and page coordinates are the same. Because it is usually more important to know an event's coordinates with respect to the document than the window, the *pageX* and *pageY* properties are used most often.

Another NN/Moz/Safari property pair, *layerX* and *layerY*, borrow terminology from the now defunct layer schemes of NN4, but the properties can still be quite valuable nonetheless. These coordinates are measured relative to the positioning context of the element that received the event. For regular, unpositioned elements in the *body* part of a document, that positioning context is the *body* element. Thus, for those elements, the values of the page and layer coordinates will be the same. But if you create a positioned element, the coordinate space is measured from the top-left corner of that space. Thus, if you are using the coordinates to assist in scripted dragging of positioned elements, you can confine your scope to just the positioned element.

One coordinate system missing from the NN6+/Moz repertoire, but present in Safari, is that of the target element itself (comparable to the *offsetX* and *offsetY* properties of IE4+). These values, however, can be calculated in NN/Moz by subtracting from the page coordinate properties the *offsetLeft* and *offsetTop* properties of both the target element and its positioning context. For example, if you want to get the coordinates of a mouse event inside an image, the event handler can calculate those values as follows:

```
var clickOffsetX = evt.pageX - evt.target.offsetLeft -  
    document.body.offsetLeft;  
var clickOffsetY = evt.pageY - evt.target.offsetTop -  
    document.body.offsetTop;
```

The last set of coordinate properties, *screenX* and *screenY*, provide values relative to the entire video display. Of all these properties, only the client and screen coordinates are defined in the W3C DOM Level 2 standard.

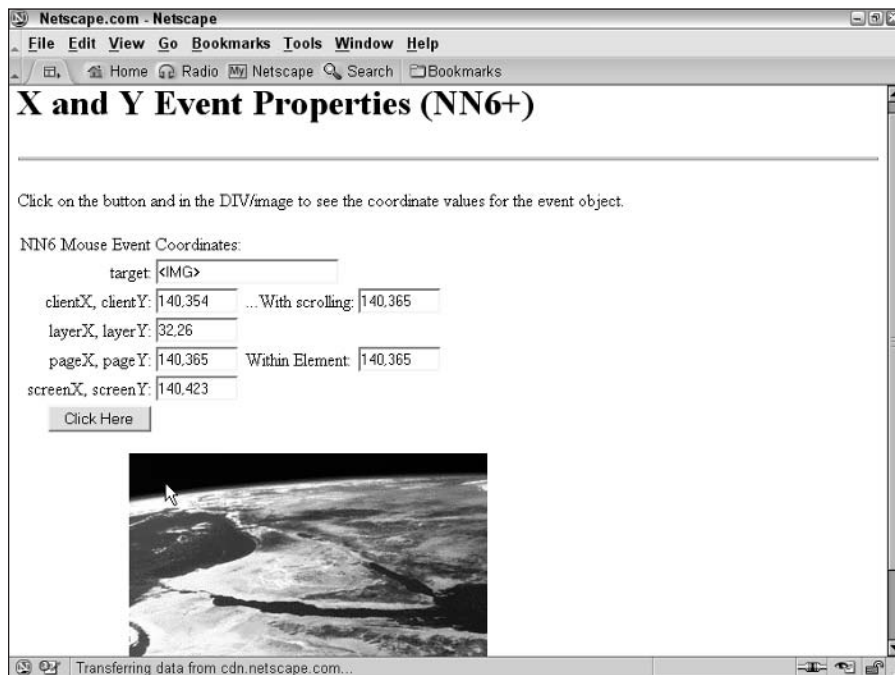

**(NN6/Moz/Safari) `eventObject.clientX`**

Keep in mind that in most W3C DOM-compatible browsers, event targets include text nodes inside elements. Because nodes do not have all the properties of elements (for example, they have no offset properties signifying their location in the document), you may sometimes have to go to the target node's parent node to get an element object whose offset properties provide the necessary page geography. This matters, of course, only if your scripts need concern themselves with mouse events on text.

## Example

You can see the effects of the coordinate systems and associated NN6+/Moz properties with the page in Listing 25-19. You can view coordinate values for all four measuring systems, as well as some calculated value. Two clickable objects are provided so that you can see the differences between an object not in any layer and an object residing within a layer (although anything you see is clickable, including text nodes). Figure 25-1 shows the results of a click inside the positioned layer.

One of the calculated fields applies window scrolling values to the client coordinates. But, as you will see, these calculated values are the same as the more convenient page coordinates. The other calculated field shows the coordinates relative to the rectangular space of the target element. Notice in the code that if the `nodeType` of the target indicates a text node, that node's parent node (an element) is used for the calculation.

**Figure 25-1:** NN6+/Moz event coordinates for a click inside a positioned element.

## Listing 25-19: NN6+/Moz/Safari Event Coordinate Properties

```

<html>
  <head>
    <title>X and Y Event Properties (NN6+)</title>
    <script type="text/javascript">
      function checkCoords(evt) {
        var form = document.forms["output"];
        var targText, targElem;
        if (evt.target.nodeType == 3) {
          targText = "[textnode] inside <" + evt.target.parentNode.tagName +
            ">";
          targElem = evt.target.parentNode;
        } else {
          targText = "<" + evt.target.tagName + ">";
          targElem = evt.target;
        }
        form.srcElemTag.value = targText;
        form.clientCoords.value = evt.clientX + "," + evt.clientY;
        form.clientScrollCoords.value = (evt.clientX + window.scrollX) +
          "," + (evt.clientY + window.scrollY);
        form.layerCoords.value = evt.layerX + "," + evt.layerY;
        form.pageCoords.value = evt.pageX + "," + evt.pageY;
        form.inElemCoords.value =
          (evt.pageX - targElem.offsetLeft - document.body.offsetLeft) +
          "," + (evt.pageY - targElem.offsetTop - document.body.offsetTop);
        form.screenCoords.value = evt.screenX + "," + evt.screenY;
        return false;
      }
    </script>
  </head>
  <body onmousedown="checkCoords(event)">

</table>
</form>
<div id="display" style="position:relative; left:100">
    
</div>
</body>
</html>

```

**Related Items:** target property.

## currentTarget

**Value:** Element object reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

As an event courses its way through its propagation paths, an event listener may process that event along the way. Though the event knows what the target is, it can also be helpful for the event listener function to know which element's event listener is now processing the event. The `currentTarget` property provides a reference to the element object whose event listener is processing the event. This allows one listener function to potentially process the event from different levels, branching the code to accommodate different element levels that process the event.

A valuable companion piece of information about the event is the `eventPhase` property, which helps your event listener function determine if the event is in capture mode, bubble mode, or is at the target. This property is demonstrated in the next section.

## Example

Listing 25-20 shows the power of the `currentTarget` property in revealing the element that is processing an event during event propagation. Similar to the code in Listing 25-7, this example is made simpler because it lets the event object's properties do more of the work to reveal the identity of each element that processes the event. Event listeners assigned for various propagation modes are assigned to a variety of nodes in the document. After you click the button, each listener in the propagation chain fires in sequence. The alert dialog shows which node is processing the event. And, as in Listing 25-7, the `eventPhase` property is used to help display the propagation mode in force at the time the event is processed by each node.

Listing 25-20: *currentTarget* and *eventPhase* Properties

```
<html>
  <head>
    <title>currentTarget and eventPhase Properties</title>
    <script type="text/javascript">
      function init() {
        // using old syntax to assign bubble-type event handlers
        document.onclick = processEvent;
        document.body.onclick = processEvent;
        // turn on click event capture for document and form
        document.addEventListener("click", processEvent, true);
        document.forms[0].addEventListener("click", processEvent, true);
        // set bubble event listener for form
        document.forms[0].addEventListener("click", processEvent, false);
      }
      function processEvent(evt) {
        var currTargTag, msg;
        if (evt.currentTarget.nodeType == 1) {
          currTargTag = "<" + evt.currentTarget.tagName + ">";
        } else {
          currTargTag = evt.currentTarget.nodeName;
        }
        msg = "Event is now at the " + currTargTag + " level ";
        msg += "(" + getPhase(evt) + ").";
        alert(msg);
      }
      // reveal event phase of current event object
      function getPhase(evt) {
        switch (evt.eventPhase) {
          case 1:
            return "CAPTURING";
            break;
          case 2:
            return "AT TARGET";
            break;
          case 3:
            return "BUBBLING";
            break;
          default:
            return "";
        }
      }
    </script>
  </head>
  <body onload="init()">
    <h1>currentTarget and eventPhase Properties</h1>
    <hr />
    <form>
      <input type="button" value="A Button" name="main1"
        onclick="processEvent(event)" />
    </form>
  </body>
</html>
```

(NN6/Moz) *eventObject.originalTarget*

You can also click other places on the page. For example, if you click to the right of the button, you will be clicking the `form` element. Event propagation and processing adjusts accordingly. Similarly, if you click the header text, the only event listeners that see the event are in the document and `body` levels.

**Related Items:** `eventPhase` property.

## detail

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `detail` property is included in the W3C DOM specification as an extra property whose purpose can be determined by the browser maker. Mozilla-based browsers increment a numeric value for rapid instances of `click` events on an object; Safari appears to be holding this property in reserve.

**Related Items:** None.

## eventPhase

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

An event fires in one of three possible event phases: event capture, at the target, or bubbling. Because the same event listener function may be processing an event in multiple phases, it can inspect the value of the `eventPhase` property of the event object to see in which phase the event was when the function was invoked. Values for this property are integers 1 (capture), 2 (at target), or 3 (bubbling).

## Example

See Listing 25-20 earlier in this chapter for an example of how you can use a `switch` construction to branch function processing based on the event phase of the current event object.

**Related Items:** `currentTarget` property.

## isChar

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

You can find out from each keyboard event whether the key being pressed is a character key by examining the `isChar` property. Most typically, however, you are already filtering for character or non-character keys by virtue of the event handlers used to capture keyboard actions: `onkeypress` for character keys; `onkeydown` or `onkeyup` for non-character keys. Be aware that the `isChar` property returns inconsistent values (even for the same key) in the first release of NN6.

**Related Items:** `charCode`, `keyCode` properties.

## originalTarget

**Value:** Node object reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `originalTarget` property provides a reference to the node object that serves as the genuine first target of the event. This information is typically associated with the internal construction of certain elements, which makes it less useful for scripting purposes.

**(NN6/Moz/Safari) `eventObject.originalTarget`**

Additionally, in many cases the `originalTarget` property holds the same value as the `target` property.

**relatedTarget**

**Value:** Element object.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `relatedTarget` property allows an element to uncover where the cursor rolled in from or has rolled out to. This property extends the power of the `onmouseover` and `onmouseout` event handlers by expanding their scope to outside the current element (usually to an adjacent element). This one W3C DOM property does the same duty as the `fromElement` and `toElement` properties of the IE4+ event object.

When the `onmouseover` event fires on an element, the cursor had to be over some other element just beforehand. The `relatedTarget` property holds a reference to that element. Conversely, when the `onmouseout` event fires, the cursor is already over some other element. The `relatedTarget` property holds a reference to that element.

**Example**

Listing 25-21 provides an example of how the `relatedTarget` property can reveal the life of the cursor action before and after it rolls into an element. When you roll the cursor to the center box (a table cell), its `onmouseover` event handler displays the text from the table cell from which the cursor arrived (the `nodeValue` of the text node inside the table cell). If the cursor comes in from one of the corners (not easy to do), a different message is displayed.

The two functions that report the results employ a bit of filtering to make sure that they process the event object only if the event occurs on an element and if the `relatedTarget` element is anything other than a nested text node of the central table cell element. Because nodes respond to events in W3C DOM browsers, this extra filtering prevents processing whenever the cursor makes the transition from the central `td` element to its nested text node. Safari 1.0 reports values only on horizontal moves in this example—between cells of the same table row.

**Listing 25-21: Using the `relatedTarget` Property**

```
<html>
  <head>
    <title>relatedTarget Properties</title>
    <style type="text/css">
      .direction {background-color:#00FFFF; width:100; height:50;
        text-align:center}
      #main {background-color:#FF6666; text-align:center}
    </style>
    <script type="text/javascript">
      function showArrival(evt) {
        if (evt.target.nodeType == 1) {
          if (evt.relatedTarget != evt.target.firstChild) {
            var direction = (evt.relatedTarget.firstChild) ?
              evt.relatedTarget.firstChild.nodeValue : "parts unknown";
            window.status = "Arrived from: " + direction;
          }
        }
      }
    </script>
  </head>
</html>
```

**(NN6/Moz/Safari) eventObject.target**

```

function showDeparture(evt) {
  if (evt.target.nodeType == 1) {
    if (evt.relatedTarget != evt.target.firstChild) {
      var direction = (evt.relatedTarget.firstChild) ?
        evt.relatedTarget.firstChild.nodeValue : "parts unknown";
      window.status = "Departed to: " + direction;
    }
  }
}
</script>
</head>
<body>
  <h1>relatedTarget Properties</h1>
  <hr />
  <p>Roll the mouse to the center box and look for arrival information in
  the status bar. Roll the mouse away from the center box and look for
  departure information in the status bar.</p>
  <table cellpadding="0" cellspacing="5">
    <tr>
      <td></td>
      <td class="direction">North</td>
      <td></td>
    </tr>
    <tr>
      <td class="direction">West</td>
      <td id="main" onmouseover="showArrival(event)"
      onmouseout="showDeparture(event)">Roll</td>
      <td class="direction">East</td>
    </tr>
    <tr>
      <td></td>
      <td class="direction">South</td>
      <td></td>
    </tr>
  </table>
</body>
</html>

```

**Related Items:** target property.

## target

**Value:** Element object reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `target` property is a reference to the HTML element object that is the original target of the event. Because an event may trickle down and bubble up through the element containment hierarchy and be processed at any level along the way, having a property that points back to the element from which the event originated is comforting. As soon as you have a reference to that element, you can read or write any properties that belong to that element or invoke any of its methods.

## Example

As a simplified demonstration of the power of the `target` property, Listing 25-22 has but two event handlers defined for the `body` element, each invoking a single function. The idea is that

**(NN6/Moz/Safari) `eventObject.target`**

the `onmousedown` and `onmouseup` events will bubble up from whatever their targets are, and the event handler functions will find out which element is the target and modify the color style of that element.

An extra flair is added to the script in that each function also checks the `className` property of the target element. If the `className` is `bold`—a class name shared by three `span` elements in the paragraph—the stylesheet rule for that class is modified so that all items share the same color. Your scripts can do even more in the way of filtering objects that arrive at the functions to perform special operations on certain objects or groups of objects.

Notice that the scripts don't have to know anything about the objects on the page to address each clicked one individually. That's because the `target` property provides all of the specificity needed for acting on the target element.

**Listing 25-22: Using the `target` Property**

```
<html>
  <head>
    <title>target Property</title>
    <style type="text/css">
      .bold {font-weight:bold}
      .ital {font-style:italic}
    </style>
    <script type="text/javascript">
      function highlight(evt) {
        var elem = (evt.target.nodeType == 3) ? evt.target.parentNode :
          evt.target;
        if (elem.className == "bold") {
          document.styleSheets[0].cssRules[0].style.color = "red";
        } else {
          elem.style.color = "#FFCC00";
        }
      }
      function restore(evt) {
        var elem = (evt.target.nodeType == 3) ? evt.target.parentNode :
          evt.target;
        if (elem.className == "bold") {
          document.styleSheets[0].cssRules[0].style.color = "black";
        } else {
          elem.style.color = "black";
        }
      }
    </script>
  </head>
  <body onmousedown="highlight(event)" onmouseup="restore(event)">
    <h1>target Property</h1>
    <hr />
    <p>One event handler...</p>
    <ul>
      <li>Can</li>
      <li>Cover</li>
      <li>Many</li>
      <li>Objects</li>
    </ul>
```

(NN6/Moz/Safari) *eventObject.timeStamp*

```

    <p>Lorem ipsum dolor sit amet, consectetur adipiscing elit, <span
      class="bold">sed do</span> eiusmod tempor incididunt <span
      class="ital">ut labore et</span> dolore magna aliqua. Ut enim adminim
      veniam, <span class="bold">quis nostrud exercitation</span> ullamco
      laboris nisi ut aliquip ex ea <span class="bold">commodo
      consequat</span>.</p>
  </body>
</html>

```

**Related Items:** `relatedTarget` property.

## timeStamp

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

Each event receives a time stamp in milliseconds, based on the same date epoch as the `Date` object (1 January 1970). Just as with the `Date` object, accuracy is wholly dependent on the accuracy of the system clock of the client computer.

Although the precise time of an event may be of value in only some situations, the time between events can be useful for applications, such as timed exercises or action games. You can preserve the time of the most recent event in a global variable, and compare the time of the current time stamp against the stored value to determine the elapsed time between events.

## Example

Listing 25-23 uses the `timeStamp` property to calculate the instantaneous typing speed when you type into a `textarea`. The calculations are pretty raw, and work only on intra-keystroke times without any averaging or smoothing that a more sophisticated typing tutor might perform. Calculated values are rounded to the nearest integer.

### Listing 25-23: Using the `timeStamp` Property

```

<html>
  <head>
    <title>timeStamp Property</title>
    <script type="text/javascript">
      var stamp;
      function calcSpeed(evt) {
        if (stamp) {
          var gross = evt.timeStamp - stamp;
          var wpm = Math.round(6000/gross);
          document.getElementById("wpm").firstChild.nodeValue = wpm +
            " wpm.";
        }
        stamp = evt.timeStamp;
      }
    </script>
  </head>

```

*Continued*

## Listing 25-23 (continued)

```

<body>
  <h1>timeStamp Property</h1>
  <hr />
  <p>Start typing, and watch your instantaneous typing speed below:</p>
  <p><textarea cols="60" rows="10" wrap="hard"
    onkeypress="calcSpeed(event)"></textarea></p>
  <p>Typing Speed: <span id="wpm">&#160;</span></p>
</body>
</html>

```

**Related Items:** Date object.

## type

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

You can find out what kind of event fired to create the current event object by way of the `type` property. The value is a string version of the event name — just the name of the event without the “on” prefix that is normally associated with event listener names in NN6+. This property can be helpful when you designate one event handler function to process different kinds of events. For example, both the `onmousedown` and `onclick` event listeners for an object can invoke one function. Inside the function, a branch is written for whether the type comes in as `mousedown` or `click`, with different processing for each event type. That is not to endorse such event handler function sharing, but be aware of this power should your script constructions find the property helpful.

This property and its values are fully compatible with the NN4 and IE4+ event models.

**Caution**

Keyboard events in Safari 1.0 report their types as `khtml_keydown`, `khtml_keypress`, and `khtml_keyup`, using the prefix referring to the name of the rendering engine on which Safari is built. This is probably to avoid committing to an unfinished W3C DOM Level 3 keyboard event specification.

**Related Items:** All event handlers (Chapter 15).

## view

**Value:** Window object reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The closest that the W3C DOM Level 2 specification comes to acknowledging the browser window is an abstract object called an *abstract view* (AbstractView class). The object’s only property is a reference to the document that it contains — the root document node that you’ve come to know and love. User events always occur within the confines of one of these views, and this is reflected in the event object’s `view` property. NN6+ returns a reference to the `window` object (which can be a frame) in which the event occurs. This reference allows an event object to be passed to scripts in other frames and those scripts can then gain access to the document object of the target element’s window.

**Related Items:** `window` object.

## Methods

```
initEvent("eventType", bubblesFlag, cancelableFlag)
initKeyEvent("eventType", bubblesFlag, cancelableFlag,
view, ctrlKeyFlag, altKeyFlag, shiftKeyFlag, metaKeyFlag,
keyCode, charCode)
initMouseEvent("eventType", bubblesFlag, cancelableFlag,
view, detailVal, screenX, screenY, clientX, clientY,
ctrlKeyFlag, altKeyFlag, shiftKeyFlag, metaKeyFlag,
buttonCode, relatedTargetNodeRef)
initMutationEvent("eventType", bubblesFlag,
cancelableFlag, relatedNodeRef, prevValue, newValue,
attrName, attrChangeCode)
initUIEvent("eventType", bubblesFlag, cancelableFlag,
view, detailVal)
```

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The W3C DOM event object initialization methods provide a means of initializing a newly created event with a complete set of property values associated with that particular event. The parameters to each of the initialization methods vary according to the type of event being initialized. However, all of the initialization methods share the first three parameters: `eventType`, `bubblesFlag`, and `cancelableFlag`. The `eventType` parameter is a string identifier for the event's type, such as "mousedown" or "keypress". The `bubblesFlag` parameter is a Boolean value that specifies whether the event's default propagation behavior is to bubble (`true`) or not (`false`). The `cancelableFlag` parameter is also a Boolean value, and its job is to specify if the event's default action may be prevented with a call to the `preventDefault()` method (`true`) or not (`false`).

A few of the methods also include `view` and `detailVal` parameters, which correspond to the window or frame in which the event occurred and the integer code of detail data associated with the event, respectively. Additional parameters are specified for some of the methods, and are unique to the event being initialized.

You don't have to use the more detailed methods if you need a simple event. For example, if you want a simple `mouseup` event, you can initialize a generic event with `initEvent()`, and dispatch the event to the desired element, without having to fill in all of the coordinate, button, and other parameters of the `initMouseEvent()` method:

```
var evt = document.createEvent("MouseEvents");
evt.initEvent("mouseup", true, true);
document.getElementById("myButton").dispatchEvent(evt);
```

For more details about W3C DOM event types and the values expected for each of the more complex initialization methods, visit <http://www.w3.org/TR/DOM-Level-2-Events/events.html#Events-eventgroupings>.

**Related Items:** `document.createEvent()` method.

**(NN6/Moz/Safari) `eventObject.preventDefault()`**

## `preventDefault()`
