**Returns:** Nothing.**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

While NN6+ continues to honor the original way of preventing default action for an event handler (that is, having the last statement of the event handler evaluate to `return false`), the W3C DOM event model provides a method that lets the cancellation of default action take place entirely within a function invoked by an event handler. For example, consider a text box that is supposed to allow only numbers to be typed in it. The `onkeypress` event handler can invoke a function that inspects each typed character. If the character is not a numeric character, it does not reach the text box for display. The following validation function may be invoked from the `onkeypress` event handler of just such a text box:

```
function checkIt(evt) {
    var charCode = evt.charCode;
    if (charCode < 48 || charCode > 57) {
        alert("Please make sure entries are numbers only.");
        evt.preventDefault();
    }
}
```

This way, the errant character won't appear in the text box.

Invoking the `preventDefault()` method in NN6+/Moz/Safari is the equivalent of assigning `true` to `event.returnValue` in IE5+.

**Related Items:** `cancelable` property.

## `stopPropagation()`

**Returns:** Nothing.**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

Use the `stopPropagation()` method to stop events from trickling down or bubbling up further through the element containment hierarchy. A statement in the event listener function that invokes

```
evt.stopPropagation();
```

is all that is needed. As an alternative, you can cancel bubbling directly in an element's event handler attribute, as in the following:

```
onclick="doButtonClick(this); event.stopPropagation()"
```

If you are writing cross-browser scripts, you also have the option of using the `cancelBubble` property, which is compatible with IE4+.

**Related Items:** `bubbles`, `cancelBubble` properties.

# Style Sheet and Style Objects

---

**V**ersion 4 browsers from Microsoft and Netscape were the first to offer full-scale support for the concept of stylesheets. Stylesheets promote a concept that makes excellent sense in the fast-paced, high-volume content creation environment that is today's World Wide Web: separating content from the rendering details of the content. Textual content may come from any number of electronic sources, but it may need to be dropped into different contexts — just like an online news feed that becomes amalgamated into dozens of Web portal sites, each with its own look and feel. All the content cares about is the text and its meaning; the Web page designer then decides how that content should be rendered on the page.

The concept has other advantages. Consider the large corporate Web site that wants to promote its identity through a distinct style. A family of stylesheets can dictate the font face, font size, the look of emphasized text, and the margin width of all body text. To apply these styles on an element-by-element basis would not only be a tedious page-authoring task, it is fraught with peril. If the style is omitted from the tags of one page, the uniformity of the look is destroyed. Worse yet, if the corporate design changes to use a different font face, the task of changing every style in every tag — even with a highly powered search-and-replace operation — is risky. But if a single external stylesheet file dictates the styles, then the designer need make only one change in that one file to cause the new look to ripple through the entire Web site.

Learning how to create and apply stylesheets is beyond the scope of this book, and this chapter assumes you already are familiar with stylesheet terminology, such as a stylesheet rule and a selector. If these terms are not in your vocabulary, you can find numerous tutorials on the subject both online and in books. Although IE, NN, and other recent browsers adhere fairly closely to W3C standards for stylesheets (called Cascading Style Sheets, or CSS for short), your first learning experience should come from sources that focus on standards, rather than browser-specific features. Microsoft includes some extras in the stylesheet vocabulary that work only on IE4+ for Windows; Netscape 7+ and other Mozilla-based browsers have specially named, preliminary properties that offer future CSS3 capabilities in advance of the final standards. Unless you develop for a single target browser brand and client operating system, learning the common denominator of stylesheet features is the right way to go. Details in this chapter cover all versions, so pay close attention to compatibility listings for each item.

## In This Chapter

Managing stylesheets by script

Changing element styles on the fly

Distinguishing among style, styleSheet, and style objects

One last compatibility note: Although NN4 implements a fair amount of CSS, it does not expose stylesheets or style rules to the object model. Part of this is linked to the static nature of an NN4 page. Because modifying a style may alter the physical layout of body elements, and because that browser does not reflow the page in response to such changes, altering styles of content that is already loaded is simply not possible. In NN6+/Moz1+, however, the page reflows, and everything relating to styles is exposed to the scriptable object model.

## Making Sense of the Object Names

The first task in this chapter is to clarify the seemingly overlapping terminology for the stylesheet-related objects that you will be scripting. Some objects are more abstract than others, but they are all important. The objects in question are

- ♦ `style` element object
- ♦ `stylesheet` object (a member of the `styleSheets` array)
- ♦ `rule` or `cssRule` object (a member of the `rules` or `cssRules` array)
- ♦ `style` object

A `style` element object is the object that represents the `<style>` tag in your document. Most of its properties are inherited from the basic HTML element objects you see detailed in Chapter 15. By and large, you won't be reading or writing stylesheet properties via the `style` element object.

A stylesheet can be embedded in a document via the `<style>` tag or it may be linked in via a `<link>` tag. One property of the document object, the `styleSheets` property, returns an array (collection) of all `stylesheet` objects that are currently “visible” to the document, whether or not they are disabled. Included in the collection are stylesheets defined by a `<style>` tag or linked in via a `<link>` tag. Even though the `<style>` tag, for example, contains lines of code that make up the rules for a stylesheet, the `style` element object is not the path to reach the individual rules. The `stylesheet` object is. It is through the `stylesheet` object that you can enable or disable an entire sheet, access individual rules (via the `rules` or `cssRules` property array), and add or delete rules for that stylesheet.

The meat of any stylesheet is the rules that define how elements are to be rendered. At this object level, the terminology forks in IE4 and NN6. The IE4+ object model calls each stylesheet rule a rule object; the W3C DOM Level 2 model (in NN6+/Moz), calls each rule a `cssRule` object. MacIE5 and Safari support both references to the same object. Despite the incompatible object names, the two objects share key property names. Assembling a reference to a rule requires array references. For example, the reference to the first rule of the first `stylesheet` object in the document is as follows for various browsers:

```
var oneRule = document.styleSheets[0].rules[0];           // IE4+, MacIE5, Safari
var oneRule = document.styleSheets[0].cssRules[0];      // MacIE5, NN6+/Moz,
Safari
```

The last object of this quartet of style-related objects is the `style` object. This object is the mother lode, where actual style definitions take place. In earlier chapters, you have seen countless examples of modifying one or more `style` properties of an element. Most typically, this modification is accomplished through the `style` property of the HTML element. For example, you would set the font color of a `span` element whose ID is “hot” as follows:

```
document.all.hot.style.color = "red";                    // IE4+
document.getElementById("hot").style.color = "red";     // IE5+, W3C
```

The `style` object is also a property of a `rule/cssRule` object. Thus, if you need to modify the style of elements affected by an existing stylesheet rule, you approach the `style` object through a different reference path, but the `style` object is treated just as it is for elements:

```
document.styleSheets[0].rules[0].style.color = "red"; // IE4+, MacIE5, Safari
document.styleSheets[0].cssRules[0].style.color = "red"; // MacIE5, NN6+/Moz, Safari
```

Many scripters concern themselves solely with the `style` object, and at that, a `style` object associated with a particular element object. Rare are instances that require manipulation of `styleSheet` objects beyond perhaps enabling and disabling them under script control. Therefore, if you are learning about these objects for the first time, pay closest attention to the `style` object details rather than to the other related objects.

## Imported Stylesheets

Stylesheets embedded in a document via the `style` element can import additional stylesheets via the `@import` selector:

```
<style type="text/css">
@import url(externalStyle.css);
p {font-size:16pt}
</style>
```

In this example scenario, the document sees just one `styleSheet` object. But that object has a stylesheet nested inside—the stylesheet defined by the external file. IE4+ calls one of these imported stylesheets an `import` object. An `import` object has all the properties of any `styleSheet` object, but its `parentStyle` property is a reference to the `styleSheet` that “owns” the `@import` rule. In fact, the `@import` statement does not even appear among the rules collection of the IE `styleSheet` object. Therefore, to access the first rule of the imported stylesheet, the reference is as the following:

```
document.styleSheets[0].imports[0].rules[0]
```

The W3C DOM and NN6+/Moz1+ treat `import` rule objects differently from the IE model. To the W3C DOM, even an at-rule is considered one of the `cssRules` collection of a `styleSheet` object. One of the properties of a `cssRule` object is `type`, which conveys an integer code value revealing whether the rule is a plain CSS rule or one of several other types, including an `import` rule. Of course, an imported rule object then has as one of its properties the `styleSheet` object that, in turn, contains the rules defined in the external stylesheet file. The parent-child relationship exists here, as well, whereby the stylesheet that contains the `@import` rule is referenced by the imported `styleSheet` object’s `parentStyle` property (just as in IE4+).

## Reading Style Properties

Both the IE4+ and W3C object models exhibit a behavior that at first glance may seem disconcerting. On the one hand, the W3C and good HTML practice encourage defining styles remotely (that is, embedded via `<style>` or `<link>` tags) rather than as values assigned to the `style` attribute of individual element tags throughout the document. This more closely adheres to the notion of separating style from content.

**style**

On the other hand, object models can be very literal beasts. Strictly speaking, if an element object presents a scriptable property that reflects an attribute for that element's tag, the first time a script tries to read that property, a value will be associated with that property *only* if the attribute is explicitly assigned in the HTML code. But if you assign stylesheet settings via remote stylesheets, the values are not explicitly set in the tag. Therefore, the `style` property of such an element comes up empty, even though the element is under the stylistic control of the remote stylesheet. If all you want to do is assign a new value to a style property, that's not a problem, because your assignment to the element object's `style` property overrides whatever style is assigned to that property in the remote stylesheet (and then that new value is subsequently readable from the `style` property). But if you want to see what the current setting is, the initial value won't be in the element's `style` object.

Microsoft (in IE5+) and the W3C DOM provide competing (and incompatible) solutions so this problem.

IE5+ provides an extra, read-only property — `currentStyle` — that reveals the stylesheet values that are currently being applied to the element, regardless of where the stylesheet definitions are. The `currentStyle` property returns an object that is in the same format and has most of the same properties as the regular `style` property. If your audience runs browsers no earlier than IE5, you should make a habit of reading styles for an element via its `currentStyle` property. If you want a change to a `style` object's property to apply to only one element, use the element's `style` property to set that value; but if the change is to apply to all elements covered by the same remote stylesheet rule, modify the `style` property of the rule object.

The W3C DOM solution is the `getComputedStyle()` method. Although the W3C DOM doesn't (yet) talk about a `window` object, it does describe an object (called the `defaultView`) which Mozilla-based browsers channel through the `window` object. To read the value of a particular style property being applied to an element, you first retrieve a *computed style* value for the element, and then read the desired CSS style property. For example, to read the `font-family` currently applied to an element whose ID is `myP`, use the following sequence:

```
var elem = document.getElementById("myP");
var computedStyle = window.getComputedStyle(elem, "");
var fontFam = computedStyle.getPropertyValue("font-family");
```

Note that you must use the CSS property name (for example, `font-family`) and not the scripted equivalent of that property (for example, `fontFamily`). Unfortunately, Safari 1.0 does not support the `getComputedStyle()` method and does not allow scripts to read stylesheet values set outside of a rendered element's `style` attribute.

## style Element Object

See Chapter 15 for items shared by all HTML elements.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
media type		

## Syntax

Accessing `style` element object properties and methods:

```
(IE4+)      document.all.objectID.property | method([parameters])  
(IE5+/W3C) document.getElementById(objectID).property | method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

The `style` element is among the classification of HTML directive elements (see Chapter 36 on the CD-ROM) in that it goes in the `head` portion of a document and does not have any of its own content rendered in the page. But the contents obviously have a great amount of control over the rendering of other elements. Most of the properties, methods, and event handlers that the `style` element inherits from all HTML elements are irrelevant.

One exception is the Boolean `disabled` property. Although there are additional ways to disable a stylesheet (the `disabled` property of the `styleSheet` object), it may be easier to disable or enable a stylesheet by way of the `style` element object. Because you can assign an ID to this element and reference it explicitly, doing so may be more convenient than trying to identify which `styleSheet` object among the document's `styleSheets` collection you intend to enable or disable.

## Properties

### media

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `media` property represents the `media` attribute of a `style` element. This attribute can define what kind of output device is governed by the stylesheet. The HTML 4.0 specification has lofty goals for this attribute, but at best, computer browsers are limited to the following values: `screen`, `print`, and `all`. Thus, you can design one set of styles to apply when the page is viewed on the computer screen and a different set for when it's printed.

### type

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `type` property represents the `type` attribute of the `style` element. For Cascading Style Sheets, this property is always set to `text/css`. If your scripts assign some other value to this property and the browser does not support that stylesheet type, the stylesheet no longer functions as a Cascading Style Sheet, and any styles it controls revert to their default styles.

*styleSheetObject*

# styleSheet Object

readOnly		
rules		
title		
type		

## Syntax

Accessing `styleSheet` object properties and methods:

```
(IE4+/W3C) document.styleSheets[index].property | method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

If the `style` element object is the concrete incarnation of a stylesheet, then the `styleSheet` object is its abstract equivalent. A `styleSheet` object exists by virtue of a stylesheet definition being embedded in the current document either by way of the `<style>` tag or linked in from an external file via the `<link>` tag. Each element that introduces a stylesheet into a document creates a separate `styleSheet` object. Access to a `styleSheet` object is via the `document.styleSheets` array. If the document contains no stylesheet definitions, then the array has a length of zero. Styles that are introduced into a document by way of an element's `style` attribute are not considered `styleSheet` objects.

Although both IE4+ and W3C DOM browsers present `styleSheet` objects—and the object represents the same “thing” in both browser families—the set of properties and methods diverges widely between browsers. In many cases, the object provides the same information but through differently named properties in the two families. Interestingly, on some important properties, such as the ones that return the array of style rules and a reference to the HTML element that is responsible for the stylesheet's being in the document, MacIE5 and Safari provide both the Microsoft and W3C terminology. Methods for this object focus on adding rules to and deleting rules from the stylesheet. For the most part, however, your use of the `styleSheet` object will be as a reference gateway to individual rules (via the `rules` or `cssRules` array).

## Properties

### cssRules

**Value:** Array of rule objects.

Read-Only

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari1+

The `cssRules` property returns an array of stylesheet rule objects. Strictly speaking, the objects are called `cssRule` objects in the W3C DOM terminology. This property is implemented in MacIE5, but not in the Windows version as of IE6. The list of rule objects is in source code order. The corresponding WinIE4+ property is `rules`.

### Example

Use The Evaluator (Chapter 13) to look at the `cssRules` property in W3C DOM browsers or MacIE5. First, view how many rules are in the first `styleSheet` object of the page by entering the following statement into the top text box:

```
document.styleSheets[0].cssRules.length
```

Now use the array with an index value to access one of the rule objects to view the rule object's properties list. Enter the following statement into the bottom text box:

```
document.styleSheets[0].cssRules[1]
```

You use this syntax to modify the style details of an individual rule belonging to the `styleSheet` object.

**Related Items:** `rules` property, `cssRule`, `rule` objects.

### cssText

**Value:** String.

Read/Write

**Compatibility:** WinIE5+, MacIE5, NN-, Moz-, Safari-

The `cssText` property contains a string of all stylesheet rules contained by the `styleSheet` object. Parsing this text in search of particular strings is not wise because the text returned by this property can have carriage returns and other formatting that is not obvious from the text that is assigned to the rules in the stylesheet. But you can use this property as a way to completely rewrite the rules of a stylesheet in a rather brute-force manner: Assemble a string consisting of all the new rules and assign that string to the `cssText` property. The more formal way of modifying rules (adding and removing them) is perhaps better form, but there is no penalty for using the `cssText` property if your audience is strictly IE5+.

### Example

Use The Evaluator (Chapter 13) to replace the style rules in one blast via the `cssText` property. Begin by examining the value returned from the property for the initially disabled stylesheet by entering the following statement into the top text box:

```
document.styleSheets[0].cssText
```

Next, enable the stylesheet so that its rules are applied to the document:

```
document.styleSheets[0].disabled = false
```

Finally, enter the following statement into the top text box to overwrite the stylesheet with entirely new rules.

```
document.styleSheets[0].cssText = "p {color:red}"
```

***styleSheetObject.cssText***

Reload the page after you are finished to restore the original state.

**Related Items:** `addRule()`, `deleteRule()`, `insertRule()`, `removeRule()` methods.

**disabled**

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

While the `disabled` property of the `style` element object works with that element only, the `styleSheet` object's `disabled` property works with a `styleSheet` object that comes into the document by a `link` element as well.

Enabling and disabling stylesheets is one way to swap different appearance styles for a page, allowing the user to select the preferred style. The page can contain multiple stylesheets that control the same selectors, but your script can enable one and disable another to change the overall style. You can even perform this action via the `onload` event handler. For example, if you have separate stylesheets for Windows and Mac browsers, you can put both of them in the document, initially both disabled. An `onload` event handler determines the operating system and enables the stylesheet tailored for that OS. Unless your stylesheets are very extensive, there is little download performance penalty for having both stylesheets in the document.

**Example**

Use The Evaluator (Chapter 13) to toggle between the enabled and disabled state of the first `styleSheet` object on the page. Enter the following statement into the top text box:

```
document.styleSheets[0].disabled = (!document.styleSheets[0].disabled)
```

The inclusion of the NOT operator (!) forces the state to change from `true` to `false` or `false` to `true` with each click of the Evaluate button.

**Related Items:** `disabled` property of the `style` element object.

**href**

**Value:** String.

Read/Write (See Text)

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

When a stylesheet is linked into a document via a `link` element, the `href` property of the `styleSheet` object contains a string with the URL to that file. Essentially, the `href` property of the `link` element is passed along to the `styleSheet` object that loads as a result. In WinIE4+ only, this property is read/write, allowing you to dynamically link in an external stylesheet file after the page has loaded. In MacIE and NN6+/Moz, this property is read-only.

**Related Items:** `link` element object.

**id**

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `id` property of a `styleSheet` object inherits the `id` property of its containing element (`style` or `link` element). This can get confusing, because it may appear as though two objects in the document have the same ID. The `id` string, however, can be used as an index to the `document.styleSheets` array in IE4+ (for example, `document.styleSheets["winLINK"]`). NN does not provide a comparable identifier associated with a `styleSheet` object.

**Related Items:** `id` property of all element objects.

## imports

**Value:** Array of `styleSheet` objects.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

A stylesheet can contain one or more `@import` rules to import an external stylesheet file into the document. Each imported `styleSheet` object is treated as an `import` object. The `imports` property is a collection of all imported `styleSheet` objects that belong to the current `styleSheet` object. Imported stylesheets are not added to the `document.styleSheets` collection, so that references to an imported `styleSheet` object must be through the `document.styleSheets[i].imports[i]` array.

An `import` object is, itself, a `styleSheet` object. All properties and methods applicable to a `styleSheet` object also apply to an `import` object. Therefore, if you want to load a different external stylesheet into the page, you can assign the new URL to the imported `styleSheet` object's `href` property:

```
document.styleSheets[0].imports[0].href = "alternate.css";
```

Modifications of this nature work in IE for Windows, but not in MacIE.

**Related Items:** `styleSheet` object.

## media

**Value:** See text.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Cascading Style Sheets can be defined to apply to specific output media, such as the video display screen, printer, and, in the future, devices such as speech synthesizers or Braille generators. A stylesheet gets this direction from the `media` attribute of a `style` or `link` element. That value is represented in the `media` property of the `styleSheet` object.

In IE4+, the `media` property value is a string with one of three possible values: `screen`, `printer`, `all`. The W3C DOM and NN6+ take this one step further by allowing for potentially multiple values being assigned to the `media` attribute. The NN6+/Moz/Safari value is an array of string media names (returned in an object called a `mediaList`).

**Related Items:** None.

## ownerNode

**Value:** Node reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `ownerNode` property is a reference to the document node in which the `styleSheet` object is defined. For `styleSheet` objects defined inside `style` and `link` elements, the `ownerNode` property is a reference to that element. The corresponding property in IE4+ is `owningElement`. Oddly, MacIE5 has an additional, misnamed property called `owningNode`, whose value equals that of the `owningElement` property.

## Example

Use The Evaluator (Chapter 13) with NN6+/Moz1+/Safari to inspect the `ownerNode` of the first `styleSheet` object in the document. Enter the following statement into the top text box:

```
document.styleSheets[0].ownerNode.tagName
```

The returned value is the `style` element tag name.

**Related Items:** `ownerRule`, `owningElement` property.

***styleSheetObject.ownerRule*****ownerRule****Value:** `cssRule` object.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `ownerRule` property applies to a `styleSheet` object that has been imported into a document via the `@import` rule. The property returns a reference to the `@import` rule responsible for loading the external stylesheet. There is an interaction between the `ownerRule` and `ownerNode` properties in that an imported rule has an `ownerRule` but its `ownerNode` property is `null`; conversely, a regular `styleSheet` has an `ownerNode`, but its `ownerRule` property is `null`.

**Related Items:** `ownerNode` property.**owningElement****Value:** Element reference.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `owningElement` property is a reference to the element object in which the `styleSheet` object is defined. For `styleSheet` objects defined inside `style` and `link` elements, the `owningElement` property is a reference to that element. The corresponding property in NN6+ is `ownerNode`. Oddly, MacIE5 has an additional, misnamed property called `owningNode`, whose value equals that of the `owningElement` property.

**Example**

Use The Evaluator (Chapter 13) with IE4+ to inspect the `owningElement` of the first `styleSheet` object in the document. Enter the following statement into the top text box:

```
document.styleSheets[0].owningElement.tagName
```

The returned value is the `style` element tag name.

**Related Items:** `ownerNode` property.**pages****Value:** Array of `@page` rules.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

An `@page` style rule defines the dimensions and margins for printed versions of a Web page. The `pages` property returns a collection of `@page` rules contained by the current `styleSheet` object. If no `@page` rules are defined in the stylesheet, the array has a length of zero.

While an `@page` rule has the same properties as any rule object, it has one more read-only property, the `pseudoClass` property, which returns any pseudo-class definitions in the rule. For example, the following `@page` rules define different rectangle specifications for the left and right printed pages:

```
@page :left {margin-left:4cm; margin-right:3cm;}
@page :right {margin-left:3cm; margin-right:4cm;}
```

Values for the `pseudoClass` property of these two page rules are `:left` and `:right`, respectively.

To the W3C DOM, an `@page` rule is just another rule object, but one whose `type` property returns `page`.

For more information about the paged media specification, see <http://www.w3.org/TR/REC-CSS2/page.html>.

**Related Items:** None.

## parentStyleSheet

**Value:** `styleSheet` object.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

An imported stylesheet is present thanks to the hosting of a `styleSheet` object created by a `style` or `link` element. That host `styleSheet` object is referenced by the `parentStyleSheet` property. For most `styleSheet` objects (that is, those not imported via the `@import` rule), the `parentStyleSheet` property is `null`. Take note of the distinction between the `parentStyleSheet` property, which points to a `styleSheet` object, and the various properties that refer to the HTML element that “owns” the `styleSheet` object.

**Related Items:** None.

## readOnly

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `readOnly` property’s name is a bit misleading. Its Boolean value lets your script know whether the current stylesheet was embedded in the document by way of the `style` element or brought in from an external file via the `link` element or `@import` rule. When embedded by a `style` element, the `readOnly` property is `false`; for stylesheets defined outside the page, the property is `true`. But a value of `true` doesn’t mean that your scripts cannot modify the style properties. Style properties can still be modified on the fly, but of course the changes will not be reflected in the external file from which the initial settings came.

**Related Items:** `owningElement` property.

## rules

**Value:** Array of `rule` objects.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari1+

The `rules` property returns an array of all rule objects (other than `@` rules) defined in the current stylesheet. The order of rule objects in the array is based on source code order of the rules defined in the `style` element or in the external file.

Use the `rules` array as the primary way to reference an individual rule inside a stylesheet. If you use a `for` loop to iterate through all rules in search of a particular rule, you will most likely be looking for a match of the rule object’s `selectorText` property. This assumes, of course, that each selector is unique within the stylesheet. Using unique selectors is good practice, but no restrictions prevent you from reusing a selector name in a stylesheet for additional style information applied to the same selector elements.

The corresponding property name for NN6+/Moz is `cssRules`. MacIE5 and Safari respond to both the `rules` and `cssRules` properties.

**styleSheetObject.rules****Example**

Use The Evaluator (Chapter 13) with IE4+ to examine the `rules` property of the first `styleSheet` object in the page. First, find out how many rules are in the first `styleSheet` object by entering the following statement into the top text box:

```
document.styleSheets[0].rules.length
```

Next, examine the properties of one of the rules by entering the following statement into the bottom text box:

```
document.styleSheets[0].rules[1]
```

You now see the all the properties that IE4+ exposes for a rule object.

**Related Items:** `rule` object; `cssRules` property.

**title**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

If you assign a value to the `title` attribute of a `style` element or a `link` element that loads a stylesheet, that string value filters down to the `title` property of the `styleSheet` object. You can use the string value as a kind of identifier, but it is not usable as a true identifier that you can use as an index to the `styleSheets` array. In visible HTML elements, the `title` attribute usually sets the text that displays with the tooltip over the element. But for the unseen `style` and `link` elements, the attribute has no impact on the rendered display of the page. Therefore, you can use this attribute and corresponding property to convey any string value you want.

**Related Items:** `title` property of all HTML elements.

**type**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `type` property of a `styleSheet` object picks up the `type` attribute of the `style` or `link` element that embeds a stylesheet into the page. Unless you are experimenting with some new types of stylesheet language (assuming it is even supported in the browser), the value of the `type` property is `text/css`.

**Related Items:** None.

**Methods****addImport("URL" [, index])**

**Returns:** Integer.

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `addImport()` method lets you add an `@import` rule to a `styleSheet` object. A required first parameter is the URL of the external `.css` file that contains one or more stylesheet rules. If you omit the second parameter, the `@import` rule is appended to the end of rules in the

***StyleSheetObject.addRule()***

`styleSheet` object. Or you can specify an integer as the index of the position within the rules collection where the rule should be inserted. The order of rules in a `styleSheet` object can influence the cascading order of overlapping stylesheet rules (that is, multiple rules that apply to the same elements).

The value returned by the method is an integer representing the index position of the new rule within the rules collection of the `styleSheet`. If you need subsequent access to the new rule, you can preserve the value returned by the `addImport()` method and use it as the index to the `rules` collection.

**Related Items:** `addRule()` method.

```
addRule("selector", "styleSpec"[, index])
removeRule(index)
```

**Returns:** Integer (for `addRule()`).

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `addRule()` method appends or inserts a stylesheet rule into the current `styleSheet` object. The first two parameters are strings for the two components of every rule: the selector and the style specification. Any valid selector, including multiple, space-delimited selectors, is permitted. For the style specification, the string should contain the semicolon-delimited list of style *attribute:value* pairs, but without the curly braces that surround the specification in a regular stylesheet rule.

If you omit the last parameter, the rule is appended to the end of the `rules` collection for the stylesheet. Or, you can specify an integer index value signifying the position within the `rules` collection where the new rule should go. The order of rules in a `styleSheet` object can influence the cascading order of overlapping stylesheet rules (meaning multiple rules that apply to the same elements).

The return value conveys no meaningful information.

To remove a rule from a `styleSheet` object's `rules` collection, invoke the `removeRule()` method. Exercise some care here, because you must have the correct index value for the rule that you want to remove. Your script can use a `for` loop to iterate through the rules collection, looking for a match of the `selectorText` property (assuming that you have unique selectors). The index for the matching rule can then be used as the parameter to `removeRule()`. This method returns no value.

For NN6+, the corresponding methods are called `insertRule()` and `deleteRule()`.

## Example

Use The Evaluator (Chapter 13) with IE4+ to add a stylesheet rule to the first `styleSheet` object of the page. First, make sure the stylesheet is enabled by entering the following statement into the top text box:

```
document.styleSheets[0].disabled = false
```

Next, append a style that sets the color of the `textarea` element:

```
document.styleSheets[0].addRule("textarea", "color:red")
```

***StyleSheetObject.addRule()***

Enter any valid object (such as `document.body`) into the bottom text box to see how the style has been applied to the `textarea` element on the page.

Now remove the style, using the index of the last item of the `rules` collection as the index:

```
document.styleSheets[0].removeRule(document.styleSheets[0].rules.length - 1)
```

The text in the `textarea` returns to its default color.

**Related Items:** `deleteRule()`, `insertRule()` methods.

**`deleteRule(index)`****`insertRule("rule", index)`**

**Returns:** Integer (for `insertRule()`).

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari1+

The `insertRule()` method appends or inserts a stylesheet rule into the current `StyleSheet` object. The first parameter is a string containing the style rule as it would normally appear in a stylesheet, including the selector and curly braces surrounding the semicolon-delimited list of style *attribute: value* pairs.

You must supply an index location within the `cssRules` array where the new rule is to be inserted. If you want to append the rule to the end of the list, use the `length` property of the `cssRules` collection for the parameter. The order of rules in a `StyleSheet` object can influence the cascading order of overlapping stylesheet rules (meaning multiple rules that apply to the same elements).

The return value is an index for the position of the inserted rule.

**Note**

Safari 1.0 executes the method without complaint, but the inserted rule does not alter any of the page's rendering.

To remove a rule from a `StyleSheet` object's `cssRules` collection, invoke the `deleteRule()` method. Exercise some care here, because you must have the correct index value for the rule that you want to remove. Your script could use a `for` loop to iterate through the `cssRules` collection, looking for a match of the `selectorText` property (assuming that you have unique selectors). The index for the matching rule can then be used as the parameter to `deleteRule()`. This method returns no value.

For IE4+, the corresponding methods are called `addRule()` and `removeRule()`.

**Example**

Use The Evaluator (Chapter 13) with NN6+/Moz to add a stylesheet rule to the first `StyleSheet` object of the page. First, make sure the stylesheet is enabled by entering the following statement into the top text box:

```
document.styleSheets[0].disabled = false
```

Next, append a style that sets the color of the `textarea` element:

```
document.styleSheets[0].insertRule("textarea {color:red}",
document.styleSheets[0].cssRules.length)
```

Enter any valid object (such as `document.body`) into the bottom text box to see how the style has been applied to the `textarea` element on the page.

Now remove the style, using the index of the last item of the rules collection as the index:

```
document.styleSheets[0].deleteRule(document.styleSheets[0].cssRules.length - 1)
```

**Related Items:** `addRule()`, `removeRule()` methods.

## cssRule and rule Objects

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
cssText parentStyleSheet readOnly selectorText style type		

### Syntax

Accessing rule or `cssRule` object properties:

```
(IE4+)      document.styleSheets[index].rules[index].property
(MacIE5/W3C) document.styleSheets[index].cssRules[index].property
```

### About these objects

The `rule` and `cssRule` objects are different object model names for the same objects. For IE4+, the object is known as a *rule* (and a collection of them the `rules` collection); for NN6+/Moz/Safari (and MacIE5), the object follows the W3C DOM recommendation, calling the object a *cssRule* (and a collection of them the `cssRules` collection). For the remainder of this section, they will be referred to generically as the rule object.

A rule object has two major components. The first is the selector text, which governs which element(s) are to be influenced by the style rule. The second component is the style definition, with its set of semicolon-delimited *attribute:value* pairs. In both the IE4+ and NN6+/W3C object models, the style definition is treated as an object: the `style` object, which has tons of properties representing the style attributes available in the browser. The `style` object that belongs to a rule object is precisely the same `style` object that is associated with every HTML element object. Accessing `style` properties of a stylesheet rule requires a fairly long reference, as in

```
document.styleSheets[0].rules[0].style.color = "red";
```

but the format follows the logic of JavaScript's dot-syntax to the letter.

*ruleObject.cssText*

## Properties

### cssText

**Value:** String.

Read/Write

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari1+

The `cssText` property returns the full text of the current `cssRule` object. While the text returned from this property can be parsed to locate particular strings, it is easier and more reliable to access individual style properties and their values via the `style` property of a `cssRule` object. Safari 1.0 returns an empty string.

**Related Items:** `style` property.

### parentStyleSheet

**Value:** `styleSheet` object.

Read-Only

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari1+

The `parentStyleSheet` property is a reference to the `styleSheet` object that contains the current `cssRule` object. The return value is a reference to a `styleSheet` object, from which scripts can read and write properties related to the entire stylesheet.

**Related Items:** `parentRule` property.

### readOnly

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE5+, MacIE5, NN-, Moz-, Safari-

The `readOnly` property's name is a bit misleading. Its Boolean value lets your script know whether the current rule's `styleSheet` was embedded in the document by way of the `style` element or brought in from an external file via the `link` element or `@import` rule. When embedded by a `style` element, the `readOnly` property is `false`; for stylesheets defined outside the page, the property is `true`. But a value of `true` doesn't mean that your scripts cannot modify the style properties. Style properties can still be modified on the fly, but of course the changes are not reflected in the external file from which the initial settings came.

**Related Items:** `styleSheet.readOnly` property.

### selectorText

**Value:** String.

Read-Only

**Compatibility:** WinIE5+, MacIE5, NN6+, Moz1+, Safari1+

The `selectorText` property returns only the selector portion of a stylesheet rule. The value is a string, and if the selector contains multiple, space-delimited items, the `selectorText` value returns the same space-delimited string. For selectors that are applied to classes (preceded by a period) or ids (preceded by a crosshatch), those leading characters are returned as part of the string as well.

If you want to change the selector for a rule, removing the original rule and adding a new one in its place is better. You can always preserve the `style` property of the original rule and assign the style to the new rule.

## Example

Use The Evaluator (Chapter 13) to examine the `selectorText` property of rules in the first `styleSheet` object of the page. Enter each of the following statements in the top text box:

```
document.styleSheets[0].rules[0].selectorText  
document.styleSheets[0].rules[1].selectorText
```

Compare these values against the source code view for the `style` element in the page.

**Related Items:** `style` property.

## style

**Value:** `style` object.

Read/Write

**Compatibility:** WinIE5+, MacIE5, NN6+, Moz1+, Safari1+

The `style` property of a rule (or `cssRule`) is, itself, an object whose properties consist of the CSS style properties supported by the browser. Modifying a property of the `style` object requires a fairly long reference, as in

```
document.styleSheets[0].rules[0].style.color = "red";
```

Any change you make to the rule's `style` properties is reflected in the rendered style of whatever elements are denoted by the rule's selector. If you want to change the style of just one element, access the `style` property of just that element. Style values applied directly to an element override whatever stylesheet style values are associated with the element.

## Example

Use The Evaluator (Chapter 13) to modify a `style` property of one of the `styleSheet` rules in the page. The syntax shown here is for IE4+, but you can substitute the `cssRules` reference for the `rules` collection reference in NN6+, MacIE5, and W3C browsers if you like.

Begin by reloading the page and making sure the stylesheet is enabled. Enter the following statement into the top text box:

```
document.styleSheets[0].disabled = false
```

The first rule is for the `myP` element on the page. Change the rule's `font-size` style:

```
document.styleSheets[0].rules[0].style.fontSize = "20pt"
```

Look over the `style` object properties in the discussion of the `style` object later in this chapter and have fun experimenting with different style properties. After you are finished, reload the page to restore the styles to their default states.

**Related Items:** `style` object.

## type

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The W3C DOM defines several classes of stylesheet rules. To make it easier for a script to identify the kind of `cssRule` it is working with, the `type` property returns an integer whose value is associated with one of the known `cssRule` types. While not all of these rule types may be implemented in current browsers, the complete W3C DOM list is as follows:

***ruleObject.type***

<b>Type</b>	<b>Description</b>
0	Unknown type
1	Regular style rule
2	@charset rule
3	@import rule
4	@media rule
5	@font-face rule
6	@page rule

Most of the stylesheet rules you work with are type 1. To learn more about these rule types, consult the W3C specification for CSS at <http://www.w3.org/TR/REC-CSS2>.

**Related Items:** None.

## currentStyle , runtimeStyle , and style Objects

<b>Properties</b>	<b>Methods</b>	<b>Event Handlers</b>
(See below)		

### Syntax

Accessing `currentStyle`, `runtimeStyle`, or `style` object properties:

(IE4+/W3C)	<code>elementReference.style.property</code>
(IE4+/W3C)	<code>document.styleSheets[index].style.property</code>
(IE5+)	<code>elementReference.currentStyle.property</code>
(IE5.5)	<code>elementReference.runtimeStyle.property</code>

### About these objects

All three of these objects — `currentStyle`, `runtimeStyle`, and `style` — return an object that contains dozens of properties related to stylesheet specifications associated either with a `styleSheet` object (for the `style` object only) or any rendered HTML element object. With the browser page reflow facilities of modern browsers, changes made to the properties of the `style` and IE-specific `runtimeStyle` objects are reflected immediately by the rendered content on the page.

The primary object, the `style` object, is accessed as a property of either a `styleSheet` object or an HTML element object. It is vital to remember that style properties of an HTML element are reflected by the `style` object only if the specifications are made via the `style` attribute inside the element's tag. If your coding style requires that stylesheets be applied via `style` or `link` tags, and if your scripts need to access the `style` property values as set by those stylesheets, then you must read the properties of the effective stylesheet through the read-only `currentStyle` property (available in IE5+) or the W3C DOM `window.getComputedStyle()` method (NN6+/Moz).

IE's `currentStyle` object does not have precisely the same properties as its `style` object. Missing from the `currentStyle` object are the properties that contain combination values, such as `border` or `borderBottom`. On the other hand, `currentStyle` provides separate properties for each of the sides of a clipping rectangle (`clipTop`, `clipRight`, `clipBottom`, and `clipLeft`), which the `clip` property does not provide.

Microsoft introduced one more flavor of style object — the `runtimeStyle` object — in IE5.5. This object lets scripts override any style property that is set in a stylesheet or via the `style` attribute. In other words, the `runtimeStyle` object is like a read/write version of `currentStyle` except that assigning a new value to one of its properties does not modify the stylesheet definition or the value assigned in a `style` attribute. By and large, however, your scripts will modify the `style` property of an element to make changes, unless you modify styles by enabling and disabling stylesheets (or changing the `className` property of an element so that it is under the control of a different selector).

## Style properties

If you add up all the `style` object properties available in browsers starting with IE4 and NN6, you have a list approximately 180 properties long. A sizable percentage are in common among all browsers and are scriptable versions of W3C Cascading Style Sheet properties. The actual CSS property names are frequently script-unfriendly in that multiple-worded properties have hyphens in them, such as `font-size`. JavaScript identifiers do not allow hyphens, so multiple-worded properties are converted to interCap versions, such as `fontSize`.

Not all style properties are supported by all browsers that have the `style` object in their object models. Microsoft, in particular, has added many properties that are sometimes unique to IE and sometimes unique to just IE for Windows. On the Netscape side, you find some properties that appear to be supported by the `style` object, but the browser doesn't genuinely support the attributes. For example, the CSS specification defines several attributes that enhance the delivery of content that is rendered through a speech synthesizer. Although NN6 and NN7 don't qualify, the Gecko browser engine at their core could be adapted to such a browser. Therefore, if you see a property in the following listings that doesn't make sense to you, test it out in the compatible browsers to verify that it works as you need it. You will also find some properties that are proprietary to Mozilla-based browsers — properties that begin with `moz`. These properties are preliminary implementations of as yet unreleased CSS Level 3 properties. The `moz` prefix lets you use these properties today without conflicting with future, sanctioned implementations of the properties (which won't have the `moz` prefix). When specifying these properties in CSS syntax for your stylesheets, the properties begin with the special prefix `-moz-`, as in `-moz-opacity` (and the scripted equivalent, `mozOpacity`).

Some browsers also expose advanced `style` object properties to scripters, when, in fact, they are not genuinely supported in the browser. For example, an inspection of the `style` object for MacIE5 and NN6+ shows a `quotes` property, which matches the `quotes` style property in the W3C CSS2 specification. But in truth, the `quotes` style property cannot be set by script in these browsers. When you see that a property is supported by MacIE5 and NN6+ but none others, testing out the `style` property (and the stylesheet attribute as well) in The Evaluator is a good idea before attempting to employ the property in your application.

With so many properties associated with an object, it may be difficult to locate the specific property you need for a particular style effect. To help you locate properties, the listings that follow are divided into functional categories, ordered by popularity:

*elementRef.style*

<i>Category</i>	<i>Description</i>
Text & Fonts	Font specifications, text rendering, text alignment
Inline Display & Layout	Element flow, alignment, and display
Positioning	Explicit positioning of “layers”
Background	Background images and colors
Borders & Edges	Borders, padding, and margins around elements
Lists	Details for <code>ul</code> and <code>ol</code> elements
Scroll bars	Scroll bar colors (WinIE5.5+ only)
Tables	Details for <code>table</code> elements and components
Printing	Page breaks and alignment for printed pages
Miscellaneous	Odds and ends
Aural	For rendering via speech-synthesis

## Property values

All `style` object property values are strings. Moreover, many groups of style properties share the same format for their values. Knowing the formats for the frequently used values is helpful. The purpose of this chapter is not to teach you about stylesheets but to show you how to script them. Therefore, if you see unfamiliar terminology here, consult online or print instructional material about Cascading Style Sheets.

## Length

Values for length cover a wide range, but they all define an amount of physical space in the document. Because content can be displayed on a video monitor or printed on a sheet of paper, any kind of length value should include a unit of measure as well as the quantity. One group of units (`px`, `em`, `ex`) are considered *relative* units, because the precise size depends on factors beyond the control of the stylesheet (for example, the pixel density of the display) or units set by elements with more global scope (for example, a `p` element’s margin `em` length dependent upon the `body` element’s font-size setting). *Absolute* units (`in`, `cm`, `mm`, `pt`, `pi`) are more appropriate for printed output. Length units are referred in script according to the following table:

<i>Unit</i>	<i>Script Version</i>	<i>Example</i>
pixel	<code>px</code>	<code>14px</code>
em	<code>em</code>	<code>1.5em</code>
ex	<code>ex</code>	<code>1.5ex</code>
inch	<code>in</code>	<code>3.0in</code>
centimeter	<code>cm</code>	<code>4.0cm</code>
millimeter	<code>mm</code>	<code>40mm</code>
pica	<code>pi</code>	<code>72pi</code>
point	<code>pt</code>	<code>14pt</code>

A length value can also be represented by a percentage as a string. For example, the `lineHeight` style for a paragraph would be set to 120% of the font size established for the paragraph by the following statement:

```
document.getElementById("myP").style.lineHeight = "120%";
```

Style inheritance—an important CSS concept—often has significant impact on style properties whose values are lengths.

## Color

Values for colors can be one of three types:

- ♦ RGB values (in a few different formats)
- ♦ plain-language versions of the color names
- ♦ plain-language names of system user interface items

RGB values can be expressed as hexadecimal values. The most common way is with a crosshatch character followed by six hex numbers, as in `#ff00ff` (letters can be uppercase or lowercase). A special shortcut is also available to let you specify three numbers with the assumption that they will be expanded to pairs of numbers. For example, a color of `#f0f` is expanded internally to be `#ff00ff`.

An alternative RGB expression is with the `rgb()` prefix and three numbers (from 0 to 255) or percentages corresponding to the red, green, and blue components of the color. Here are a couple of examples:

```
document.styleSheets[0].rules[0].style.color = "rgb(0, 255, 0)";
document.styleSheets[0].rules[0].style.color = "rgb(0%, 100%, 0%)";
```

Browsers also respond to a long list of plain-language color names originally devised by Netscape. You can see the list with sample colors at <http://developer.netscape.com/library/manuals/1998/htmlguide/colortab.htm>. Not all of those colors are necessarily part of what are known as “Web safe” colors. For a demonstration of Web safe colors, visit <http://www.lynda.com/hexh.html>.

The last category of color values references user interface pieces, many of which are determined by the user’s control panel for video display. The string values correspond to recognizable UI components (also called system colors), as follows:

<code>activeborder</code>	<code>highlight</code>	<code>scrollbar</code>
<code>activecaption</code>	<code>highlighttext</code>	<code>threeddarkshadow</code>
<code>appworkspace</code>	<code>inactiveborder</code>	<code>threeface</code>
<code>background</code>	<code>inactivecaption</code>	<code>threehighlight</code>
<code>buttonface</code>	<code>inactivecaptiontext</code>	<code>threedlightshadow</code>
<code>buttonhighlight</code>	<code>infobackground</code>	<code>threedshadow</code>
<code>buttonshadow</code>	<code>infotext</code>	<code>window</code>
<code>buttontext</code>	<code>menu</code>	<code>windowframe</code>
<code>captiontext</code>	<code>menutext</code>	<code>windowtext</code>
<code>graytext</code>		

***elementRef.style***

Using these color settings may be risky for public sites, because you are at the mercy of the color settings the user has chosen. For a corporate environment where system installations and preferences are strictly controlled, these values could help define a safe color scheme for your pages.

**Rectangle sides**

Many style properties control the look of sides of rectangles (for example, thickness of a border around a block element). In most cases, the style values can be applied to individual sides or combinations of sides, depending on the number of values supplied to the property. The number of values affects the four sides of the rectangle according to the following matrix:

<b><i>Number of Values</i></b>	<b><i>Impact</i></b>
1	All four sides set to the one value
2	Top and bottom sides set to first value; left and right sides set to second value
3	Top side set to first value; left and right sides set to second value; bottom side set to third value
4	Top, right, bottom, and left sides set to individual values in that order

For example, to set the border color of an element so that all sides are red, the syntax is

```
elementRef.style.borderColor = "red";
```

To set the top and bottom to red but the left and right to green, the syntax is

```
elementRef.style.borderColor = "red green";
```

Properties that accept these multiple values cover a wide range of styles. Values may be colors, lengths, or selections from a fixed list of possible values.

**Combination values**

Another category of style values includes properties that act as shortcuts for several related properties. For example, the `border` property encompasses the `borderWidth`, `borderStyle`, and `borderColor` properties. This is possible because very different classes of values represent the three component properties: `borderWidth` is a length; `borderStyle` is based on a fixed list of values; and `borderColor` is a color value. Therefore, you can specify one or more of these property values (in any order), and the browser knows how to apply the values to the detailed subproperty. Only one value is permitted for any one of these subproperties, which means that if the property is one of the four-sided styles described in the previous section, the value is applied to all four sides equally.

For example, setting the `border` property to a single value, as in

```
elementRef.style.border = "blue";
```

is the same as setting

```
elementRef.style.borderColor = "blue";
```

But if you set multiple items, as in

```
elementRef.style.border = "groove blue 3px";
```

*elementRef.style.fontFamily*

then you have set the equivalent of the following three statements:

```
elementRef.style.borderStyle = "groove"  
elementRef.style.borderColor = "blue";  
elementRef.style.borderWidth = "3px";
```

In the property descriptions that follow, these combination values are denoted by their scripted property names and the OR (|) operator, as in

```
border = "borderStyle || borderColor || borderWidth";
```

## URLs

Unlike other property values containing URLs, a `style` property requires a slightly different format. This format includes the `url()` prefix, with the actual URL (relative or absolute) located inside the parentheses. The URL itself is not quoted, but the entire property value is, as in

```
elementRef.style.backgroundImage = "url(chainlink.jpg)";
```

URLs should not have any spaces in them, but if they do, use the URL-encoded version for the file specification: convert spaces to `%20`. This format distinguishes a URL value from some other string value for shortcut properties.

## Text and font properties

### color

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Foreground color of an element, primarily used to assign color to text. May also affect edges and highlights of other elements in some browsers.

**Value:** Color specification.

**Example:** `elementRef.style.color = "rgb(#22FF00)";`

### font

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Up to six font-related style properties.

**Value:** Combination values: `fontStyle || fontVariant || fontWeight || fontSize || lineHeight || fontFamily`. See individual properties for their value formats.

**Example:** `elementRef.style.font = "bold sans-serif 16px";`

### fontFamily

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Font family to be applied to an element in order of priority.

**Value:** Comma-delimited list of font families to be applied to element, starting with the most preferred font family name. You can also use one of several generic family names that rely on the browser to choose the optimal font to match the class: `serif | sans-serif | cursive | fantasy | monospace`. Not all browsers support all constants, but `serif`, `sans-serif`, and `monospace` are commonly implemented.

**Example:** `elementRef.style.fontFamily = "Bauhaus 93, Arial, monospace";`

**elementRef.style.fontSize****fontSize**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Size of the characters of the current font family.

**Value:** Lengths (generally px or pt values); **relative size constants:** larger | smaller; **absolute size constants:** xx-small | x-small | small | medium | large | x-large | xx-large

**Examples:** `elementRef.style.fontSize = "16px"; elementRef.style.fontSize = "small";`

**fontSizeAdjust**

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari-

**Controls:** Aspect value of a secondary font family so that it maintains a similar character height as the primary font family.

**Value:** Number (including floating-point value) or none

**Example:** `elementRef.style.fontSizeAdjust = "1.05";`

**fontStretch**

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari-

**Controls:** Rendered width of a font's characters.

**Value:** Constant ultra-condensed | extra-condensed | condensed | semi-condensed | semi-expanded | expanded | extra-expanded | ultra-expanded or wider | narrower | inherit | normal

**Example:** `elementRef.style.fontStretch = "expanded";`

**fontStyle**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Italic style of characters.

**Value:** Constant normal | italic | oblique | inherit

**Example:** `elementRef.style.fontStyle = "italic";`

**fontVariant**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari-

**Controls:** Rendering characters as small caps.

**Value:** Constant normal | small-caps | inherit

**Example:** `elementRef.style.fontVariant = "small-caps";`

**fontWeight**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Rendering characters in bold or light weights. Fonts that support numbered gradations can be controlled by those numbers. Normal = 400; Bold = 700.

**Value:** Constant bold | bolder | lighter | normal | 100 | 200 | 300 | 400 | 500 | 600 | 700 | 800 | inherit

**Example:** `elementRef.style.fontWeight = "bold";`

## letterSpacing

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Spacing between characters. Used to override a font family's own characteristics.

**Value:** Length (usually em units, relative to current font size); Constant `normal` | `inherit`

**Example:** `elementRef.style.letterSpacing = "1.2em";`

## lineBreak

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Line-break rules for Japanese text content.

**Value:** Constant `normal` | `strict`

**Example:** `elementRef.style.lineBreak = "strict";`

## lineHeight

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Height of the rectangular space that holds a line of text characters.

**Value:** Length (usually em units, relative to current font size); number (a multiplier on the inherited line height); percentage (relative to inherited line height); constant `normal` | `inherit`

**Example:** `elementRef.style.lineHeight = "1.1";`

## quotes

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari-

**Controls:** Characters to be used for quotation marks.

**Value:** Space-delimited pairs of open and close quotation symbols; Constant `none` | `inherit`

**Example:** `elementRef.style.quotes = "« »";`

## rubyAlign

**Compatibility:** WinIE5+, MacIE5, NN-, Moz-, Safari-

**Controls:** Alignment of ruby text within a ruby element.

**Value:** Constant `auto` | `left` | `center` | `right` | `distribute-letter` | `distribute-space` | `line-edge`

**Example:** `RUBYelementRef.style.rubyAlign = "distribute=letter";`

## rubyOverhang

**Compatibility:** WinIE5+, MacIE5, NN-, Moz-, Safari-

**Controls:** Overhang of ruby text within a ruby element.

**Value:** Constant `auto` | `whitespace` | `none`

**Example:** `RUBYelementRef.style.rubyOverhang = "whitespace";`

## rubyPosition

**Compatibility:** WinIE5+, MacIE5, NN-, Moz-, Safari-

**Controls:** Placement of ruby text with respect to the ruby element's base text.

**Value:** Constant `above` | `inline`

**Example:** `RUBYelementRef.style.rubyPosition = "inline";`

***elementRef.style.textAlign*****textAlign**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Horizontal alignment of text with respect to its containing element.

**Value:** Constant center | justify | left | right

**Example:** `elementRef.style.textAlign = "center";`

**textAlignLast**

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Horizontal alignment of last line of text in a paragraph.

**Value:** Constant auto | center | justify | left | right

**Example:** `elementRef.style.textAlignLast = "justify";`

**textAutospace**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Extra spacing between ideographic and non-ideographic text.

**Value:** Constant none | ideograph-alpha | ideograph-numeric | ideograph-parenthesis | ideograph-space

**Example:** `elementRef.style.textAutospace = "ideograph=alpha";`

**textDecoration**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Display of underline, overline, or line-through with text.

**Value:** Constant none | blink | line-through | overline | underline

**Example:** `elementRef.style.textDecoration = "underline";`

**textDecorationBlink****textDecorationLineThrough****textDecorationNone****textDecorationOverline****textDecorationUnderline**

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

**Controls:** Individual text decoration characteristics for text, allowing for multiple decorations to be applied to the same text.

**Value:** Boolean (not strings) true | false

**Example:** `elementRef.style.textDecorationUnderline = true;`

**textIndent**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Amount of indentation for the first line of a block text element (for example, p).

**Value:** Length (negative values for outdenting); percentage (relative to inherited value)

**Example:** `elementRef.style.textIndent = "2.5em";`

## textJustify

**Compatibility:** WinIE5+, MacIE5, NN-, Moz-, Safari-

**Controls:** Additional detailed specifications for an element whose `textAlign` property is set to `justify`.

**Value:** Constant `auto` | `distribute` | `distribute-all-lines` | `distribute-center-last` | `inter-cluster` | `inter-ideograph` | `inter-word` | `kashida` | `newspaper`

**Example:** `elementRef.style.textJustify = "distribute";`

## textJustifyTrim

**Compatibility:** WinIE5+, MacIE5, NN-, Moz-, Safari-

Reserved for future use.

## textKashidaSpace

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Ratio of kashida expansion to white space expansion for Arabic writing systems.

**Value:** Percentage

**Example:** `elementRef.style.textKashidaSpace = "90%";`

## TextOverflow

**Compatibility:** WinIE6+, MacIE-, NN-, Moz-, Safari-

**Controls:** Whether an ellipsis (`...`) is displayed at the end of a line of overflowed text to indicate that more text is available.

**Value:** Constant `clip` | `ellipsis`

## textShadow

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari-

**Controls:** Shadow rendering around text characters. Note: The `style` attribute for this property is not implemented in MacIE5 or NN6/7, but the property is listed as valid for a style object.

**Value:** Each shadow specification consists of an optional color and three space-delimited length values (horizontal shadow offset, vertical shadow offset, blur radius length). Multiple shadow specifications are comma-delimited.

## textTransform

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Case rendering of the text (meaning without altering the case of the original text).

**Value:** Constant `none` | `capitalize` | `lowercase` | `uppercase`

**Example:** `elementRef.style.textTransform = "uppercase";`

## textUnderlinePosition

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Whether an underline text decoration is displayed above or below the text. Seems redundant with `textDecorationUnderline` and `textDecorationOverline`.

**Value:** Constant `above` | `below`

**Example:** `elementRef.style.textUnderlinePosition = "above";`

***elementRef.style.unicodeBidi*****unicodeBidi**

**Compatibility:** WinIE5+, MacIE5, NN6+, Moz1+, Safari1+

**Controls:** Within bidirectional text (for example, English and Arabic), to what extent an alternate direction text block is embedded within the outer element.

**Value:** Constant `normal` | `embed` | `bidirectional-override`

**Example:** `elementRef.style.unicodeBidi = "embed";`

**whiteSpace**

**Compatibility:** WinIE5.5+, MacIE5, NN6+, Moz1+, Safari1+

**Controls:** Treatment of white space characters within an element's source code.

**Value:** Constant `normal` | `nowrap` | `pre`

**Example:** `elementRef.style.whiteSpace = "nowrap";`

**wordBreak**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Word breaking characteristics, primarily for Asian-language text or text containing a mixture of Asian and Latin characters.

**Value:** Constant `normal` | `break-all` | `keep-all`

**Example:** `elementRef.style.wordBreak = "break-all";`

**wordSpacing**

**Compatibility:** WinIE6+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Spacing between words.

**Value:** Length (usually in em units); Constant `normal`

**Example:** `elementRef.style.wordSpacing = "1em";`

**wordWrap**

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Word wrapping characteristics of text in a block element, explicitly sized inline element, or positioned element.

**Value:** Constant `normal` | `break-word`

**Example:** `elementRef.style.wordWrap = "break-word";`

**writingMode**

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Direction of content flow (left-to-right/top-to-bottom or top-to-bottom/right-to-left, as in some Asian languages).

**Value:** Constant `lr-tb` | `tb-rl`

**Example:** `elementRef.style.writingMode = "tb-rl";`

## Inline display and layout properties

### clear

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Layout orientation of an element with respect to a neighboring floating element.

**Value:** Constant both | left | none | right

**Example:** `elementRef.style.clear = "right";`

### clip

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** The clipping rectangle of an element (that is, the position of the rectangle through which the user sees an element's content).

**Value:** `rect(topLength, rightLength, bottomLength, leftLength) | auto`

**Example:** `elementRef.style.clip = "rect(10px, 300px, 200px, 0px)";`

### clipBottom

### clipLeft

### clipRight

### clipTop

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Individual edges of the clipping rectangle of an element. These properties are read-only properties of the `currentStyle` object.

**Value:** Length | auto

**Example:** `var leftEdge = elementRef.currentStyle.clipLeft;`

### content

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari-

**Controls:** The content rendered in addition to the element, usually to be applied with a `:before` or `:after` pseudo-class. This feature will become more useful when CSS counters are implemented in browsers. They'll provide automatic section or paragraph numbering. While the CSS equivalent is implemented in NN7/Moz1/Safari, changes to the scripted property are not rendered.

**Value:** See <http://www.w3.org/TR/REC-CSS2/generate.html#propdef-content>.

### counterIncrement

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari-

**Controls:** The jumps in counter values to be displayed via the `content` style property. Note: The CSS property is not implemented in MacIE5 or NN6/7, but the property is listed as valid for a `style` object.

**Value:** One or more pairs of counter identifier and integers.

***elementRef.style.counterReset*****counterReset**

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari-

**Controls:** Resets a named counter for content to be displayed via the `content` style property. Note: The CSS property is not implemented in MacIE5 or NN6/7, but the property is listed as valid for a `style` object.

**Value:** One or more pairs of counter identifier and integers.

**cssFloat**

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari1+

**Controls:** Horizontal alignment of an element that allows other content to wrap around the element (usually text wrapping around an image). Corresponds to the CSS `float` style attribute. See also the `floatStyle` property, below. Floating (non-positioned) elements follow a long sequence of rules for their behavior, detailed at

<http://www.w3.org/TR/REC-CSS2/visuren.html#propdef-float>.

**Value:** Constant `left` | `right` | `none`

**Example:** `elementRef.style.cssFloat = "right";`

**CURSOR**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari-

**Controls:** The icon used for the cursor on the screen from a library of system-generated cursors. The CSS2 specification defines syntax for downloadable cursors, but this feature is not implemented as of IE5.5 or NN6/7. You can change this style property only if a `:hover` pseudo-class is initially defined for the element.

**Value:** Constant `auto` | `crosshair` | `default` | `e-resize` | `help` | `move` | `n-resize` | `ne-resize` | `nw-resize` | `pointer` | `s-resize` | `se-resize` | `sw-resize` | `text` | `w-resize` | `wait`. **New values for IE6 are:** `all-scroll` | `col-resize` | `no-drop` |

`not-allowed` | `progress` | `row-resize` | `url` | `vertical-text`. **Mozilla-based browsers include:** `alias` | `cell` | `context-menu` | `copy` | `count-down` | `count-up` | `count-up-down` | `grab` | `grabbing` | `spinning`.

**Example:** `elementRef.style.cursor = "hand";`

**direction**

**Compatibility:** WinIE5+, MacIE5, NN6+, Moz1+, Safari1+

**Controls:** Layout direction (left-to-right or right-to-left) of inline text (same as `dir` attribute of an element).

**Value:** Constant `ltr` | `rtl`

**Example:** `elementRef.style.direction = "rtl";`

**display**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Whether an element is displayed on the page and in which display mode. Content surrounding an undisplayed element cinches up to occupy the undisplayed element's space—as if the element didn't exist for rendering purposes (see the `visibility` property for a different approach). Commonly used to hide or show segments of a graphical tree structure.

*elementRef.style.layoutGridMode*

Also used to direct the browser to display an element as inline or block-level element. Some special-purpose values are associated with specific element types (for example, lists, table cells, and so on).

**Value:** Constant `block` | `compact` | `inline` | `inline-table` | `list-item` | `none` | `run-in` | `table` | `table-caption` | `table-cell` | `table-column-group` | `table-footer-group` | `table-header-group` | `table-row` | `table-row-group`

**Example:** `elementRef.style.display = "none";` // removes element from page

**filter**

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

**Controls:** Rendering effects on static content and on transitions between hiding and showing elements. Microsoft made a massive overhaul of the `filter` stylesheet syntax in WinIE5.5 (using the `DXImageTransform` ActiveX control). Scripting transitions require several steps to load the transition and actions before playing the transition. Use `style.filter` to read or write the entire filter specification string; use the `elem.styles[i]` object to access individual filter properties. See the discussion of the `filter` object later in this chapter.

**Value:** Filter specification as string.

**Example:** `var filterSpec = elementRef.style.filter = "alpha(opacity=50) flipH()";`

**layoutGrid**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Page grid properties (primarily for Asian-language pages).

**Value:** Combination values: `layoutGridMode` | `layoutGridType` | `layoutGridLine` | `layoutGridChar`. See individual properties for their value formats.

**Example:** `elementRef.style.layoutGrid = "2em fixed";`

**layoutGridChar**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Size of the character grid (Asian languages).

**Value:** Length; Percentage; Constant `none` | `auto`

**Example:** `elementRef.style.layoutGridChar = "2em";`

**layoutGridLine**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Line height of the grid (Asian languages).

**Value:** Length; Percentage; Constant `none` | `auto`

**Example:** `elementRef.style.layoutGridLine = "110%";`

**layoutGridMode**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** One- or two-dimensional grid (Asian languages).

**Value:** Constant `both` | `none` | `line` | `char`

**Example:** `elementRef.style.layoutGridMode = "both";`

***elementRef.style.layoutGridType*****layoutGridType**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Type of grid for text content (Asian languages).

**Value:** Constant `loose` | `strict` | `fixed`

**Example:** `elementRef.style.layoutGridType = "strict";`

**markerOffset**

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

**Controls:** Distance between the edges of a marker box (content whose display is of a marker type) and a block-level element's box. Note: The CSS property is not implemented in MacIE5 or NN6/7, but the property is listed as valid for a `style` object.

**Value:** Length; Constant `auto`

**Example:** `elementRef.style.markerOffset = "2em";`

**marks**

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari-

**Controls:** Rendering of crop marks and the like on the printed page. Note: The CSS property is not implemented in MacIE5 or NN6/7, but the property is listed as valid for a `style` object.

**Value:** Constant `crop` | `cross` | `none`

**Example:** `elementRef.style.marks = "crop";`

**maxHeight****maxWidth****minHeight****minWidth**

**Compatibility:** WinIE (see text), MacIE-, NN6+, Moz1+, Safari-

**Controls:** Maximum or minimum height or width of an element. IE6 supports `minHeight` only.

**Value:** Length; Percentage; Constant (for max properties only) `none`

**Example:** `elementRef.style.maxWidth = "300px";`

**overflow**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** The rendering of a block-level element's content when its native rectangle exceeds that of its next outermost rectangular space. A `hidden` overflow clips the block-level content; a `scrolled` overflow forces the outermost rectangle to display scroll bars so that users can scroll around the block-level element's content; a `visible` overflow causes the block-level element to extend beyond the outermost container's rectangle (indeed, "overflowing" the container).

**Value:** Constant `auto` | `hidden` | `scroll` | `visible`

**Example:** `elementRef.style.overflow = "scroll";`

## overflowX

## overflowY

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** The rendering of a block-level element's content when its native rectangle exceeds the width (`overflowX`) or height (`overflowY`) of its next outermost rectangular space.

A hidden overflow clips the block-level content; a scrolled overflow forces the outermost rectangle to display scroll bars so that users can scroll around the block-level element's content; a visible overflow causes the block-level element to extend beyond the outermost container's rectangle (indeed, "overflowing" the container).

**Value:** Constant `auto` | `hidden` | `scroll` | `visible`

**Example:** `elementRef.style.overflowX = "scroll";`

## styleFloat

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

**Controls:** Horizontal alignment of an element that allows other content to wrap around the element (usually text wrapping around an image). Corresponds to the CSS `float` style attribute. See also the `cssFloat` property, above. Floating (non-positioned) elements follow a long sequence of rules for their behavior, detailed at <http://www.w3.org/TR/REC-CSS2/visuren.html#propdef-float>.

**Value:** Constant `left` | `right` | `none`

**Example:** `elementRef.style.styleFloat = "right";`

## verticalAlign

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari-

**Controls:** How inline and table cell content aligns vertically with surrounding content. Not all constant values are supported by all browsers.

**Value:** Constant `baseline` | `bottom` | `middle` | `sub` | `super` | `text-bottom` | `text-top` | `top`; Length; Percentage.

**Example:** `elementRef.style.verticalAlign = "baseline";`

## visibility

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Whether an element is displayed on the page. The element's space is preserved as empty space when the element is hidden. To cinch up surrounding content, see the `display` property. This property is used frequently for hiding and showing positioned element under script control.

**Value:** Constant `collapse` | `hidden` | `visible`

**Example:** `elementRef.style.visibility = "hidden";`

***elementRef.style.width*****width**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Horizontal dimension of a block-level element. Earlier browsers exhibit unexpected behavior when nesting elements that have their `width` style properties set.

**Value:** Length; Percentage; Constant `auto`

**Example:** `elementRef.style.width = "200px";`

**ZOOM**

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Magnification factor of a rendered element.

**Value:** Constant `normal`; Percentage (where 100% is normal); floating-point number (scale multiplier, where 1.0 is normal)

**Example:** `elementRef.style.zoom = ".9";`

## Positioning properties

(See Chapter 39 on the CD-ROM for coding examples of positioned elements and their `style` properties.)

**bottom****right**

**Compatibility:** WinIE5+, MacIE5, NN6+, Moz1+, Safari1+

**Controls:** The offset measure of a positioned element from its containing rectangle's bottom and right edges, respectively. In practice, you should adjust the size of a positioned element via the style's `height` and `width` properties.

**Value:** Length; Percentage; Constant `auto`

**Example:** `elementRef.style.bottom = "20px";`

**left****top**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** The offset measure of a positioned element from its containing rectangle's left and top edges, respectively. In practice, use these properties to position an element under script control. To position an absolute-positioned element atop an inline element, calculate the position of the inline element via the `offsetTop` and `offsetLeft` properties with some browser-specific adjustments, as shown in Chapter 39 on the CD-ROM.

**Value:** Length; Percentage; Constant `auto`

**Example:** `elementRef.style.top = "250px";`

**height****width**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Height and width of a block-level element's box. Used most commonly to adjust the dimensions of a positioned element (Chapter 39 on the CD-ROM).

**Value:** Length; Percentage; Constant `auto`

**Example:** `elementRef.style.height = "300px";`

pixelBottom  
pixelHeight  
pixelLeft  
pixelRight  
pixelTop  
pixelWidth

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari1+

**Controls:** Integer pixel values for (primarily positioned) elements. Because the non-pixel versions of these properties return strings that also contain the unit measure (for example, 30px), these properties let you work exclusively in integers for pixel units. The same can be done cross-platform by using `parseInt()` on the non-pixel versions of these properties. The `pixelBottom` and `pixelRight` properties are not in MacIE4.

**Value:** Integer

**Example:** `elementRef.style.pixelTop = elementRef.style.pixelTop + 20;`

posBottom  
posHeight  
posLeft  
posRight  
posTop  
posWidth

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

**Controls:** Numeric values for (primarily positioned) elements in whatever unit was specified by the corresponding `style` attribute. Because the non-pos versions of these properties return strings that also contain the unit measure (for example, 1.2em), these properties let you work exclusively in numbers in the same units as the style was originally defined. The same can be done cross-platform by using `parseFloat()` on the non-pixel versions of these properties.

**Value:** Integer

**Example:** `elementRef.style.posTop = elementRef.style.posTop + 0.5;`

position

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** The type of positioning to be applied to the element. An element that is not explicitly positioned is said to be *static*. A relative-positioned element appears in its normal page flow location but can be explicitly positioned relative to that location. An absolute-positioned element must have its `top` and `left` style attributes set to give the element a set of coordinates for its location. MacIE5 and NN6+/Moz/Safari also allow for a fixed positioned element, which remains at its designated position in the browser window, even if the page scrolls (for example, for a watermark effect). You cannot use scripts to change between positioned and non-positioned style settings. See Chapter 39 on the CD-ROM for more information on positioned elements.

**Value:** Constant `absolute | fixed | relative | static`

**Example:** `elementRef.style.position = "absolute";`

**elementRef.style.zIndex****zIndex**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Front-to-back layering of positioned elements. Multiple items with the same `zIndex` value are layered in source code order (earliest item at the bottom). The higher the value, the closer to the user's eye the element is.

**Value:** Integer number; Constant `auto`

**Example:** `elementRef.style.zIndex = "3";`

## Background properties

**background**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Up to five background style properties for an element.

**Value:** Combination values: `backgroundAttachment` || `backgroundColor` || `backgroundImage` || `backgroundPosition` || `backgroundRepeat`

**Example:** `elementRef.style.background = "scroll url(bricks.jpg) repeat-x";`

**backgroundAttachment**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari-

**Controls:** Whether the background image remains fixed or scrolls with the content. Default is `scroll`.

**Value:** Constant `fixed` | `scroll`

**Example:** `elementRef.style.backgroundAttachment = "fixed";`

**backgroundColor**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Solid, opaque color for the background, or completely transparent. If you assign a background image, the color is layered behind the image so that any transparent spots of the image show the background color.

**Value:** Color value; Constant `transparent`

**Example:** `elementRef.style.backgroundColor = "salmon";`

**backgroundImage**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** The URL (if any) of an image to be used for the background for the element.

**Value:** URL value; Constant `none`

**Example:** `elementRef.style.backgroundImage = "url(bricks.jpg)";`

**backgroundPosition**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** The left-top location of the background image. Any offset from the left-top corner (default value "0% 0%") allows background color to show through along left and top edges of the element.

**Value:** Length values; Percentages; Constant `left` | `center` | `right` || `top` | `center` | `bottom`. While single values are accepted, their behavior may not be as expected. Providing space-delimited pairs of values is more reliable.

**Example:** `elementRef.style.backgroundPosition = "left top";`

backgroundPositionX

backgroundPositionY

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

**Controls:** The left (backgroundPositionX) and top (backgroundPositionY) locations of the background image. Any offset from the left-top corner (default value "0%") allows background color to show through along left and top edges of the element.

**Value:** Length value; Percentage; Constant left | center | right (for backgroundPositionX); Constant top | center | bottom (for backgroundPositionY).

**Example:** `elementRef.style.backgroundPositionX = "5px";`

backgroundRepeat

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Image repetition characteristics of a background image. You can force the image to repeat along a single axis, if you want.

**Value:** Constant repeat | repeat-x | repeat-y | no-repeat

**Example:** `elementRef.style.backgroundRepeat = "repeat-y";`

## Border and edge properties

border

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Up to three border characteristics (color, style, and width) for all four edges of an element.

**Value:** Combination values `borderColor || borderStyle || borderWidth`

**Example:** `elementRef.style.border = "green groove 2px";`

borderBottom

borderLeft

borderRight

borderTop

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Up to three border characteristics (color, style, and width) for a single edge of an element.

**Value:** Combination values

(for borderBottom) `borderBottomColor || borderBottomStyle || borderBottomWidth`

(for borderLeft) `borderLeftColor || borderLeftStyle || borderLeftWidth`

(for borderRight) `borderRightColor || borderRightStyle || borderRightWidth`

(for borderTop) `borderTopColor || borderTopStyle || borderTopWidth`

**Example:** `elementRef.style.borderLeft = "#3300ff solid 2px";`

***elementRef.style.borderBottomColor***

`borderBottomColor`  
`borderLeftColor`  
`borderRightColor`  
`borderTopColor`

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Color for a single border edge of an element.

**Value:** Color values; Constant `transparent`

**Example:** `elementRef.style.borderTopColor = "rgb(30%, 50%, 0%)";`

`borderBottomStyle`  
`borderLeftStyle`  
`borderRightStyle`  
`borderTopStyle`

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Rendered style for a border edge of an element.

**Value:** Constant `none` | `hidden` | `dotted` | `dashed` | `solid` | `double` | `groove` | `ridge` | `inset` | `outset`. WinIE versions prior to IE5.5 do not respond to the dotted or dashed types; MacIE does not respond to the hidden type.

**Example:** `elementRef.style.borderRightStyle = "double";`

`borderBottomWidth`  
`borderLeftWidth`  
`borderRightWidth`  
`borderTopWidth`

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Thickness of a border edge of an element.

**Value:** Length value; Constant `thin` | `medium` | `thick` (precise measure is at browser's discretion).

**Example:** `elementRef.style.borderBottomWidth = "5px";`

`borderColor`

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Rendered color for one to four sides of an element.

**Value:** Color values for one to four rectangle sides.

**Example:** `elementRef.style.borderColor = "green black";`

`borderStyle`

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Rendered style for one to four sides of an element.

**Value:** One to four rectangle side constants `none` | `hidden` | `dotted` | `dashed` | `solid` | `double` | `groove` | `ridge` | `inset` | `outset`. WinIE versions prior to IE5.5 do not respond to the dotted or dashed types; MacIE does not respond to the hidden type.

**Example:** `elementRef.style.borderStyle = "ridge";`

*elementRef.style.mozOpacity*

## borderWidth

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Thickness of border for one to four sides of an element.

**Value:** One to four rectangle side length value or constants `thin` | `medium` | `thick` (precise dimension is at browser's discretion).

**Example:** `elementRef.style.borderWidth = "5px 4px 5px 3px";`

## margin

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Thickness of transparent margin space outside the element's borders for one to four edges.

**Value:** One to four rectangle side length values.

**Example:** `elementRef.style.margin = "10px 5px";`

## marginBottom

## marginLeft

## marginRight

## marginTop

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Thickness of transparent margin space outside the element's borders for a single border edge.

**Value:** Length value

**Example:** `elementRef.style.marginBottom = "50px";`

## mozBorderRadius

## mozBorderRadiusBottomLeft

## mozBorderRadiusBottomRight

## mozBorderRadiusTopLeft

## mozBorderRadiusTopRight

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1+, Safari

**Controls:** Radius of the border around the element. You can specify each radius corner as a series of values in the `mozBorderRadius` style (one value for all four corners; two values for top-left/bottom-right and top-right/bottom-left; three values for top-left, top-right/bottom-left, and bottom-right; four values for top-left, top-right, bottom-right, bottom-left), or set each corner radius individually with its own property.

**Value:** Radius length value

**Example:** `elementRef.style.mozBorderRadius = "20px 10px 20px 10px";`

## mozOpacity

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1+, Safari

**Controls:** The level of opacity (transparency) of the element as a percentage; the lower the value, the more transparent the element becomes (0% or 0.0 is completely transparent, while 100% or 1.0 is completely opaque).

**Value:** Percentage, or numeric value between 0.0 and 1.0.

**Example:** `elementRef.style.mozOpacity = "75%";`

***elementRef.style.outline*****outline**

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari1+

**Controls:** Up to three characteristics of an outline surrounding an element (similar to a border, but not shifting the location of internal content). This style is not fully supported in the above browsers, even though the properties are reflected in the `style` object. It does, however, work well in Safari 1.0.

**Value:** Combination values: `outlineColor` | `outlineStyle` | `outlineWidth`

**Example:** `elementRef.style.outline = "red groove 2px";`

**outlineColor**

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari1+

**Controls:** Color of all four edges of an outline. This style is not fully supported in the above browsers, even though the properties are reflected in the `style` object. It does, however, work well in Safari 1.0.

**Value:** Color values; Constant `invert`

**Example:** `elementRef.style.outlineColor = "cornflowerblue";`

**outlineStyle**

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari1+

**Controls:** Rendered style for all four sides of an element outline. This style is not fully supported in the above browsers, even though the properties are reflected in the `style` object. It does, however, work well in Safari 1.0.

**Value:** Constant `none` | `hidden` | `dotted` | `dashed` | `solid` | `double` | `groove` | `ridge` | `inset` | `outset`

**Example:** `elementRef.style.outlineStyle = "ridge";`

**outlineWidth**

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari1+

**Controls:** Thickness of all four sides of an element outline. This style is not fully supported in the above browsers, even though the properties are reflected in the `style` object. It does, however, work well in Safari 1.0.

**Value:** Length value or constant `thin` | `medium` | `thick` (precise dimension is at browser's discretion)

**Example:** `elementRef.style.outlineWidth = "4px";`

**padding**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Thickness of space between an element's content and its borders for one to four edges.

**Value:** One to four rectangle side length values.

**Example:** `elementRef.style.padding = "5px";`

paddingBottom  
paddingLeft  
paddingRight  
paddingTop

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Thickness of space between an element's content and its borders for a single edge.

**Value:** Length value

**Example:** `elementRef.style.paddingBottom = "20px";`

## List properties

listStyle

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Up to three characteristics of a list (`ol` or `ul`) presentation. Also applies to `dd`, `dt`, and `li` elements.

**Value:** Combination values `listStyleImage` || `listStylePosition` || `listStyleType`

**Example:** `elementRef.style.listStyle = "none inside lower-alpha";`

listStyleImage

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** URL of the image to be used as a marker for a list item.

**Value:** URL value; Constant `none`

**Example:** `elementRef.style.listStyleImage = "url(custombullet.jpg)";`

listStylePosition

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Whether the marker should be formatted inside the wrapped text of its content or dangle outside the wrapped text (default).

**Value:** Constant `inside` | `outside`

**Example:** `elementRef.style.listStylePosition = "inside";`

listStyleType

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**Controls:** Which of the standard marker sets should be used for items in the list. A change to this property for a single `li` element causes succeeding items to be in the same style.

**Value:** For `ul` elements, constant `circle` | `disc` | `square`

For `ol` elements, constant `decimal` | `decimal-leading-zero` | `lower-alpha` | `lower-greek` | `lower-latin` | `lower-roman` | `upper-alpha` | `upper-greek` | `upper-latin` | `upper-roman`, and non-Roman formats when supported by the operating system (as in Mozilla for MacOS X): `armenian` | `georgian` | `hebrew` | `cjk-ideographic` | `hiragana` | `hiragana-iroha` | `katakana` | `katakana-iroha`.

**Example:** `elementRef.style.listStyleType = "upper-roman";`

*elementRef.style.scrollbar3dLightColor*

## Scroll bar properties

`scrollbar3dLightColor`  
`scrollbarArrowColor`  
`scrollbarBaseColor`  
`scrollbarDarkShadowColor`  
`scrollbarFaceColor`  
`scrollbarHighlightColor`  
`scrollbarShadowColor`  
`scrollbarTrackColor`

**Compatibility:** WinIE5.5, Mac-, NN-, Moz-, Safari-

**Controls:** Colors of individual components of scroll bars when they are displayed for `applet`, `body`, `div`, `embed`, `object`, or `textarea` elements. To experiment with how different colors can affect the individual components, visit <http://msdn.microsoft.com/workshop/samples/author/dhtml/refs/scrollbarColor.htm>.

**Value:** Color values; Constant `none`

**Example:** `elementRef.style.scrollbarTrackColor = "hotpink";`

## Table properties

`borderCollapse`

**Compatibility:** WinIE5+, MacIE5, NN6+, Moz1+, Safari-

**Controls:** Whether a table element adheres to the CSS2 separated borders model or the collapsed borders model. Style is not fully supported in MacIE5.

**Value:** Constant `collapse` | `separate`

**Example:** `elementRef.style.borderCollapse = "separate";`

`borderSpacing`

**Compatibility:** WinIE5+, MacIE5, NN6+, Moz1+, Safari1+

**Controls:** For a table following the separated borders model, the thickness of the spacing between cell rectangles (akin to the `cellspacing` attribute of table elements). Style is not fully supported in MacIE5.

**Value:** One length value (for horizontal and vertical spacing) or comma-delimited list of two length values (the first for horizontal; the second for vertical).

**Example:** `elementRef.style.borderSpacing = "10px";`

`captionSide`

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari1+

**Controls:** Position of the caption element inside a table element. Style is not implemented in MacIE5 and is only partially implemented in Safari.

**Value:** Constant `top` | `right` | `bottom` | `left`

**Example:** `elementRef.style.captionSide = "bottom";`

## emptyCells

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari-

**Controls:** Rendering of cells and their borders when the cells have no content. Default behavior is to not render borders around empty cells. Style is not implemented in MacIE5.

**Value:** Constant `show` | `hide`

**Example:** `elementRef.style.emptyCells = "show";`

## tableLayout

**Compatibility:** WinIE5+, MacIE5, NN6+, Moz1+, Safari1+

**Controls:** Whether table is rendered progressively based on fixed width settings of the first row of cells or is rendered after the widths of all row content can be determined. Modifying this property after a table loads has no effect on the table.

**Value:** Constant `auto` | `fixed`

**Example:** `elementRef.style.tableLayout = "auto";`

## Page and printing properties

### orphans

### widows

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari-

**Controls:** The minimum number of lines of a paragraph to be displayed at the bottom of a page (orphans) or top of a page (widows) when a page break occurs.

**Value:** Integer

**Example:** `elementRef.style.orphans = "4";`

### page

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari-

**Controls:** The page (defined in an `@page` rule) with which the current element should be associated for printing.

**Value:** Identifier assigned to an existing `@page` rule

**Example:** `elementRef.style.page = "landscape";`

### pageBreakAfter

### pageBreakBefore

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari-

**Controls:** Whether a printed page break should be before or after the current element and the page break type.

**Value:** Constant `auto` | `always` | `avoid` | `left` | `right`

**Example:** `elementRef.style.pageBreakBefore = "always";`

### pageBreakInside

**Compatibility:** WinIE-, MacIE5, NN6+, Moz1+, Safari-

**Controls:** Whether a printed page break is allowed inside an element.

**Value:** Constant `auto` | `avoid`

**Example:** `elementRef.style.pageBreakInside = "avoid";`

***elementRef.style.size*****size**

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

**Controls:** The size or orientation of the page box (linked to the style rule via the page property) used to determine printed pages.

**Value:** One (same value for width and height) or two space-delimited (width and height) length values; constant `auto | portrait | landscape`

**Example:** `elementRef.style.size = "portrait";`

## Miscellaneous properties

**accelerator**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Whether an accelerator key is defined for an element.

**Value:** Boolean

**Example:** `elementRef.style.accelerator = "true";`

**behavior**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** The external behavior to be applied to the current element.

**Value:** Space-delimited list of URL values. URLs can be a file location, an object element ID, or one of the built-in (default) behaviors.

**Example:** `elementRef.style.behavior = "url(#default#anchorClick)";`

**cssText**

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari-

**Controls:** Actual CSS rule text (read-only). This property exists by virtue of the browser's object model and is not part of the CSS specification. There is no corresponding CSS attribute.

**Value:** String

**Example:** `var cssRuleText = elementRef.style.cssText;`

**imeMode**

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

**Controls:** Whether text is entered into a text input or text area element through the Input Method Editor (for languages, such as Chinese, Japanese, or Korean).

**Value:** Constant `auto | active | inactive | disabled`

**Example:** `elementRef.style.imeMode = "active";`

## Aural properties

Although these properties are defined in the CSS2 specification and placeholders exist for them in Mozilla-based browsers the styles are not implemented. The script equivalent properties are listed here for the sake of completeness only.

azimuth  
 cue  
 cueAfter  
 cueBefore  
 elevation  
 pause  
 pauseAfter  
 pauseBefore  
 pitch  
 pitchRange  
 playDuring  
 richness  
 speak  
 speakHeader  
 speakNumeral  
 speakPunctuation  
 speechRate  
 stress  
 voiceFamily  
 volume

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

**Controls:** A variety of styles primarily for browsers that support speech synthesis output.

**Value:** Consult <http://www.w3.org/TR/REC-CSS2/aural.html> for details on aural stylesheets.

## filter Object

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
See text		

## Syntax

Accessing filter object properties and methods:

```

(IE4+)  document.all.objectID.filters[i].property | method([parameters])
(IE5.5+) document.all.objectID.filters[filterName].property |
method([parameters])
  
```

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

## About this object

Earlier in this chapter, the `style.filter` property was shown to allow reading and writing of the string value that is assigned to an element's `style.filter` property. Filters are available in WinIE only, even though MacIE5 returns the `style.filter` property value. The purpose of this section is to teach you not how to use filters but rather, how to script them.

Multiple filters are merely part of the space-delimited list of filters. Some filter types have additional specifications. For example, the `glow()` filter has three properties that more clearly define how the element should be rendered with a glow effect. The stylesheet rule for an element whose ID is `glower` looks like the following:

```
#glower {filter:glow(color=yellow, strength=5, enabled=true)}
```

Accessing the `currentStyle.filter` property for that element yields the string value:

```
glow(color=yellow, strength=5, enabled=true)
```

Attempting to modify a single subproperty of the `glow()` filter by way of string parsing would be cumbersome and hazardous at best. For example, imagine trying to increment the glow filter's `strength` property by 5.

## Reading and writing subproperties

A cleaner way to work with individual properties of a filter is to access the filter as an object belonging to the element affected by the filter. Each type of filter object has as its properties the individual sub-properties that you set in the stylesheet. Continuing with the `glow()` filter example, you could access just the `color` property of the filter as follows:

```
var currColor = document.all.glower.filters["glow"].color;
```

To modify the color, assign a new value to the filter object's property:

```
document.all.glower.filters["glow"].color = "green";
```

To increment a numeric value, such as increasing the `glow()` filter's `strength` property by 5, use a construction such as the following (long-winded though it may be):

```
document.all.glower.filters["glow"].strength =  
document.all.glower.filters["glow"].strength + 5;
```

Table 26-1 lists the filter object names that work all the way back to IE4 and the properties associated with each filter type.

---

**Table 26-1: IE4-Compatible Static Filter Types**

---

<i>Filter Name</i>	<i>Description and Properties</i>	
<code>alpha()</code>	Transparency level	
	Properties:	
	<code>opacity</code>	(0 to 100)
	<code>finishopacity</code>	(0 to 100)
	<code>style</code>	(gradient shape 0 to 3)
	<code>startX</code>	(coordinate integer)
	<code>startY</code>	(coordinate integer)
	<code>finishX</code>	(coordinate integer)
	<code>finishY</code>	(coordinate integer)

<b>Filter Name</b>	<b>Description and Properties</b>
<code>blur()</code>	Simulating blurred motion Properties: <code>add</code> (1 or 0) <code>direction</code> (0, 45, 90, 135, 180, 225, 270, 315) <code>strength</code> (pixel count)
<code>chroma()</code>	Color transparency Properties: <code>color</code> (color value)
<code>dropShadow()</code>	Shadow effect Properties: <code>color</code> (color value) <code>offx</code> (horizontal offset pixels) <code>offy</code> (vertical offset pixels) <code>positive</code> (1 or 0)
<code>flipH()</code>	Horizontally mirrored image Properties: None
<code>flipV()</code>	Vertically mirrored image Properties: None
<code>glow()</code>	Outer edge radiance Properties: <code>color</code> (color value) <code>strength</code> (intensity 1 to 255)
<code>gray()</code>	Eliminate color Properties: None
<code>invert()</code>	Opposite hue, saturation, brightness levels Properties: None
<code>light()</code>	Add light source (controlled by methods) Properties: None
<code>mask()</code>	Overlay transparent mask Properties: <code>color</code> (color value)
<code>shadow()</code>	Render as silhouette Properties: <code>color</code> (color value) <code>direction</code> (0, 45, 90, 135, 180, 225, 270, 315)
<code>wave()</code>	Add sine-wave distortion Properties: <code>add</code> (1 or 0) <code>freq</code> (integer number of waves) <code>light</code> (strength 0 to 100) <code>phase</code> (percentage offset 0 to 100) <code>strength</code> (intensity 0 to 255)
<code>xRay()</code>	Render edges only Properties: None

In addition to the static filter types, which are applied to content and sit there unless modified by script, the IE4+ `filter` object also provides types for blends and reveals for transitions between visible and invisible elements. Scripting transitions to act when a script hides or shows an element requires a few lines of code, including calls to some of the `filter` object's methods. First, Table 26-2 shows the IE4+ syntax for transition filters.

**Table 26-2: IE4+ Transition Filters**

<i>FilterName</i>	<i>Description and Properties</i>
<code>blendTrans()</code>	Fades out old element, fades in new element Properties: <code>duration</code> (floating-point number of seconds) Methods: <code>apply()</code> (freezes current display) <code>play()</code> (plays the transition) <code>stop()</code> (stops transition mid-stream)
<code>revealTrans()</code>	Reveals element to be shown through an effect Properties: <code>duration</code> (floating-point number of seconds) <code>transition</code> (code number for effect) 0 Box in 1 Box out 2 Circle in 3 Circle out 4 Wipe up 5 Wipe down 6 Wipe right 7 Wipe left 8 Vertical blinds 9 Horizontal blinds 10 Checkerboard across 11 Checkerboard down 12 Random dissolve 13 Split vertical in 14 Split vertical out 15 Split horizontal in 16 Split horizontal out 17 Strips left down 18 Strips left up 19 Strips right down 20 Strips right up 21 Random bars horizontally 22 Random bars vertically 23 Random effect Methods: <code>apply()</code> (freezes current display) <code>play()</code> (plays the transition) <code>stop()</code> (stops transition mid-stream)

To make a transition work under script control, a filter must be applied to the element that you want the transition to work on. That can be done by script or by assigning a filter style to the element. As for the scripting, you begin by invoking the `apply()` method of the desired filter object. Next, script the change, such as assigning a new URL to the `src` property of an `img` element. While you do this, the `apply()` method freezes the image until you invoke

the `play()` method on the filter. Listing 26-1 effects a checkerboard transition between two images after you click the image.

### Listing 26-1: A Reveal Transition Between Images

```
<html>
  <head>
    <title>IE4+ Transition</title>
    <style type="text/css">
      img {filter:revealTrans(transition=10)}
    </style>
    <script type="text/javascript">
      function doReveal() {
        document.all.myIMG.filters["revealTrans"].apply();
        if (document.all.myIMG.src.indexOf("desk1") != -1) {
          document.all.myIMG.src = "desk3.gif";
        } else {
          document.all.myIMG.src = "desk1.gif";
        }
        document.all.myIMG.filters["revealTrans"].play();
      }
    </script>
  </head>
  <body>
    <h1>IE4+ Transition</h1>
    <hr />
    <p>Click on the image to cause a reveal transition.</p>
    
  </body>
</html>
```

Building on the example in Listing 26-1, the next example in Listing 26-2 demonstrates how a script can also modify a filter object's property, including a transition filter. Before the transition filter has its `apply()` method invoked, the script sets the transition type based on a user choice in a select list.

### Listing 26-2: Choosing Reveal Transitions Between Images

```
<html>
  <head>
    <title>IE4+ Transition and Choices</title>
    <style type="text/css">
      img {filter:revealTrans(transition=10)}
    </style>
    <script type="text/javascript">
      function doReveal() {
        document.all.myIMG.filters["revealTrans"].transition =
document.forms[0].transChoice.value;
        document.all.myIMG.filters["revealTrans"].apply();
        if (document.all.myIMG.src.indexOf("desk1") != -1) {
          document.all.myIMG.src = "desk3.gif";
        } else {
```

*Continued*

## Listing 26-2 (continued)

```

        document.all.myIMG.src = "desk1.gif";
    }
    document.all.myIMG.filters["revealTrans"].play();
}
</script>
</head>
<body>
  <h1>IE4+ Transition and Choices</h1>
  <hr />
  <form>
    <p>Choose the desired transition type: <select name="transChoice">
      <option value="0">Box in</option>
      <option value="1">Box out</option>
      <option value="2">Circle in</option>
      <option value="3">Circle out</option>
      <option value="4">Wipe up</option>
      <option value="5">Wipe down</option>
      <option value="6">Wipe right</option>
      <option value="7">Wipe left</option>
      <option value="8">Vertical blinds</option>
      <option value="9">Horizontal blinds</option>
      <option value="10">Checkerboard across</option>
      <option value="11">Checkerboard down</option>
      <option value="12">Random dissolve</option>
      <option value="13">Split vertical in</option>
      <option value="14">Split vertical out</option>
      <option value="15">Split horizontal in</option>
      <option value="16">Split horizontal out</option>
      <option value="17">Strips left down</option>
      <option value="18">Strips left up</option>
      <option value="19">Strips right down</option>
      <option value="20">Strips right up</option>
      <option value="21">Random bars horizontally</option>
      <option value="22">Random bars vertically</option>
      <option value="23">Random effect</option>
    </select></p>
  </form>
  <p>Click on the image to cause a reveal transition.</p>
  
</body>
</html>

```

## WinIE5.5+ filter syntax changes

While WinIE5.5+ still supports the original IE4 way of controlling filters, the browser also implements a new filter component, which Microsoft strongly encourages authors to use (as evidenced by the difficulty in finding documentation for the IE4 syntax at its developer Web site). In the process of implementing this new filter component, the names of many filters change, as do their individual properties. Moreover, the way the filter component is invoked in the stylesheet is also quite different from the original component.

The stylesheet syntax requires a reference to the new component as well as the filter name. Here is the old way:

```
#glower {filter:glow(color=yellow, strength=5, enabled=true)}
```

And here is the new way:

```
#glower {filter:progid:DXImageTransform.Microsoft.Glow(color=yellow,
  strength=5, enabled=true)}
```

Don't overlook the extra `progid:` pointer in the reference. This program identifier becomes part of the filter name that your scripts use to reference the filter:

```
document.getElementById("glower").filters[
  "DXImageTransform.Microsoft.Glow"].color = "green";
```

While some of the filter names and properties stay the same (except for the huge prefix), several older properties are subsumed by new filters whose properties help identify the specific effect. The former `revealTrans()` filter is now divided among several new filters dedicated to transition effects. Table 26-3 shows the IE5.5+ syntax.

**Note**

Using the new syntax in IE5.5+ can cause frequent crashes of the browser (at least early released versions), especially transition filters. If you implement the new syntax, be sure to torture-test your pages extensively. Ideally, you should encourage users of these pages to run IE6+.

---

**Table 26-3: IE5.5 DXImageTransform.Microsoft Filter Names**

---

<i>Filter Name</i>	<i>Description and Properties</i>	
Alpha()	Transparency level	
	Properties:	opacity (0 to 100)
		finishopacity (0 to 100)
		style (gradient shape 0 to 3)
		startX (coordinate integer)
		startY (coordinate integer)
		finishX (coordinate integer)
		finishY (coordinate integer)
Barn()	Barn-door style transition	
	Properties:	duration (floating-point number of seconds)
		motion (in or out)
		orientation (horizontal or vertical)
		percent (0 to 100)
		status 0 (stopped), 1 (applied), 2 (playing)
	Methods:	apply() (freezes current display)
		play() (plays the transition)
		stop() (stops transition mid-stream)

*Continued*

**Table 26-3** (continued)

# The String Object

Chapter 6's tutorial introduced you to the concepts of values and the types of values that JavaScript works with—features, such as strings, numbers, and Boolean values. In this chapter, you look more closely at the very important String data type, as well as its relationship to the Number data type. Along the way, you encounter the many ways in which JavaScript enables scripters to manipulate strings.

**Note**

Much of the syntax that you see in this chapter is identical to that of the Java programming language. Because the scope of JavaScript activity is narrower than that of Java, you don't have nearly as much to learn for JavaScript as for Java.

## String and Number Data Types

Although JavaScript is what is known as a “loosely typed” language, you still need to be aware of several data types because of their impact on the way you work with the information in those forms. In this section, I focus on strings and two types of numbers.

### Simple strings

A *string* consists of one or more standard text characters between matching quote marks. JavaScript is forgiving in one regard: You can use single or double quotes, as long as you match two single quotes or two double quotes around a string. Another benefit to this scheme becomes apparent when you try to include a quoted string inside a string. For example, say that you're assembling a line of HTML code in a variable that you will eventually write to a new window completely controlled by JavaScript. The line of text that you want to assign to a variable is the following:

```
<input type="checkbox" name="candy" />Chocolate
```

To assign this entire line of text to a variable, you have to surround the line in quotes. But because quotes appear inside the string, JavaScript (or any language) has problems deciphering where the string begins or ends. By carefully placing the other kind of quote pairs, however, you can make the assignment work. Here are two equally valid ways:

```
result = '<input type="checkbox" name="candy" />Chocolate';  
result = "<input type='checkbox' name='candy' />Chocolate";
```

Notice that in both cases, the same unique pair of quotes surrounds the entire string. Inside the string, two quoted strings appear that are treated as such by JavaScript. I recommend that you settle on one form or the other, and then use that form consistently throughout your scripts.

### In This Chapter

How to parse and work with text

Performing search-and-replace operations

Scripted alternatives to text formatting

## Building long string variables

The act of joining strings together — concatenation — enables you to assemble long strings out of several little pieces. This feature is very important for some of your scripting — for example, when you need to build an HTML page's specifications entirely within a variable before writing the page to another frame with one `document.write()` statement.

One tactic that I use keeps the length of each statement in this building process short enough so that it's easily readable in your text editor. This method uses the add-by-value assignment operator (`+=`) that appends the right-hand side of the equation to the left-hand side. Here is a simple example, which begins by initializing a variable as an empty string:

```
var newDocument = "";
newDocument += "<html><head><title>Life and Times</title></head>";
newDocument += "<body><h1>My Life and Welcome to It</h1>";
newDocument += "by Sidney Finortny<hr />";
```

Starting with the second line, each statement adds more data to the string being stored in `newDocument`. You can continue appending string data until the entire page's specification is contained in the `newDocument` variable.

**Note**

Excessive use of the add-by-value operator involving large quantities of text can become inefficient. If you are experiencing slow performance when accumulating large strings, try pushing your string segments into items of an array (see Chapter 30). Then use the array's `join()` method to generate the resulting large string value.

## Joining string literals and variables

In some cases, you need to create a string out of literal strings (characters with quote marks around them) and string variable values. The methodology for concatenating these types of strings is no different from that of multiple string literals. The plus-sign operator does the job. Therefore, in the following example, a variable contains a name. That variable value is made a part of a larger string whose other parts are string literals:

```
yourName = prompt("Please enter your name:","");
var msg = "Good afternoon, " + yourName + ".";
alert(msg);
```

Some common problems that you may encounter while attempting this kind of concatenation include the following:

- ♦ Accidentally omitting one of the quotes around a literal string
- ♦ Failing to insert blank spaces in the string literals to accommodate word spaces
- ♦ Forgetting to concatenate punctuation after a variable value

Also, don't forget that what I show here as variable values can be any expression that evaluates to a string, including property references and the results of some methods. For example

```
var msg = "The name of this document is " + document.title + ".";
alert(msg);
```

## Special inline characters

The way string literals are created in JavaScript makes adding certain characters to strings difficult. I'm talking primarily about adding quotes, carriage returns, apostrophes, and tab characters to strings. Fortunately, JavaScript provides a mechanism for entering such

characters into string literals. A backslash symbol, followed by the character that you want to appear as inline, makes that task happen. For the “invisible” characters, a special set of letters following the backslash tells JavaScript what to do.

The most common backslash pairs are as follows:

- ♦ `\"` Double quote
- ♦ `\'` Single quote (apostrophe)
- ♦ `\\` Backslash
- ♦ `\b` Backspace
- ♦ `\t` Tab
- ♦ `\n` New line
- ♦ `\r` Carriage return
- ♦ `\f` Form feed

Use these “inline characters” (also known as “escaped characters,” but this terminology has a different connotation for Internet strings) inside quoted string literals to make JavaScript recognize them. When assembling a block of text that needs a new paragraph, insert the `\n` character pair. Here are some examples of syntax using these special characters:

```
msg = "You\'re doing fine.";
msg = "This is the first line.\nThis is the second line.";
msg = document.title + "\n" + document.links.length + " links present.";
```

Technically speaking, a complete carriage return, as known from typewriting days, is both a line feed (advance the line by one) and a carriage return (move the carriage all the way to the left margin). Although JavaScript strings treat a line feed (`\n` new line) as a full carriage return, you may have to construct `\r\n` breaks when assembling strings that go back to a `cgi` script on a server. The format that you use all depends on the string-parsing capabilities of the `cgi` program. (Also see the special requirements for the `textarea` object in Chapter 20.)

Confusing the strings assembled for display in `textarea` objects or alert boxes with strings to be written as HTML is easy. For HTML strings, make sure that you use the standard HTML tags for line-breaks (`<br>`) and paragraph breaks (`<p>`) rather than the inline return or line feed symbols.

†Member of the static `String` object

## Syntax

### Creating a string object:

```
var myString = new String("characters");
```

### Creating a string value:

```
var myString = "characters";
```

### Accessing static `String` object properties and methods:

```
String.property | method([parameters])
```

### Accessing string object properties and methods:

```
string.property | method([parameters])
```

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

## About this object

JavaScript draws a fine line between a string value and a string object. Both let you use the same methods on their contents, so that by and large, you do not have to create a string object (with the `new String()` constructor) every time you want to assign a string value to a variable. A simple assignment operation (`var myString = "fred"`) is all you need to create a string value that behaves on the surface very much like a full-fledged string object.

Where the difference comes into play is when you want to exploit the “object-ness” of a genuine string object, which I explain further in the discussion of the `string.prototype` property later in this chapter. You may also encounter the need to use a full-fledged string object when passing string data to Java applets. If you find that your applet doesn’t receive a string value as a Java `String` data type, then create a new string object via the JavaScript constructor function before passing the value onto the applet.

With string data often comes the need to massage that text in scripts. In addition to concatenating strings, you at times need to extract segments of strings, delete parts of strings, and replace one part of a string with some other text. Unlike many plain-language scripting languages, JavaScript is fairly low-level in its built-in facilities for string manipulation. This characteristic means that unless you can take advantage of the regular expression powers of NN4+/IE4+ or advanced array techniques, you must fashion your own string handling routines out of very elemental powers built into JavaScript. Later in this chapter, I provide several functions that you can use in your own scripts for common string handling in a manner fully compatible with older browsers.

As you work with string values, visualize every string value as an object with properties and methods like other JavaScript objects. The latest versions of JavaScript define a few properties and a slew of methods for any string value (and one extra property for the static `String` object that is always present in the context of the browser window). The syntax is the same for string methods as it is for any other object method:

```
stringObject.method()
```

What may seem odd at first is that the `stringObject` part of this reference can be any expression that evaluates to a string, including string literals, variables containing strings, methods or functions that return strings, or other object properties. Therefore, the following examples of calling the `toUpperCase()` method are all valid:

```
"george burns".toUpperCase()  
yourName.toUpperCase() // yourName is a variable containing a string  
window.prompt("Enter your name","").toUpperCase()  
document.forms[0].entry.value.toUpperCase() // entry is a text field object
```

An important concept to remember is that invoking a string method does not change the string object that is part of the reference. Rather, the method returns a value, which can be used as a parameter to another method or function call, or assigned to a variable value.

Therefore, to change the contents of a string variable to the results of a method, you must use an assignment operator, as in

```
yourName = yourName.toUpperCase(); // variable is now all uppercase
```

## Properties

### constructor

**Value:** Function reference.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

Read/Write

**stringObject.constructor**

The `constructor` property is a reference to the function that was invoked to create the current string. For a native JavaScript string object, the constructor function is the built-in `String()` constructor.

When you use the new `String()` constructor to create a string object, the type of the value returned by the constructor is `object` (meaning the `typeof` operator returns `object`). Therefore, you can use the `constructor` property on an object value to see if it is a string object:

```
if (typeof someValue == "object" ) {
  if (someValue.constructor == String) {
    // statements to deal with string object
  }
}
```

Although the property is read/write, and you can assign a different constructor to the `String.prototype`, the native behavior of a `String` object persists through the new constructor.

**Example**

Use The Evaluator (Chapter 13) to test the value of the `constructor` property. Enter the following statements into the top text box:

```
a = new String("abcd")
a.constructor == String
a.constructor == Number
```

**Related Items:** `prototype` property.

**length**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The most frequently used property of a string is `length`. To derive the length of a string, read its property as you would read the `length` property of any object:

```
string.length
```

The `length` value represents an integer count of the number of characters within the string. Spaces and punctuation symbols count as characters. Any backslash special characters embedded in a string count as one character, including such characters as newline and tab. Here are some examples:

```
"Lincoln".length // result = 7
"Four score".length // result = 10
"One\two".length // result = 7
"".length // result = 0
```

The `length` property is commonly summoned when dealing with detailed string manipulation in repeat loops.

**prototype**

**Value:** String object.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

`String` objects defined with the new `String("stringValue")` constructor are robust objects compared with plain, old variables that are assigned string values. You certainly don't

***stringObject.charAt()***

have to create this kind of string object for every string in your scripts, but these objects do come in handy if you find that strings in variables go awry. This happens occasionally while trying to preserve string information as script variables in other frames or windows. By using the string object constructor, you can be relatively assured that the string value will be available in the distant frame when needed.

Another byproduct of true string objects is that you can assign prototype properties and methods to all string objects in the document. A *prototype* is a property or method that becomes a part of every new object created after the prototype items are added. For strings, as an example, you may want to define a new method for converting a string into a new type of HTML font tag not already defined by the JavaScript string object. Listing 27-1 shows how to create and use such a prototype.

**Listing 27-1: A String Object Prototype**

```
<html>
  <head>
    <title>String Object Prototype</title>
    <script type="text/javascript">
      function makeItHot() {
        return "<font color='red'>" + this.toString() + "</font>";
      }
      String.prototype.hot = makeItHot;
    </script>
  </head>
  <body>
    <script type="text/javascript">
      document.write("<h1>This site is on " + "FIRE".hot() + "!!</h1>");
    </script>
  </body>
</html>
```

A function definition (`makeItHot()`) accumulates string data to be returned to the object when the function is invoked as the object's method. The `this` keyword refers to the object making the call, which you convert to a string for concatenation with the rest of the strings to be returned. In the page's Body, that prototype method is invoked in the same way one invokes existing `String` methods that turn strings into HTML tags (discussed later in this chapter).

In the next sections, I divide string object methods into two distinct categories. The first, parsing methods, focuses on string analysis and character manipulation within strings. The second group, formatting methods, is devoted entirely to assembling strings in HTML syntax for those scripts that assemble the text to be written into new documents or other frames.

## Parsing methods

### *string.charAt(index)*

**Returns:** One-character string.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Use the `string.charAt()` method to read a single character from a string when you know the position of that character. For this method, you specify an index value in the string as a

***stringObject.charAt()***

parameter to the method. The index value of the first character of the string is 0. To grab the last character of a string, mix string methods:

```
myString.charAt(myString.length - 1)
```

If your script needs to get a range of characters, use the *string.substring()* method. Using *string.substring()* to extract a character from inside a string is a common mistake, when the *string.charAt()* method is more efficient.

**Example**

Enter each of the following statements into the top text box of The Evaluator:

```
a = "banana daiquiri"  
a.charAt(0)  
a.charAt(5)  
a.charAt(6)  
a.charAt(20)
```

Results from each of the *charAt()* methods should be b, a (the third “a” in “banana”), a space character, and an empty string, respectively.

**Related Items:** *string.lastIndexOf()*, *string.indexOf()*, *string.substring()* methods.

***string.charCodeAt([index])*****String.fromCharCode(*num1* [, *num2* [, ... *numn*]])**

**Returns:** Integer code number for a character; concatenated string value of code numbers supplied as parameters.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

Conversions from plain language characters to their numeric equivalents have a long tradition in computer programming. For a long time, the most common numbering scheme was the ASCII standard, which covers the basic English, alphanumeric characters and punctuation within 128 values (numbered 0 through 127). An extended version with a total of 256 characters, with some variations depending on the operating system, accounts for other roman characters in other languages, particularly vowels with umlauts and other pronunciation marks. To bring all languages, including pictographic languages and other non-Roman alphabets, into the computer age, a world standard called Unicode provides space for thousands of characters.

In JavaScript, the character conversions are string methods. Acceptable values depend on the browser that you are using. NN4 works only with the 256 ISO-Latin-I values; IE4+, NN6+, and W3C browsers work with the Unicode system.

The two methods that perform these conversions work in very different ways syntactically. The first, *string.charCodeAt()*, converts a single string character to its numerical equivalent. The string being converted is the one to the left of the method name—and the string may be a literal string or any other expression that evaluates to a string value. If no parameter is passed, the character being converted is by default the first character of the string. However, you can also specify a different character as an index value into the string (first character is 0), as demonstrated here:

```
"abc".charCodeAt() // result = 97  
"abc".charCodeAt(0) // result = 97  
"abc".charCodeAt(1) // result = 98
```

If the string value is an empty string or the index value is beyond the last character, the result is NaN.

*stringObject.charCodeAt()*

To convert numeric values to their characters, use the `String.fromCharCode()` method. Notice that the object beginning the method call is the static `String` object, not a string value. Then, as parameters, you can include one or more integers separated by commas. In the conversion process, the method combines the characters for all of the parameters into one string, an example of which is shown here:

```
String.fromCharCode(97, 98, 99) // result "abc"
```

**Note**

Although recent browsers support character values across the entire Unicode range, the browser won't render characters above 255 unless the computer is equipped with language and font support for the designated language.

**Example**

Listing 27-2 provides examples of both methods on one page. Moreover, because one of the demonstrations relies on the automatic capture of selected text on the page, the scripts include code to accommodate the different handling of selection events and capture of the selected text in a variety of browsers.

After you load the page, select part of the body text anywhere on the page. If you start the selection with the lowercase letter “a,” the character code displays as 97. If you select no text, the result is NaN.

Try entering numeric values in the three fields at the bottom of the page. Values below 32 are ASCII control characters that most fonts represent as hollow squares. But try all other values to see what you get. Notice that the script passes all three values as a group to the `String.fromCharCode()` method, and the result is a combined string. Thus, Figure 27-1 shows what happens when you enter the uppercase ASCII values for a three-letter animal name.

**Listing 27-2: Character Conversions**

```
<html>
  <head>
    <title>Character Codes</title>
    <script type="text/javascript">
      function showCharCode() {
        var theText = "";
        if (window.getSelection) {
          theText = window.getSelection().toString();
        } else if (document.getSelection) {
          theText = document.getSelection();
        } else if (document.selection && document.selection.createRange) {
          theText = document.selection.createRange().text;
        }
        if (theText) {
          document.forms[0].charCodeDisplay.value = theText.charCodeAt();
        } else {
          document.forms[0].charCodeDisplay.value = " ";
        }
      }
      function showString(form) {
        form.result.value =
String.fromCharCode(form.entry1.value,form.entry2.value,form.entry3.value);
      }
    </script>
  </head>
</html>
```

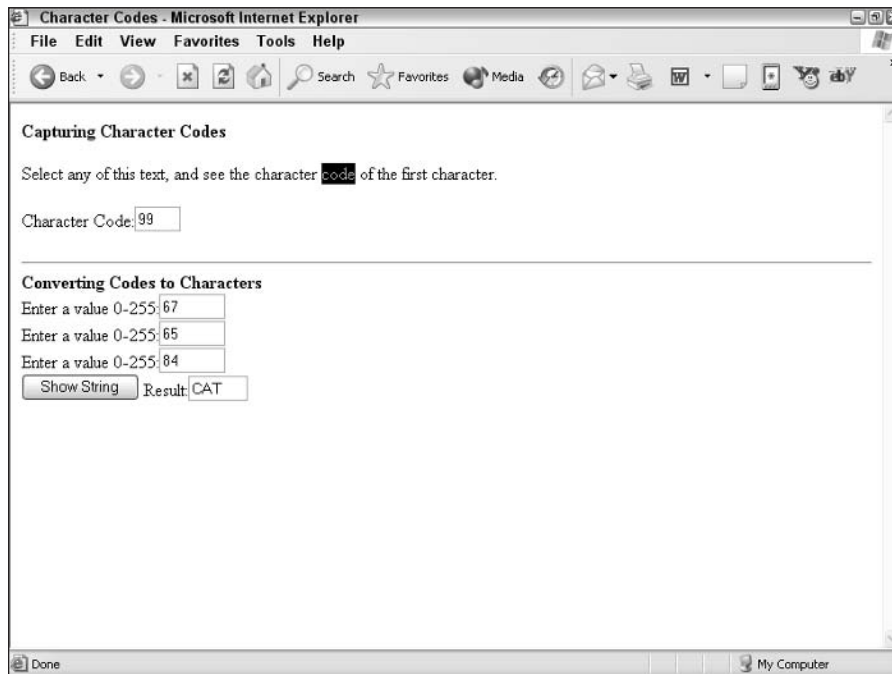

*Continued*

**stringObject.charCodeAt()****Listing 27-2 (continued)**

```

    document.onmouseup = showCharCode;
  </script>
</head>

    name="result" size="5" />
  </form>
</body>
</html>

```

**Figure 27-1:** Conversions from text characters to ASCII values and vice versa.

**Related Items:** None.

### *string.concat(string2)*

**Returns:** Combined string.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

JavaScript's add-by-value operator (+) provides a convenient way to concatenate strings. Recent browsers, however, include a string object method that performs the same task. The base string to which more text is appended is the object or value to the left of the period. The string to be appended is the parameter of the method, as the following example demonstrates:

```
"abc".concat("def") // result: "abcdef"
```

As with the add-by-value operator, the `concat()` method doesn't know about word endings. You are responsible for including the necessary space between words if the two strings require a space between them in the result.

**Related Items:** Add-by-value (+) operator.

### *string.indexOf(searchString [, startIndex])*

**Returns:** Index value of the character within *string* where *searchString* begins.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Like some languages' offset string function, JavaScript's `indexOf()` method enables your script to obtain the number of the character in the main string where a search string begins. Optionally, you can specify where in the main string the search should begin—but the returned value is always relative to the very first character of the main string. Such as all string object methods, index values start their count with 0. If no match occurs within the main string, the returned value is -1. Thus, this method is a convenient way to determine whether one string contains another, regardless of position.

### Example

Enter each of the following statements (up to but not including the “//” comment symbols) into the top text box of The Evaluator (you can simply replace the parameters of the `indexOf()` method for each statement after the first one). Compare your results with the results shown below.

```
a = "bananas"
a.indexOf("b") // result = 0 (index of 1st letter is zero)
a.indexOf("a") // result = 1
a.indexOf("a",1) // result = 1 (start from 2nd letter)
a.indexOf("a",2) // result = 3 (start from 3rd letter)
a.indexOf("a",4) // result = 5 (start from 5th letter)
a.indexOf("nan") // result = 2
a.indexOf("nas") // result = 4
a.indexOf("s") // result = 6
a.indexOf("z") // result = -1 (no "z" in string)
```

**Related Items:** `string.lastIndexOf()`, `string.charAt()`, `string.substring()` methods.

***string*.lastIndexOf()*****string*.lastIndexOf(*searchString*[, *startIndex*])**

**Returns:** Index value of the last character within *string* where *searchString* begins.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The *string*.lastIndexOf() method is closely related to the method *string*.indexOf(). The only difference is that this method starts its search for a match from the end of the string (*string*.length - 1) and works its way backward through the string. All index values are still counted, starting with 0, from the front of the string. The examples that follow use the same values as in the examples for *string*.indexOf() so that you can compare the results. In cases where only one instance of the search string is found, the results are the same; but when multiple instances of the search string exist, the results can vary widely—hence the need for this method.

**Example**

Enter each of the following statements (up to, but not including the “//” comment symbols) into the top text box of The Evaluator (you can simply replace the parameters of the lastIndexOf() method for each statement after the first one). Compare your results with the results shown below.

```
a = "bananas"
a.lastIndexOf("b") // result = 0 (index of 1st letter is zero)
a.lastIndexOf("a") // result = 5
a.lastIndexOf("a",1) // result = 1 (from 2nd letter toward the front)
a.lastIndexOf("a",2) // result = 1 (start from 3rd letter working toward front)
a.lastIndexOf("a",4) // result = 3 (start from 5th letter)
a.lastIndexOf("nan") // result = 2 [except for -1 Nav 2.0 bug]
a.lastIndexOf("nas") // result = 4
a.lastIndexOf("s") // result = 6
a.lastIndexOf("z") // result = -1 (no "z" in string)
```

**Related Items:** *string*.lastIndexOf(), *string*.charAt(), *string*.substring() methods.

***string*.localeCompare(*string2*)**

**Returns:** Integer.

**Compatibility:** WinIE5.5+, MacIE-, NN6+, Moz1+, Safari1+

The localeCompare() method lets a script compare the cumulative Unicode values of two strings, taking into account the language system for the browser. The need for this method affects only some language systems (Turkish is said to be one). If the two strings, adjusted for the language system, are equal, the value returned is zero. If the string value on which the method is invoked (meaning the string to the left of the period) sorts ahead of the parameter string, the value returned is a negative integer; otherwise the returned value is a positive integer.

The ECMA standard for this method leaves the precise positive or negative values up to the browser designer. NN6+ calculates the cumulative Unicode values for both strings and subtracts the string parameter's sum from the string value's sum. IE5.5+, on the other hand, returns -1 or 1 if the strings are not colloquially equal.

**Related Items:** *string*.toLocaleLowerCase(), *string*.toLocaleUpperCase() methods.

## *string.match(regExpression)*

**Returns:** Array of matching strings.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The *string.match()* method relies on the `RegExp` (regular expression) object introduced to JavaScript in version 4 browsers. The string value under scrutiny is to the left of the dot, while the regular expression to be used by the method is passed as a parameter. The parameter must be a regular expression object, created according to the two ways these objects can be generated.

This method returns an array value when at least one match turns up; otherwise the returned value is `null`. Each entry in the array is a copy of the string segment that matches the specifications of the regular expression. You can use this method to uncover how many times a substring or sequence of characters appears in a larger string. Finding the offset locations of the matches requires other string parsing.

### Example

To help you understand the *string.match()* method, Listing 27-3 provides a workshop area for experimentation. Two fields occur for data entry: the first is for the long string to be examined by the method; the second is for a regular expression. Some default values are provided in case you're not yet familiar with the syntax of regular expressions (see Chapter 42 on the CD-ROM). A checkbox lets you specify whether the search through the string for matches should be case-sensitive. After you click the "Execute match()" button, the script creates a regular expression object out of your input, performs the *string.match()* method on the big string, and reports two kinds of results to the page. The primary result is a string version of the array returned by the method; the other is a count of items returned.

#### Listing 27-3: Regular Expression Match Workshop

```
<html>
  <head>
    <title>Regular Expression Match</title>
    <script type="text/javascript">
      function doMatch(form) {
        var str = form.entry.value;
        var delim = (form.caseSens.checked) ? "/"g" : "/gi";
        var regexp = eval("/" + form.regexp.value + delim);
        var resultArray = str.match(regexp);
        if (resultArray) {
          form.result.value = resultArray.toString();
          form.count.value = resultArray.length;
        } else {
          form.result.value = "<no matches>";
          form.count.value = "";
        }
      }
    </script>
  </head>
```

*Continued*

*stringObject.match()*

## Listing 27-3 (continued)

```

<body>
  <b>String Match with Regular Expressions</b>
  <hr />
  <form>
    Enter a main string:<input type="text" name="entry" size="60"
    value="Many a maN and womAN have meant to visit GerMAny." /><br />
    Enter a regular expression to match:<input type="text" name="regexp"
    size="25" value="\w\w" /> <input type="checkbox"
    name="caseSens" />Case-sensitive
    <p><input type="button" value="Execute match()"
    onclick="doMatch(this.form)" /> <input type="reset" /></p>
    <p>Result:<input type="text" name="result" size="40" /><br />
    Count:<input type="text" name="count" size="3" /><br /></p>
  </form>
</body>
</html>

```

The default value for the main string has unusual capitalization intentionally. The capitalization lets you see more clearly where some of the matches come from. For example, the default regular expression looks for any three-character string that has the letter “a” in the middle. Six string segments match that expression. With the help of capitalization, you can see where each of the four strings containing “man” are extracted from the main string. The following table lists some other regular expressions to try with the default main string.

<i>RegExp</i>	<i>Description</i>
man	Both case-sensitive and not
man\b	Where “man” is at the end of a word
\bman	Where “man” is at the start of a word
me*an	Where zero or more “e” letters occur between “m” and “a”
.a.	Where “a” is surrounded by any one character (including space)
\sa\s	Where “a” is surrounded by a space on both sides
z	Where a “z” occurs (none in the default string)

In the scripts for Listing 27-3, if the `string.match()` method returns `null`, you are informed politely, and the count field is emptied.

**Related Items:** `RegExp` object (Chapter 42 on the CD-ROM).

*string.replace(regExpression, replaceString)*

**Returns:** Changed string.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

Regular expressions are commonly used to perform search-and-replace operations. JavaScript’s `string.replace()` method provides a simple framework in which to perform this kind of operation on any string.

***stringObject.replace()***

Searching and replacing requires three components. The first is the main string that is the target of the operation. Second is the regular expression to search for. And third is the string to replace each instance of the text found by the operation. For the *string.replace()* method, the main string is the string value or object referenced to the left of the period. This string can also be a literal string (that is, text surrounded by quotes). The regular expression to search for is the first parameter, while the replacement string is the second parameter.

The regular expression definition determines whether the replacement is of just the first match encountered in the main string or all matches in the string. If you add the *g* parameter to the end of the regular expression, then one invocation of the *replace()* method performs global search-and-replace through the entire main string.

As long as you know how to generate a regular expression, you don't have to be a whiz to use the *string.replace()* method to perform simple replacement operations. But using regular expressions can make the operation more powerful. Consider these soliloquy lines by Hamlet:

```
To be, or not to be: that is the question:  
Whether 'tis nobler in the mind to suffer
```

If you wanted to replace both instances of “be” with “exist,” you can do it in this case by specifying

```
var regexp = /be/g;  
soliloquy.replace(regexp, "exist");
```

But you can't always be assured that the letters “b” and “e” will be standing alone as a word. What happens if the main string contains the word “being” or “saber”? The above example replaces the “be” letters in them as well.

The regular expression help comes from the special characters to better define what to search for. In the example here, the search is for the word “be.” Therefore, the regular expression surrounds the search text with word boundaries (the `\b` special character), as in

```
var regexp = /\bbe\b/g;  
soliloquy.replace(regexp, "exist");
```

This syntax also takes care of the fact that the first two “be” words are followed by punctuation, rather than a space, as you may expect for a freestanding word. For more about regular expression syntax, see Chapter 42 on the CD-ROM.

## Example

The page in Listing 27-4 lets you practice with the *string.replace()* and *string.search()* methods and regular expressions in a friendly environment. The source text is a five-line excerpt from *Hamlet*. You can enter the regular expression to search for, and the replacement text as well. Note that the script completes the job of creating the regular expression object, so that you can focus on the other special characters used to define the matching string. All replacement activities act globally, because the *g* parameter is automatically appended to any expression you enter.

Default values in the fields replace the contraction ‘tis with “it is” after you click the “Execute replace()” button (see Figure 27-2). Notice that the backslash character in front of the apostrophe of ‘tis (in the string assembled in `mainString`) makes the apostrophe a non-word boundary, and thus allows the `\B't` regular expression to find a match there. As described in the section on the *string.search()* method, the button connected to that method returns the offset character number of the matching string (or `-1` if no match occurs).

*stringObject.replace()*

**Figure 27-2:** Using the default replacement regular expression.

You could modify the listing so that it actually replaces text in the HTML paragraph for IE4+ and W3C browsers. The steps include wrapping the paragraph in its own element (for example, a `span`) and invoking the `replace()` method on the `innerHTML` of that element. Assign the results to the `innerHTML` property of that element to complete the job.

#### Listing 27-4: Lab for `string.replace()` and `string.search()`

```
<html>
<head>
  <title>Regular Expression Replace and Search</title>
  <script type="text/javascript">
    var mainString = "To be, or not to be: that is the question:\n";
    mainString += "Whether 'tis nobler in the mind to suffer\n";
    mainString += "The slings and arrows of outrageous fortune,\n";
    mainString += "Or to take arms against a sea of troubles,\n";
    mainString += "And by opposing end them.";

    function doReplace(form) {
      var replaceStr = form.replaceEntry.value;
      var delim = (form.caseSens.checked) ? "/" : "/gi";
      var regexp = eval("/") + form.regexp.value + delim;
      form.result.value = mainString.replace(regexp, replaceStr);
    }

    function doSearch(form) {
      var replaceStr = form.replaceEntry.value;
      var delim = (form.caseSens.checked) ? "/" : "/gi";
```

*stringObject.slice()*

```

        var regexp = eval("/" + form.regexp.value + delim);
        form.result.value = mainString.search(regexp);
    }
</script>
</head>
<body>
  <b>String Replace and Search with Regular Expressions</b>
  <hr />
  Text used for string.replace() and string.search() methods:<br />
  <b>To be, or not to be: that is the question:<br />
  Whether 'tis nobler in the mind to suffer<br />
  The slings and arrows of outrageous fortune,<br />
  Or to take arms against a sea of troubles,<br />
  And by opposing end them.</b>
  <form>
    Enter a regular expression to match:<input type="text" name="regexp"
    size="25" value="\B't" /> <input type="checkbox"
    name="caseSens" />Case-sensitive<br />
    Enter a string to replace the matching strings:<input type="text"
    name="replaceEntry" size="30" value="it " />
    <p><input type="button" value="Execute replace()"
    onclick="doReplace(this.form)" /> <input type="reset" /> <input
    type="button" value="Execute search()"
    onclick="doSearch(this.form)" /></p>
    <p>Result:<br />
    <textarea name="result" cols="60" rows="5" wrap="virtual">
    </textarea></p>
  </form>
</body>
</html>

```

**Related Items:** `string.match()` method; `RegExp` object.

*string.search(regExpression)*

**Returns:** Offset integer.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The results of the `string.search()` method may remind you of the `string.indexOf()` method. In both cases, the returned value is the character number where the matching string first appears in the main string, or `-1` if no match occurs. The big difference, of course, is that the matching string for `string.search()` is a regular expression.

**Example**

Listing 27-4, for the `string.replace()` method, also provides a laboratory to experiment with the `string.search()` method.

**Related Items:** `string.match()` method; `RegExp` object.

*string.slice(startIndex [, endIndex])*

**Returns:** String.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `string.slice()` method resembles the method `string.substring()` in that both let you extract a portion of one string and create a new string as a result (without modifying the

***stringObject.slice()***

original string). A helpful improvement in *string.slice()*, however, is that specifying an ending index value relative to the end of the main string is easier.

Using *string.substring()* to extract a substring that ends before the end of the string requires machinations, such as the following:

```
string.substring(4, (string.length-2))
```

Instead, you can assign a negative number to the second parameter of *string.slice()* to indicate an offset from the end of the string:

```
string.slice(4, -2)
```

The second parameter is optional. If you omit the second parameter, the returned value is a string from the starting offset to the end of the main string.

**Example**

With Listing 27-5, you can try several combinations of parameters with the *string.slice()* method (see Figure 27-3). A base string is provided (along with character measurements). Select from the different choices available for parameters and study the outcome of the slice.

**Listing 27-5: Slicing a String**

```
<html>
  <head>
    <title>String Slicing and Dicing, Part I</title>
    <script type="text/javascript">
      var mainString = "Electroencephalograph";
      function showResults() {
        var form = document.forms[0];
        var param1 = parseInt(
          form.param1.options[form.param1.selectedIndex].value);
        var param2 = parseInt(
          form.param2.options[form.param2.selectedIndex].value);
        if (!param2) {
          form.result1.value = mainString.slice(param1);
        } else {
          form.result1.value = mainString.slice(param1, param2);
        }
      }
    </script>
  </head>
  <body onload="showResults()">
    <b>String slice() Method</b>
    <hr />

    ----5----5----5----5-</b></tt></font>
    <form>
      <table>
        <tr>
          <th>String Method</th>
          <th>Method Parameters</th>
          <th>Results</th>
        </tr>
        <tr>
          <td>string.slice()</td>
```

*stringObject.slice()*

```

<td rowspan="3" valign="middle">
(&nbsp;&nbsp;&nbsp;<select name="param1" onchange="showResults()">
  <option value="0">0</option>
  <option value="1">1</option>
  <option value="2">2</option>
  <option value="3">3</option>
  <option value="5">5</option>
</select>, <select name="param2" onchange="showResults()">
  <option>(None)</option>
  <option value="5">5</option>
  <option value="10">10</option>
  <option value="-1">-1</option>
  <option value="-5">-5</option>
  <option value="-10">-10</option>
</select>&nbsp;&nbsp;&nbsp;);
</td>
<td><input type="text" name="result1" size="25" /></td>
</tr>
</table>
</form>
</body>
</html>

```

**Figure 27-3:** Lab for exploring the `string.slice()` method.

**Related Items:** `string.substr()`, `string.substring()` methods.

***stringObject.split()***

*string.split("delimiterCharacter" [, limitInteger])*

**Returns:** Array of delimited items.

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

The `split()` method is the functional opposite of the `array.join()` method (see Chapter 30). From the string object point of view, JavaScript splits a long string into pieces delimited by a specific character and then creates a dense array with those pieces. You do not need to initialize the array via the new `Array()` constructor. Given the powers of array object methods, such as `array.sort()`, you may want to convert a series of string items to an array to take advantage of those powers. Also, if your goal is to divide a string into an array of single characters, you can still use the `split()` method, but specify an empty string as a parameter. For NN3 and IE4, only the first parameter is observed.

In NN4+, IE4+, and W3C browsers, you can use a regular expression object for the first parameter, enhancing the powers of finding delimiters in strings. For example, consider the following string:

```
var nameList = "1.Fred,2.Jane,3.Steve";
```

To convert that string into a three-element array of only the names takes a lot of parsing without regular expressions before you can even use `string.split()`. However, with a regular expression as a parameter,

```
var regexp = /,*\d.\b/;
var newArray = nameList.split(regexp);
// result = an array "Fred", "Jane", "Steve"
```

the new array entries hold only the names and not the leading numbers or periods. A second addition is an optional second parameter. This integer value allows you to specify a limit to the number of array elements generated by the method.

### Example

Use The Evaluator (Chapter 13) to see how the `string.split()` method works. Begin by assigning a comma-delimited string to a variable:

```
a = "Anderson,Smith,Johnson,Washington"
```

Now split the string at comma positions so that the string pieces become items in an array, saved as b:

```
b = a.split(",")
```

To prove that the array contains four items, inspect the array's `length` property:

```
b.length // result: 4
```

**Related Items:** `array.join()` method.

*string.substr(start [, length])*

**Returns:** String.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `string.substr()` method offers a variation of the `string.substring()` method that has been in the language since the beginning. The distinction is that the `string.substr()` method's parameters specify the starting index and a number of characters to be included from that start point. In contrast, the `string.substring()` method parameters specify index points for the start and end characters within the main string.

*stringObject.substr()*

As with all string methods requiring an index value, the *string.substr()* first parameter is zero-based. If you do not specify a second parameter, the returned substring starts at the indexed point and extends to the end of the string. A second parameter value that exceeds the end point of the string means that the method returns a substring to the end of the string.

Even though this method is newer than its partner, it is not part of the ECMA standard as of Edition 3 of the language spec. But because the method is so widely used, the standard does acknowledge it so that other scripting contexts can implement the method consistent with browser practice.

## Example

Listing 27-6 lets you experiment with a variety of values to see how the *string.substr()* method works.

### Listing 27-6: Reading a Portion of a String

```
<html>
  <head>
    <title>String Slicing and Dicing, Part II</title>
    <script type="text/javascript">
      var mainString = "Electroencephalograph";
      function showResults() {
        var form = document.forms[0];
        var param1 = parseInt(
          form.param1.options[form.param1.selectedIndex].value);
        var param2 = parseInt(
          form.param2.options[form.param2.selectedIndex].value);
        if (!param2) {
          form.result1.value = mainString.substr(param1);
        } else {
          form.result1.value = mainString.substr(param1, param2);
        }
      }
    </script>
  </head>
  <body onload="showResults()">
    <b>String substr() Method</b>

    <form>
      <table>
        <tr>
          <th>String Method</th>
          <th>Method Parameters</th>
          <th>Results</th>
        </tr>
        <tr>
          <td>string.substr()</td>
          <td rowspan="3" valign="middle">
            (&nbsp;  <select name="param1" onchange="showResults()">
              <option value="0">0</option>
              <option value="1">1</option>
            </td>
```

*Continued*

***stringObject.toLocaleLowerCase()***

```

        form.param2.options[form.param2.selectedIndex].value);
    if (!param2) {
        form.result1.value = mainString.substring(param1);
    } else {
        form.result1.value = mainString.substring(param1, param2);
    }
}
</script>
</head>
<body onload="showResults()">
  <b>String substr() Method</b>
  <hr />
  Text used for the methods:<br />
  <font size="+1"><tt><b>Electroencephalograph<br />
  ----5----5----5----5-</b></tt></font>
  <form>
    <table>
      <tr>
        <th>String Method</th>
        <th>Method Parameters</th>
        <th>Results</th>
      </tr>
      <tr>
        <td>string.substring()</td>
        <td>(&nbsp;<select name="param1" onchange="showResults()">
          <option value="0">0</option>
          <option value="1">1</option>
          <option value="2">2</option>
          <option value="3">3</option>
          <option value="5">5</option>
        </select>, <select name="param2" onchange="showResults()">
          <option>(None)</option>
          <option value="3">3</option>
          <option value="5">5</option>
          <option value="10">10</option>
        </select>&nbsp;  )</td>
        <td><input type="text" name="result1" size="25" /></td>
      </tr>
    </table>
  </form>
</body>
</html>

```

**Related Items:** `string.substr()`, `string.slice()` methods.

### *string.toLocaleLowerCase()*

### *string.toLocaleUpperCase()*

**Returns:** String.

**Compatibility:** WinIE5.5+, MacIE-, NN6+, Moz1+, Safari-

These two methods are variations on the standard methods for changing the case of a string. They take into account some language systems whose cases for a particular character don't necessarily map to the Latin alphabet character mappings.

**Related Items:** `string.toLowerCase()`, `string.toUpperCase()` methods.

***string*.toLowerCase()***string*.toLowerCase()*string*.toUpperCase()**Returns:** The string in all lower- or uppercase, depending on which method you invoke.**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

A great deal of what takes place on the Internet (and in JavaScript) is case-sensitive. URLs on some servers, for instance, are case-sensitive for directory names and filenames. These two methods, the simplest of the string methods, return a copy of a string converted to either all lowercase or all uppercase. Any mixed-case strings get converted to a uniform case. If you want to compare user input from a field against some coded string without worrying about matching case, you can convert both strings to the same case for the comparison.

**Example**

You can use the `toLowerCase()` and `toUpperCase()` methods on literal strings, as follows:

```
var newString = "HTTP://www.Netscape.COM".toLowerCase();
// result = "http://www.netscape.com"
```

The methods are also helpful in comparing strings when case is not important, as follows:

```
if (guess.toUpperCase() == answer.toUpperCase()) {...}
// comparing strings without case sensitivity
```

**Related Items:** `string.toLocaleLowerCase()`, `string.toLocaleUpperCase()` methods.*string*.toString()*string*.valueOf()**Returns:** String value.**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

Both of these methods return string values (as opposed to full-fledged string objects). If you have created a string object via the `new String()` constructor, the type of that item is object. Therefore, if you want to examine more precisely what kind of value is held by the object, you can use the `valueOf()` method to get the value and then examine it via the `typeof` operator. The `toString()` method is present for this object primarily because a string object inherits the method from the root object of JavaScript.

**Example**

Use The Evaluator (Chapter 13) to test the `valueOf()` method. Enter the following statements into the top text box and examine the values that appear in the Results field:

```
a = new String("hello")
typeof a
b = a.valueOf()
typeof b
```

Because all other JavaScript core objects also have the `valueOf()` method, you can build generic functions that receive a variety of object types as parameters, and the script can branch its code based on the type of value that is stored in the object.

**Related Items:** `typeof` operator (Chapter 32).

## String Utility Functions

Figuring out how to apply the various string object methods to a string manipulation challenge is not always an easy task, especially if you need backward compatibility with older scriptable browsers. I also find it difficult to anticipate every possible way you may need to massage strings in your scripts. But to help you get started, Listing 27-8 contains a fully backward-compatible library of string functions for inserting, deleting, and replacing chunks of text in a string. If your audience uses browsers capable of including external `.js` library files, that would be an excellent way to make these functions available to your scripts.

### Listing 27-8: Utility String Handlers

```
// extract front part of string prior to searchString
function getFront(mainStr,searchStr){
    foundOffset = mainStr.indexOf(searchStr);
    if (foundOffset == -1) {
        return null;
    }
    return mainStr.substring(0,foundOffset);
}

// extract back end of string after searchString
function getEnd(mainStr,searchStr) {
    foundOffset = mainStr.indexOf(searchStr);
    if (foundOffset == -1) {
        return null;
    }
    return mainStr.substring(foundOffset+searchStr.length,mainStr.length);
}

// insert insertString immediately before searchString
function insertString(mainStr,searchStr,insertStr) {
    var front = getFront(mainStr,searchStr);
    var end = getEnd(mainStr,searchStr);
    if (front != null && end != null) {
        return front + insertStr + searchStr + end;
    }
    return null;
}

// remove deleteString
function deleteString(mainStr,deleteStr) {
    return replaceString(mainStr,deleteStr,"");
}

// replace searchString with replaceString
function replaceString(mainStr,searchStr,replaceStr) {
    var front = getFront(mainStr,searchStr);
    var end = getEnd(mainStr,searchStr);
    if (front != null && end != null) {
        return front + replaceStr + end;
    }
    return null;
}
```

The first two functions extract the front or end components of strings as needed for some of the other functions in this suite. The final three functions are the core of these string-handling functions. If you plan to use these functions in your scripts, be sure to notice the dependence that some functions have on others. Including all five functions as a group ensures that they work as designed.

A modern alternative to Listing 27-8 utilizes a combination of string and array methods to perform a global replace operation in a one-statement function:

```
function replaceString(mainStr, searchStr, replaceStr) {
    return mainStr.split(searchStr).join(replaceStr);
}
```

Going one step further, you can create a custom method to use with all string values or objects in your scripts. Simply let the following statement execute as the page loads:

```
String.prototype.replaceString = function(mainStr, searchStr, replaceStr) {
    return mainStr.split(searchStr).join(replaceStr);
}
```

Then invoke this method of any string value in other scripts on the page, as in:

```
myString = myString.replaceString(" CD ", " MP3 ");
```

## Formatting methods

Now we come to the other group of string object methods, which ease the process of creating the numerous string display characteristics when you use JavaScript to assemble HTML code. The following is a list of these methods:

<code>string.anchor("anchorName")</code>	<code>string.link(locationOrURL)</code>
<code>string.blink()</code>	<code>string.big()</code>
<code>string.bold()</code>	<code>string.small()</code>
<code>string.fixed()</code>	<code>string.strike()</code>
<code>string.fontcolor(colorValue)</code>	<code>string.sub()</code>
<code>string.fontsize(integer1to7)</code>	<code>string.sup()</code>
<code>string.italics()</code>	

---

First examine the methods that don't require any parameters. You probably see a pattern: All of these methods are font-style attributes that have settings of on or off. To turn on these attributes in an HTML document, you surround the text in the appropriate tag pairs, such as `<b>...</b>` for boldface text. These methods take the string object, attach those tags, and return the resulting text, which is ready to be put into any HTML that your scripts are building. Therefore, the expression

```
"Good morning!".bold()
```

evaluates to

```
<b>Good morning!</b>
```

Of course, nothing is preventing you from building your HTML by embedding real tags instead of by calling the string methods. The choice is up to you. One advantage to the string methods is that they never forget the ending tag of a tag pair. Listing 27-9 shows an example of incorporating a few simple string methods in a string variable that is eventually written to

the page as it loads. Internet Explorer does not support the `<blink>` tag and therefore ignores the `string.blink()` method.

### Listing 27-9: Using Simple String Methods

```
<html>
  <head>
    <title>HTML by JavaScript</title>
  </head>
  <body>
    <script type="text/javascript">
      var page = "";
      page += "JavaScript can create HTML on the fly.<P>Numerous string object
        methods facilitate creating text that is " +
        "boldfaced".bold() + ", " + "italicized".italics() +
        ", or even the terribly annoying " + "blinking text".blink() + ".";
      document.write(page);
    </script>
  </body>
</html>
```

Of the remaining string methods, two more (`string.fontSize()` and `string.fontcolor()`) also affect the font characteristics of strings displayed in the HTML page. The parameters for these items are pretty straightforward—an integer between 1 and 7 corresponding to the seven browser font sizes and a color value (as either a hexadecimal triplet or color constant name) for the designated text. Listing 27-10 adds a line of text to the string of Listing 27-9. This line of text not only adjusts the font size of some parts of the string but also nests multiple attributes inside one another to set the color of one word in a large-font-size string. Because these string methods do not change the content of the string, you can safely nest methods here.

### Listing 27-10: Nested String Methods

```
<html>
  <head>
    <title>HTML by JavaScript</title>
  </head>
  <body>
    <script type="text/javascript">
      var page = "";
      page += "JavaScript can create HTML on the fly.<P>Numerous string object
        methods facilitate creating text that is " + "boldfaced".bold() +
        ", " + "italicized".italics() + ", or even the terribly annoying " +
        "blinking text".blink() + ".<br />";
      page += "We can make " + "some words big".fontSize(5) + " and some words
        both " + ("big and " + "colorful".fontcolor('coral')).fontSize(5) +
        " at the same time.";
      document.write(page);
    </script>
  </body>
</html>
```

The final two string methods let you create an anchor and a link out of a string. The `string.anchor()` method uses its parameter to create a name for the anchor. Thus, the following expression

```
"Table of Contents".anchor("toc")
```

evaluates to

```
<a name="toc">Table of Contents</a>
```

In a similar fashion, the `string.link()` method expects a valid location or URL as its parameter, creating a genuine HTML link out of the string:

```
"Back to Home".link("index.html")
```

This evaluates to the following:

```
<a href="index.html">Back to Home</a>
```

Again, the choice of whether you use string methods to build HTML anchors and links over assembling the actual HTML is up to you. The methods may be a bit easier to work with if the values for the string and the parameters are variables whose content may change based on user input elsewhere in your Web site.

## URL String Encoding and Decoding

When browsers and servers communicate, some non-alphanumeric characters that we take for granted (such as a space) cannot make the journey in their native form. Only a narrower set of letters, numbers, and punctuation is allowed. To accommodate the rest, the characters must be encoded with a special symbol (%) and their hexadecimal ASCII values. For example, the space character is hex 20 (ASCII decimal 32). When encoded, it looks like %20. You may have seen this symbol in browser history lists or URLs.

JavaScript includes two functions, `escape()` and `unescape()`, that offer instant conversion of whole strings. To convert a plain string to one with these escape codes, use the `escape` function, as in

```
escape("Howdy Pardner"); // result = "Howdy%20Pardner"
```

The `unescape()` function converts the escape codes into human-readable form. Both of these functions and some newer, more robust versions for recent browsers are covered in Chapter 34.

# The Math, Number, and Boolean Objects

---

The introduction to data types and values in Chapter 6's tutorial scratched the surface of JavaScript's numeric and Boolean powers. In this chapter, you look more closely at JavaScript's way of working with numbers and Boolean data.

Math often frightens away budding programmers; but as you've seen so far in this book, you don't really have to be a math genius to program in JavaScript. The powers described in this chapter are here when you need them — if you need them. So if math is not your strong suit, don't freak out over the terminology here.

An important point to remember about the objects described in this chapter is that (like string values and string objects) numbers and Booleans are both values and objects. Fortunately for script writers, the differentiation is rarely, if ever, a factor unless you get into some very sophisticated programming. To those who actually write the JavaScript interpreters inside the browsers we use, the distinctions are vital.

For most scripters, the information about numeric data types and conversions as well as the `Math` object are important to know. I present other details in this chapter about the number and Boolean objects primarily for completeness because their direct powers are almost never used in day-to-day scripting of Web applications.

## Numbers in JavaScript

More powerful programming languages have many different kinds of numbers, each related to the amount of memory it occupies in the computer. Managing all these different types may be fun for some, but it gets in the way of quick scripting. A JavaScript number has only two possibilities. It can be an integer or a floating-point value. An *integer* is any whole number within a humongous range that does not have any fractional part. Integers never contain a decimal point in their representation. *Floating-point numbers* in JavaScript spread across the same range, but they are represented with a decimal point and some fractional value. If you are an experienced programmer,

### In This Chapter

Advanced math operations

Number base conversions

Working with integers and floating-point numbers

refer to the discussion about the `number` object later in this chapter to see how the JavaScript number type lines up with numeric data types you use in other programming environments.

## Integers and floating-point numbers

Deep inside a computer, the microprocessor has an easier time performing math on integer values as compared to any number with a decimal value tacked on it, which requires the microprocessor to go through extra work to add even two such floating-point numbers. We, as scripters, are unfortunately saddled with this historical baggage and must be conscious of the type of number used in certain calculations.

Most internal values generated by JavaScript, such as index values and `length` properties, consist of integers. Floating-point numbers usually come into play as the result of the division of numeric values, special values such as pi, and human-entered values such as dollars and cents. Fortunately, JavaScript is forgiving if you try to perform math operations on mixed numeric data types. Notice how the following examples resolve to the appropriate data type:

```
3 + 4 = 7 // integer result
3 + 4.1 = 7.1 // floating-point result
3.9 + 4.1 = 8 // integer result
```

Of the three examples, perhaps only the last result is unexpected. When two floating-point numbers yield a whole number, the result is rendered as an integer.

When dealing with floating-point numbers, be aware that not all browser versions return the precise same value down to the last digit to the right of the decimal. For example, the following table shows the result of 8/9 as calculated by numerous scriptable browsers (all in Windows) and converted for string display:

Navigator 2	0.88888888888888884
Navigator 3 & 4	.8888888888888888
Navigator 6+/Mozilla 1+/Safari 1+	0.8888888888888888
Internet Explorer 3	0.888888888888889
Internet Explorer 4+	0.8888888888888888

Clearly, from this display, you don't want to use floating-point math in JavaScript browsers to plan space flight trajectories. For everyday math, however, you need to be cognizant of floating-point errors that accrue in PC arithmetic.

In Navigator, JavaScript relies on the operating system's floating-point math for its own math. Operating systems that offer accuracy to as many places to the right of the decimal as JavaScript displays are exceedingly rare. As you can detect from the preceding table, the modern versions of browsers from Netscape and Microsoft agree about how many digits to display and how to perform internal rounding for this display. That's good for the math, but not particularly helpful when you need to display numbers in a specific format.

Until you get to IE5.5, NN6, and W3C-compatible browsers, JavaScript does not offer built-in facilities for formatting the results of floating-point arithmetic. (For the newer browsers, see the `Number` object later in this chapter for formatting methods.) Listing 28-1 demonstrates a generic formatting routine for positive values, plus a specific call that turns a value into a dollar value. Remove the comments and the routine is fairly compact.

## Listing 28-1: A Generic Number-Formatting Routine

```

<html>
  <head>
    <title>Number Formatting</title>
    <script type="text/javascript">
      // generic positive number decimal formatting function
      function format(expr, decplaces) {
        // raise incoming value by power of 10 times the
        // number of decimal places; round to an integer; convert to string
        var str = "" + Math.round(eval(expr) * Math.pow(10,decplaces));
        // pad small value strings with zeros to the left of rounded number
        while (str.length <= decplaces) {
          str = "0" + str;
        }
        // establish location of decimal point
        var decpoint = str.length - decplaces;
        // assemble final result from: (a) the string up to the position of
        // the decimal point; (b) the decimal point; and (c) the balance
        // of the string. Return finished product.
        return str.substring(0,decpoint) + "." +
          str.substring(decpoint,str.length);
      }
      // turn incoming expression into a dollar value
      function dollarize(expr) {
        return "$" + format(expr,2);
      }
    </script>
  </head>
  <body>
    <h1>How to Make Money</h1>
    <form>
      Enter a positive floating point value or arithmetic expression to be
      converted to a currency format:
      <p><input type="text" name="entry" value="1/3" /> <input type="button"
        value="&gt;Dollars and Cents&gt;"
        onclick="this.form.result.value=dollarize(this.form.entry.value)"
        />
        <input type="text" name="result" /></p>
    </form>
  </body>
</html>

```

This routine may seem like a great deal of work, but it's essential if your application relies on floating-point values and specific formatting for all browsers.

You can also enter floating-point numbers with exponents. An exponent is signified by the letter "e" (upper- or lowercase), followed by a sign (+ or -) and the exponent value. Here are examples of floating-point values expressed as exponents:

```

1e6 // 1,000,000 (the "+" symbol is optional on positive exponents)
1e-4 // 0.0001 (plus some error further to the right of the decimal)
-4e-3 // -0.004

```

For values between 1e-5 and 1e15, JavaScript renders numbers without exponents (although you can force a number to display in exponential notation in IE5.5+, NN6+, and W3C browsers). All other values outside these boundaries return with exponential notation in all browsers.

## Hexadecimal and octal integers

JavaScript enables you to work with values in decimal (base-10), hexadecimal (base-16), and octal (base-8) formats. You have only a few rules to follow when dealing with any of these values.

Decimal values cannot begin with a leading 0. Therefore, if your page asks users to enter decimal values that begin with a 0, your script must strip those zeros from the input string or use the number parsing global functions (described in the next section) before performing any math on the values.

Hexadecimal integer values are expressed with a leading 0x or 0X. (That's a zero, not the letter "o.") The A through F values can appear in upper- or lowercase, as you prefer. Here are some hex values:

```
0X2B
0X1a
0xcc
```

Don't confuse the hex values used in arithmetic with the hexadecimal values used in color property specifications for Web documents. Those values are expressed in a special *hexadecimal triplet* format, which begins with a crosshatch symbol followed by the three hex values bunched together (such as #c0c0c0).

Octal values are represented by a leading 0 followed by any digits between 0 and 7. Octal values consist only of integers.

You are free to mix and match base values in arithmetic expressions, but JavaScript renders all results in decimal form. For conversions to other number bases, you have to employ a user-defined function in your script. Listing 28-2, for example, is a function that converts any decimal value from 0 to 255 into a JavaScript hexadecimal value.

### Listing 28-2: Decimal-to-Hexadecimal Converter Function

```
function toHex(dec) {
  hexChars = "0123456789ABCDEF";
  if (dec > 255) {
    return null;
  }
  var i = dec % 16;
  var j = (dec - i) / 16;
  result = "0X";
  result += hexChars.charAt(j);
  result += hexChars.charAt(i);
  return result;
}
```

The `toHex()` conversion function assumes that the value passed to the function is a decimal integer. If you simply need a hexadecimal representation of a number in string format, see the `toString()` method in Chapter 34.

## Converting strings to numbers

What is missing so far from this discussion is a way to convert a number represented as a string to a number with which the JavaScript arithmetic operators can work. Before you get too concerned about this, be aware that most JavaScript operators and math methods gladly accept string representations of numbers and handle them without complaint. You will run into data type incompatibilities most frequently when trying to accomplish addition with the `+` operator (which is also the string concatenation operator). Also know that if you perform math operations on values retrieved from form text boxes, those object `value` properties are strings. Therefore, in many cases, you need to convert those values to values of the number type for math operations.

Conversion to numbers requires one of two JavaScript functions:

```
parseInt(string [,radix])  
parseFloat(string [,radix])
```

These functions are inspired by the Java language. The term *parsing* has many implied meanings in programming. One meaning is the same as *extracting*. The `parseInt()` function returns whatever integer value it can extract from the string passed to it; the `parseFloat()` function returns the floating-point number that can be extracted from the string. Here are some examples and their resulting values:

```
parseInt("42")           // result = 42  
parseInt("42.33")       // result = 42  
parseFloat("42.33")    // result = 42.33  
parseFloat("42")       // result = 42  
parseFloat("fred")     // result = NaN
```

Because the `parseFloat()` function can also work with an integer and return an integer value, you may prefer using this function in scripts that have to deal with either kind of number, depending on the string entered into a text field by a user.

An optional second parameter to both functions enables you to specify the base of the number represented by the string. This comes in handy particularly when you need a decimal number from a string that starts with one or more zeros. Normally, the leading zero indicates an octal value. But if you force the conversion to recognize the string value as a decimal, it is converted the way you expect:

```
parseInt("010")         // result = 8  
parseInt("010",10)     // result = 10  
parseInt("F2")         // result = NaN  
parseInt("F2", 16)     // result = 242
```

Use these functions wherever you need the integer or floating-point value. For example:

```
var result = 3 + parseInt("3"); // result = 6  
var ageVal = parseInt(document.forms[0].age.value);
```

The latter technique ensures that the string value of this property is converted to a number (although you should do more data validation — see Chapter 43 on the CD-ROM — before trying any math on a user-entered value).

Both the `parseInt()` and `parseFloat()` methods start working on the first character of a string and continue until there are no more numbers or decimal characters. That's why you can use them on strings—such as the one returned by the `navigator.appVersion` property (for example, `5.0 (Windows; en-US)`)—to obtain just the leading, numeric part of the string. If the string does not begin with an acceptable character, the methods return `NaN` (not a number).

## Converting numbers to strings

If you attempt to pass a numeric data type value to many of the string methods discussed in Chapter 27, JavaScript complains. Therefore, you should convert any number to a string before you, for example, find out how many digits make up a number.

Several ways exist to force conversion from any numeric value to a string. The old-fashioned way is to precede the number with an empty string and the concatenation operator. For example, assume that a variable named `dollars` contains the integer value of 2500. To use the string object's `length` property (discussed later in this chapter) to find out how many digits the number has, use this construction:

```
("" + dollars).length    // result = 4
```

The parentheses force JavaScript to evaluate the concatenation before attempting to extract the `length` property.

A more elegant way is to use the `toString()` method. Construct such statements as you do to invoke any object's method. For example, to convert the `dollars` variable value to a string, use this statement:

```
dollars.toString()    // result = "2500"
```

This method has one added power in NN3+ and IE4+: You can specify a number base for the string representation of the number. Called the *radix*, the base number is added as a parameter to the method name. Here is an example of creating a numeric value for conversion to its hexadecimal equivalent as a string:

```
var x = 30;
var y = x.toString(16);    // result = "1e"
```

Use a parameter of 2 for binary results and 8 for octal. The default is base 10. Be careful not to confuse these conversions with true numeric conversions. You cannot use results from the `toString()` method as numeric operands in other statements.

Finally, in IE5.5+, NN6, and W3C browsers, three additional methods of the `Number` object—`toExponential()`, `toFixed()`, and `toPrecision()`—return string versions of numbers formatted according to the rules and parameters passed to the methods. I describe these in detail later in this chapter.

## When a number isn't a number

In a couple of examples in the previous section, you probably noticed that the result of some operations was a value named `NaN`. That value is not a string but rather a special value that stands for Not a Number. For example, if you try to convert the string `"joe"` to an integer with `parseFloat()`, the function cannot possibly complete the operation. It reports back that the source string, when converted, is not a number.

When you design an application that requests user input or retrieves data from a server-side database, you cannot be guaranteed that a value you need to be numeric is, or can be converted to, a number. If that's the case, you need to see if the value is a number before performing some math operation on it. JavaScript provides a special global function, `isNaN()`, that enables you to test the “numberness” of a value. The function returns `true` if the value is not a number and `false` if it is a number. For example, you can examine a form field that should be a number:

```
var ageEntry = parseInt(document.forms[0].age.value);
if (isNaN(ageEntry)) {
    alert("Try entering your age again.");
}
```

## Math Object

Whenever you need to perform math that is more demanding than simple arithmetic, look through the list of `Math` object methods for the solution.

### Syntax

Accessing `Math` object properties and methods:

```
Math.property
Math.method(value [, value])
```

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

### About this object

In addition to the typical arithmetic operations (covered in detail in Chapter 32), JavaScript includes more advanced mathematical powers that you can access in a way that may seem odd to you if you have not programmed in true object-oriented environments before. Although most arithmetic takes place on the fly (such as `var result = 2 + 2`), the rest requires use of the JavaScript internal `Math` object (with a capital “M”). The `Math` object brings with it several properties (which behave like some other languages’ constants) and many methods (which behave like some other languages’ math functions).

The way you use the `Math` object in statements is the same way you use any JavaScript object: You create a reference beginning with the `Math` object’s name, a period, and the name of the property or method you need:

```
Math.property | method([parameter]. . . [,parameter])
```

Property references return the built-in values (things such as `pi`). Method references require one or more values to be sent as parameters of the method. Every method returns a result.

### Properties

JavaScript `Math` object properties represent a number of valuable constant values in `math`. Table 28-1 shows you those methods and their values as displayed to 16 decimal places.

## Math

Table 28-1: JavaScript Math Properties

<i>Property</i>	<i>Value</i>	<i>Description</i>
Math.E	2.718281828459045091	Euler's constant
Math.LN2	0.6931471805599452862	Natural log of 2
Math.LN10	2.302585092994045901	Natural log of 10
Math.LOG2E	1.442695040888963387	Log base-2 of E
Math.LOG10E	0.4342944819032518167	Log base-10 of E
Math.PI	3.141592653589793116	$\pi$
Math.SQRT1_2	0.7071067811865475727	Square root of 0.5
Math.SQRT2	1.414213562373095145	Square root of 2

Because these property expressions return their constant values, you use them in your regular arithmetic expressions. For example, to obtain the circumference of a circle whose diameter is in variable *d*, employ this statement:

```
circumference = d * Math.PI;
```

Perhaps the most common mistakes scripters make with these properties are failing to capitalize the *Math* object name and observing the case-sensitivity of property names.

## Methods

Methods make up the balance of JavaScript *Math* object powers. With the exception of the *Math.random()* method, all *Math* object methods take one or more values as parameters. Typical trigonometric methods operate on the single values passed as parameters; others determine which of the numbers passed along are the highest or lowest of the group. The *Math.random()* method takes no parameters but returns a randomized, floating-point value between 0 and 1 (note that the method does not work on Windows or Macintosh versions of Navigator 2). Table 28-2 lists all the *Math* object methods with their syntax and descriptions of the values they return.

Table 28-2: Math Object Methods

<i>Method Syntax</i>	<i>Returns</i>
Math.abs( <i>val</i> )	Absolute value of <i>val</i>
Math.acos( <i>val</i> )	Arc cosine (in radians) of <i>val</i>
Math.asin( <i>val</i> )	Arc sine (in radians) of <i>val</i>
Math.atan( <i>val</i> )	Arc tangent (in radians) of <i>val</i>
Math.atan2( <i>val1</i> , <i>val2</i> )	Angle of polar coordinates <i>x</i> and <i>y</i>
Math.ceil( <i>val</i> )	Next integer greater than or equal to <i>val</i>
Math.cos( <i>val</i> )	Cosine of <i>val</i>
Math.exp( <i>val</i> )	Euler's constant to the power of <i>val</i>
Math.floor( <i>val</i> )	Next integer less than or equal to <i>val</i>
Math.log( <i>val</i> )	Natural logarithm (base e) of <i>val</i>

<i>Method Syntax</i>	<i>Returns</i>
<code>Math.max(val1, val2)</code>	The greater of <b>val1</b> or <b>val2</b>
<code>Math.min(val1, val2)</code>	The lesser of <b>val1</b> or <b>val2</b>
<code>Math.pow(val1, val2)</code>	<b>val1</b> to the <b>val2</b> power
<code>Math.random()</code>	Random number between 0 and 1
<code>Math.round(val)</code>	N+1 when <b>val</b> $\geq$ n.5; otherwise N
<code>Math.sin(val)</code>	Sine (in radians) of <b>val</b>
<code>Math.sqrt(val)</code>	Square root of <b>val</b>
<code>Math.tan(val)</code>	Tangent (in radians) of <b>val</b>

HTML is not exactly a graphic artist's dream environment, so using trig functions to obtain a series of values for HTML-generated charting is not a hot JavaScript prospect. Only with the advent of positionable elements have scripters been able to apply their knowledge of using these functions to define fancy trajectories for flying elements. For scripters who are not trained in programming, math is often a major stumbling block. But as you've seen so far, you can accomplish a great deal with JavaScript by using simple arithmetic and a little bit of logic — leaving the heavy-duty math for those who love it.

## Creating random numbers

The `Math.random()` method returns a floating-point value between 0 and 1. If you design a script to act like a card game, you need random integers between 1 and 52; for dice, the range is 1 to 6 per die. To generate a random integer between zero and any top value, use the following formula:

```
Math.floor(Math.random() * n)
```

Here, *n* is the top number. To generate random numbers between a different range, use this formula:

```
Math.floor(Math.random() * (n - m + 1)) + m
```

Here, *m* is the lowest possible integer value of the range and *n* equals the top number of the range. For the dice game, the formula for each die is

```
newDieValue = Math.floor(Math.random() * 6) + 1;
```

## Math object shortcut

In Chapter 31, you see details about a JavaScript construction that enables you to simplify the way you address multiple `Math` object properties and methods in statements. The trick is to use the `with` statement.

In a nutshell, the `with` statement tells JavaScript that the next group of statements (inside the braces) refers to a particular object. In the case of the `Math` object, the basic construction looks like this:

```
with (Math) {
    //statements
}
```

**Math**

For all intervening statements, you can omit the specific references to the `Math` object. Compare the long reference way of calculating the area of a circle (with a radius of six units)

```
result = Math.pow(6,2) * Math.PI;
```

to the shortcut reference way:

```
with (Math) {
    result = pow(6,2) * PI;
}
```

Though the latter occupies more lines of code, the object references are shorter and more natural when reading the code. For a longer series of calculations involving `Math` object properties and methods, the `with` construction saves keystrokes and reduces the likelihood of a case-sensitive mistake with the object name in a reference. You can also include other full-object references within the `with` construction; JavaScript attempts to attach the object name only to those references lacking an object name. On the downside, the `with` construction is not particularly efficient in JavaScript because it must perform a lot of internal tracking in order to work.

## Number Object

<i>Properties</i>	<i>Methods</i>
Constructor	<code>toExponential()</code>
<code>MAX_VALUE</code>	<code>toFixed()</code>
<code>MIN_VALUE</code>	<code>toLocaleString()</code>
<code>NaN</code>	<code>toString()</code>
<code>NEGATIVE_INFINITY</code>	<code>toPrecision()</code>
<code>POSITIVE_INFINITY</code>	<code>valueOf()</code>
Prototype	

## Syntax

Creating a number object:

```
var val = new Number(number);
```

Accessing number and `Number` object properties and methods:

```
number.property | method([parameters])
Number.property | method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

## About this object

The `Number` object is rarely used because (for the most part) JavaScript satisfies day-to-day numeric needs with a plain number value. But the `Number` object contains some information and power of value to serious programmers.

**Number.NaN**

First on the docket are properties that define the ranges for numbers in the language. The largest number is 1.79E+308; the smallest number is 2.22E-308. Any number larger than the maximum is `POSITIVE_INFINITY`; any number smaller than the minimum is `NEGATIVE_INFINITY`. Rarely will you accidentally encounter these values.

More to the point of a JavaScript object, however, is the `prototype` property. Chapter 27 shows how to add a method to a `string` object's `prototype` such that every newly created object contains that method. The same goes for the `Number.prototype` property. If you have a need to add common functionality to every number object, this is where to do it. This prototype facility is unique to full-fledged number objects and does not apply to plain number values. For experienced programmers who care about such matters, JavaScript number objects and values are defined internally as IEEE double-precision 64-bit values.

## Properties

### constructor

(See `string.constructor` in Chapter 27)

### MAX\_VALUE

### MIN\_VALUE

### NEGATIVE\_INFINITY

### POSITIVE\_INFINITY

**Value:** Number.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

The `Number.MAX_VALUE` and `Number.MIN_VALUE` properties belong to the static `Number` object. They represent constants for the largest and smallest possible positive numbers that JavaScript (and ECMAScript) can work with. Their actual values are  $1.7976931348623157 \times 10^{308}$ , and  $5 \times 10^{-324}$ , respectively.

A number that falls outside the range of allowable numbers is equal to the constant `Number.POSITIVE_INFINITY` or `Number.NEGATIVE_INFINITY`.

### Example

Enter each of the four `Number` object expressions into the top text field of The Evaluator (Chapter 13) to see how the browser reports each value.

```
Number.MAX_VALUE
Number.MIN_VALUE
Number.NEGATIVE_INFINITY
Number.POSITIVE_INFINITY
```

**Related Items:** NaN property; `isNaN()` global function.

### NaN

**Value:** NaN.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

The NaN property is a constant that JavaScript uses to report when a number-related function or method attempts to work on a value other than a number or the result is something other

**Number.NaN**

than a number. You encounter the NaN value most commonly as the result of the `parseInt()` and `parseFloat()` functions whenever a string undergoing conversion to a number lacks a numeral as the first character. Use the `isNaN()` global function to see if a value is an NaN value.

**Example**

See the discussion of the `isNaN()` function in Chapter 34.

**Related Item:** `isNaN()` global function.

**prototype**

(See `String.prototype` in Chapter 27)

**Methods**

`number.toExponential(fractionDigits)`

`number.toFixed(fractionDigits)`

`number.toPrecision(precisionDigits)`

**Returns:** String.

**Compatibility:** WinIE5.5+, MacIE-, NN6+, Moz1+, Safari1+

A recent addition to the ECMA language—and thus to the JavaScript-enabled browsers—are three `Number` object methods that let scripts control the formatting of numbers for display as string text. Each method has a unique purpose, but they all return strings. You should perform all math operations as unformatted number objects because the values have the most precision. Only after you are ready to display the results should you use one of these methods to convert the number to a string for display as body text or assignment to a text field.

The `toExponential()` method forces a number to display in exponential notation, even if the number is in the range in which JavaScript normally uses standard notation. The parameter is an integer specifying how many digits to the right of the decimal should be returned. All digits to the right of the decimal are returned, even if they are zero. For example, if a variable contains the numeric value 345, applying `toExponential(3)` to that value yields `3.450e+2`, which is JavaScript's exponential notation for  $3.45 \times 10^2$ .

Use the `toFixed()` method when you want to format a number with a specific number of digits to the right of the decimal. This is the method you use, for instance, to display the results of a financial calculation in units and hundredths of units (for example, dollars and cents).

The parameter to the method is an integer indicating the number of digits to be displayed to the right of the decimal. If the number being formatted has more numbers to the right of the decimal than the number of digits specified by the parameter, the method rounds the right-most visible digit—but only with respect to the unrounded value of the next digit. For example, the value 123.455 fixed to two digits to the right of the decimal is rounded up to 123.46. But if the starting value is 123.4549, the method ignores the 9 and sees that the 4 to the right of the 5 should be rounded down; therefore, the result is 123.45. Do not consider the `toFixed()` method to be an accurate rounder of numbers; however, it does a satisfactory job in most cases.

The final method is `toPrecision()`, which enables you to define how many total digits (including digits to the left and right of the decimal) to display of a number. In other words, you define the precision of a number. The following list demonstrates the results of several parameter values signifying a variety of precisions:

***numberObject.toString()***

```
var num = 123.45
num.toPrecision(1) // result = 1e+2
num.toPrecision(2) // result = 1.2e+2
num.toPrecision(3) // result = 123
num.toPrecision(4) // result = 123.5
num.toPrecision(5) // result = 123.45
num.toPrecision(6) // result = 123.450
```

Notice that the same kind of rounding can occur with `toPrecision()` as it does for `toFixed()`.

**Example**

You can use The Evaluator (Chapter 13) to experiment with all three of these methods with a variety of parameter values. Before invoking any method, be sure to assign a numeric value to one of the built-in global variables in The Evaluator (a through z).

```
a = 10/3
a.toFixed(4)
"$" + a.toFixed(2)
```

None of these methods works with number literals (for example, `123.toExponential(2)` does not work).

**Related Item:** Math object.

***number.toLocaleString()***

**Returns:** String.

**Compatibility:** WinIE5.5+, MacIE5+, NN6+, Moz1+, Safari1+

The `number.toLocaleString()` method returns a string value version of the current number in a format that may vary according to a browser's locale settings. According to the ECMA Edition 3 standard, browsers have some leeway in determining exactly how the `toLocaleString()` method should return a string value that conforms with the language standard of the client system or browser.

**Related Items:** `number.toFixed()`, `number.toString()` methods.

***number.toString([radix])***

**Returns:** String.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `number.toString()` method returns a string value version of the current number. The default radix parameter (10) converts the value to base-10 notation if the original number isn't already of that type. Or you can specify other number bases (for example, 2 for binary, 16 for hexadecimal) to convert the original number to the other base — as a string, not a number, for further calculation.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `toString()` method. Assign the number 12 to the variable a and see how the number is converted to strings in a variety of number bases:

***numberObject.toString()***

```
a = 12
a.toString()    // base 10
a.toString(2)
a.toString(16)
```

**Related Item:** `toLocaleString()` method.

***number.valueOf()***

(See `string.valueOf()` in Chapter 27)

## Boolean Object

<i>Properties</i>	<i>Methods</i>
constructor	<code>toString()</code>
prototype	<code>valueOf()</code>

### Syntax

Creating a Boolean object:

```
var val = new Boolean(BooleanValue);
```

Accessing Boolean object properties:

```
BooleanObject.property | method
```

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

### About this object

You work with Boolean values a lot in JavaScript—especially as the result of conditional tests. Just as string values benefit from association with string objects and their properties and methods, so, too, do Boolean values receive aid from the Boolean object. For example, when you display a Boolean value in a text box, the "true" or "false" string is provided by the Boolean object's `toString()` method so you don't have to invoke it directly.

The only time you need to even think about a Boolean object is if you wish to attach some property or method to Boolean objects that you create with the new `Boolean()` constructor. Parameter values for the constructor include the string versions of the values, numbers (0 for false; any other integer for true), and expressions that evaluate to a Boolean value. Any such new Boolean object is imbued with the new properties or methods you add to the prototype property of the core Boolean object.

For details about the properties and methods of the Boolean object, see the corresponding listings for the String object in Chapter 27.

# The Date Object

---

Perhaps the most untapped power of JavaScript is its date and time handling. Scripters passed over the `Date` object with good cause in the early days of JavaScript, because in earlier versions of scriptable browsers, significant bugs and platform-specific anomalies made date and time programming hazardous without significant testing. Even with the improved bug situation, working with dates requires a working knowledge of the world's time zones and their relationships with the standard reference point, known as Greenwich Mean Time (GMT) or Coordinated Universal Time (abbreviated UTC).

Now that date- and time-handling has improved in the latest browsers, I hope more scripters look into incorporating these kinds of calculations into their pages. In Chapter 54 on the CD-ROM, for example, I show you an application that lets your Web site highlight the areas that have been updated since each visitor's last surf ride through your pages — an application that relies heavily on date arithmetic and time zone conversion.

Before getting to the JavaScript part of date discussions, however, the chapter summarizes key facts about time zones and their impact on scripting date and time on a browser. If you're not sure what GMT and UTC mean, the following section is for you.

## Time Zones and GMT

By international agreement, the world is divided into distinct time zones that allow the inhabitants of each zone to say with confidence that when the Sun appears directly overhead, it is roughly noon, squarely in the middle of the day. The current time in the zone is what we set our clocks to — the local time.

That's fine when your entire existence and scope of life go no further than the width of your own time zone. But with instant communication among all parts of the world, your scope reaches well beyond local time. Periodically you must be aware of the local time in other zones. After all, if you live in New York, you don't want to wake up someone in Los Angeles before dawn with a phone call from your office.

**Note**

For the rest of this section, I speak of the Sun "moving" as if Earth were the center of the solar system. I do so for the convenience of our daily perception of the Sun arcing across what appears to us as a stationary sky. In point of fact, I believe Copernicus's theories, so delete that e-mail you were about to send me.

### In This Chapter

Working with date and time values in JavaScript

Performing date calculations

Validating date entry form fields

From the point of view of the time zone over which the Sun is positioned at any given instant, all time zones to the east have already had their noon, so it is later in the day for them — one hour later per time zone (except for those few time zones offset by fractions of an hour). That’s why when U.S. television networks broadcast simultaneously to the eastern and central time zones, the announced schedule for a program is “10 eastern, 9 central.”

Many international businesses must coordinate time schedules of far-flung events. Doing so and taking into account the numerous time zone differences (not to mention seasonal national variations, such as daylight saving time) would be a nightmare. To help everyone out, a standard reference point was devised: the time zone running through the celestial observatory at Greenwich (pronounced GREN-itch), England. This time zone is called Greenwich Mean Time, or GMT for short. The “mean” part comes from the fact that on the exact opposite side of the globe (through the Pacific Ocean) is the international date line, another world standard that decrees where the first instance of the next calendar day appears on the planet. Thus, GMT is located at the middle, or mean, of the full circuit of the day. Not that many years ago, GMT was given another abbreviation that is not based on any one language of the planet. The abbreviation is UTC (pronounced as its letters: yu-tee-see), and the English version is Coordinated Universal Time. Whenever you see UTC, it is for all practical purposes the same as GMT.

If your personal computer’s system clock is set correctly, the machine ticks away in GMT time. But because you set your local time zone in the appropriate control panel, all file time stamps and clock displays are in your local time. The machine knows what the offset time is between your local time and GMT. For daylight saving time, you may have to check a preference setting so that the offset is adjusted accordingly; in Windows 95 and later, the operating system knows when the changeover occurs and prompts you if changing the offset is okay. In any case, if you travel across time zones with a laptop, you should change the computer’s time zone setting, not its clock.

JavaScript’s inner handling of date and time works a lot like the PC clock (on which your programs rely). Date values that you generate in a script are stored internally in GMT time; however, almost all the displays and extracted values are in the local time of the visitor (not the Web site server). And remember that the date values are created on the visitor’s machine by virtue of your script’s generating that value — you don’t send “living” date objects to the client from the server. This concept is perhaps the most difficult to grasp as you work with JavaScript date and time.

Whenever you program time and date in JavaScript for a public Web page, you must take the worldview. This view requires knowing that the visitor’s computer settings determine the accuracy of the conversion between GMT and local time. You’ll also have to do some testing by changing your PC’s clock to times in other parts of the world and making believe you are temporarily in those remote locations, which isn’t always easy to do. It reminds me of the time I was visiting Sydney, Australia. I was turning in for the night and switched on the television in the hotel. This hotel received a live satellite relay of a long-running U.S. television program, *Today*. The program broadcast from New York was for the morning of the same day I was just finishing in Sydney. Yes, this time zone stuff can make your head hurt.

## The Date Object

Like a handful of other objects in JavaScript and the document object models, there is a distinction between the single, static `Date` object that exists in every window (or frame) and a date object that contains a specific date and time. The static `Date` object (uppercase “D”) is used in only a few cases: Primarily to create a new instance of a date and to invoke a couple of methods that the `Date` object offers for the sake of some generic conversions.

Most of your date and time work, however, is with instances of the `Date` object. These instances are referred to generically as date objects (lowercase “d”). Each date object is a snapshot of an exact millisecond in time, whether it be for the instant at which you generate the object or for a specific time in the past or future you need for calculations. If you need to have a live clock ticking away, your scripts will repeatedly create new date objects to grab up-to-the-millisecond snapshots of your computer’s clock. To show the time on the page, extract the hours, minutes, and seconds from the snapshot date object, and then display the values as you like (for example, a digital readout, a graphical bar chart, and so on). By and large, it is the methods of a date object instance that your scripts invoke to read or modify individual components of a date object (for example, the month or hour).

Despite its name, every date object contains information about date and time. Therefore, even if you’re concerned only about the date part of an object’s data, time data is standing by as well. As you learn in a bit, the time element can catch you off-guard for some operations.

## Creating a date object

The statement that asks JavaScript to make an object for your script uses the special object construction keyword `new`. The basic syntax for generating a new date object is as follows:

```
var dateObjectName = new Date([parameters]);
```

The date object evaluates to an object data type rather than to some string or numeric value.

With the date object’s reference safely tucked away in the variable name, you access all date-oriented methods in the dot-syntax fashion with which you’re already familiar:

```
var result = dateObjectName.method();
```

With variables, such as `result`, your scripts perform calculations or displays of the date object’s data (some methods extract pieces of the date and time data from the object). If you then want to put some new value into the date object (such as adding a year to the date object), you assign the new value to the object by way of the method that lets you set the value:

```
dateObjectName.method(newValue);
```

This example doesn’t look like the typical JavaScript assignment statement, which has an equals sign operator. But this statement is the way in which methods that set date object data work.

You cannot get very far into scripting dates without digging into time zone arithmetic. Although JavaScript may render the string equivalent of a date object in your local time zone, the internal storage is strictly GMT.

Even though you haven’t yet seen details of a date object’s methods, here is how you use two of them to add one year to today’s date:

```
var oneDate = new Date();           // creates object with current GMT date
var theYear = oneDate.getYear();    // theYear is now storing the value 2004
theYear = theYear + 1;              // theYear now is 2005
oneDate.setYear(theYear);           // new year value now in the object
```

At the end of this sequence, the `oneDate` object automatically adjusts all the other date components for the next year’s date. The day of the week, for example, will be different, and JavaScript takes care of that for you, should you need to extract that data. With next year’s data in the `oneDate` object, you may now want to extract that new date as a string value for display in a field on the page or submit it quietly to a CGI program on the server.

The issue of parameters for creating a new date object is a bit complex, mostly because of the flexibility that JavaScript offers the scripter. Recall that the job of the `new Date()` statement is to create a place in memory for all data that a date needs to store. What is missing from that task is the data—what date and time to enter into that memory spot. That’s where the parameters come in.

If you leave the parameters empty, JavaScript takes that to mean you want today’s date and the current time to be assigned to that new date object. JavaScript isn’t any smarter, of course, than the setting of the internal clock of your page visitor’s personal computer. If the clock isn’t correct, JavaScript won’t do any better of a job identifying the date and time.

Note

Remember that when you create a new date object, it contains the current time as well. The fact that the current date may include a time of 16:03:19 (in 24-hour time) may throw off things, such as days-between-dates calculations. Be careful.

To create a date object for a specific date or time, you have five ways to send values as a parameter to the `new Date()` constructor function:

```
new Date("Month dd, yyyy hh:mm:ss")
new Date("Month dd, yyyy")
new Date(yy,mm,dd,hh,mm,ss)
new Date(yy,mm,dd)
new Date(milliseconds)
```

The first four variations break down into two styles—a long string versus a comma-delimited list of data—each with optional time settings. If you omit time settings, they are set to 0 (midnight) in the date object for whatever date you entered. You cannot omit date values from the parameters—every date object must have a real date attached to it, whether you need it or not.

In the long string versions, the month is spelled out in full in English. No abbreviations are allowed. The rest of the data is filled with numbers representing the date, year, hours, minutes, and seconds, even if the order is different from your local way of indicating dates. For single-digit values, you can use either a one- or two-digit version (such as 4:05:00). Colons separate hours, minutes, and seconds.

The short versions contain a non-quoted list of integer values in the order indicated. JavaScript cannot know that a 30 means the date if you accidentally place it in the month slot.

You use the last version only when you have the millisecond value of a date and time available. This generally occurs after some math arithmetic (described later in this chapter), leaving you with a date and time in millisecond format. To convert that numeric value to a date object, use the `new Date()` constructor. From the new date object created, you can retrieve more convenient values about the date and time.

## Native object properties and methods

Like the `String` and `Array` objects, the `Date` object features a small handful of properties and methods that all native JavaScript objects have in common. On the property side, the `Date` object has a `prototype` property, which enables you to apply new properties and methods to every date object created in the current page. You can see examples of how this works in discussions of the `prototype` property for `String` and `Array` objects (Chapters 27 and 30, respectively). At the same time, every instance of a date object in IE4+/W3C has a `constructor` property that references the constructor function that generated the object.

A date object has numerous methods that convert date object types to strings, most of which are more specific than the generic `toString()` one. The `valueOf()` method returns the millisecond integer that is stored for a particular date.

## Date methods

The bulk of a date object's methods are for reading parts of the date and time information and for changing the date and time stored in the object. These two categories of methods are easily identifiable because they all begin with the word “get” or “set.” Table 29-1 lists all of the methods of both the static `Date` object and, by inheritance, date object instances. The list is impressive—some would say frightening—but there are patterns you should readily observe. Most methods deal with a single component of a date and time value: year, month, date, and so forth. Each block of “get” and “set” methods also has two sets of methods: one for the local date and time conversion of the date stored in the object; one for the actual UTC date stored in the object. After you see the patterns, the list should be more manageable. Unless otherwise noted, a method has been part of the `Date` object since the first generation of scriptable browsers, and is therefore also supported in new browsers.

**Table 29-1: Date Object Methods**

<i>Method</i>	<i>Value Range</i>	<i>Description</i>
<code>dateObj.getFullYear()</code>	1970-...	Specified year (NN4+, IE3+)
<code>dateObj.getYear()</code>	70-...	(See Text)
<code>dateObj.getMonth()</code>	0-11	Month within the year (January = 0)
<code>dateObj.getDate()</code>	1-31	Date within the month
<code>dateObj.getDay()</code>	0-6	Day of week (Sunday = 0)
<code>dateObj.getHours()</code>	0-23	Hour of the day in 24-hour time
<code>dateObj.getMinutes()</code>	0-59	Minute of the specified hour
<code>dateObj.getSeconds()</code>	0-59	Second within the specified minute
<code>dateObj.getTime()</code>	0-...	Milliseconds since 1/1/70 00:00:00 GMT
<code>dateObj.getMilliseconds()</code>	0-999	Milliseconds since the previous full second (NN4+, IE3+)
<code>dateObj.getUTCFullYear()</code>	1970-...	Specified UTC year (NN4+, IE3+)
<code>dateObj.getUTCMonth()</code>	0-11	UTC month within the year (January = 0) (NN4+, IE3+)
<code>dateObj.getUTCDate()</code>	1-31	UTC date within the month (NN4+, IE3+)
<code>dateObj.getUTCDay()</code>	0-6	UTC day of week (Sunday = 0) (NN4+, IE3+)
<code>dateObj.getUTCHours()</code>	0-23	UTC hour of the day in 24-hour time (NN4+, IE3+)
<code>dateObj.getUTCMinutes()</code>	0-59	UTC minute of the specified hour (NN4+, IE3+)
<code>dateObj.getUTCSeconds()</code>	0-59	UTC second within the specified minute (NN4+, IE3+)
<code>dateObj.getUTCMilliseconds()</code>	0-999	UTC milliseconds since the previous full second (NN4+, IE3+)
<code>dateObj.setYear(val)</code>	1970-...	Be safe: always specify a four-digit year
<code>dateObj.setFullYear(val)</code>	1970-...	Specified year (NN4+, IE3+)
<code>dateObj.setMonth(val)</code>	0-11	Month within the year (January = 0)

*Continued*

Table 29-1 (continued)

<i>Method</i>	<i>Value Range</i>	<i>Description</i>
<code>dateObj.setDate(val)</code>	1-31	Date within the month
<code>dateObj.setDay(val)</code>	0-6	Day of week (Sunday = 0)
<code>dateObj.setHours(val)</code>	0-23	Hour of the day in 24-hour time
<code>dateObj.setMinutes(val)</code>	0-59	Minute of the specified hour
<code>dateObj.setSeconds(val)</code>	0-59	Second within the specified minute
<code>dateObj.setMilliseconds(val)</code>	0-999	Milliseconds since the previous full second (NN4+, IE3+)
<code>dateObj.setTime(val)</code>	0-...	Milliseconds since 1/1/70 00:00:00 GMT
<code>dateObj.setUTCFullYear(val)</code>	1970-...	Specified UTC year (NN4+, IE3+)
<code>dateObj.setUTCMonth(val)</code>	0-11	UTC month within the year (January = 0) (NN4+, IE3+)
<code>dateObj.setUTCDate(val)</code>	1-31	UTC date within the month (NN4+, IE3+)
<code>dateObj.setUTCDay(val)</code>	0-6	UTC day of week (Sunday = 0) (NN4+, IE3+)
<code>dateObj.setUTCHours(val)</code>	0-23	UTC hour of the day in 24-hour time (NN4+, IE3+)
<code>dateObj.setUTCMinutes(val)</code>	0-59	UTC minute of the specified hour (NN4+, IE3+)
<code>dateObj.setUTCSeconds(val)</code>	0-59	UTC second within the specified minute (NN4+, IE3+)
<code>dateObj.setUTCMilliseconds(val)</code>	0-999	UTC milliseconds since the previous full second (NN4+, IE3+)
<code>dateObj.getTimezoneOffset()</code>	0-...	Minutes offset from GMT/UTC
<code>dateObj.toString()</code>		Date-only string in a format determined by browser (WinIE5.5+)
<code>dateObj.toGMTString()</code>		Date/time string in universal format
<code>dateObj.toLocaleDateString()</code>		Date-only string in your system's localized format (NN6+, WinIE5.5+)
<code>dateObj.toLocaleString()</code>		Date/time string in your system's localized format
<code>dateObj.toLocaleTimeString()</code>		Time-only string in your system's localized format (NN6+, WinIE5.5+)
<code>dateObj.toString()</code>		Date/time string in a format determined by browser
<code>dateObj.toTimeString()</code>		Time-only string in a format determined by browser (WinIE5.5+)
<code>dateObj.toUTCString()</code>		Date/time string in universal format (NN4+, IE3+)
<code>Date.parse("dateString")</code>		Converts string date to milliseconds integer
<code>Date.UTC(date values)</code>		Converts GMT string date to milliseconds integer

Deciding between using the UTC or local versions of the methods depends on several factors. If the browsers you must support go back to the beginning, you will be stuck with the local versions in any case. But even for newer browsers, activities, such as calculating the number of days between dates or creating a countdown timer for a quiz, won't care which set you use, but you must use the same set for all calculations. If you start mixing local and UTC versions of date methods, you'll be destined to get wrong answers. The UTC versions come in most handy when your date calculations must take into account the time zone of the client machine compared to some absolute in another time zone—calculating the time remaining to the chiming of Big Ben signifying the start of the New Year in London.

JavaScript maintains its date information in the form of a count of milliseconds (thousandths of a second) starting from January 1, 1970, in the GMT (UTC) time zone. Dates before that starting point are stored as negative values (but see the section on bugs and gremlins later in this chapter). Regardless of the country you are in or the date and time formats specified for your computer, the millisecond is the JavaScript universal measure of time. Any calculations that involve adding or subtracting times and dates should be performed in the millisecond values to ensure accuracy. Therefore, though you may never display the milliseconds value in a field or dialog box, your scripts will probably work with them from time to time in variables. To derive the millisecond equivalent for any date and time stored in a date object, use the `dateObj.getTime()` method, as in

```
var startDate = new Date();
var started = startDate.getTime();
```

Although the method has the word “time” in its name, the fact that the value is the total number of milliseconds from January 1, 1970, means the value also conveys a date.

Other date object get methods read a specific component of the date or time. You have to exercise some care here, because some values begin counting with 0 when you may not expect it. For example, January is month 0 in JavaScript's scheme; December is month 11. Hours, minutes, and seconds all begin with 0, which, in the end, is logical. Calendar dates, however, use the actual number that would show up on the wall calendar: The first day of the month is date value 1. For the twentieth-century years, the year value is whatever the actual year number is, minus 1900. For 1996, that means the year value is 96. But for years before 1900 and after 1999, JavaScript uses a different formula, showing the full year value. This means you have to check whether a year value is less than 100 and add 1900 to it before displaying that year.

```
var today = new Date();
var thisYear = today.getYear();
if (thisYear < 100) {
    thisYear += 1900;
}
```

This assumes, of course, you won't be working with years before A.D. 100. If your audience is strictly IE3+/NN4+, which is quite likely, use only the `getFullYear()` method. This method returns the complete set of year digits from all ranges.

To adjust any one of the elements of a date value, use the corresponding set method in an assignment statement. If the new value forces the adjustment of other elements, JavaScript takes care of that. For example, consider the following sequence and how some values are changed for us:

```
myBirthday = new Date("September 11, 2001");
result = myBirthday.getDay(); // result = 2, a Tuesday
myBirthday.setYear(2002); // bump up to next year
result = myBirthday.getDay(); // result = 3, a Wednesday
```

Because the same date in the following year is on a different day, JavaScript tracks that for you.

## Accommodating time zones

Understanding the `dateObj.getTimezoneOffset()` method involves both your operating system's time control panel setting and an internationally recognized (in computerdom, anyway) format for representing dates and times. If you have ignored the control panel stuff about setting your local time zone, the values you get for this property may be off for most dates and times. In the eastern part of North America, for instance, the eastern standard time zone is five hours earlier than Greenwich Mean Time. With the `getTimezoneOffset()` method producing a value of minutes' difference between GMT and the PC's time zone, the five hours difference of eastern standard time is rendered as a value of 300 minutes. On the Windows platform, the value automatically changes to reflect changes in daylight saving time in the user's area (if applicable). Offsets to the east of GMT (to the date line) are expressed as negative values.

## Dates as strings

When you generate a date object, JavaScript automatically applies the `toString()` method to the object if you attempt to display that date either in a page or alert box. The format of this string varies with browser and operating system platform. For example, in IE6 for Windows XP, the string is in the following format:

```
Mon Jan 5 14:11:49 CDT 2004
```

But in NN7 for Windows XP, the string is

```
Mon Jan 05 2004 14:11:49 GMT-0500 (Central Standard Time)
```

Other browsers return their own variations on the string. The point is not to rely on a specific format and character location of this string for the components of dates. Use the date object methods to read date object components.

JavaScript does, however, provide two methods that return the date object in more constant string formats. One, `dateObj.toGMTString()`, converts the date and time to the GMT equivalent on the way to the variable that you use to store the extracted data. Here is what such data looks like:

```
Mon, 05 Jan 2004 19:11:49 GMT
```

If you're not familiar with the workings of GMT and how such conversions can present unexpected dates, exercise great care in testing your application. Eight o'clock on a Friday evening in California in the winter is four o'clock on Saturday morning GMT.

If time zone conversions make your head hurt, you can use the second string method, `dateObj.toLocaleString()`. In NN7 for North American Windows users, the returned value looks like this:

```
Monday, January 05, 2004 14:11:49
```

Starting with IE5.5 and NN6, you can also have JavaScript convert a date object to just the date or time portions in a nicely formatted version. The best pair of methods for this are `toLocaleDateString()` and `toLocaleTimeString()`, because these methods return values that make the most sense to the user, based on the localization settings of the user's operating system and browser.

## Friendly date formats for older browsers

If you don't have the luxury of writing only for IE5.5+/NN6+/W3C, you can create your own formatting function to do the job for a wide range of browsers. Listing 29-1 demonstrates one way of creating this kind of string from a date object (in a form compatible with IE4+ and NN4+).

**Listing 29-1: Creating a Friendly Date String**

```
<html>
  <head>
    <title>Date String Maker</title>
    <script type="text/javascript">
      monthNames = ["January", "February", "March", "April", "May", "June",
"July",
      "August", "September", "October", "November", "December"];
      dayNames = ["Sunday", "Monday", "Tuesday", "Wednesday", "Thursday",
      "Friday", "Saturday"];

      function customDateString(oneDate) {
        var theDay = dayNames[oneDate.getDay()];
        var theMonth = monthNames[oneDate.getMonth()];
        var theYear = oneDate.getFullYear();
        return theDay + ", " + theMonth + " " + oneDate.getDate() +
          ", " + theYear;
      }
    </script>
  </head>
  <body>
    <h1>
      Welcome!
    </h1>
    <script type="text/javascript">
      document.write(customDateString(new Date()))
    </script>
    <hr />
  </body>
</html>
```

Assuming the user has the PC's clock set correctly (a big assumption), the date appearing just below the opening headline is the current date — making it appear as though the document had been updated today. The downside to this approach (as opposed to the newer `toLocaleDateString()` method) is that international users are forced to view dates in the format you design, which may be different from their local custom.

## More conversions

The last two methods shown in Listing 29-1 are methods of the static `Date` object. These utility methods convert dates from string or numeric forms into millisecond values of those dates. The primary beneficiary of these actions is the `dateObj.setTime()` method, which requires a millisecond measure of a date as a parameter. You use this method to throw an entirely different date into an existing date object.

`Date.parse()` accepts as a parameter date strings similar to the ones you've seen in this section, including the internationally approved version. `Date.UTC()`, on the other hand, requires the comma-delimited list of values (in proper order: *yy, mm, dd, hh, mm, ss*) in the GMT zone. The `Date.UTC()` method gives you a backward-compatible way to hard-code a GMT time (you can do the same in NN4+ and IE4+ via the UTC methods). The following is an example that creates a new date object for 6 p.m. on March 4, 2004, GMT in WinIE6:

```
var newObj = new Date(Date.UTC(2004,2,4,18,0,0));
result = newObj.toString(); // result = "Thu, Mar 04 10:00:00 PST 2004"
```

The second statement returns a value in a local time zone, because all non-UTC methods automatically convert the GMT time stored in the object to the client's local time.

## Date and time arithmetic

You may need to perform some math with dates for any number of reasons. Perhaps you need to calculate a date at some fixed number of days or weeks in the future or figure out the number of days between two dates. When calculations of these types are required, remember the *lingua franca* of JavaScript date values: milliseconds.

What you may need to do in your date-intensive scripts is establish some variable values representing the number of milliseconds for minutes, hours, days, or weeks, and then use those variables in your calculations. Here is an example that establishes some practical variable values, building on each other:

```
var oneMinute = 60 * 1000;
var oneHour = oneMinute * 60;
var oneDay = oneHour * 24;
var oneWeek = oneDay * 7;
```

With these values established in a script, I can use one to calculate the date one week from today:

```
var targetDate = new Date();
var dateInMs = targetDate.getTime();
dateInMs += oneWeek;
targetDate.setTime(dateInMs);
```

Another example uses components of a date object to assist in deciding what kind of greeting message to place in a document, based on the local time of the user's PC clock. Listing 29-2 adds to the scripting from Listing 29-1, bringing some quasi-intelligence to the proceedings.

### Listing 29-2: A Dynamic Welcome Message

```
<html>
  <head>
    <title>Date String Maker</title>
    <script type="text/javascript">
      monthNames = ["January", "February", "March", "April", "May", "June",
"July",
      "August", "September", "October", "November", "December"];
      dayNames = ["Sunday", "Monday", "Tuesday", "Wednesday", "Thursday",
      "Friday", "Saturday"];

      function customDateString(oneDate) {
        var theDay = dayNames[oneDate.getDay()];
        var theMonth = monthNames[oneDate.getMonth()];
        var theYear = oneDate.getFullYear();
        return theDay + ", " + theMonth + " " + oneDate.getDate() +
          ", " + theYear;
      }
      function dayPart(oneDate) {
        var theHour = oneDate.getHours();
        if (theHour < 6 )
          return "wee hours";
        if (theHour < 12)
          return "morning";
```

```

        if (theHour < 18)
            return "afternoon";
        return "evening";
    }
</script>
</head>
<body>
    <h1>Welcome!</h1>
    <script type="text/javascript">
        today = new Date();
        var header = (customDateString(today)).italics();
        header += "<BR>We hope you are enjoying the ";
        header += dayPart(today) + ".";
        document.write(header);
    </script>
    <hr />
</body>
</html>

```

The script divides the day into four parts and presents a different greeting for each part of the day. The greeting that plays is based, simply enough, on the hour element of a date object representing the time the page is loaded into the browser. Because this greeting is embedded in the page, the greeting does not change no matter how long the user stays logged on to the page.

## Counting the days...

You may find one or two more date arithmetic applications useful. One displays the number of shopping days left until Christmas (in the user's time zone); the other is a countdown timer to the start of the year 2100.

Listing 29-3 demonstrates how to calculate the number of days between the current day and some fixed date in the future. The assumption in this application is that all calculations take place in the user's time zone. The example shows the display of the number of shopping days before the next Christmas day (December 25). The basic operation entails converting the current date and the next December 25 to milliseconds, calculating the number of days represented by the difference in milliseconds. If you let the millisecond values represent the dates, JavaScript automatically takes care of leap years.

The only somewhat tricky part is setting the year of the next Christmas day correctly. You can't just slap the fixed date with the current year, because if the program is run on December 26, the year of the next Christmas must be incremented by one. That's why the constructor for the Christmas date object doesn't supply a fixed date as its parameters, but rather, sets individual components of the object.

### Listing 29-3: How Many Days Until Christmas

```

<html>
<head>
    <title>Christmas Countdown</title>
    <script type="text/javascript">
        function getDaysUntilXmas() {
            var oneMinute = 60 * 1000;

```

*Continued*

## Listing 29-3 (continued)

```

    var oneHour = oneMinute * 60;
    var oneDay = oneHour * 24;
    var today = new Date();
    var nextXmas = new Date();
    nextXmas.setMonth(11);
    nextXmas.setDate(25);
    if (today.getMonth() == 11 && today.getDate() > 25) {
        nextXmas.setFullYear(nextXmas.getFullYear() + 1);
    }
    var diff = nextXmas.getTime() - today.getTime();
    diff = Math.floor(diff/oneDay);
    return diff;
}
</script>
</head>
<body>
  <h1>
    <script type="text/javascript">
      var header = "You have <i>" + getDaysUntilXmas() + "</i> ";
      header += "shopping days until Christmas.";
      document.write(header);
    </script>
  </h1>
  <hr />
</body>
</html>

```

The second variation on calculating the amount of time before a certain event takes time zones into account. For this demonstration, the page is supposed to display a countdown timer to the precise moment when the flame for the 2008 Summer Games in Beijing is to be lit. That event takes place in a time zone that may be different from that of the page's viewer, so the countdown timer must calculate the time difference accordingly.

Listing 29-4 shows a simplified version that simply displays the ticking timer in a text field. The output, of course, could be customized in any number of ways, depending on the amount of dynamic HTML you want to employ on a page. The time of the lighting for this demo is set at 11:00 GMT on August 8, 2008 (the date is certainly accurate, but the officials may set a different time closer to the actual event).

Because this application is implemented as a live ticking clock, the code starts by setting some global variables that should be calculated only once so that the function that gets invoked repeatedly has a minimum of calculating to do (to be more efficient). The `Date.UTC()` method provides the target time and date in standard time. The `getTimeUntil()` function accepts a millisecond value (as provided by the `targetDate` variable) and calculates the difference between the target date and the actual internal millisecond value of the client's PC clock.

The core of the `getCountDown()` function peels off the number of whole days, hours, minutes, and seconds from the total number of milliseconds difference between now and the target date. Notice that each chunk is subtracted from the total so that the next smaller chunk can be calculated from the leftover milliseconds.

One extra touch on this page is a display of the local date and time of the actual event.

## Listing 29-4: Summer Games Countdown

```
<html>
  <head>
    <title>Summer Games Countdown</title>
    <script type="text/javascript">
      // globals -- calculate only once
      // set target date to 1100GMT on August 8, 2008
      var targetDate = Date.UTC(2008, 7, 8, 11, 0, 0, 0);
      var oneMinute = 60 * 1000;
      var oneHour = oneMinute * 60;
      var oneDay = oneHour * 24;

      function getTimeUntil(targetMS) {
        var today = new Date();
        var diff = targetMS - today.valueOf();
        return Math.floor(diff);
      }
      function getCountDown() {
        var ms = getTimeUntil(targetDate);
        var output = "";
        var days, hrs, mins, secs;
        if (ms >= 0) {
          days = Math.floor(ms/oneDay);
          ms -= oneDay * days;
          hrs = Math.floor(ms/oneHour);
          ms -= oneHour * hrs;
          mins = Math.floor(ms/oneMinute);
          ms -= oneMinute * mins;
          secs = Math.floor(ms/1000);
          output += days + " Days, " + hrs + " Hours, " +
            mins + " Minutes, " + secs + " Seconds";
        } else {
          output += "The time has passed.";
        }
        return output;
      }
      function updateCountDown() {
        document.forms[0].timer.value = getCountDown();
        setTimeout("updateCountDown()", 1000);
      }
    </script>
  </head>
  <body onload="updateCountDown()">
    <h1>Beijing Games Torch Lighting Countdown</h1>
    <p>
      <script type="text/javascript">
        document.write("(" + (new Date(targetDate)).toLocaleString());
        document.write(" in your time zone.");
      </script>
    </p>
    <form>
      <input type="text" name="timer" size="60" />
    </form>
    <hr />
  </body>
</html>
```

## Early browser date bugs and gremlins

Each new browser generation improves the stability and reliability of scripted date objects. Unfortunately, Navigator 2 has enough bugs and crash problems across many platforms to make scripting complex world-time applications for this browser impossible. The Macintosh version also has bugs that throw off dates by as much as a full day. I recommend avoiding NN2 on all platforms for serious date and time scripting.

The situation is much improved for NN3. Still, some bugs persist. One bug in particular affects Macintosh versions of NN3. Whenever you create a new date object with daylight saving time engaged in the Date and Time control panel, the browser automatically adds one hour to the object. See the time-based application in Chapter 54 on the CD-ROM for an example of how to counteract the effects of typical time bugs. Also afflicting the Macintosh in NN3 is a faulty calculation of the time zone offset for all time zones east of GMT. Instead of generating these values as negative numbers (getting lower and lower as you head east), the offset values increase continuously as you head west from Greenwich. While the Western Hemisphere is fine, the values continue to increase past the international date line, rather than switch over to the negative values.

Internet Explorer 3 isn't free of problems. It cannot handle dates before January 1, 1970 (GMT). Attempts to generate a date before that one result in that base date as the value. IE3 also completely miscalculates the time zone offset, following the erroneous pattern of NN2. Even Navigators 3 and 4 have problems with historic dates. You are asking for trouble if the date extends earlier than January 1, A.D. 1. Internet Explorer 4, on the other hand, appears to sail very well into ancient history.

You should be aware of one more discrepancy between Mac and Windows versions of Navigator through Version 4. In Windows, if you generate a date object for a date in another part of the year, the browser sets the time zone offset for that object according to the time zone setting for that time of year. On the Mac, the current setting of the control panel governs whether the normal or daylight saving time offset is applied to the date, regardless of the actual date within the year. This discrepancy affects Navigator 3 and 4 and can throw off calculations from other parts of the year by one hour.

It may sound as though the road to Date object scripting is filled with land mines. While date and time scripting is far from hassle free, you can put it to good use with careful planning and a lot of testing.

## Validating Date Entries in Forms

Given the bug horror stories in the previous section, you may wonder how you can ever perform data entry validation for dates in forms. The problem is not so much in the calculations as it is in the wide variety of acceptable date formats around the world. No matter how well you instruct users to enter dates in a particular format, many will follow their own habits and conventions. Moreover, how can you know whether an entry of 03/04/2002 is the North American March 4, 2002, or the European April 3, 2002? The answer: You can't.

My recommendation is to divide a date field into three components: month, day, and year. Let the user enter values into each field and validate each field individually for its valid range. Listing 29-5 shows an example of how this is done. The page includes a form that is to be validated before it is submitted. Each component field does its own range checking on the fly as the user enters values. But because this kind of validation can be defeated, the page includes one further check triggered by the form's `onsubmit` event handler. If any field is out of whack, the form submission is cancelled.

## Listing 29-5: Date Validation in a Form

```

<html>
  <head>
    <title>Date Entry Validation</title>
    <script type="text/javascript">
      // **BEGIN GENERIC VALIDATION FUNCTIONS**
      // general purpose function to see if an input value has been entered at
all
      function isEmpty(inputStr) {
        if (inputStr == "" || inputStr == null) {
          return true;
        }
        return false;
      }

      // function to determine if value is in acceptable range for this
application
      function inRange(inputStr, lo, hi) {
        var num = parseInt(inputStr, 10);
        if (num < lo || num > hi) {
          return false;
        }
        return true;
      }
      // **END GENERIC VALIDATION FUNCTIONS**

      function validateMonth(field, bypassUpdate) {
        var input = field.value;
        if (isEmpty(input)) {
          alert("Be sure to enter a month value.");
          select(field);
          return false;
        } else {
          input = parseInt(field.value, 10);
          if (isNaN(input)) {
            alert("Entries must be numbers only.");
            select(field);
            return false;
          } else {
            if (!inRange(input,1,12)) {
              alert("Enter a number between 1 (January) and 12
(December).");
              select(field);
              return false;
            }
          }
        }
      }
      if (!bypassUpdate) {
        calcDate();
      }
      return true;
    }

    function validateDate(field) {
      var input = field.value;

```

*Continued*

## Listing 29-5 (continued)

```

    if (isEmpty(input)) {
        alert("Be sure to enter a date value.");
        select(field);
        return false;
    } else {
        input = parseInt(field.value, 10);
        if (isNaN(input)) {
            alert("Entries must be numbers only.");
            select(field);
            return false;
        } else {
            var monthField = document.birthdate.month;
            if (!validateMonth(monthField, true))
                return false;
            var monthVal = parseInt(monthField.value, 10);
            var monthMax = new Array(31,31,29,31,30,31,30,31,31,30,31,30,31);
            var top = monthMax[monthVal];
            if (!inRange(input,1,top)) {
                alert("Enter a number between 1 and " + top + ".");
                select(field);
                return false;
            }
        }
    }
    calcDate();
    return true;
}

function validateYear(field) {
    var input = field.value;
    if (isEmpty(input)) {
        alert("Be sure to enter a year value.");
        select(field);
        return false;
    } else {
        input = parseInt(field.value, 10);
        if (isNaN(input)) {
            alert("Entries must be numbers only.");
            select(field);
            return false;
        } else {
            if (!inRange(input,1900,2005)) {
                alert("Enter a number between 1900 and 2005.");
                select(field);
                return false;
            }
        }
    }
    calcDate();
    return true;
}

function select(field) {
    field.focus();
    field.select();
}

```

```

function calcDate() {
    var mm = parseInt(document.birthdate.month.value, 10);
    var dd = parseInt(document.birthdate.date.value, 10);
    var yy = parseInt(document.birthdate.year.value, 10);
    document.birthdate.fullDate.value = mm + "/" + dd + "/" + yy;
}

function checkForm(form) {
    if (validateMonth(form.month)) {
        if (validateDate(form.date)) {
            if (validateYear(form.year)) {
                return true;
            }
        }
    }
    return false;
}
</script>
</head>
<body>
<form name="birthdate" action="mailto:fun@dannyg.com" method="POST"
onsubmit="return checkForm(this)">
    Please enter your birthdate...<br />
    Month:<input type="text" name="month" value="1" size="2"
onchange="validateMonth(this)" /> Date:<input type="text" name="date"
value="1" size="2" onchange="validateDate(this)" /> Year:<input
type="text" name="year" value="1900" size="4"
onchange="validateYear(this)" />
    <p>Thank you for entering:<input type="text" name="fullDate"
size="10" /></p>
    <p><input type="submit" /> <input type="Reset" /></p>
</form>
</body>
</html>

```

The page shows the three entry fields as well as a field that is normally hidden on a form to be submitted to a CGI program. On the server end, the CGI program responds only to the hidden field with the complete date, which is in a format for entry into, for example, an Informix database.

Not every date entry validation must be divided in this way. For example, an intranet application can be more demanding in the way users are to enter data. Therefore, you can have a single field for date entry, but the parsing required for such a validation is quite different from that shown in Listing 29-5. See Chapter 43 on the CD-ROM for an example of such a one-field date validation routine.

# The Array Object

---

**A**n array is the sole JavaScript data structure provided for storing and manipulating ordered collections of data. But unlike some other programming languages, JavaScript's arrays are very forgiving as to the kind of data you store in each cell or entry of the array. This allows, for example, an array of arrays, providing the equivalent of multidimensional arrays customized to the kind of data your application needs.

If you have not done a lot of programming in the past, the notion of arrays may seem like an advanced topic. But if you ignore their capabilities, you set yourself up for a harder job when implementing many kinds of tasks. Whenever I approach a script, one of my first thoughts is about the data being controlled by the application and whether handling it as an array will offer some shortcuts for creating the document and handling interactivity with the user.

I hope that by the end of this chapter, you will not only be familiar with the properties and methods of JavaScript arrays, but you will begin to look for ways to make arrays work for you.

## Structured Data

In programming, an *array* is defined as an ordered collection of data. You can best visualize an array as a table, not much different from a spreadsheet. In JavaScript, arrays are limited to a table holding one column of data, with as many rows as needed to hold your data. As you have seen in many chapters in Part III, a JavaScript-enabled browser creates a number of internal arrays for the objects in your HTML documents and browser properties. For example, if your document contains five links, the browser maintains a table of those links. You access them by number (with 0 being the first link) in the array syntax: the array name is followed by the index number in square brackets, as in `document.links[0]`, which represents the first link in the document.

### In This Chapter

Working with ordered collections of data

Simulating multidimensional arrays

Manipulating information stored in an array

For many JavaScript applications, you will want to use an array as an organized warehouse for data that users of your page access, depending on their interaction with form elements. In the application shown in Chapter 50 on the CD-ROM, for example, I demonstrate an extended version of this usage in a page that lets users search a small table of data for a match between the first three digits of their U.S. Social Security numbers and the state in which they registered with the agency. Arrays are the way JavaScript-enhanced pages can re-create the behavior of more sophisticated CGI programs on servers. When the collection of data you embed in the script is no larger than a typical .gif image file, the user won't experience significant delays in loading your page; yet he or she has the full power of your small database collection for instant searching without any calls back to the server. Such database-oriented arrays are important applications of JavaScript for what I call *serverless CGIs*.

As you design an application, look for clues as to potential application of arrays. If you have a number of objects or data points that interact with scripts the same way, you have a good candidate for array structures. For example, you can assign like names to every text field in a column of an order form. In that sequence, like-named objects are treated as elements of an array. To perform repetitive row calculations down an order form, your scripts can use array syntax to perform all the extensions within a handful of JavaScript statements, rather than perhaps dozens of statements hard-coded to each field name. Chapter 51 (on the CD-ROM) shows an example of this application.

You can also create arrays that behave like the Java hash table: a lookup table that gets you to the desired data point instantaneously if you know the name associated with the entry. If you can conceive your data in a table format, an array is in your future.

## Creating an Empty Array

Full-fledged array objects were first implemented in NN3 and IE4. It was possible to simulate some array characteristics in earlier browsers, but since those first-generation browsers have largely disappeared from users' computers, this chapter focuses on the modern array and its hefty powers.

To create a new array object, use the static `Array` object's constructor method. For example:

```
var myArray = new Array();
```

An array object automatically has a `length` property (0 for an empty array).

Should you want to presize the array (for example, preload entries with `null` values), you can specify an initial size as a parameter to the constructor. For example, here is how to create a new array to hold information about a 500-item compact disc collection:

```
var myCDCollection = new Array(500);
```

Unlike many other programming languages presizing a JavaScript array does not give you any particular advantage, because you can assign a value to any slot in an array at any time: The `length` property adjusts itself accordingly. For instance, if you assign a value to `myCDCollection[700]`, the array object adjusts its length upward to meet that slot (with the count starting at 0):

```
myCDCollection [700] = "Gloria Estefan/Destiny";  
collectionSize = myCDCollection.length; // result = 701
```

A true array object also features a number of methods and the capability to add prototype properties, described later in this chapter.

## Populating an Array

Entering data into an array is as simple as creating a series of assignment statements, one for each element of the array. Listing 30-1 generates an array containing a list of the nine planets of the solar system.

### Listing 30-1: Generating and Populating a New Array

```
solarSys = new Array(9);
solarSys[0] = "Mercury";
solarSys[1] = "Venus";
solarSys[2] = "Earth";
solarSys[3] = "Mars";
solarSys[4] = "Jupiter";
solarSys[5] = "Saturn";
solarSys[6] = "Uranus";
solarSys[7] = "Neptune";
solarSys[8] = "Pluto";
```

This way of populating a single array is a bit tedious when you're writing the code, but after the array is set, it makes accessing information collections as easy as any array reference:

```
onePlanet = solarSys[4];    // result = "Jupiter"
```

A more compact way to create an array is available if you know that the data will be in the desired order (as the preceding `solarSys` array). Instead of writing a series of assignment statements (as in Listing 30-1), you can create what is called a *dense array* by supplying the data as comma-delimited parameters to the `Array()` constructor:

```
solarSys = new Array("Mercury","Venus","Earth","Mars","Jupiter","Saturn",
    "Uranus","Neptune","Pluto");
```

The term “dense array” means that data is packed into the array, without gaps, starting at index position 0.

The example in Listing 30-1 shows what you may call a vertical collection of data. Each data point contains the same type of data as the other data points—the name of a planet—and the data points appear in the relative order of the planets from the Sun.

## JavaScript Array Creation Enhancements

The JavaScript version in NN4+/IE4+ provides one more way to create a dense array and also clears up a bug in the old way. A new, simpler way to create a dense array does not require the `Array` object constructor. Instead, JavaScript 1.2 (and later) accepts what is called *literal notation* to generate an array. To demonstrate the difference, the following statement is the regular dense array constructor that works with NN3:

```
solarSys = new Array("Mercury","Venus","Earth","Mars","Jupiter","Saturn",
    "Uranus","Neptune","Pluto");
```

While JavaScript 1.2+ fully accepts the preceding syntax, it also accepts the new literal notation:

```
solarSys = ["Mercury","Venus","Earth","Mars","Jupiter","Saturn",
    "Uranus","Neptune","Pluto");
```

The square brackets stand in for the call to the `Array` constructor. Unless your audience is stuck using ancient browsers, you should use this streamlined approach to array creation.

The bug fix has to do with how to treat the earlier dense array constructor if the scripter enters only the numeric value 1 as the parameter—`new Array(1)`. In NN3 and IE4, JavaScript erroneously creates an array of length 1, but that element is `undefined`. For NN4 and all later browsers (IE5+, NN6+, W3C), the same statement creates that one-element array and places the value in that element.

## Deleting Array Entries

You can always set the value of an array entry to `null` or an empty string to wipe out any data that used to occupy that space. But until the `delete` operator in version 4 browsers, you could not completely remove the element.

Deleting an array element eliminates the index from the list of accessible index values but does not reduce the array's length, as in the following sequence of statements:

```
myArray.length    // result: 5
delete myArray[2]
myArray.length    // result: 5
myArray[2]        // result: undefined
```

The process of deleting an array entry does not necessarily release memory occupied by that data. The JavaScript interpreter's internal garbage collection mechanism (beyond the reach of scripters) is supposed to take care of such activity. See the `delete` operator in Chapter 32 for further details.

Newer browsers feature the `splice()` method of an array, which lets you remove an item (or sequence of items) from an array—causing the array's length to adjust to the new item count. See the `splice()` method later in this chapter.

## Parallel Arrays

Using an array to hold data is frequently desirable so that a script can do a lookup to see if a particular value is in the array (perhaps verifying that a value typed into a text box by the user is permissible); however, even more valuable is if, upon finding a match, a script can look up some related information in another array. One way to accomplish this is with two or more parallel arrays: the same indexed slot of each array contains related information.

Consider the following three arrays:

```
var regionalOffices = new Array("New York", "Chicago", "Houston", "Portland");
var regionalManagers = new Array("Shirley Smith", "Todd Gaston",
    "Leslie Jones", "Harold Zoot");
var regOfficeQuotas = new Array(300000, 250000, 350000, 225000);
```

The assumption for these statements is that Shirley Smith is the regional manager out of the New York office, and her office's quota is 300,000. This represents the data that is included with the document, perhaps retrieved by a CGI program on the server that gets the latest data from a SQL database and embeds the data in the form of array constructors. Listing 30-2 shows how this data appears in a simple page that looks up the manager name and quota values for whichever office is chosen in the `select` element. The order of the items in the list of `select` is not accidental: The order is identical to the order of the array for the convenience of the lookup script.

Lookup action in Listing 30-2 is performed by the `getData()` function. Because the index values of the options inside the `select` element match those of the parallel arrays index values, the `selectedIndex` property of the `select` element makes a convenient way to get directly at the corresponding data in other arrays.

### Listing 30-2: A Simple Parallel Array Lookup

```

<html>
  <head>
    <title>Parallel Array Lookup</title>
    <script type="text/javascript">
      // the data
      var regionalOffices = new Array("New York", "Chicago", "Houston",
        "Portland");
      var regionalManagers = new Array("Shirley Smith", "Todd Gaston",
        "Leslie Jones", "Harold Zoot");
      var regOfficeQuotas = new Array(300000, 250000, 350000, 225000);
      // do the lookup into parallel arrays
      function getData(form) {
        var i = form.offices.selectedIndex;
        form.manager.value = regionalManagers[i];
        form.quota.value = regOfficeQuotas[i];
      }
    </script>
  </head>
  <body onload="getData(document.officeData)">
    <h1>Parallel Array Lookup</h1>
    <hr />
    <form name="officeData">
      <p>Select a regional office: <select name="offices"
        onchange="getData(this.form)">
        <option>New York</option>
        <option>Chicago</option>
        <option>Houston</option>
        <option>Portland</option>
      </select></p>
      <p>The manager is: <input type="text" name="manager" size="35" />
      <br />The office quota is: <input type="text" name="quota"
        size="8" /></p>
    </form>
  </body>
</html>

```

On the other hand, if the content to be looked up is typed into a text box by the user, you have to loop through one of the arrays to get the matching index. Listing 30-3 is a variation of Listing 30-2, but instead of the `select` element, a text field asks users to type in the name of the region. Assuming that users will always spell the input correctly (an outrageous assumption), the version of `getData()` in Listing 30-3 performs actions that more closely resemble what you may think a “lookup” should be doing: looking for a match in one array, and displaying corresponding results from the parallel arrays. The `for` loop iterates through items in the `regionalOffices` array. An `if` condition compares all uppercase versions of both the input and each array entry. If there is a match, the `for` loop breaks, with the value of `i` still pointing to the matching index value. Outside the `for` loop, another `if` condition makes sure that the index value has not reached the length of the array, which means that no match is found.

Only when the value of `i` points to one of the array entries does the script retrieve corresponding entries from the other two arrays.

### Listing 30-3: A Looping Array Lookup

```
<html>
  <head>
    <title>Parallel Array Lookup II</title>
    <script type="text/javascript">
      // the data
      var regionalOffices = new Array("New York", "Chicago", "Houston",
        "Portland");
      var regionalManagers = new Array("Shirley Smith", "Todd Gaston",
        "Leslie Jones", "Harold Zoot");
      var regOfficeQuotas = new Array(300000, 250000, 350000, 225000);
      // do the lookup into parallel arrays
      function getData(form) {
        // make a copy of the text box contents
        var inputText = form.officeInp.value;
        // loop through all entries of regionalOffices array
        for (var i = 0; i < regionalOffices.length; i++) {
          // compare uppercase versions of entered text against one entry
          // of regionalOffices
          if (inputText.toUpperCase() == regionalOffices[i].toUpperCase()) {
            // if they're the same, then break out of the for loop
            break;
          }
        }
        // make sure the i counter hasn't exceeded the max index value
        if (i < regionalOffices.length) {
          // display corresponding entries from parallel arrays
          form.manager.value = regionalManagers[i];
          form.quota.value = regOfficeQuotas[i];
        } else { // loop went all the way with no matches
          // empty any previous values
          form.manager.value = "";
          form.quota.value = "";
          // advise user
          alert("No match found for " + inputText + ".");
        }
      }
    </script>
  </head>
  <body>
    <h1>Parallel Array Lookup II</h1>
    <hr />
    <form name="officeData">
      <p>Enter a regional office: <input type="text" name="officeInp"
        size="35" /> <input type="button" value="Search"
        onclick="getData(this.form)" /></p>
      <p>The manager is: <input type="text" name="manager"
        size="35" /><br />
        The office quota is: <input type="text" name="quota"
        size="8" /></p>
    </form>
  </body>
</html>
```

## Multidimensional Arrays

An alternate to parallel arrays is the simulation of a multidimensional array. While it's true that JavaScript arrays are one-dimensional, you can create a one-dimensional array of other arrays or objects. A logical approach is to make an array of custom objects, because the objects easily allow for naming of object properties, making references to multidimensional array data more readable (custom objects are discussed at length in Chapter 33).

Using the same data from the examples of parallel arrays, the following statements define an object constructor for each “data record.” A new object is then assigned to each of four entries in the main array.

```
// custom object constructor
function officeRecord(city, manager, quota) {
    this.city = city;
    this.manager = manager;
    this.quota = quota;
}

// create new main array
var regionalOffices = new Array();
// stuff main array entries with objects
regionalOffices[0] = new officeRecord("New York", "Shirley Smith", 300000);
regionalOffices[1] = new officeRecord("Chicago", "Todd Gaston", 250000);
regionalOffices[2] = new officeRecord("Houston", "Leslie Jones", 350000);
regionalOffices[3] = new officeRecord("Portland", "Harold Zoot", 225000);
```

The object constructor function (`officeRecord()`) assigns incoming parameter values to properties of the object. Therefore, to access one of the data points in the array, you use both array notations to get to the desired entry in the array and the name of the property for that entry's object:

```
var eastOfficeManager = regionalOffices[0].manager;
```

You can also assign string index values for this kind of array, as in

```
regionalOffices["east"] = new officeRecord("New York", "Shirley Smith",
    300000);
```

and access the data via the same index:

```
var eastOfficeManager = regionalOffices["east"].manager;
```

But if you're more comfortable with the traditional multidimensional array (from your experience in other programming languages), you can also implement the above as an array of arrays with less code:

```
// create new main array
var regionalOffices = new Array();
// stuff main array entries with arrays
regionalOffices[0] = new Array("New York", "Shirley Smith", 300000);
regionalOffices[1] = new Array("Chicago", "Todd Gaston", 250000);
regionalOffices[2] = new Array("Houston", "Leslie Jones", 350000);
regionalOffices[3] = new Array("Portland", "Harold Zoot", 225000);
```

or, for the extreme of unreadable brevity with literal notation:

```
// create new main array
var regionalOffices = [ ["New York", "Shirley Smith", 300000],
    ["Chicago", "Todd Gaston", 250000],
```

**array.constructor**

```
["Houston", "Leslie Jones", 350000],  
["Portland", "Harold Zoot", 225000] ];
```

Accessing a single data point of an array of arrays requires a double array reference. For example, retrieving the manager's name for the Houston office requires the following syntax:

```
var HoustonMgr = regionalOffices[2][1];
```

The first index in brackets is for the outermost array (`regionalOffices`); the second index in brackets points to the item of the array returned by `regionalOffices[2]`.

## Simulating a Hash Table

All arrays shown so far in this chapter have used integers as their index values. A JavaScript array is a special type of object (the `object` type is covered in Chapter 33). As a result, you can also assign values to customized properties of an array without interfering with the data stored in the array or the length of the array. In other words, you can “piggy-back” data in the array object. You may reference the values of these properties either using “dot” syntax (`array.propertyName`) or through array-looking syntax consisting of square brackets and the property name as a string inside the brackets (`array["propertyName"]`).

Addressing object properties by way of string indexes is sometimes very useful. For example, the multidimensional array described in the previous section consists of four objects. If your page contains a form whose job is to look through the array to find a match for a city chosen from a `select` list, the typical array lookup would loop through the length of the array, compare the chosen value against the `city` property of each object, and then retrieve the other properties when there was a match. For a 4-item list, this isn't a big deal. But for a 100-item list, the process could get time consuming. A faster approach would be to jump directly to the array entry whose `city` property is the chosen value. That's what a simulated hash table can do for you (some programming languages have formal hash table constructions especially designed to act like a lookup table).

Create a simulated hash table after the array is populated by looping through the array and assigning properties to the array object as string values. Use string values that you expect to use for lookup purposes. For example, after the `regionalOffices` array has its component objects assigned, run through the following routine to make the hash table:

```
for (var i = 0; i < regionalOffices.length; i++) {  
    regionalOffices[regionalOffices[i].city] = regionalOffices[i];  
}
```

You can retrieve the manager property of the Houston office object as follows:

```
var HoustonMgr = regionalOffices["Houston"].manager;
```

With the aid of the hash table component of the array, your scripts have the convenience of both numeric lookup (if the script needs to cycle through all items) and an immediate jump to an item.

## Array Object Properties

### constructor

(See `string.constructor` in Chapter 27)

*array.prototype*

## length

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

A true array object's `length` property reflects the number of entries in the array. An entry can be any kind of JavaScript value, including `null`. If an entry is in the 10th cell and the rest are `null`, the length of that array is 10. Note that because array index values are zero-based, the index of the last cell of an array is one less than the length. This characteristic makes it convenient to use the property as an automatic counter to append a new item to an array:

```
myArray[myArray.length] = valueOfAppendedItem;
```

Thus, a generic function does not have to know which specific index value to apply to an additional item in the array.

## prototype

**Value:** Variable or function.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

Inside JavaScript, an array object has its dictionary definition of methods and `length` property—items that all array objects have in common. The `prototype` property enables your scripts to ascribe additional properties or methods that apply to all the arrays you create in the currently loaded documents. You can override this prototype, however, for any individual object.

## Example

To demonstrate how the `prototype` property works, Listing 30-4 creates a `prototype` property for all array objects generated from the static `Array` object. As the script generates new arrays (instances of the `Array` object, just as a date object is an instance of the `Date` object), the property automatically becomes a part of those arrays. In one array, `c`, you override the value of the `prototype` `sponsor` property. By changing the value for that one object, you don't alter the value of the `prototype` for the `Array` object. Therefore, another array created afterward, `d`, still gets the original `sponsor` property value.

### Listing 30-4: Adding a prototype Property

```
<html>
  <head>
    <title>Array prototypes</title>
    <script type="text/javascript">
      // add prototype to all Array objects
      Array.prototype.sponsor = "DG";
      a = new Array(5);
      b = new Array(5);
      c = new Array(5);
      // override prototype property for one 'instance'
      c.sponsor = "JS";
      // this one picks up the original prototype
      d = new Array(5);
    </script>
  </head>
</body>
```

*Continued*

**array.prototype****Listing 30-4 (continued)**

```

<h2>
  <script type="text/javascript">
    document.write("Array a is brought to you by: " + a.sponsor +
      "<br />");
    document.write("Array b is brought to you by: " + b.sponsor +
      "<br />");
    document.write("Array c is brought to you by: " + c.sponsor +
      "<br />");
    document.write("Array d is brought to you by: " + d.sponsor +
      "<br />");
  </script>
</h2>
</body>
</html>

```

You can assign properties and functions to a prototype. To assign a function, define the function as you normally would in JavaScript. Then assign the function to the prototype by name:

```

function newFunc(param1) {
  // statements
}
Array.prototype.newMethod = newFunc; // omit parentheses in this reference

```

When you need to call upon that function (which has essentially become a new temporary method for the Array object), invoke it as you would any object method. Therefore, if an array named `CDCollection` has been created and a prototype method `showCoverImage()` has been attached to the array, the call to invoke the method for a tenth listing in the array is

```
CDCollection.showCoverImage(9);
```

where the parameter of the function uses the index value to perhaps retrieve an image whose URL is a property of an object assigned to the 10th item of the array.

## Array Object Methods

After you have information stored in an array, JavaScript provides several methods to help you manage that data. These methods, all of which belong to array objects you create, have evolved over time, so observe carefully which browser versions a desired method works with.

### *array.concat(array2)*

**Returns:** Array object.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `array.concat()` method allows you to join two array objects into a new, third array object. The action of concatenating the arrays does not alter the contents or behavior of the two original arrays. To join the arrays, you refer to the first array object to the left of the period before the method; a reference to the second array is the parameter to the method. For example:

```

var array1 = new Array(1,2,3);
var array2 = new Array("a","b","c");
var array3 = array1.concat(array2);
// result: array with values 1,2,3,"a","b","c"

```

**array.concat()**

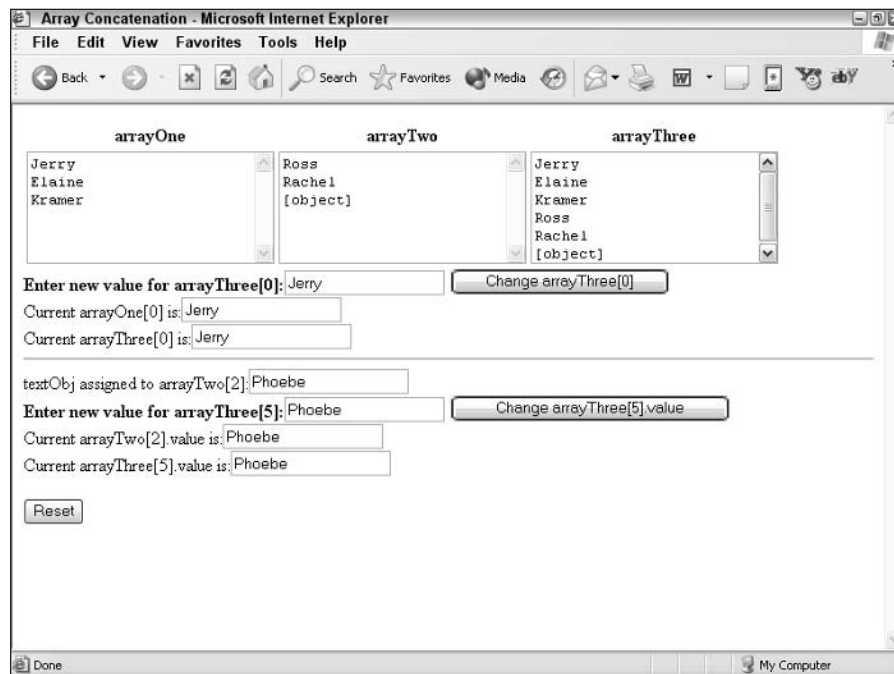

If an array element is a string or number value (not a string or number object), the values are copied from the original arrays into the new one. All connection with the original arrays ceases for those items. But if an original array element is a reference to an object of any kind, JavaScript copies a reference from the original array's entry into the new array. So if you make a change to either array's entry, the change occurs to the object, and both array entries reflect the change to the object.

## Example

Listing 30-5 is a bit complex, but it demonstrates both how arrays can be joined with the `array.concat()` method and how values and objects in the source arrays do or do not propagate based on their data type. The page is shown in Figure 30-1.

After you load the page, you see readouts of three arrays. The first array consists of all string values; the second array has two string values and a reference to a form object on the page (a text box named "original" in the HTML). In the initialization routine of this page, not only are the two source arrays created, but they are joined with the `array.concat()` method, and the result is shown in the third box. To show the contents of these arrays in columns, I use the `array.join()` method, which brings the elements of an array together as a string delimited in this case by a return character — giving us an instant column of data.

Two series of fields and buttons let you experiment with the way values and object references are linked across concatenated arrays. In the first group, if you enter a new value to be assigned to `arrayThree[0]`, the new value replaces the string value in the combined array. Because regular values do not maintain a link back to the original array, only the entry in the combined array is changed. A call to `showArrays()` proves that only the third array is affected by the change.

**Figure 30-1:** Object references remain “alive” in a concatenated array.

**array.concat()**

More complex is the object relationship for this demonstration. A reference to the first text box of the second grouping has been assigned to the third entry of `arrayTwo`. After concatenation, the same reference is now in the last entry of the combined array. If you enter a new value for a property of the object in the last slot of `arrayThree`, the change goes all the way back to the original object—the first text box in the lower grouping. Thus, the text of the original field changes in response to the change of `arrayThree[5]`. And because all references to that object yield the same result, the reference in `arrayTwo[2]` points to the same text object, yielding the same new answer. The display of the array contents doesn't change, because both arrays still contain a reference to the same object (and the `value` attribute showing in the `<input>` tag of the column listings refers to the default value of the tag, not to its current algorithmically retrievable value shown in the last two fields of the page).

**Listing 30-5: Array Concatenation**

```

<html>
  <head>
    <title>Array Concatenation</title>
    <script type="text/javascript">
      // global variables
      var arrayOne, arrayTwo, arrayThree, textObj;
      // initialize after load to access text object in form
      function initialize() {
        var form = document.forms[0];
        textObj = form.original;
        arrayOne = new Array("Jerry", "Elaine", "Kramer");
        arrayTwo = new Array("Ross", "Rachel", textObj);
        arrayThree = arrayOne.concat(arrayTwo);
        update1(form);
        update2(form);
        showArrays();
      }
      // display current values of all three arrays
      function showArrays() {
        var form = document.forms[0];
        form.array1.value = arrayOne.join("\n");
        form.array2.value = arrayTwo.join("\n");
        form.array3.value = arrayThree.join("\n");
      }
      // change the value of first item in Array Three
      function update1(form) {
        arrayThree[0] = form.source1.value;
        form.result1.value = arrayOne[0];
        form.result2.value = arrayThree[0];
        showArrays();
      }
      // change value of object property pointed to in Array Three
      function update2(form) {
        arrayThree[5].value = form.source2.value;
        form.result3.value = arrayTwo[2].value;
        form.result4.value = arrayThree[5].value;
        showArrays();
      }
    </script>
  </head>
  <body onload="initialize()">
    <form>

```

```

```

**Related Items:** `array.join()` method.

### `array.join(separatorString)`

**Returns:** String of entries from the array delimited by the *separatorString* value.

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

You cannot view data in an array when it's in that form. Nor can you put an array into a form element for transmittal to a server CGI program. To make the transition from discrete array elements to string, the `array.join()` method handles what would otherwise be a nasty string manipulation exercise.

The sole parameter for this method is a string of one or more characters that you want to act as a delimiter between entries. For example, if you want commas between array items in their text version, the statement is

```
var arrayText = myArray.join(",");
```

Invoking this method does not change the original array in any way. Therefore, you need to assign the results of this method to another variable or a value property of a form element.

**array.join()****Example**

The script in Listing 30-6 converts an array of planet names into a text string. The page provides you with a field to enter the delimiter string of your choice and shows the results in a text area.

**Listing 30-6: Using the Array.join() Method**

```
<html>
  <head>
    <title>Array.join()</title>
    <script type="text/javascript">
      solarSys = new Array(9);
      solarSys[0] = "Mercury";
      solarSys[1] = "Venus";
      solarSys[2] = "Earth";
      solarSys[3] = "Mars";
      solarSys[4] = "Jupiter";
      solarSys[5] = "Saturn";
      solarSys[6] = "Uranus";
      solarSys[7] = "Neptune";
      solarSys[8] = "Pluto";

      // join array elements into a string
      function convert(form) {
        var delimiter = form.delim.value;
        form.output.value = unescape(solarSys.join(delimiter));
      }
    </script>
  </head>
  <body>
    <h2>Converting arrays to strings</h2>
    This document contains an array of planets in our solar system.
    <hr />
    <form>
      Enter a string to act as a delimiter between entries: <input
      type="text" name="delim" value="." size="5" />
      <p><input type="button" value="Display as String"
      onclick="convert(this.form)" /> <input type="reset" /> <textarea
      name="output" rows="4" cols="40" wrap="virtual">
      </textarea></p>
    </form>
  </body>
</html>
```

Notice that this method takes the parameter very literally. If you want to include non-alphanumeric characters, such as a newline or tab, do so with URL-encoded characters (%0D for a carriage return; %09 for a tab) instead of inline string literals. In Listing 30-7, the results of the `array.join()` method are subjected to the `unescape()` function in order to display them in the text area.

**Related Items:** `string.split()` method.

**array.reverse()**

```
array.pop()  
array.push(valueOrObject)  
array.shift()  
array.unshift(valueOrObject)
```

**Returns:** One array entry value.

**Compatibility:** WinIE5.5+, MacIE-, NN4+, Moz1+, Safari1+

The notion of a *stack* is well known to experienced programmers, especially those who know about the inner workings of assembly language at the CPU level. Even if you've never programmed a stack before, you have encountered the concept in real life many times. The classic analogy is the spring-loaded pile of cafeteria trays. If the pile were created one tray at a time, each tray would be pushed into the stack of trays. When a customer comes along, the topmost tray (the last one to be pushed onto the stack) gets popped off. The last one to be put on the stack is the first one to be taken off.

JavaScript in NN4+, IE5.5+, and W3C browsers lets you turn an array into one of these spring-loaded stacks. But instead of placing trays on the pile, you can place any kind of data at either end of the stack, depending on which method you use to do the stacking. Similarly, you can extract an item from either end.

Perhaps the most familiar terminology for this is *push* and *pop*. When you `push()` a value onto an array, the value is appended as the last entry in the array. When you issue the `array.pop()` method, the last item in the array is removed from the stack and is returned, and the array shrinks in length by one. In the following sequence of statements, watch what happens to the value of the array used as a stack:

```
var source = new Array("Homer", "Marge", "Bart", "Lisa", "Maggie");  
var stack = new Array();  
    // stack = <empty>  
stack.push(source[0]);  
    // stack = "Homer"  
stack.push(source[2]);  
    // stack = "Homer", "Bart"  
var Simpson1 = stack.pop();  
    // stack = "Homer" ; Simpson1 = "Bart"  
var Simpson2 = stack.pop();  
    // stack = <empty> ; Simpson2 = "Homer"
```

While `push()` and `pop()` work at the end of an array, another pair of methods works at the front. Their names are not as picturesque as `push()` and `pop()`. To insert a value at the front of an array, use the `array.unshift()` method; to grab the first element and remove it from the array, use `array.shift()`. Of course, you are not required to use these methods in matching pairs. If you `push()` a series of values onto the back end of an array, you can `shift()` them off from the front end without complaint. It all depends on how you need to process the data.

**Related Items:** `array.concat()`, `array.slice()` method.

```
array.reverse()
```

**Returns:** Array of entries in the opposite order of the original.

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

Occasionally, you may find it more convenient to work with an array of data in reverse order. Although you can concoct repeat loops to count backward through index values, a CGI program on the server may prefer the data in a sequence opposite to the way it was most convenient for you to script it.

**array.reverse()**

You can have JavaScript switch the contents of an array for you: Whatever element was last in the array becomes the 0 index item in the array. Bear in mind that if you do this, you're restructuring the original array, not copying it, even though the method also returns a copy of the reversed version. A reload of the document restores the order as written in the HTML document.

**Example**

Listing 30-7 is an enhanced version of Listing 30-6, which includes another button and function that reverse the array and display it as a string in a text area.

**Listing 30-7: Array.reverse() Method**

```
<html>
  <head>
    <title>Array.reverse()</title>
    <script type="text/javascript">
      solarSys = new Array(9);
      solarSys[0] = "Mercury";
      solarSys[1] = "Venus";
      solarSys[2] = "Earth";
      solarSys[3] = "Mars";
      solarSys[4] = "Jupiter";
      solarSys[5] = "Saturn";
      solarSys[6] = "Uranus";
      solarSys[7] = "Neptune";
      solarSys[8] = "Pluto";

      // show array as currently in memory
      function showAsIs(form) {
        var delimiter = form.delim.value;
        form.output.value = unescape(solarSys.join(delimiter));
      }
      // reverse array order, then display as string
      function reverseIt(form) {
        var delimiter = form.delim.value;
        solarSys.reverse(); // reverses original array
        form.output.value = unescape(solarSys.join(delimiter));
      }
    </script>
  </head>
  <body>
    <h2>Reversing array element order</h2>
    This document contains an array of planets in our solar system.
    <hr />
    <form>
      Enter a string to act as a delimiter between entries: <input
      type="text" name="delim" value="," size="5" />
      <p><input type="button" value="Array as-is"
      onclick="showAsIs(this.form)" /> <input type="button"
      value="Reverse the array" onclick="reverseIt(this.form)" /> <input
      type="reset" /> <input type="button" value="Reload"
      onclick="self.location.reload()" /> <textarea name="output"
      rows="4" cols="60">
      </textarea></p>
    </form>
  </body>
</html>
```

**array.sort()**

Notice that the `solarSys.reverse()` method stands by itself (meaning, nothing captures the returned value) because the method modifies the `solarSys` array. You then run the now inverted `solarSys` array through the `array.join()` method for your text display.

**Related Items:** `array.sort()` method.

**array.slice(startIndex [, endIndex])**

**Returns:** Array.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

Behaving as its like-named string method, `array.slice()` lets you extract a contiguous series of items from an array. The extracted segment becomes an entirely new array object. Values and objects from the original array have the same kind of behavior as arrays created with the `array.concat()` method.

One parameter is required — the starting index point for the extraction. If you don't specify a second parameter, the extraction goes all the way to the end of the array; otherwise the extraction goes to, *but does not include*, the index value supplied as the second parameter. For example, extracting Earth's neighbors from an array of planet names looks like the following:

```
var solarSys = new Array("Mercury", "Venus", "Earth", "Mars",
    "Jupiter", "Saturn", "Uranus", "Neptune", "Pluto");
var nearby = solarSys.slice(1,4);
    // result: new array of "Venus", "Earth", "Mars"
```

**Related Items:** `array.splice()`, `string.slice()` methods.

**array.sort([compareFunction])**

**Returns:** Array of entries in the order as determined by the `compareFunction` algorithm.

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

JavaScript array sorting is both powerful and a bit complex to script if you haven't had experience with this kind of sorting methodology. The purpose, obviously, is to let your scripts sort entries of an array by almost any kind of criterion that you can associate with an entry. For entries consisting of strings, the criterion may be their alphabetical order or their length; for numeric entries, the criterion may be their numerical order.

Look first at the kind of sorting you can do with the `array.sort()` method by itself (for example, without calling a comparison function). When no parameter is specified, JavaScript takes a snapshot of the contents of the array and converts items to strings. From there, it performs a string sort of the values. ASCII values of characters govern the sort, which means that numbers are sorted by their string values, not their numeric values. This fact has strong implications if your array consists of numeric data: The value 201 sorts before 88, because the sorting mechanism compares the first characters of the strings ("2" versus "8") to determine the sort order. For simple alphabetical sorting of string values in arrays, the plain `array.sort()` method does the trick.

Fortunately, additional intelligence is available that you can add to array sorting. The key tactic is to define a function that helps the `sort()` method compare items in the array. A comparison function is passed two values from the array (what you don't see is that the `array.sort()` method rapidly sends numerous pairs of values from the array to help it sort through all entries). The comparison function lets the `sort()` method know which of the two items comes before the other, based on the value the function returns. Assuming that the function compares two values, `a` and `b`, the returned value reveals information to the `sort()` method, as shown in Table 30-1.

**array.sort()****Table 30-1: Comparison Function Return Values**

<i>Return Value Range</i>	<i>Meaning</i>
< 0	Value b should sort later than a
0	The order of a and b should not change
> 0	Value a should sort later than b

Consider the following example:

```
myArray = new Array(12, 5, 200, 80);
function compare(a,b) {
    return a - b;
}
myArray.sort(compare);
```

The array has four numeric values in it. To sort the items in numerical order, you define a comparison function (arbitrarily named `compare()`), which is called from the `sort()` method. Note that unlike invoking other functions, the parameter of the `sort()` method uses a reference to the function, which lacks parentheses.

When the `compare()` function is called, JavaScript automatically sends two parameters to the function in rapid succession until each element has been compared with the others. Every time `compare()` is called, JavaScript assigns two of the array's values to the parameter variables (`a` and `b`). In the preceding example, the returned value is the difference between `a` and `b`. If `a` is larger than `b`, then a positive value goes back to the `sort()` method, telling it to sort `a` later than `b` (that is, position `a` at a higher value index position than `b`). Therefore, `b` may end up at `myArray[0]`, whereas `a` ends up at a higher index-valued location. On the other hand, if `a` is smaller than `b`, the returned negative value tells `sort()` to put `a` in a lower index value spot than `b`.

Evaluations within the comparison function can go to great lengths, as long as some data connected with array values can be compared. For example, instead of numerical comparisons, as just shown, you can perform string comparisons. The following function sorts alphabetically by the last character of each array string entry:

```
function compare(a,b) {
    // last character of array strings
    var aComp = a.charAt(a.length - 1);
    var bComp = b.charAt(b.length - 1);
    if (aComp < bComp)
        return -1;
    if (aComp > bComp)
        return 1;
    return 0;
}
```

First, this function extracts the final character from each of the two values passed to it. Then, because strings cannot be added or subtracted like numbers, you compare the ASCII values of the two characters, returning the corresponding values to the `sort()` method to let it know how to treat the two values being checked at that instant.

When an array's entries happen to be objects, you can even sort by properties of those objects. If you bear in mind that the `a` and `b` parameters of the sort function are references to two array entries, then by extension you can refer to properties of those objects. For example, if an array

**array.sort()**

contains objects whose properties define information about employees, one of the properties of those objects can be the employee's age as a string. You can then sort the array based on the numeric equivalent of the age property of the objects by way of the following comparison function:

```
function compare(a,b) {
    return parseInt(a.age) - parseInt(b.age);
}
```

Array sorting, unlike sorting routines you may find in other scripting languages, is not a stable sort. Not being stable means that succeeding sort routines on the same array are not cumulative. Also, remember that sorting changes the sort order of the original array. If you don't want the original array harmed, make a copy of it before sorting or reload the document to restore an array to its original order. Should an array element be `null`, the method sorts such elements at the end of the sorted array.

JavaScript array sorting is extremely powerful stuff. Array sorting is one reason why it's not uncommon to take the time during the loading of a page containing an IE XML data island to make a JavaScript copy of the data as an array of objects (see Chapter 57 on the CD-ROM). Converting the XML to JavaScript arrays makes the job of sorting the data much easier and faster than cobbling together your own sorting routines on the XML elements.

## Example

You can look to Listing 30-8 for a few examples of sorting an array of string values (see Figure 30-2). Four buttons summon different sorting routines, three of which invoke comparison functions. This listing sorts the planet array alphabetically (forward and backward) by the last character of the planet name and also by the length of the planet name. Each comparison function demonstrates different ways of comparing data sent during a sort.

### Listing 30-8: **Array.sort()** Possibilities

```
<html>
  <head>
    <title>Array.sort()</title>
    <script type="text/javascript">
      solarSys = new Array(9);
      solarSys[0] = "Mercury";
      solarSys[1] = "Venus";
      solarSys[2] = "Earth";
      solarSys[3] = "Mars";
      solarSys[4] = "Jupiter";
      solarSys[5] = "Saturn";
      solarSys[6] = "Uranus";
      solarSys[7] = "Neptune";
      solarSys[8] = "Pluto";
      // comparison functions
      function compare1(a,b) {
        // reverse alphabetical order
        if (a > b)
          return -1;
        if (b > a)
          return 1;
        return 0;
      }
    </script>
  </head>
</html>
```

*Continued*

**array.sort()****Listing 30-8 (continued)**

```

    }
    function compare2(a,b) {
        // last character of planet names
        var aComp = a.charAt(a.length - 1);
        var bComp = b.charAt(b.length - 1);
        if (aComp < bComp)
            return -1;
        if (aComp > bComp)
            return 1;
        return 0;
    }
    function compare3(a,b) {
        // length of planet names
        return a.length - b.length;
    }
    // sort and display array
    function sortIt(form, compFunc) {
        var delimiter = ";";
        if (compFunc == null) {
            solarSys.sort();
        } else {
            solarSys.sort(compFunc);
        }
        // display results in field
        form.output.value = unescape(solarSys.join(delimiter));
    }
</script>
</head>
<body onload="document.forms[0].output.value =
unescape(solarSys.join(';'))">
<h2>Sorting array elements</h2>
This document contains an array of planets in our solar system.
<hr />
<form>
    Click on a button to sort the array:
    <p><input type="button" value="Alphabetical A-Z"
onclick="sortIt(this.form)" /> <input type="button"
value="Alphabetical Z-A" onclick="sortIt(this.form,compare1)" />
<input type="button" value="Last Character"
onclick="sortIt(this.form,compare2)" /> <input type="button"
value="Name Length" onclick="sortIt(this.form,compare3)" /> <input
type="button" value="Reload Original"
onclick="self.location.reload()" /> <input type="text"
name="output" size="62" /></p>
</form>
</body>
</html>

```

**Related Items:** `array.reverse()` method.

**Note**

As I show you in Chapter 42 on the CD-ROM, many regular expression object methods generate arrays as their result (for example, an array of matching values in a string). These special arrays have a custom set of named properties that assist your script in analyzing the findings of the method. Beyond that, these regular expression result arrays behave like all others.

**Figure 30-2:** Sorting an array of planet names alphabetically by last character.

```
array.splice(startIndex , deleteCount[, item1[,  
item2[,...itemN]]])
```

**Returns:** Array.

**Compatibility:** WinIE5.5+, MacIE-, NN4+, Moz1+, Safari1+

If you need to remove items from the middle of an array, the `array.splice()` method simplifies a task that would otherwise require assembling a new array from selected items of the original array. The first of two required parameters is a zero-based index integer that points to the first item to be removed from the current array. The second parameter is another integer that indicates how many sequential items are to be removed from the array. Removing array items affects the length of the array, and those items that are removed are returned by the `splice()` method as their own array.

You can also use the `splice()` method to replace array items. Optional parameters beginning with the third let you provide data elements that are to be inserted into the array in place of the items being removed. Each added item can be any JavaScript data type, and the number of new items does not have to be equal to the number of items removed. In fact, by specifying a second parameter of zero, you can use `splice()` to insert one or more items into any position of the array.

## Example

Use The Evaluator (Chapter 13) to experiment with the `splice()` method. Begin by creating an array with a sequence of numbers:

```
a = new Array(1,2,3,4,5)
```

***array.splice()***

Next, remove the center three items, and replace them with one string item:

```
a.splice(1, 3, "two/three/four")
```

The Results box shows a string version of the three-item array returned by the method. To view the current contents of the array, enter `a` into the top text box.

To put the original numbers back into the array, swap the string item with three numeric items:

```
a.splice(1, 1, 2, 3, 4)
```

The method returns the single string, and the `a` array now has five items in it again.

**Related Items:** `array.slice()` method.

***array.toLocaleString()***

**Returns:** String.

**Compatibility:** WinIE5.5+, MacIE-, NN6+, Moz1+, Safari1+

***array.toString()***

**Returns:** String.

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

The `array.toLocaleString()` and the older, more compatible `array.toString()` are methods to retrieve the contents of an array in string form. Browsers use the `toString()` method on their own whenever you attempt to display an array in text boxes, in which case the array items are comma-delimited.

The precise string conversion of the `toLocaleString()` is left up to the specific browser implementation. That IE and NN differ in some details is not surprising, even in the U.S. English versions of operating systems and browsers. For example, if the array contains integer values, the `toLocaleString()` method in IE5.5+ returns the numbers comma-and-space-delimited, formatted with two digits to the right of the decimal (as if dollars and cents). NN6+, on the other hand, returns just the integers, but these are also comma-and-space-delimited.

If you need to convert an array to a string for purposes of passing array data to other venues (for example, as data in a hidden text box submitted to a server or as search string data conveyed to another page), use the `array.join()` method instead. `Array.join()` gives you more reliable and flexible control over the item delimiters, and you are assured of the same results regardless of locale.

**Related Items:** `array.join()` method.

# Control Structures and Exception Handling

---

**Y**ou get up in the morning, go about your day's business, and then turn out the lights at night. That's not much different from what a program does from the time it starts to the time it ends. But along the way, both you and a program take lots of tiny steps, not all of which advance the "processing" in a straight line. At times, you have to control what's going on by making a decision or repeating tasks until the whole job is finished. Control structures are the facilities that make these tasks possible in JavaScript.

JavaScript control structures follow along the same lines of many programming languages, particularly with additions made in Navigator 4 and Internet Explorer 4. Basic decision-making and looping constructions satisfy the needs of just about all programming tasks.

Another vital program control mechanism — error (or exception) handling — is formally addressed in Edition 3 of the ECMA-262 language standard. The concept of exception handling was added to the JavaScript version introduced in IE5.5 and NN6, but it is well known to programmers in many other environments. Adopting exception-handling techniques in your code can greatly enhance recovery from processing errors caused by errant user input or network glitches.

## If and If. . .Else Decisions

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

JavaScript programs frequently have to make decisions based on the current values of variables or object properties. Such decisions can have only two possible outcomes at a time. The factor that determines the path that the program takes at these decision points is the truth of some statement. For example, when you enter a room of your home at night, the statement under test is something such as "It is too dark to see without a light." If that statement is true, you switch on the light; if that statement is false, you carry on with your primary task.

### In This Chapter

Branching script execution down multiple paths

Looping through ordered collections of data

Applying exception handling techniques

**if**

## Simple decisions

JavaScript syntax for this kind of simple decision always begins with the keyword `if`, followed by the condition to test, and then the statements that execute if the condition yields a true result. JavaScript uses no “then” keyword (as some other languages do); the keyword is implied by the way parentheses and braces surround the various components of this construction. The formal syntax is

```
if (condition) {
    statementsIfTrue
}
```

This construction means that if the condition is true, program execution takes a detour to execute statements inside the braces. No matter what happens, the program continues executing statements beyond the closing brace (`}`). If household navigation were part of the scripting language, the code would look like this:

```
if (tooDark == true) {
    feel for light switch
    turn on light switch
}
```

If you're not used to C/C++, the double equals sign may have caught your eye. You learn more about this type of operator in the next chapter, but for now, know that this operator compares the equality of items on either side of it. In other words, the `condition` statement of an `if` construction must always yield a Boolean (`true` or `false`) value. Some object properties, you may recall, are Booleans, so you can stick a reference to that property into the `condition` statement by itself. Otherwise, the `condition` statement consists of two values separated by a comparison operator, such as `==` (equals) or `!=` (does not equal).

Next, look at some real JavaScript. The following function receives a form object containing a text object called `entry`:

```
function notTooHigh(form) {
    if (parseInt(form.entry.value) > 100) {
        alert("Sorry, the value you entered is too high. Try again.");
        return false;
    }
    return true;
}
```

The condition (in parentheses) tests the contents of the field against a hard-wired value of 100. If the entered value is larger than that, the function alerts you and returns a `false` value to the calling statement elsewhere in the script. But if the value is less than 100, all intervening code is skipped and the function returns `true`.

## About (*condition*) expressions

A lot of condition testing for control structures compares a value against some very specific condition, such as a string's being empty or a value's being `null`. You can use a couple of shortcuts to take care of many circumstances. Table 31-1 details the values that evaluate to a true or false (or equivalent) to satisfy a control structure's *condition* expression.

**Table 31-1: Condition Value Equivalents**

<i>True</i>	<i>False</i>
Nonempty string	Empty string
Nonzero number	0
Nonnull value	Null
Object exists	Object doesn't exist
Property is defined	Undefined property

Instead of having to spell out an equivalency expression for a condition involving these kinds of values, you can simply supply the value to be tested. For example, if a variable named `myVal` may reach an `if` construction with a value of `null`, an empty string, or a string value for further processing, you can use the following shortcut:

```
if (myVal) {  
  // do processing on myVal  
}
```

All null or empty string conditions evaluate to `false`, so that only the cases of `myVal`'s being a processable value get inside the `if` construction. This mechanism is the same that you have seen elsewhere in this book to employ object detection for browser branching. For example, the code nested inside the following code segment executes only if the `document` object has an `images` array property:

```
if (document.images) {  
  // do processing on image objects  
}
```

## Complex decisions

The simple type of `if` construction described earlier is fine when the decision is to take a small detour before returning to the main path. But not all decisions—in programming or in life—are like that. To present two alternate paths in a JavaScript decision, you can add a component to the construction. The syntax is

```
if (condition) {  
  statementsIfTrue  
} else {  
  statementsIfFalse  
}
```

By appending the `else` keyword, you give the `if` construction a path to follow in case the condition evaluates to `false`. The `statementsIfTrue` and `statementsIfFalse` do not have to be balanced in any way: One statement can be one line of code, the other 100 lines. But when either one of those branches completes, execution continues after the last closing brace. To demonstrate how this construction can come in handy, the following example is a script fragment that assigns the number of days in February based on whether or not the year is a leap year (using modulo arithmetic, explained in Chapter 32, to determine if the year is evenly divisible by four, and setting aside all other leap year calculation details for the moment):

```
var howMany = 0;  
var theYear = 2002;  
if (theYear % 4 == 0) {  
  howMany = 29;  
}
```

**if...else**

```
} else {  
    howMany = 28;  
}
```

Here is a case where execution has to follow only one of two possible paths to assign the number of days to the `howMany` variable. Had I not used the `else` portion, as in

```
var howMany = 0;  
var theYear = 2002;  
if (theYear % 4 == 0) {  
    howMany = 29;  
}  
howMany = 28;
```

then the variable would always be set to 28, occasionally after momentarily being set to 29. The `else` construction is essential in this case.

## Nesting `if. . .else` statements

Designing a complex decision process requires painstaking attention to the logic of the decisions your script must process and the statements that must execute for any given set of conditions. The need for many complex constructions disappeared with the advent of `switch` construction in NN4+/IE4+ (described later in this chapter), but there may still be times when you must fashion complex decision behavior out of a series of nested `if. . .else` constructions. Without a JavaScript-aware text editor to help keep everything properly indented and properly terminated (with closing braces), you have to monitor the authoring process very carefully. Moreover, the error messages that JavaScript provides when a mistake occurs (see Chapter 45 on the CD-ROM) may not point directly to the problem line but only to the region of difficulty.

**Note**

Another important point to remember about nesting `if. . .else` statements in JavaScript before Version 1.2 is that the language does not provide a mechanism for script execution to break out of a nested part of the construction. For that reason, you have to construct complex assemblies with extreme care to make sure only the desired statement executes for each set of conditions. Extensive testing, of course, is also required (see Chapter 45 on the CD-ROM).

To demonstrate a deeply nested set of `if. . .else` constructions, Listing 31-1 presents a simple user interface to a complex problem. A single text object asks the user to enter one of three letters — A, B, or C. The script behind that field processes a different message for each of the following conditions:

- ♦ The user enters no value.
- ♦ The user enters A.
- ♦ The user enters B.
- ♦ The user enters C.
- ♦ The user enters something entirely different.

### Listing 31-1: Deeply Nested `if. . .else` Constructions

```
<html>  
  <head>  
    <title></title>
```

```
<script type="text/javascript">
function testLetter(form){
  inpVal = form.entry.value; // assign to shorter variable name
  if (inpVal != "") { // if entry is not empty then dive in...
    if (inpVal == "A") { // Is it an "A"?
      alert("Thanks for the A.");
    } else if (inpVal == "B") { // No. Is it a "B"?
      alert("Thanks for the B.");
    } else if (inpVal == "C") { // No. Is it a "C"?
      alert("Thanks for the C.");
    } else { // Nope. None of the above
      alert("Sorry, wrong letter or case.");
    }
  } else { // value was empty, so skipped all other stuff above
    alert("You did not enter anything.");
  }
}
</script>
</head>
<body>
  <form onsubmit="return false">
    Please enter A, B, or C: <input type="text" name="entry"
      onchange="testLetter(this.form)" />
  </form>
</body>
</html>
```

Each condition executes only the statements that apply to that particular condition, even if it takes several queries to find out what the entry is. You do not need to break out of the nested construction because when a true response is found, the relevant statement executes, and no other statements occur in the execution path to run.

Even if you understand how to construct a hair-raising nested construction, such as the one in Listing 31-1, the trickiest part is making sure that each left brace has a corresponding right brace. My technique for ensuring this pairing is to enter the right brace immediately after I type the left brace. I typically type the left brace, press Enter twice (once to open a free line for the next statement, once for the line that is to receive the right brace); tab, if necessary, to the same indentation as the line containing the left brace; and then type the right brace.

Later, if I have to insert something indented, I just push down the right braces that I entered earlier. If I keep up this methodology throughout the process, the right braces appear at the desired indentation after I'm finished, even if the braces end up being dozens of lines below their original spot.

## What's with the Formatting?

Indentation of the `if` construction and the further indentation of the statements executed on a true condition are not required by JavaScript. What you see here, however, is a convention that most JavaScript scripters follow. As you write the code in your text editor, you can use the Tab key to make each indentation level; some developers prefer using a setting in their editor that converts tabs to spaces, which guarantees that indentations are consistent across different editors. The browser ignores these tab characters (and/or spaces) when loading the HTML documents containing your scripts.

**for**

## Conditional Expressions

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

While I'm showing you decision-making constructions in JavaScript, now is a good time to introduce a special type of expression that you can use in place of an `if . . . else` control structure for a common type of decision — the instance where you want to assign one of two values to a variable, depending on the outcome of some condition. The formal definition for the conditional expression is as follows:

```
variable = (condition) ? val1 : val2;
```

This expression means that if the Boolean result of the `condition` statement is true, JavaScript assigns `val1` to the variable; otherwise, it assigns `val2` to the variable. Like other instances of condition expressions, this one must also be written inside parentheses. The question mark is key here, as is the colon separating the two possible values.

A conditional expression, though not particularly intuitive or easy to read inside code, is very compact. Compare an `if . . . else` version of an assignment decision that follows

```
var collectorStatus;  
if (CDCCount > 500) {  
    collectorStatus = "fanatic";  
} else {  
    collectorStatus = "normal";  
}
```

with the conditional expression version:

```
var collectorStatus = (CDCCount > 500) ? "fanatic" : "normal";
```

The latter saves a lot of code lines (although the internal processing is the same as that of an `if . . . else` construction). Of course, if your decision path contains more statements than just one setting the value of a variable, the `if . . . else` or `switch` construction is preferable. This shortcut, however, is a handy one to remember if you need to perform very binary actions, such as setting a true-or-false flag in a script.

## Repeat (for) Loops

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

As you have seen in numerous examples throughout other chapters, the capability to cycle through every entry in an array or through every item of a form element is vital to many JavaScript scripts. Perhaps the most typical operation is inspecting a property of many similar items in search of a specific value, such as to determine which radio button in a group is selected. One JavaScript structure that allows for these repetitious excursions is the `for` loop, so-named after the keyword that begins the structure. Two other structures, called the `while` loop and `do-while` loop, are covered in the following sections.

The JavaScript `for` loop lets a script repeat a series of statements any number of times and includes an optional loop counter that can be used in the execution of the statements. The following is the formal syntax definition:

```
for ( [initial expression]; [condition]; [update expression] ) {  
    statements  
}
```

**for**

The three statements inside the parentheses (parameters to the `for` statement) play a key role in the way a `for` loop executes.

An initial expression in a `for` loop is executed one time, the first time the `for` loop begins to run. The most common application of the initial expression is to assign a name and starting value to a loop counter variable. Thus, seeing a `var` statement that both declares a variable name and assigns an initial value (generally 0 or 1) to it is not uncommon. An example is

```
var i = 0;
```

You can use any variable name, but conventional usage calls for the letter `i`, which is short for *index*. If you prefer the word `counter` or another word that reminds you of what the variable represents, that's fine, too. In any case, the important point to remember about this statement is that it executes once at the outset of the `for` loop.

The second statement is a *condition*, precisely like the `condition` statement you saw in `if` constructions earlier in this chapter. When a loop-counting variable is established in the initial expression, the `condition` statement usually defines how high the loop counter should go before the looping stops. Therefore, the most common statement here is one that compares the loop counter variable against some fixed value—is the loop counter less than the maximum allowed value? If the condition is false at the start, the body of the loop is not executed. But if the loop does execute, then every time execution comes back around to the top of the loop, JavaScript reevaluates the condition to determine the current result of the expression. If the loop counter increases with each loop, eventually the counter value goes beyond the value in the `condition` statement, causing the `condition` statement to yield a Boolean value of `false`. The instant that happens, execution drops out of the `for` loop entirely.

The final statement, the *update expression*, is executed at the end of each loop execution—after all statements nested inside the `for` construction have run. Again, the loop counter variable can be a factor here. If you want the counter value to increase by one the next time through the loop (called incrementing the value), you can use the JavaScript operator that makes that happen: the `++` operator appended to the variable name. That task is the reason for the appearance of all those `i++` symbols in the `for` loops that you've seen already in this book. You're not limited to incrementing by one. You can increment by any multiplier you want or even drive a loop counter backward by decrementing the value (`i--`).

Now, take this knowledge and beef up the formal syntax definition with one that takes into account a typical loop-counting variable, `i`, and the common ways to use it:

```
//incrementing loop counter
for (var i = minValue; i <= maxValue; i++) {
    statements
}
//decrementing loop counter
for (var i = maxValue; i >= minValue; i--) {
    statements
}
```

In the top format, the variable, `i`, is initialized at the outset to a value equal to that of `minValue`. Variable `i` is immediately compared against `maxValue`. If `i` is less than or equal to `maxValue`, processing continues into the body of the loop. At the end of the loop, the update expression executes. In the top example, the value of `i` is incremented by 1. Therefore, if `i` is initialized as 0, then the first time through the loop, the `i` variable maintains that 0 value during the first execution of statements in the loop. The next time around, the variable has the value of 1.

As you may have noticed in the formal syntax definition, each of the parameters to the `for` statement is optional. For example, the statements that execute inside the loop may control the value of the loop counter based on data that gets manipulated in the process. Therefore,

**for**

the `update` statement would probably interfere with the intended running of the loop. But I suggest that you use all three parameters until such time as you feel absolutely comfortable with their roles in the `for` loop. If you omit the `condition` statement, for instance, and you don't program a way for the loop to exit on its own, your script may end up in an infinite loop—which does your users no good.

## Putting the loop counter to work

Despite its diminutive appearance, the `i` loop counter (or whatever name you want to give it) can be a powerful tool for working with data inside a repeat loop. For example, examine a version of the classic JavaScript function that creates an array while initializing entries to a value of 0:

```
// initialize array with n entries
function MakeArray(n) {
    this.length = n;
    for (var i = 1; i <= n; i++) {
        this[i] = 0;
    }
    return this;
}
```

The loop counter, `i`, is initialized to a value of 1, because you want to create an array of empty entries (with value 0) starting with the one whose index value is 1 (the zeroth entry is assigned to the `length` property) in the previous line. In the `condition` statement, the loop continues to execute as long as the value of the counter is less than or equal to the number of entries being created (`n`). After each loop, the counter increments by 1. In the nested statement that executes within the loop, you use the value of the `i` variable to substitute for the index value of the assignment statement:

```
this[i] = 0;
```

The first time the loop executes, the value expression evaluates to

```
this[1] = 0;
```

The next time, the expression evaluates to

```
this[2] = 0;
```

and so on, until all entries are created and stuffed with 0.

Recall the HTML page in Listing 30-2, where a user chooses a regional office from a `select` list (triggering a script to look up the manager's name and sales quota for that region). Because the regional office names are stored in an array, the page could be altered so that a script populates the `select` element's options from the array. That way, if there is ever a change to the alignment of regional offices, there need be only one change to the array of offices, and the HTML doesn't have to be modified. As a reminder, here is the definition of the regional offices array, created while the page loads:

```
var regionalOffices = new Array("New York", "Chicago", "Houston", "Portland");
```

A script inside the HTML form can be used to dynamically generate the `select` list as follows:

```
<script type="text/javascript">
var elem = ""; // start assembling next part of page and form
elem += "<p>Select a regional office: ";
elem += "<select name='offices' onchange='getData(this.form)'>";
// build options list from array office names
```

**break**

```
for (var i = 0; i < regionalOffices.length; i++) {
    elem += "<option"; // option tags
    if (i == 0) { // pre-select first item in list
        elem += " selected='selected'";
    }
    elem += ">" + regionalOffices[i];
}
elem += "</select></p>"; // close select item tag
document.write(elem); // write element to the page
</script>
```

Notice one important point about the `condition` statement of the `for` loop: JavaScript extracts the `length` property from the array to be used as the loop counter boundary. From a code maintenance and stylistic point of view, this method is preferable to hard-wiring a value there. If the company added a new regional office, you would make the addition to the array “database,” whereas everything else in the code would adjust automatically to those changes, including creating a longer pop-up menu in this case.

Notice, too, that the operator for the `condition` statement is less-than (`<`): The zero-based index values of arrays mean that the maximum index value we can use is one less than the actual count of items in the array. This is vital information, because the index counter variable (`i`) is used as the index to the `regionalOffices` array each time through the loop to read the string for each item’s entry. You also use the counter to determine which is the first option, so that you can take a short detour (via the `if` construction) to add the `selected` attribute to the first option’s definition.

The utility of the loop counter in `for` loops often influences the way you design data structures, such as two-dimensional arrays (see Chapter 30) for use as databases. Always keep the loop-counter mechanism in the back of your mind when you begin writing JavaScript script that relies on collections of data that you embed in your documents.

## Breaking out of a loop

Some loop constructions perform their job as soon as a certain condition is met, at which point they have no further need to continue looping through the rest of the values in the loop counter’s range. A common scenario for this is the cycling of a loop through an entire array in search of a single entry that matches some criterion. That criterion test is set up as an `if` construction inside the loop. If that criterion is met, you break out of the loop and let the script continue with the more meaningful processing of succeeding statements in the main flow. To accomplish that exit from the loop, use the `break` statement. The following schematic shows how the `break` statement may appear in a `for` loop:

```
for (var i = 0; i < array.length; i++) {
    if (array[i].property == magicValue) {
        statements that act on entry array[i]
        break;
    }
}
```

The `break` statement tells JavaScript to bail out of the nearest `for` loop (in case you have nested `for` loops). Script execution then picks up immediately after the closing brace of the `for` statement. The variable value of `i` remains whatever it was at the time of the `break`, so that you can use that variable later in the same script to access, say, that same array entry.

I use a construction similar to this in Chapter 22. There, the discussion of radio buttons demonstrates this construction, where, in Listing 22-8, you see a set of radio buttons whose `value` attributes contain the full names of four members of the Three Stooges. A function

**break**

uses a `for` loop to find out which button was selected and then uses that item's index value — after the `for` loop breaks out of the loop — to alert the user. Listing 31-2 shows the relevant function.

**Listing 31-2: Breaking Out of a for Loop**

```
function fullName(form) {
  for (var i = 0; i < form.stooges.length; i++) {
    if (form.stooges[i].checked) {
      break;
    }
  }
  alert("You chose " + form.stooges[i].value + ".");
}
```

In this case, breaking out of the `for` loop was for more than mere efficiency; the value of the loop counter (frozen at the break point) is used to summon a different property outside of the `for` loop. As of version 4 browsers, the `break` statement gained additional powers in cooperation with the new `label` feature of control structures. This subject is covered later in this chapter.

## Directing loop traffic with `continue`

One other possibility in a `for` loop is that you may want to skip execution of the nested statements for just one condition. In other words, as the loop goes merrily on its way round and round, executing statements for each value of the loop counter, one value of that loop counter may exist for which you don't want those statements to execute. To accomplish this task, the nested statements need to include an `if` construction to test for the presence of the value to skip. When that value is reached, the `continue` command tells JavaScript to immediately skip the rest of the body, execute the `update` statement, and loop back around to the top of the loop (also skipping the `condition` statement part of the `for` loop's parameters).

To illustrate this construction, you create an artificial example that skips over execution when the counter variable is the superstitious person's unlucky 13:

```
for (var i = 0; i <= 20; i++) {
  if (i == 13) {
    continue;
  }
  statements
}
```

In this example, the `statements` part of the loop executes for all values of `i` except 13. The `continue` statement forces execution to jump to the `i++` part of the loop structure, incrementing the value of `i` for the next time through the loop. In the case of nested `for` loops, a `continue` statement affects the `for` loop in whose immediate scope the `if` construction falls. The `continue` statement was enhanced in version 4 browsers with the `label` feature of control structures, which is covered later in this chapter.

## The while Loop

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

**while**

The `for` loop is not the only kind of repeat loop you can construct in JavaScript. Another statement, called a `while` statement, sets up a loop in a slightly different format. Rather than providing a mechanism for modifying a loop counter, a `while` repeat loop assumes that your script statements will reach a condition that forcibly exits the repeat loop.

The basic syntax for a `while` loop is

```
while (condition) {  
    statements  
}
```

The *condition* expression is the same kind that you saw in `if` constructions and in the middle parameter of the `for` loop. You introduce this kind of loop if some condition exists in your code (evaluates to `true`) before reaching this loop. The loop then performs some action, which affects that condition repeatedly until that condition becomes `false`. At that point, the loop exits, and script execution continues with statements after the closing brace. If the statements inside the `while` loop do not affect the values being tested in *condition*, your script never exits, and it becomes stuck in an infinite loop.

Many loops can be rendered with either the `for` or `while` loops. In fact, Listing 31-3 shows a `while` loop version of the `for` loop from Listing 31-2.

**Listing 31-3: A while Loop Version of Listing 31-2**

```
function fullName(form) {  
    var i = 0;  
    while (!form.stooges[i].checked) {  
        i++;  
    }  
    alert("You chose " + form.stooges[i].value + ".");  
}
```

One point you may notice is that if the condition of a `while` loop depends on the value of a loop counter, the scripter is responsible for initializing the counter prior to the `while` loop construction and managing its value within the `while` loop.

Should you need their powers, the `break` and `continue` control statements work inside `while` loops as they do in `for` loops. But because the two loop styles treat their loop counters and conditions differently, be extra careful (do lots of testing) when applying `break` and `continue` statements to both kinds of loops.

No hard-and-fast rules exist for which type of loop construction to use in a script. I generally use `while` loops only when the data or object I want to loop through is already a part of my script before the loop. In other words, by virtue of previous statements in the script, the values for any condition or loop counting (if needed) are already initialized. But if I need to cycle through an object's properties or an array's entries to extract some piece of data for use later in the script, I favor the `for` loop.

Another point of style, particularly with the `for` loop, is where a scripter should declare the `i` variable. Some programmers prefer to declare (or initialize if initial values are known) all variables in the opening statements of a script or function. That is why you tend to see a lot of `var` statements in those positions in scripts. If you have only one `for` loop in a function, for example, nothing is wrong with declaring and initializing the `i` loop counter in the initial expression part of the `for` loop (as demonstrated frequently in the previous sections). But if your function utilizes multiple `for` loops that reuse the `i` counter variable (that is, the loops

**while**

run completely independently of one another), then you can declare the `i` variable once at the start of the function and simply assign a new initial value to `i` in each `for` construction.

## The do-while Loop

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

JavaScript brings you one more looping construction, called the `do-while` loop. The formal syntax for this construction is as follows:

```
do {  
    statements  
} while (condition)
```

An important difference distinguishes the `do-while` loop from the `while` loop. In the `do-while` loop, the statements in the construction always execute at least one time before the condition can be tested; in a `while` loop, the statements may never execute if the condition tested at the outset evaluates to `false`.

Use a `do-while` loop when you know for certain that the looped statements are free to run at least one time. If the condition may not be met the first time, use the `while` loop. For many instances, the two constructions are interchangeable, although only the `while` loop is compatible with all scriptable browsers.

## Looping through Properties (for-in)

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

JavaScript includes a variation of the `for` loop, called a `for-in` loop, which has special powers of extracting the names and values of any object property currently in the browser's memory. The syntax looks like this:

```
for (var in object) {  
    statements  
}
```

The `object` parameter is not the string name of an object but a reference to the object itself. JavaScript delivers an object reference if you provide the name of the object as an unquoted string, such as `window` or `document`. Using the `var` variable, you can create a script that extracts and displays the range of properties for any given object.

Listing 31-4 shows a page containing a utility function that you can insert into your HTML documents during the authoring and debugging stages of designing a JavaScript-enhanced page. In the example, the current `window` object is examined and its properties are presented in the page (note that Safari 1.0 doesn't expose `window` object properties).

### Listing 31-4: Property Inspector Function

```
<html>  
  <head>  
    <title></title>  
    <script type="text/javascript">  
      function showProps(obj,objName) {
```

```

        var result = "";
        for (var i in obj) {
            result += objName + "." + i + " = " + obj[i] + "<br />";
        }
        return result;
    }
</script>
</head>
<body>
    <b>Here are the properties of the current window:</b>
    <p>
        <script type="text/javascript">
            document.write(showProps(window, "window"));
        </script>
    </p>
</body>
</html>

```

For debugging purposes, you can revise the function slightly to display the results in an alert dialog box. Replace the `<br>` HTML tag with the `\n` carriage return character for a nicely formatted display in the alert dialog box. You can call this function from anywhere in your script, passing both the object reference and a string to it to help you identify the object after the results appear in an alert dialog box. If the `showProps()` function looks familiar to you, it is because it closely resembles the property inspector routines of The Evaluator (see Chapter 13). In Chapter 45 on the CD-ROM, you can see how to embed functionality of The Evaluator into a page under construction so that you can view property values while debugging your scripts.

## The with Statement

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

A `with` statement enables you to preface any number of statements by advising JavaScript on precisely which object your scripts will be talking about, so that you don't have to use full, formal addresses to access properties or invoke methods of the same object. The formal syntax definition of the `with` statement is as follows:

```

with (object) {
    statements
}

```

The object reference is a reference to any valid object currently in the browser's memory. An example of this appears in Chapter 28's discussion of the `Math` object. By embracing several `Math`-encrusted statements inside a `with` construction, your scripts can call the properties and methods without having to make the object part of every reference to those properties and methods.

An advantage of the `with` structure is that it can make heavily object-dependent statements easier to read and understand. Consider this long version of a function that requires multiple calls to the same object (but different properties):

```

function seeColor(form) {
    newColor = (form.colorsList.options[form.colorsList.selectedIndex].text);
    return newColor;
}

```

**with**

Using the `with` structure, you can shorten the long statement:

```
function seeColor(form) {
  with (form.colorsList) {
    newColor = (options[selectedIndex].text);
  }
  return newColor;
}
```

When JavaScript encounters an otherwise unknown identifier inside a `with` statement, it tries to build a reference out of the object specified as its parameter and that unknown identifier. You cannot, however, nest `with` statements that build on one another. For instance, in the preceding example, you cannot have a `with (colorsList)` nested inside a `with (form)` statement and expect JavaScript to create a reference to `options` out of the two object names.

As clever as the `with` statement may seem, be aware that it introduces some inherent performance penalties in your script (because of the way the JavaScript interpreter must artificially generate references). You probably won't notice degradation with occasional use of this construction, but if it's used inside a loop that must iterate many times, processing speed will almost certainly be affected negatively.

## Labeled Statements

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

Crafting multiple nested loops can sometimes be difficult when the final condition your script is looking for is met deep inside the nests. The problem is that the `break` or `continue` statement by itself has scope only to the nearest loop level. Therefore, even if you break out of the inner loop, the outer loop(s) continue to execute. If all you want to do is exit the function after the condition is met, a simple `return` statement performs the same job as some other languages' exit command. But if you also need some further processing within that function after the condition is met, you need the NN4+/IE4+/W3C facility that lets you assign labels to blocks of JavaScript statements. Your `break` and `continue` statements can then alter their scope to apply to a labeled block other than the one containing the statement.

A *label* is any identifier (that is, name starting with a letter and containing no spaces or odd punctuation other than an underscore) followed by a colon preceding a logical block of executing statements, such as an `if . . . then` or loop construction. The formal syntax looks like the following:

```
labelID:
  statements
```

For a `break` or `continue` statement to apply itself to a labeled group, the label is added as a kind of parameter to each statement, as in

```
break labelID;
continue labelID;
```

To demonstrate how valuable this can be in the right situation, Listing 31-5 contains two versions of the same nested loop construction. The goal of each version is to loop through two different index variables until both values equal the target values set outside the loop. When those targets are met, the entire nested loop construction should break off and continue processing afterward. To help you visualize the processing that goes on during the execution of the loops, the scripts output intermediate and final results to a text area.

In the version without labels, when the targets are met, only the simple `break` statement is issued. This breaks the inner loop at that point, but the outer loop picks up on the next iteration.

By the time the entire construction has ended, a lot of wasted processing has gone on. Moreover, the values of the counting variables max themselves out, because the loops execute in their entirety several times after the targets are met.

But in the labeled version, the inner loop breaks out of the labeled outer loop as soon as the targets are met. Far fewer lines of code are executed, and the loop counting variables are equal to the targets, as desired. Experiment with Listing 31-5 by changing the `break` statements to `continue` statements. Then closely analyze the two results in the Results textarea to see how the two versions behave.

### Listing 31-5: Labeled Statements

```
<html>
  <head>
    <title>Breaking Out of Nested Labeled Loops</title>
    <script type="text/javascript">
      var targetA = 2;
      var targetB = 2;
      var range = 5;
      function run1() {
        var out = document.forms[0].output;
        out.value = "Running WITHOUT labeled break\n";
        for (var i = 0; i <= range; i++) {
          out.value += "Outer loop #" + i + "\n";
          for (var j = 0; j <= range; j++) {
            out.value += "  Inner loop #" + j + "\n";
            if (i == targetA && j == targetB) {
              out.value += "***BREAKING OUT OF INNER LOOP**\n";
              break;
            }
          }
        }
        out.value += "After looping, i = " + i + ", j = " + j + "\n";
      }
      function run2() {
        var out = document.forms[0].output;
        out.value = "Running WITH labeled break\n";
        outerLoop:
        for (var i = 0; i <= range; i++) {
          out.value += "Outer loop #" + i + "\n";
          innerLoop:
          for (var j = 0; j <= range; j++) {
            out.value += "  Inner loop #" + j + "\n";
            if (i == targetA && j == targetB) {
              out.value += "***BREAKING OUT OF OUTER LOOP**\n";
              break outerLoop;
            }
          }
        }
        out.value += "After looping, i = " + i + ", j = " + j + "\n";
      }
    </script>
  </head>
  <body>
    <h1>Breaking Out of Nested Labeled Loops</h1>
```

*Continued*

label

    onclick="run2()" /></p>
  <p>Results:</p>
  <textarea name="output" rows="43" cols="60"></textarea>
</form>
</body>
</html>
```

## The switch Statement

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

In some circumstances, a binary—true or false—decision path is not enough to handle the processing in your script. An object property or variable value may contain any one of several values, and a separate execution path is required for each one. In the past, the way to accommodate this was with a series of `if . . . else` constructions. The more conditions you must test, the less efficient the processing is, because each condition must be tested. Moreover, the sequence of clauses and braces can get very confusing.

In version 4 browsers, a control structure in use by many languages was introduced to JavaScript. The implementation is similar to that of Java and C, using the `switch` and `case` keywords. The basic premise is that you can create any number of execution paths based on the value of some expression. At the beginning of the structure, you identify what that expression is and then, for each execution path, assign a label matching a particular value.

The formal syntax for the `switch` statement is

```
switch (expression) {
  case label1:
    statements
    [break]
  case label2:
    statements
    [break]
  ...
  [default:
    statements]
}
```

The *expression* parameter of the `switch` statement can evaluate to any string or number value. Labels are surrounded by quotes when the labels represent string values of the expression. Notice that the `break` statements are optional. A `break` statement forces the switch expression to bypass all other checks of succeeding labels against the expression value. Another option is the `default` statement, which provides a catchall execution path when the expression value does not match any of the `case` statement labels. If you'd rather not have any execution take place with a non-matching expression value, omit the default part of the construction.

**switch**

To demonstrate the syntax of a working `switch` statement, Listing 31-6 provides the skeleton of a larger application of this control structure. The page contains two separate arrays of different product categories. Each product has its name and price stored in its respective array. A `select` list displays the product names. After a user chooses a product, the script looks up the product name in the appropriate array and displays the price.

The trick behind this application is the values assigned to each product in the `select` list. While the displayed text is the product name, the `value` attribute of each `<option>` tag is the array category for the product. That value is the expression used to decide which branch to follow. Notice, too, that I assign a label to the entire `switch` construction. The purpose of that is to let the deeply nested repeat loops for each case completely bail out of the `switch` construction (via a labeled `break` statement) whenever a match is made. You can extend this example to any number of product category arrays with additional `case` statements to match.

**Listing 31-6: The `switch` Construction in Action**

```
<html>
  <head>
    <title>Switch Statement and Labeled Break</title>
    <script type="text/javascript">
      // build two product arrays, simulating two database tables
      function product(name, price) {
        this.name = name;
        this.price = price;
      }
      var ICs = new Array();
      ICs[0] = new product("Septium 900MHz", "$149");
      ICs[1] = new product("Septium Pro 1.0GHz", "$249");
      ICs[2] = new product("Octium BFD 750MHz", "$329");
      var snacks = new Array();
      snacks[0] = new product("Rays Potato Chips", "$1.79");
      snacks[1] = new product("Cheezey-ettes", "$1.59");
      snacks[2] = new product("Tortilla Flats", "$2.29");

      // lookup in the 'table' associated with the product
      function getPrice(selector) {
        var chipName = selector.options[selector.selectedIndex].text;
        var outField = document.forms[0].cost;
        master:
        switch(selector.options[selector.selectedIndex].value) {
          case "ICs":
            for (var i = 0; i < ICs.length; i++) {
              if (ICs[i].name == chipName) {
                outField.value = ICs[i].price;
                break master;
              }
            }
            break;
          case "snacks":
            for (var i = 0; i < snacks.length; i++) {
              if (snacks[i].name == chipName) {
                outField.value = snacks[i].price;
                break master;
              }
            }
        }
      }
    }
  </script>
</head>
</html>
```

*Continued*

## switch

## Listing 31-6 (continued)

```

        break;
    default:
        outField.value = "Not Found";
    }
}
</script>

      <option></option>
      <option value="ICs">Septium 900MHz</option>
      <option value="ICs">Septium Pro 1.0GHz</option>
      <option value="ICs">Octium BFD 750MHz</option>
      <option value="snacks">Rays Potato Chips</option>
      <option value="snacks">Cheezey-ettes</option>
      <option value="snacks">Tortilla Flats</option>
      <option>Poker Chipset</option>
    </select>&nbsp; Price:<input type="text" name="cost" size="10" />
  </form>
</body>
</html>

```

## Exception Handling

The subject of exception handling is relatively new to JavaScript. Formalized in Edition 3 of ECMA-262, parts of the official mechanism are implemented in IE5, with more complete implementations in IE6 and NN6, and of course in Mozilla and Safari.

### Exceptions and errors

If you've done any scripting, you are certainly aware of JavaScript errors, whether they be from syntax errors in your code, or what are known as *runtime* errors — errors that occur while scripts are processing information. Ideally, a program should be aware of when an error occurs and handle it as gracefully as possible. This self-healing can prevent lost data (usually not a big problem in Web applications) and prevent users from seeing the ugliness of error messages. Chapter 16 covers the `onerror` event handler (and `window.onerror` property), which were early attempts at letting scripts gain a level of control over runtime errors. This event-driven mechanism works on a global level (that is, in the `window` object) and processes every error that occurs throughout the page. This event handler ends up being used primarily as a last-ditch defense against displaying any error message to the user and is a long way from what programmers consider to be exception handling.

In the English language, the term “exception” can mean the same as something out of the ordinary, or something abnormal. This definition seems quite distant from the word “error,” which usually means a mistake. In the realm of programming languages, however, the two words tend to be used interchangeably, and the difference between the two depends primarily on one's point of view.

Consider, for example, a simple script whose job is to multiply numbers that the user enters into two text fields on the page. The script is supposed to display the results in a third text box. If the script contains no data entry validation, JavaScript will attempt to multiply whatever values are entered into the text boxes. If the user enters two numbers, JavaScript is smart enough to recognize that even though the `value` properties of the two input text fields are strings, the strings contain numbers that can be converted to number types for the proper multiplication. Without complaint, the product of the two numbers gets calculated and displayed into the results.

But what if the user types a letter into one of the text boxes? Again, without any entry validation in the script, JavaScript has a fixed way of responding to such a request: The result of the multiplication operation is the `NaN` (not a number) constant. If you are an untrained user, you have no idea what `NaN` means, but your experience with computers tells you that some kind of error has occurred. You may blame the computer or you may blame yourself.

To shift the point of view to the programmer, however, the script was designed to be run by a user who never makes a typing mistake, intentional or not. That, of course, is not very good programming practice. Users make mistakes. Therefore, anticipating user input that is not what would be expected is the programmer's job — input that is an exception to the rules your program wants to operate by. You must include some additional code that handles the exceptions gracefully so as to not confuse the user with unintelligible output and perhaps even help the user repair the input to get a result. This extra programming code handles the undesirable and erroneous input.

As it turns out, JavaScript and the W3C Document Object Model liberally mix terms of exception and error within the vocabulary used to handle exceptions. As you see shortly, an exception creates an *error object*, which contains information about the exception. It is safe to say that you can think of exceptions and errors as the same things.

## The exception mechanism

Newcomers to JavaScript (or any programming environment, for that matter) may have a difficult time at first creating a mental model of how all this stuff runs within the context of the browser. It may be easy enough to understand how pages load and create object models, and how event handlers (or listeners in the W3C DOM terminology) cause script functions to run. But a lot of action also seems to be going on in the background. For example, the event object that is generated automatically with each event action (see Chapter 25) seems to sit “somewhere” while event handler functions run so that they can retrieve details about the event. After the functions finish their processing, the event object disappears, without even leaving behind a Cheshire Cat smile. Mysterious.

Browsers equipped for exception handling have more of this “stuff” running in the background, ready for your scripts when you need it. Because you have certainly viewed the details of at least one scripting error, you have already seen some of the exception-handling mechanism that is built into browsers. If a script error occurs, the browser creates in its memory an error object, whose properties contain details about the error. The precise details (described later in this chapter) vary from one browser brand to the next, but what you see in the error details readout is the default way the browser handles exceptions/errors. As browsers have matured, their makers have gone to great lengths to tone down the intrusion of script errors. For example in NN4+, errors appear in a separate JavaScript Console window (which must be invoked in NN4 by typing `javascript:` into the Location field; or opened directly via the Tools menu in NN6+ and Mozilla). In IE4+ for Windows, the status bar comes into play again, as the icon at the bottom-left corner turns into an alert icon: Double-clicking the icon displays more information about the error. MacIE users can turn off scripting error alerts altogether. Safari 1.0 doesn't divulge any script errors (see Chapter 45 on the CD-ROM to engage this feature).

## Exceptions

True exception handling, however, goes further than just displaying error messages. It also provides a uniform way to let scripts guard against unusual occurrences. Ideally, the mechanism makes sure that *all* runtime errors get funneled through the same mechanism to help simplify the scripting of exception handling. The mechanism is also designed to be used intentionally as a way for your own code to generate errors in a uniform way so that other parts of your scripts can handle them quietly and intelligently. In other words, you can use the exception handling mechanism as a kind of “back channel” to communicate from one part of your scripts to another.

The JavaScript exception handling mechanism is built around two groups of program execution statements. The first group consists of the `try-catch-finally` statement triumvirate; the second group is the single `throw` statement.

## Using try-catch-finally Constructions

The purpose of the `try-catch-finally` group of related statements is to provide a controlled environment in which script statements that may encounter runtime errors can run, such that if an exception occurs, your scripts can act upon the exception without alarming the rest of the browser’s error mechanisms. Each of the three statements precedes a block of code in the following syntax:

```
try {
    statements to run
}
catch (errorInfo) {
    statements to run if exception occurs in try block
}
finally {
    statements to run whether or not an exception occurred [optional]
}
```

Each `try` block must be mated with a `catch` and/or `finally` block at the same nesting level, with no intervening statements. For example, a function can have a one-level `try-catch` construction inside it as follows:

```
function myFunc() {
    try {
        statements
    }
    catch (e) {
        statements
    }
}
```

But if there were another `try` block nested one level deeper, a balancing `catch` or `finally` block would also have to be present at that deeper level:

```
function myFunc() {
    try {
        statements
        try {
            statements
        }
        catch (e) {
            statements
        }
    }
}
```

## try-catch-finally

```

    }
    catch (e) {
        statements
    }
}

```

The statements inside the `try` block include statements that you believe are capable of generating a runtime error because of user input errors, the failure of some page component to load, or a similar error. The presence of the `catch` block prevents errors from appearing in the browser’s regular script error reporting system (for example, the JavaScript Console of NN6+ and Mozilla).

An important term to know about exception handling of this type is *throw*. The convention is that when an operation or method call triggers an exception, it is said to “throw an exception.” For example, if a script statement attempts to invoke a method of a string object, but that method does not exist for the object (perhaps you mistyped the method name), JavaScript throws an exception. Exceptions have names associated with them — a name that sometimes, but not always, reveals important information about the exception. In the mistyped method example just cited, the name of that exception is a `TypeError` (yet more evidence of how “exception” and “error” become intertwined).

The JavaScript language (in IE5+/NN6+/W3C) is not the only entity that can throw exceptions. The W3C DOM also defines categories of exceptions for DOM objects. For example, according to the Level 2 specification, the `appendChild()` method (see Chapter 15) can throw (or *raise*, in the W3C terminology) one of three exceptions:

Exception Name	When Thrown
HIERARCHY_REQUEST_ERR	If the current node is of a type that does not allow children of the type of the <i>newChild</i> node, or if the node to append is one of this node’s ancestors
WRONG_DOCUMENT_ERR	If <i>newChild</i> was created from a different document than the one that created the current node
NO_MODIFICATION_ALLOWED_ERR	If the current node is read-only

Because the `appendChild()` method is capable of throwing exceptions, a JavaScript statement that invokes this method should ideally be inside a `try` block. If an exception is thrown, then script execution immediately jumps to the `catch` or `finally` block associated with the `try` block. Execution does not come back to the `try` block.

A `catch` block has special behavior. Its format looks similar to a function in a way, because the `catch` keyword is followed by a pair of parentheses and an arbitrary variable that is assigned a reference to the error object whose properties are filled by the browser when the exception occurs. One of the properties of that error object is the name of the error. Therefore, the code inside the `catch` block can examine the name of the error and perhaps include some branching code to take care of a variety of different errors that are caught.

To see how this construction may look in code, look at a hypothetical generic function whose job is to create a new element and append it to some other node. Both the type of element to be created and a reference to the parent node are passed as parameters. To take care of potential misuses of this function through the passage of improper parameter values, it includes extra error handling to treat all possible exceptions from the two DOM methods: `createElement()` and `appendChild()`. Such a function looks like Listing 31-7.

## try-catch-finally

## Listing 31-7: A Hypothetical try-catch Routine

```
// generic appender
function attachToEnd(theNode, newTag) {
  try {
    var newElem = document.createElement(newTag);
    theNode.appendChild(newElem);
  }
  catch (e) {
    switch (e.name) {
      case "INVALID_CHARACTER_ERR" :
        statements to handle this createElement() error
        break;
      case "HIERARCHY_REQUEST_ERR" :
        statements to handle this appendChild() error
        break;
      case "WRONG_DOCUMENT_ERR" :
        statements to handle this appendChild() error
        break;
      case "NO_MODIFICATION_ALLOWED_ERR" :
        statements to handle this appendChild() error
        break;
      default:
        statements to handle any other error
    }
    return false;
  }
  return true;
}
```

The single `catch` block in Listing 31-7 executes only if one of the statements in the `try` block throws an exception. The exceptions may be not only one of the four specific ones named in the `catch` block but also syntax or other errors that could occur inside the `try` block. That's why you have a last-ditch case to handle truly unexpected errors. Your job as scripter is to not only anticipate errors but also to provide clean ways for the exceptions to be handled, whether they be through judiciously worded alert dialog boxes or perhaps even some self-repair. For example, in the case of the invalid character error for `createElement()`, your script may attempt to salvage the data passed to the `attachToEnd()` function and reinvoke the method passing the `theNode` value as-is and the repaired value originally passed to `newTag`. If your repairs were successful, the `try` block would execute without error and carry on with the user's being completely unaware that a nasty problem had been averted.

A `finally` block contains code that always executes after a `try` block, whether or not the `try` block succeeds without throwing an error. Unlike the `catch` block, a `finally` block does not receive an `error` object as a parameter, so it operates very much in the dark about what transpires inside the `try` block. If you include both `catch` and `finally` blocks after a `try` block, the execution path depends on whether an exception is thrown. If no exception is thrown, the `finally` block executes after the last statement of the `try` block runs. But if the `try` block throws an exception, program execution runs first to the `catch` block. After all processing within the `catch` block finishes, the `finally` block executes. In development environments that give programmers complete control over resources, such as memory allocation, a `finally` block may be used to delete some temporary items generated in the `try` block, whether or not an exception occurs in the `try` block. Currently, JavaScript has less need for that kind of maintenance, but you should be aware of the program execution possibilities of the `finally` block in the `try-catch-finally` context.

**throw**

## Real-life exceptions

The example shown in Listing 31-7 is a bit idealized. The listing assumes that the browser dutifully reports every W3C DOM exception precisely as defined in the formal specification. Unfortunately, that's not how it is (yet) in browsers through IE6 and NN7. Both browsers implement additional error naming conventions and layers between actual DOM exceptions and what gets reported with the error object at the time of the exception.

If you think these discrepancies make cross-browser exception handling difficult, you're right. Even simple errors are reported differently among the two major browser brands and the W3C DOM specification. Until the browsers exhibit a greater unanimity in exception reporting, the smoothest development road will be for those scripters who have the luxury of writing for one of the browser platforms, such as IE6 for Windows or NN7.

That said, however, one aspect of exception handling can still be used in both IE5+ and NN6+/W3C. You can take advantage of `try-catch` constructions to throw your own exceptions — a practice that is quite common in advanced programming environments.

## Throwing Exceptions

The last exception handling keyword not covered yet — `throw` — makes it possible to utilize exception-handling facilities for your own management of processes, such as data entry validation. At any point inside a `try` block, you can manually throw an exception that gets picked up by the associated `catch` block. The details of the specific exception are up to you.

Syntax for the `throw` statement is as follows:

```
throw value;
```

The value you throw can be of any type, but good practice suggests that the value be an error object (described more fully later in this chapter). Whatever value you throw is assigned to the parameter of the `catch` block. Look at the following two examples. In the first, the value is a string message; in the second, the value is an error object.

Listing 31-8 presents one input text box for a number between 1 and 5. Clicking a button looks up a corresponding letter in an array and displays the letter in a second text box. The lookup script has two simple data validation routines to make sure the entry is a number and is in the desired range. Error checking here is done manually by script. If either of the error conditions occurs, `throw` statements force execution to jump to the `catch` block. The `catch` block assigns the incoming `string` parameter to the variable `e`. The design here assumes that the message being passed is text for an alert dialog box. Not only does a single `catch` block take care of both error conditions (and conceivably any others to be added later), but the `catch` block runs within the same variable scope as the function, so that it can use the reference to the input text box to focus and select the input text if there is an error.

### Listing 31-8: Throwing String Exceptions

```
<html>
  <head>
    <title>Throwing a String Exception</title>
    <script type="text/javascript">
      var letters = new Array("A","B","C","D","E");
```

*Continued*

**throw****Listing 31-8 (continued)**

```

function getLetter(fld) {
  try {
    var inp = parseInt(fld.value, 10);
    if (isNaN(inp)) {
      throw "Entry was not a number.";
    }
    if (inp < 1 || inp > 5) {
      throw "Enter only 1 through 5.";
    }
    fld.form.output.value = letters[inp - 1];
  }
  catch (e) {
    alert(e);
    fld.form.output.value = "";
    fld.focus();
    fld.select();
  }
}
</script>
</head>
<body>
<h1>Throwing a String Exception</h1>
<hr />
<form>
  Enter a number from 1 to 5: <input type="text" name="input"
  size="5" /> <input type="button" value="Get Letter"
  onclick="getLetter(this.form.input)" /> Matching Letter is:<input
  type="text" name="output" size="5" />
</form>
</body>
</html>

```

The flaw with Listing 31-8 is that if some other kind of exception were thrown inside the `try` block, the value passed to the `catch` block would be an error object, not a string. The alert dialog box displayed to the user would be meaningless. Therefore, it is better to be uniform in your `throw-catch` constructions and pass an error object.

Listing 31-9 is an updated version of Listing 31-8, demonstrating how to create an error object that gets sent to the `catch` block via `throw` statements.

**Listing 31-9: Throwing an Error Object Exception**

```

<html>
<head>
  <title>Throwing an Error Object Exception</title>
  <script type="text/javascript">
    var letters = new Array("A","B","C","D","E");
    function getErrorObj(msg) {
      var err = new Error(msg);
      return err;
    }

```

throw

```
function getLetter(fld) {
  try {
    var inp = parseInt(fld.value, 10);
    if (isNaN(inp)) {
      throw getErrorObj("Entry was not a number.");
    }
    if (inp < 1 || inp > 5) {
      throw getErrorObj("Enter only 1 through 5.");
    }
    fld.form.output.value = letters[inp - 1];
  }
  catch (e) {
    alert(e.message);
    fld.form.output.value = "";
    fld.focus();
    fld.select();
  }
}
</script>
</head>
<body>
  <h1>Throwing an Error Object Exception</h1>
  <hr />
  <form>
    Enter a number from 1 to 5: <input type="text" name="input"
      size="5" /> <input type="button" value="Get Letter"
      onclick="getLetter(this.form.input)" /> Matching Letter is:<input
      type="text" name="output" size="5" />
  </form>
</body>
</html>
```

The only difference to the `catch` block is that it now reads the `message` property of the incoming error object. This means that if some other exception is thrown inside the `try` block, the browser-generated message will be displayed in the alert dialog box.

In truth, however, the job really isn't complete. In all likelihood, if a browser-generated exception is thrown, the message in the alert dialog box won't mean much to the user. The error message will probably be some kind of syntax or type error—the kind of meaningless error message you often get from your favorite operating system. A better design is to branch the `catch` block so that “intentional” exceptions thrown by your code are handled through the alert dialog box messages you've put there, but other types are treated differently. To accomplish this, you can take over one of the other properties of the error object—`name`—so that your `catch` block treats your custom messages separately.

In Listing 31-10, the `getErrorObj()` function adds a custom value to the `name` property of the newly created error object. The name you assign can be any name, but you want to avoid exception names used by JavaScript or the DOM. Even if you don't know what all of those are, you can probably conjure up a suitably unique name for your error. Down in the `catch` block, a `switch` construction branches to treat the two classes of errors differently. In this simplified example, about the only possible problem other than the ones being trapped for explicitly in the `try` block would be some corruption to the page during downloading. Therefore, for this example, the branch for all other errors simply asks that the user reload the page and try again. The point is, however, that you can have as many classifications of custom and system errors as you want and handle them in a single `catch` block accordingly.

## throw

## Listing 31-10: A Custom Object Exception

```

<html>
  <head>
    <title>Throwing a Custom Error Object Exception</title>
    <script type="text/javascript">
      var letters = new Array("A","B","C","D","E");
      function getErrorObj(msg) {
        var err = new Error(msg);
        err.name = "MY_ERROR";
        return err;
      }
      function getLetter(fld) {
        try {
          var inp = parseInt(fld.value, 10);
          if (isNaN(inp)) {
            throw getErrorObj("Entry was not a number.");
          }
          if (inp < 1 || inp > 5) {
            throw getErrorObj("Enter only 1 through 5.");
          }
          fld.form.output.value = letters[inp - 1];
        }
        catch (e) {
          switch (e.name) {
            case "MY_ERROR" :
              alert(e.message);
              fld.form.output.value = "";
              fld.focus();
              fld.select();
              break;
            default :
              alert("Reload the page and try again.");
          }
        }
      }
    </script>
  </head>
  <body>
    <h1>Throwing a Custom Error Object Exception</h1>
    <hr />
    <form>
      Enter a number from 1 to 5: <input type="text" name="input"
        size="5" /> <input type="button" value="Get Letter"
        onclick="getLetter(this.form.input)" /> Matching Letter is:<input
        type="text" name="output" size="5" />
    </form>
  </body>
</html>

```

If you want to see how the alternative branch of Listing 31-10 looks, copy the listing file from the CD-ROM to your hard disk and modify the last line of the `try` block so that one of the letters is dropped from the name of the array:

```
fld.form.output.value = letter[inp - 1];
```

This may simulate the faulty loading of the page. If you enter one of the allowable values, the reload alert appears, rather than the actual message of the error object: letter is undefined. Your users will thank you.

All that's left now on this subject are the details on the error object.

## Error Object

<b>Properties</b>	<b>Methods</b>
<code>Error.prototype</code>	<code>errorObject.toString()</code>
<code>errorObject.constructor</code>	
<code>errorObject.description</code>	
<code>errorObject.filename</code>	
<code>errorObject.lineNumber</code>	
<code>errorObject.message</code>	
<code>errorObject.name</code>	
<code>errorObject.number</code>	

### Syntax

Creating an error object:

```
var myError = new Error("message");
var myError = Error("message");
```

Accessing static Error object property:

```
Error.property
```

Accessing error object properties and methods:

```
errorObject.property | method([parameters])
```

**Compatibility:** WinIE5+, MacIE-, NN6+, Moz1+, Safari1+

### About this object

An error object instance is created whenever an exception is thrown or when you invoke either of the constructor formats for creating an error object. Properties of the error object instance contain information about the nature of the error so that `catch` blocks can inspect the error and process error handling accordingly.

IE5 implemented an error object in advance of the ECMA-262 formal error object, and the IE5 version ended up having its own set of properties that are not part of the ECMA standard. Those proprietary properties are still part of IE5.5+, which includes the ECMA properties as well. NN6, on the other hand, started with the ECMA properties and adds two proprietary properties of its own. The browser uses these additional properties in its own script error reporting. The unfortunate bottom line for cross-browser developers is that no properties in common among all browsers support the error object. However, two common denominators (name and message) are between IE5.5+ and NN6+.

**errorObject**

As described earlier in this chapter, you are encouraged to create an error object whenever you use the `throw` statement for your own error control. See the discussion surrounding Listing 31-9 about handling missing properties in IE.

## Properties

### constructor

(See `string.constructor` in Chapter 27)

### description

**Value:** String.

Read/Write

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `description` property contains a descriptive string that provides some level of detail about the error. For errors thrown by the browser, the description is the same text that appears in the script error dialog box in IE. Although this property continues to be supported, the `message` property is preferred.

**Related Items:** `message` property.

### fileName

### lineNumber

**Value:** String.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN6+, Moz-, Safari-

The NN6 browser uses the `fileName` and `lineNumber` properties of an error object for its own internal script error processing—these values appear as part of the error messages that are listed in the JavaScript Console. The `fileName` is the URL of the document causing the error; the `lineNumber` is the source code line number of the statement that threw the exception. These properties are exposed to JavaScript, as well, so that your error processing may use this information if it is meaningful to your application.

See the discussion of the `window.error` property in Chapter 16 for further ideas on how to use this information for bug reporting from users.

**Related Items:** `window.error` property.

### message

**Value:** String.

Read/Write

**Compatibility:** WinIE5.5+, MacIE-, NN6+, Moz1+, Safari1+

The `message` property contains a descriptive string that provides some level of detail about the error. For errors thrown by the browser, the message is the same text that appears in the script error dialog box in IE and the JavaScript Console in NN6+. By and large, these messages are more meaningful to scripters than to users. Unfortunately, there are no standards for the wording of a message for a given error. Therefore, it is hazardous at best to use the message content in a `catch` block as a means of branching to handle particular kinds of errors. You may get by with this approach if you are developing for a single browser platform, but you have no assurances that the text of a message for a particular exception may not change in future browser versions.

Custom messages for errors that your code explicitly throws can be in user-friendly language if you intend to display such messages to users. See Listings 31-8 through 31-10 for examples of this usage.

**errorObject.toString()****Related Items:** description property.

## name

**Value:** String.

Read/Write

**Compatibility:** WinIE5.5+, MacIE-, NN6+, Moz1+, Safari1+

The `name` property generally contains a word that identifies the type of error that has been thrown. The most general kind of error (and the one that is created via the new `Error()` constructor) has a `name` `Error`. But JavaScript errors can be of several varieties: `EvalError`, `RangeError`, `ReferenceError`, `SyntaxError`, `TypeError`, and `URIError`. Some of these error types are not necessarily intended for exposure to scripters (they're used primarily in the inner workings of the JavaScript engine), but some browsers do expose them. Unfortunately, there are some discrepancies as to the specific name supplied to this property for script errors.

When JavaScript is being used in a W3C-compatible browser, some DOM exception types are returned via the `name` property. But browsers frequently insert their own error types for this property, and, as is common in this department, little uniformity exists among browser brands.

For custom exceptions that your code explicitly throws, you can assign names as you want. As shown in Listings 31-9 and 31-10, this information can assist a `catch` block in handling multiple categories of errors.

**Related Items:** message property.

## number

**Value:** Number.

Read/Write

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

IE5+ assigns unique numbers to each error description or message. The value of the `number` property must be massaged somewhat to retrieve a meaningful error description. Following is an example of how you must apply binary arithmetic to an error number to arrive at a meaningful result:

```
var errNum = errorObj.number & x0FFFF;
```

To find out what an error number means, just look it up on Microsoft's Developer Network (MSDN) site at <http://msdn.microsoft.com/library/en-us/script56/html/js56jsmsscRunTimeErrors.asp>.

**Related Items:** description property.

## Methods

### toString()

**Returns:** String (see text).**Compatibility:** WinIE5+, MacIE-, NN6+, Moz1+, Safari1+

The `toString()` method for an error object should return a string description of the error. In IE5+, however, the method returns a reference to the very same error object. In NN6+, the method returns the `message` property string, preceded by the string `Error:` (with a space after the colon). Most typically, if you want to retrieve a human-readable expression of an error object, read its `message` (or, in IE5+, `description`) property.

**Related Items:** message property.

# JavaScript Operators

---

JavaScript is rich in *operators*: words and symbols in expressions that perform operations on one or two values to arrive at another value. Any value on which an operator performs some action is called an *operand*. An expression may contain one operand and one operator (called a *unary operator*) or two operands separated by one operator (called a *binary operator*). Many of the same symbols are used in a variety of operators. The combination and order of those symbols are what distinguish their powers.

**Note**

The vast majority of JavaScript operators have been in the language since the very beginning. But, as you may expect from an evolving language, some new entries have been added to the lexicon. In the rest of this chapter, compatibility charts typically govern an entire category of operator. If there are version anomalies for a particular operator within a category, they are covered in the text.

## Operator Categories

To help you grasp the range of JavaScript operators, I group them into seven categories. I assign a wholly untraditional name to the second group — but a name that I believe better identifies its purpose in the language. Table 32-1 shows the operator types.

**Table 32-1: JavaScript Operator Categories**

Type	What It Does
Comparison	Compares the values of two operands, deriving a result of either true or false (used extensively in condition statements for <code>if...else</code> and for loop constructions)
Connubial	Joins together two operands to produce a single value that is a result of an arithmetical or other operation on the two

*Continued*

### In This Chapter

Understanding operator categories

Exploring the role of operators in script statements

Recognizing operator precedence

## Comparison Operators

Table 32-1 (continued)

Type	What It Does
Assignment	Stuffs the value of the expression of the right-hand operand into a variable name on the left-hand side, sometimes with minor modification, as determined by the operator symbol
Boolean	Performs Boolean arithmetic on one or two Boolean operands
Bitwise	Performs arithmetic or column-shifting actions on the binary (base-2) representations of two operands
Object	Helps scripts examine the heritage and capabilities of a particular object before they need to invoke the object and its properties or methods
Miscellaneous	A handful of operators that have special behaviors

Any expression that contains an operator evaluates to a value of some kind. Sometimes the operator changes the value of one of the operands; other times the result is a new value. Even this simple expression

```
5 + 5
```

shows two integer operands joined by the addition operator. This expression evaluates to 10. The operator is what provides the instruction for JavaScript to follow in its never-ending drive to evaluate every expression in a script.

Doing an equality comparison on two operands that, on the surface, look very different is not at all uncommon. JavaScript doesn't care what the operands look like—only how they evaluate. Two very dissimilar-looking values can, in fact, be identical when they are evaluated. Thus, an expression that compares the equality of two values, such as

```
fred == 25
```

does, in fact, evaluate to `true` if the variable `fred` has the number 25 stored in it from an earlier statement.

## Comparison Operators

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Anytime you compare two values in JavaScript, the result is a Boolean `true` or `false` value. You have a wide selection of comparison operators to choose from, depending on the kind of test you want to apply to the two operands. Table 32-2 lists all comparison operators.

Table 32-2: JavaScript Comparison Operators

Syntax	Name	Operand Types	Results
<code>==</code>	Equals	All	Boolean
<code>!=</code>	Does not equal	All	Boolean
<code>===</code>	Strictly equals	All	Boolean (IE4+, NN4+, W3C)
<code>!==</code>	Strictly does not equal	All	Boolean (IE4+, NN4+, W3C)
<code>&gt;</code>	Is greater than	All	Boolean

## Comparison Operators

<i>Syntax</i>	<i>Name</i>	<i>Operand Types</i>	<i>Results</i>
>=	Is greater than or equal to	All	Boolean
<	Is less than	All	Boolean
<=	Is less than or equal to	All	Boolean

For numeric values, the results are the same as those you'd expect from your high school algebra class. Some examples follow, including some that may not be obvious.

```
10 == 10           // true
10 == 10.0        // true
9 != 10           // true
9 > 10            // false
9.99 <= 9.98     // false
```

Strings can also be compared on all of these levels:

```
"Fred" == "Fred" // true
"Fred" == "fred" // false
"Fred" > "fred"  // false
"Fran" < "Fred"  // true
```

To calculate string comparisons, JavaScript converts each character of a string to its ASCII value. Each letter, beginning with the first of the left-hand operator, is compared to the corresponding letter in the right-hand operator. With ASCII values for uppercase letters being less than those of their lowercase counterparts, an uppercase letter evaluates to being less than its lowercase equivalent. JavaScript takes case-sensitivity very seriously.

Values for comparison can also come from object properties or values passed to functions from event handlers or other functions. A common string comparison used in data-entry validation is the one that sees if the string has anything in it:

```
form.entry.value != "" // true if something is in the field
```

## Equality of Disparate Data Types

For all versions of JavaScript before 1.2, when your script tries to compare string values consisting of numerals and real numbers (for example, "123" == 123 or "123" != 123), JavaScript anticipates that you want to compare apples to apples. Internally it does some data type conversion that does not affect the data type of the original values (for example, if the values are in variables). But the entire situation is more complex, because other data types, such as objects, need to be dealt with. Therefore, prior to JavaScript 1.2, the rules of comparison are as shown in Table 32-3.

**Table 32-3: Equality Comparisons for JavaScript 1.0 and 1.1**

<i>Operand A</i>	<i>Operand B</i>	<i>Internal Comparison Treatment</i>
Object reference	Object reference	Compare object reference evaluations
Any data type	Null	Convert nonnull to its object type and compare against null
Object reference	String	Convert object to string and compare strings
String	Number	Convert string to number and compare numbers

**Comparison Operators**

The logic to what goes on in equality comparisons from Table 32-3 requires a lot of forethought on the scripter's part, because you have to be very conscious of the particular way data types may or may not be converted for equality evaluation (even though the values themselves are not converted). In this situation, supplying the proper conversion where necessary in the comparison statement is best. This ensures that what you want to compare—for example, the string versions of two values or the number versions of two values—is compared, rather than leaving the conversion up to JavaScript.

Backward-compatible conversion from a number to string entails concatenating an empty string to a number:

```
var a = "09";
var b = 9;
a == "" + b; // result: false, because "09" does not equal "9"
```

For converting strings to numbers, you have numerous possibilities. The simplest is subtracting zero from a numeric string:

```
var a = "09";
var b = 9;
a-0 == b; // result: true because number 9 equals number 9
```

You can also use the `parseInt()` and `parseFloat()` functions to convert strings to numbers:

```
var a = "09";
var b = 9;
parseInt(a, 10) == b; // result: true because number 9 equals number 9
```

To clear up the ambiguity of JavaScript's equality internal conversions, JavaScript 1.2 uses two more operators to force the equality comparison to be extremely literal in its comparison. The strictly equals (`===`) and strictly does not equal (`!==`) operators compare both the data type and value. The only time the `===` operator returns true is if the two operands are of the same data type (for example, both are numbers) and the same value. Therefore, no number is ever automatically equal to a string version of that same number. Data and object types must match before their values are compared.

JavaScript 1.2 also provides some convenient global functions for converting strings to numbers and vice versa: `String()` and `Number()`. To demonstrate these methods, the following examples use the `typeof` operator to show the data type of expressions using these functions:

```
typeof 9; // result: number
typeof String(9); // result: string
typeof "9"; // result: string
typeof Number("9"); // result: number
```

None of these functions alters the data type of the value being converted. But the value of the function is what gets compared in an equality comparison:

```
var a = "09";
var b = 9;
a == String(b); // result: false, because "09" does not equal "9"
typeof b; // result: still a number
Number(a) == b; // result: true, because 9 equals 9
typeof a; // result: still a string
```

This discussion should impress upon you the importance of considering data types when testing the equality of two values.

## Connubial Operators

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

*Connubial operators* is my terminology for those operators that join two operands to yield a value related to the operands. Table 32-4 lists the connubial operators in JavaScript.

**Table 32-4: JavaScript Connubial Operators**

<i>Syntax</i>	<i>Name</i>	<i>Operand Types</i>	<i>Results</i>
+	Plus	Integer, float, string	Integer, float, string
-	Minus	Integer, float	Integer, float
*	Multiply	Integer, float	Integer, float
/	Divide	Integer, float	Integer, float
%	Modulo	Integer, float	Integer, float
++	Increment	Integer, float	Integer, float
--	Decrement	Integer, float	Integer, float
+val	Positive	Integer, float, string	Integer, float
-val	Negation	Integer, float, string	Integer, float

The four basic arithmetic operators for numbers are straightforward. The plus operator also works on strings to join them together, as in

```
"Howdy " + "Doody" // result = "Howdy Doody"
```

In object-oriented programming terminology, the plus sign is considered *overloaded*, meaning that it performs a different action depending on its context. Remember, too, that string concatenation does not do anything on its own to monitor or insert spaces between words. In the preceding example, the space between the names is part of the first string.

Modulo arithmetic is helpful for those times when you want to know if one number divides evenly into another. You used it in an example in Chapter 31 to figure out if a particular year was a leap year. Although some other leap year considerations exist for the turn of each century, the math in the example simply checked whether the year was evenly divisible by four. The result of the modulo math is the remainder of division of the two values: When the remainder is 0, one divides evenly into the other. Here are some samples of years evenly divisible by four:

```
2002 % 4 // result = 2
2003 % 4 // result = 3
2004 % 4 // result = 0 (Bingo! Leap year!)
```

Thus, I used this modulo operator in a condition statement of an `if . . . else` structure:

```
var howMany = 0;
today = new Date();
var theYear = today.getYear();
if (theYear % 4 == 0) {
    howMany = 29;
} else {
    howMany = 28;
}
```

### Connubial Operators

Some other languages offer an operator that results in the integer part of a division problem solution: integral division, or `div`. Although JavaScript does not have an explicit operator for this behavior, you can re-create it reliably if you know that your operands are always positive numbers. Use the `Math.floor()` or `Math.ceil()` methods with the division operator, as in

```
Math.floor(4/3);    // result = 1
```

In this example, `Math.floor()` works only with values greater than or equal to 0; `Math.ceil()` works with values less than 0.

The increment operator (`++`) is a *unary* operator (only one operand) and displays two different behaviors, depending on the side of the operand on which the symbols lie. Both the increment and decrement (`--`) operators can be used in conjunction with assignment operators, which I cover next.

As its name implies, the increment operator increases the value of its operand by one. But in an assignment statement, you have to pay close attention to precisely when that increase takes place. An assignment statement stuffs the value of the right operand into a variable on the left. If the `++` operator is located in front of the right operand (prefix), the right operand is incremented before the value is assigned to the variable; if the `++` operator is located after the right operand (postfix), the previous value of the operand is sent to the variable before the value is incremented. Follow this sequence to get a feel for these two behaviors:

```
var a = 10;    // initialize a to 10
var z = 0;     // initialize z to zero
z = a;        // a = 10, so z = 10
z = ++a;      // a becomes 11 before assignment, so a = 11 and z becomes 11
z = a++;     // a is still 11 before assignment, so z = 11; then a becomes 12
z = a++;     // a is still 12 before assignment, so z = 12; then a becomes 13
```

The decrement operator behaves the same way, except that the value of the operand decreases by one. Increment and decrement operators are used most often with loop counters in `for` and `while` loops. The simpler `++` or `--` symbology is more compact than reassigning a value by adding 1 to it (such as, `z = z + 1` or `z += 1`). Because these are unary operators, you can use the increment and decrement operators without an assignment statement to adjust the value of a counting variable within a loop:

```
function doNothing() {
    var i = 1;
    while (i < 20) {
        ++i;
    }
    alert(i); // breaks out at i = 20
}
```

The last pair of connubial operators are also unary operators (operating on one operand). Both the positive and negation operators can be used as shortcuts to the `Number()` global function, converting a string operand consisting of number characters to a number data type. The string operand is not changed, but the operation returns a value of the number type, as shown in the following sequence:

```
var a = "123";
var b = +a;    // b is now 123
typeof a;     // result: string
typeof b;     // result: number
```

The negation operator (`-val`) has additional power. By placing a minus sign in front of any numeric value (no space between the symbol and the value), you instruct JavaScript to evaluate a positive value as its corresponding negative value, and vice versa. The operator does

not change the operand's value, but the expression returns the modified value. The following example provides a sequence of statements to demonstrate:

```
var x = 2;
var y = 8;
var z = -x;           // z equals -2, but x still equals 2
z = -(x + y);       // z equals -10, but x still equals 2 and y equals 8
z = -x + y;         // z equals 6, but x still equals 2 and y equals 8
```

To negate a Boolean value, see the Not (!) operator in the discussion of Boolean operators.

## Assignment Operators

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Assignment statements are among the most common statements you write in your JavaScript scripts. These statements appear everywhere you copy a value or the results of an expression into a variable for further manipulation of that value.

You assign values to variables for many reasons, even though you could probably use the original values or expressions several times throughout a script. Here is a sampling of reasons why you should assign values to variables:

- ♦ Variable names are usually shorter
- ♦ Variable names can be more descriptive
- ♦ You may need to preserve the original value for later in the script
- ♦ The original value is a property that cannot be changed
- ♦ Invoking the same method several times in a script is not efficient

Newcomers to scripting often overlook the last reason. For instance, if a script is writing HTML to a new document, it's more efficient to assemble the string of large chunks of the page into one variable before invoking the `document.write()` method to send that text to the document. This approach is more efficient than literally sending out one line of HTML at a time with multiple `document.writeln()` method statements. Table 32-5 shows the range of assignment operators in JavaScript.

**Table 32-5: JavaScript Assignment Operators**

<i>Syntax</i>	<i>Name</i>	<i>Example</i>	<i>Means</i>
=	Equals	x = y	x = y
+=	Add by value	x += y	x = x + y
-=	Subtract by value	x -= y	x = x - y
*=	Multiply by value	x *= y	x = x * y
/=	Divide by value	x /= y	x = x / y
%=	Modulo by value	x %= y	x = x % y
<<=	Left shift by value	x <<= y	x = x << y
>=	Right shift by value	x >= y	x = x > y
>>=	Zero fill by value	x >>= y	x = x >> y

*Continued*

## Assignment Operators

Table 32-5 (continued)

Syntax	Name	Example	Means
>>>=	Right shift by value	x >>>= y	x = x >>> y
&=	Bitwise and by value	x &= y	x = x & y
=	Bitwise or by value	x  = y	x = x   y
^=	Bitwise XOR by value	x ^= y	x = x ^ y

As clearly demonstrated in the top group (see “Bitwise Operators” later in the chapter for information on the bottom group), assignment operators beyond the simple equals sign can save some characters in your typing, especially when you have a series of values that you’re trying to bring together in subsequent statements. You’ve seen plenty of examples in previous chapters, where you used the add-by-value operator (+=) to work wonders with strings as you assemble a long string variable that you eventually send to a `document.write()` method. Look at this variation of a segment of Listing 30-3, where you could use JavaScript to create the HTML content of a select element on-the-fly:

```
var elem = ""; // start assembling next part of page and form
elem += "<p>Select a regional office: ";
elem += "<select name='offices' onchange='getData(this.form)'\>";
// build options list from array office names
for (var i = 0; i < regionalOffices.length; i++) {
    elem += "option"; // option tags
    if (i == 0) { // pre-select first item in list
        elem += " selected='selected'";
    }
    elem += ">" + regionalOffices[i];
}
elem += "</select></p>"; // close select item tag
document.write(elem); // write element to the page
```

The script segment starts with a plain equals assignment operator to initialize the `elem` variable as an empty string. In many of the succeeding lines, you use the add-by-value operator to tack additional string values onto whatever is in the `elem` variable at the time. Without the add-by-value operator, you are forced to use the plain equals assignment operator for each line of code to concatenate new string data to the existing string data. In that case, the first few lines of code look as shown:

```
var elem = ""; // start assembling next part of page and form
elem = elem + "<p>Select a regional office: ";
elem = elem + "<select name='offices' onchange='getData(this.form)'\>";
```

Within the `for` loop, the repetition of `elem +` makes the code very difficult to read, trace, and maintain. These enhanced assignment operators are excellent shortcuts that you should use at every turn.

## Boolean Operators

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

Because a great deal of programming involves logic, it is no accident that the arithmetic of the logic world plays an important role. You’ve already seen dozens of instances where programs make all kinds of decisions based on whether a statement or expression is the Boolean

value `true` or `false`. What you haven't seen much of yet is how to combine multiple Boolean values and expressions — a quality that scripts with slightly above average complexity may need to have in them.

In the various condition expressions required throughout JavaScript (such as in an `if` construction), the condition that the program must test for may be more complicated than, say, whether a variable value is greater than a certain fixed value or whether a field is not empty. Look at the case of validating a text field entry for whether the entry contains all the numbers that your script may want. Without some magical JavaScript function to tell you whether or not a string consists of all numbers, you have to break apart the entry character by character and examine whether each character falls within the range of 0 through 9. But that examination actually comprises two tests: You can test for any character whose ASCII value is less than 0 or greater than 9. Alternatively, you can test whether the character is greater than or equal to 0 and is less than or equal to 9. What you need is the bottom-line evaluation of both tests.

## Boolean math

That's where the wonder of Boolean math comes into play. With just two values — `true` and `false` — you can assemble a string of expressions that yield Boolean results and then let Boolean arithmetic figure out whether the bottom line is `true` or `false`.

But you don't add or subtract Boolean values the same way you add or subtract numbers. Instead, you use one of three JavaScript Boolean operators at your disposal. Table 32-6 shows the three operator symbols. In case you're unfamiliar with the characters in the table, the symbols for the Or operator are created by typing Shift-backslash.

**Table 32-6: JavaScript Boolean Operators**

<i>Syntax</i>	<i>Name</i>	<i>Operands</i>	<i>Results</i>
<code>&amp;&amp;</code>	And	Boolean	Boolean
<code>  </code>	Or	Boolean	Boolean
<code>!</code>	Not	One Boolean	Boolean

Using Boolean operators with Boolean operands gets tricky if you're not used to it, so I have you start with the simplest Boolean operator: Not. This operator requires only one operand. The Not operator precedes any Boolean value to switch it back to the opposite value (from `true` to `false`, or from `false` to `true`). For instance:

```
!true           // result = false
!(10 > 5)       // result = false
!(10 < 5)       // result = true
!(document.title == "Flintstones") // result = true
```

As shown here, enclosing the operand of a Not expression inside parentheses is always a good idea. This forces JavaScript to evaluate the expression inside the parentheses before flipping it around with the Not operator.

The And (`&&`) operator joins two Boolean values to reach a `true` or `false` value based on the results of both values. This brings up something called a *truth table*, which helps you visualize all the possible outcomes for each value of an operand. Table 32-7 is a truth table for the And operator.

**Boolean Operators****Table 32-7: Truth Table for the And Operator**

<i>Left Operand</i>	<i>And Operator</i>	<i>Right Operand</i>	<i>Result</i>
True	&&	True	True
True	&&	False	False
False	&&	True	False
False	&&	False	False

Only one condition yields a true result: Both operands must evaluate to true. Which side of the operator a true or false value lives doesn't matter. Here are examples of each possibility:

```
5 > 1 && 50 > 10    // result = true
5 > 1 && 50 < 10    // result = false
5 < 1 && 50 > 10    // result = false
5 < 1 && 50 < 10    // result = false
```

In contrast, the Or (||) operator is more lenient about what it evaluates to true. The reason is that if one or the other (or both) operands is true, the operation returns true. The Or operator's truth table is shown in Table 32-8.

**Table 32-8: Truth Table for the Or Operator**

<i>Left Operand</i>	<i>Or Operator</i>	<i>Right Operand</i>	<i>Result</i>
True		True	True
True		False	True
False		True	True
False		False	False

Therefore, if a true value exists on either side of the operator, a true value is the result. Take the previous examples and swap the And operators with Or operators so that you can see the Or operator's impact on the results:

```
5 > 1 || 50 > 10    // result = true
5 > 1 || 50 < 10    // result = true
5 < 1 || 50 > 10    // result = true
5 < 1 || 50 < 10    // result = false
```

Only when both operands are false does the Or operator return false.

**Boolean operators at work**

Applying Boolean operators to JavaScript the first time just takes a little time and some sketches on a pad of paper to help you figure out the logic of the expressions. Earlier I talked about using a Boolean operator to see whether a character fell within a range of ASCII values for data-entry validation. Listing 32-1 is a function discussed in more depth in Chapter 43 on the CD-ROM. This function accepts any string and sees whether each character of the string has an ASCII value less than 0 or greater than 9—meaning that the input string is not a number.

**Listing 32-1: Is the Input String a Number?**

```
function isNumber(inputStr) {
  for (var i = 0; i < inputStr.length; i++) {
    var oneChar = inputStr.substring(i, i + 1);
    if (oneChar < "0" || oneChar > "9") {
      alert("Please make sure entries are numerals only.");
      return false;
    }
  }
  return true;
}
```

Combining a number of JavaScript powers to read individual characters (substrings) from a string object within a `for` loop, the statement that you're interested in is the condition of the `if` construction:

```
(oneChar < "0" || oneChar > "9")
```

In one condition statement, you use the Or operator to test for both possibilities. If you check the Or truth table (Table 32-8), you see that this expression returns `true` if either one or both tests returns `true`. If that happens, the rest of the function alerts the user about the problem and returns a `false` value to the calling statement. Only if both tests within this condition evaluate to `false` for all characters of the string does the function return a `true` value.

From the simple Or operator, I go to the extreme, where the function checks—in one condition statement—whether a number falls within several numeric ranges. The script in Listing 32-2 comes from the array lookup application in Chapter 50 (on the CD-ROM), in which a user enters the first three digits of a U.S. Social Security number.

**Listing 32-2: Is a Number within Discontiguous Ranges?**

```
// function to determine if value is in acceptable range for this application
function inRange(inputStr) {
  num = parseInt(inputStr)
  if (num < 1 || (num > 586 && num < 596) || (num > 599 && num < 700) ||
      num > 728) {
    alert("Sorry, the number you entered is not part of our database. Try
          another three-digit number.");
    return false;
  }
  return true;
}
```

By the time this function is called, the user's data entry has been validated enough for JavaScript to know that the entry is a number. Now the function must check whether the number falls outside of the various ranges for which the application contains matching data. The conditions that the function tests here are whether the number is

- ♦ Less than 1
- ♦ Greater than 586 and less than 596 (using the And operator)

**Boolean Operators**

- ♦ Greater than 599 and less than 700 (using the And operator)
- ♦ Greater than 728

Each of these tests is joined by an Or operator. Therefore, if any one of these conditions proves true, the whole `if` condition is true, and the user is alerted accordingly.

The alternative to combining so many Boolean expressions in one `condition` statement would be to nest a series of `if` constructions. But such a construction requires not only a great deal more code but also much repetition of the alert dialog box message for each condition that could possibly fail. The combined Boolean condition is, by far, the best way to go.

## Bitwise Operators

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

For scripters, bitwise operations are an advanced subject. Unless you're dealing with external processes on CGIs or the connection to Java applets, it's unlikely that you will use bitwise operators. Experienced programmers who concern themselves with more specific data types (such as long integers) are quite comfortable in this arena, so I simply provide an explanation of JavaScript capabilities. Table 32-9 lists JavaScript bitwise operators.

**Table 32-9: JavaScript's Bitwise Operators**

<i>Operator</i>	<i>Name</i>	<i>Left Operand</i>	<i>Right Operand</i>
&	Bitwise And	Integer value	Integer value
	Bitwise Or	Integer value	Integer value
^	Bitwise XOR	Integer value	Integer value
~	Bitwise Not	(None)	Integer value
<<	Left shift	Integer value	Shift amount
>>	Right shift	Integer value	Shift amount
>>>	Zero fill right shift	Integer value	Shift amount

The numeric value operands can appear in any of the JavaScript language's three numeric literal bases (decimal, octal, or hexadecimal). As soon as the operator has an operand, the value is converted to binary representation (32 bits long). For the first three bitwise operations, the individual bits of one operand are compared with their counterparts in the other operand. The resulting value for each bit depends on the operator:

- ♦ **Bitwise And:** 1 if both digits are 1
- ♦ **Bitwise Or:** 1 if either digit is 1
- ♦ **Bitwise Exclusive Or:** 1 if only one digit is a 1

Bitwise Not, a unary operator, inverts the value of every bit in the single operand. The bitwise shift operators operate on a single operand. The second operand specifies the number of positions to shift the value's binary digits in the direction of the arrows of the operator symbols.

### Example

For example, the left shift (<<) operator has the following effect:

**delete**

```
4 << 2 // result = 16
```

The reason for this shifting is that the binary representation for decimal 4 is 00000100 (to eight digits, anyway). The left shift operator instructs JavaScript to shift all digits two places to the left, giving the binary result 00010000, which converts to 16 in decimal format. If you're interested in experimenting with these operators, use The Evaluator (Chapter 13) to evaluate sample expressions for yourself. More advanced books on C and C++ programming are also of help.

## Object Operators

The next group of operators concern themselves with objects (including native JavaScript, DOM, and custom objects) and data types. Most of these have been implemented after the earliest JavaScript browsers, so each one has its own compatibility rating.

### delete

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

Array objects do not contain a method to remove an element from the collection, nor do custom objects offer a method to remove a property. You can always empty the data in an array item or property by setting its value to an empty string or `null`, but the array element or property remains in the object. With the `delete` operator, you can completely remove the element or property.

There is special behavior about deleting an array item that you should bear in mind. If your array uses numeric indices, a deletion of a given index removes that index value from the total array but without collapsing the array (which would alter index values of items higher than the deleted item).

### Example

For example, consider the following simple dense array:

```
var oceans = new Array("Atlantic", "Pacific", "Indian", "Arctic");
```

This kind of array automatically assigns numeric indices to its entries for addressing later in constructions, such as `for` loops:

```
for (var i = 0; i < oceans.length; i++) {  
    if (oceans[i] == form.destination.value) {  
        statements  
    }  
}
```

If you then issue the statement

```
delete oceans[2];
```

the array undergoes significant changes. First, the third element is removed from the array. Note that the length of the array does not change. Even so, the index value (2) is removed from the array, such that schematically the array looks like the following:

```
oceans[0] = "Atlantic";  
oceans[1] = "Pacific";  
oceans[3] = "Arctic";
```

If you try to reference `oceans[2]` in this collection, the result is `undefined`.

**delete**

The `delete` operator works best on arrays that have named indices. Your scripts will have more control over the remaining entries and their values, because they don't rely on what could be a missing entry of a numeric index sequence.

One aspect of this deletion action that JavaScript doesn't provide is absolute control over memory utilization. All garbage collection is managed by the JavaScript interpreter engine, which tries to recognize when items occupying memory are no longer needed, at which time the unused browser's application memory may be recovered. But you cannot force the browser to perform its garbage collection task.

**in**

**Compatibility:** WinIE5.5+, MacIE-, NN6+, Moz1+, Safari1+

The `in` operator lets a script statement inspect an object to see if it has a named property or method. The operand to the left of the operator is a string reference to the property or method (just the method name, without parentheses); the operand to the right of the operator is the object being inspected. If the object knows the property or method, the expression returns `true`. Thus, you can use the `in` operator in expressions used for conditional expressions.

**Example**

You can experiment with this operator in The Evaluator (Chapter 13). For example, to prove that the `write()` method is implemented for the `document` object, the expression you type into the top text box of The Evaluator is:

```
"write" in document
```

But compare the implementation of the W3C DOM `document.defaultView` property in IE5.5+ and modern W3C browsers:

```
"defaultView" in document
```

In NN6+, Mozilla, and Safari, the result is `true`, while in IE5.5 and IE6, the result is `false`.

Having this operator around for conditional expressions lets you go much beyond simple object detection for branching code. For example, if you intend to use `document.defaultView` in your script, you can make sure that the property is supported before referencing it (assuming your users all have browsers that know the `in` operator).

**instanceof**

**Compatibility:** WinIE5+, MacIE-, NN6+, Moz1+, Safari1+

The `instanceof` operator lets a script test whether an object is an instance of a particular JavaScript native object or DOM object. The operand to the left side of the operator is the value under test; the value to the right of the operand is a reference to the root class from which the value is suspected of being constructed.

For native JavaScript classes, the kinds of object references to the right of the operator include such static objects as `Date`, `String`, `Number`, `Boolean`, `Object`, `Array`, and `RegExp`. You sometimes need to be mindful of how native JavaScript classes can sometimes be children of other native classes, which means that a value may be an instance of two different static objects.

**Example**

For example, consider the following sequence (which you can follow along in The Evaluator):

**this**

```
a = new Array(1,2,3);
a instanceof Array;
```

The second statement yields a result of `true`, because the `Array` constructor was used to generate the object. But the JavaScript `Array` is, itself, an instance of the root `Object` object. Therefore both of the following statements evaluate to `true`:

```
a instanceof Object;
Array instanceof Object;
```

**new**

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Most JavaScript core objects have constructor functions built into the language. To access those functions, you use the `new` operator along with the name of the constructor. The function returns a reference to the object instance, which your scripts can then use to get and set properties or invoke object methods. For example, creating a new date object requires invoking the `Date` object's constructor, as follows:

```
var today = new Date();
```

Some object constructor functions require parameters to help define the object. Others, as in the case of the `Date` object, can accept a number of different parameter formats, depending on the format of date information you have to set the initial object. The `new` operator can be used with the following core language objects:

<i>JavaScript 1.0</i>	<i>JavaScript 1.1</i>	<i>JavaScript 1.2</i>	<i>JavaScript 1.5</i>
Date	Array	RegExp	Error
Object	Boolean		
(Custom object)	Function		
	Image		
	Number		
	String		

**this**

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

JavaScript includes an operator that allows script statements to refer to the very object in which they are located. The self-referential operator is `this`.

The most common application of the `this` operator is in event handlers that pass references of themselves to functions for further processing, as in

```
<input type="text" name="entry" onchange="process(this)" />
```

A function receiving the value assigns it to a variable that can be used to reference the sender, its properties, and its methods.

**Example**

Because the `this` operator references an object, that object's properties can be exposed with the aid of the operator. For example, to send the `value` property of a text input object to a

**this**

function, the `this` operator stands in for the current object reference and appends the proper syntax to reference the `value` property:

```
<input type="text" name="entry" onchange="process(this.value)" />
```

The `this` operator also works inside other objects, such as custom objects. When you define a constructor function for a custom object, using the `this` operator to define properties of the object and assign values to those properties is common practice. Consider the following example of an object creation sequence:

```
function bottledWater(brand, ozSize, flavor) {
    this.brand = brand;
    this.ozSize = ozSize;
    this.flavor = flavor;
}
var myWater = new bottledWater("Crystal Springs", 16, "original");
```

When the new object is created via the constructor function, the `this` operators define each property of the object and then assign the corresponding incoming value to that property. Using the same names for the properties and parameter variables is perfectly fine and makes the constructor easy to maintain.

By extension, if you assign a function as an object's property (to behave as a method for the object), the `this` operator inside that function refers to the object invoking the function, offering an avenue to the object's properties. For example, if I add the following function definition and statement to the `myWater` object created just above, the function can directly access the `brand` property of the object:

```
function adSlogan() {
    return "Drink " + this.brand + ", it's wet and wild!";
}
myWater.getSlogan = adSlogan;
```

When a statement invokes the `myWater.getSlogan()` method, the object invokes the `adSlogan()` function, but all within the context of the `myWater` object. Thus, the `this` operator applies to the surrounding object, making the `brand` property available via the `this` operator (`this.brand`).

## Miscellaneous Operators

The final group of operators doesn't fit into any of the previous categories, but they are no less important.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The comma operator indicates a series of expressions that are to be evaluated in left-to-right sequence. Most typically, this operator is used to permit multiple variable initializations. For example, you can combine the declaration of several variables in a single `var` statement, as follows:

```
var name, address, serialNumber;
```

Another situation where you could use this operator is within the expressions of a `for` loop construction. In the following example, two different counting variables are initialized and incremented at different rates. When the loop begins, both variables are initialized at zero

**typeof**

(they don't have to be, but this example starts that way); for each subsequent trip through the loop, one variable is incremented by one, while the other is incremented by 10:

```
for (var i=0, j=0; i < someLength; i++, j+10) {
    ...
}
```

Don't confuse the comma operator with the semicolon delimiter between statements.

? :

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

The conditional operator is a shortcut way of expressing an `if . . . else` conditional construction covered in Chapter 31. This operator is typically used in concert with an assignment operator to assign one of two values to a variable based on the result of a condition expression. The formal syntax for the conditional operator is:

```
condition ? expressionIfTrue : expressionIfFalse
```

If used with an assignment operator, the syntax is:

```
var = condition ? expressionIfTrue : expressionIfFalse;
```

No matter how you use the operator, the important point to remember is that an expression that contains this operator evaluates to one of the two expressions following the question mark symbol. In truth, either expression could invoke any JavaScript, including calling other functions or even nesting further conditional operators within one of the expressions to achieve the equivalent of nested `if . . . else` constructions. To assure proper resolution of nested conditionals, surround inner expressions with parentheses to make sure that they evaluate before the outer expression evaluates. As an example, the following statement assigns one of three strings to a variable depending on the date within a month:

```
var monthPart = (dateNum <= 10) ? "early" : ((dateNum <= 20) ?
    "middle" : "late");
```

When the statement is evaluated, the inner conditional expression at the right of the first colon is evaluated, returning either `middle` or `late`; then the outer conditional expression is evaluated, returning either `early` or the result of the inner conditional expression.

## typeof

**Compatibility:** WinIE3+, MacIE3+, NN3+, Moz1+, Safari1+

Unlike most other operators, which are predominantly concerned with arithmetic and logic, the unary `typeof` operator defines the kind of value to which a variable or expression evaluates. Typically, this operator is used to identify whether a variable value is one of the following types: `number`, `string`, `boolean`, `object`, `function`, or `undefined`.

### Example

Having this investigative capability in JavaScript is helpful because variables cannot only contain any one of those data types but can change their data type on the fly. Your scripts may need to handle a value differently based on the value's type. The most common use of the `typeof` property is as part of a condition. For example:

```
if (typeof myVal == "number") {
    myVal = parseInt(myVal);
}
```

**typeof**

The evaluated value of the `typeof` operation is, itself, a string.

**void**

**Compatibility:** WinIE3+, MacIE3+, NN3+, Moz1+, Safari1+

In all scriptable browsers you can use the `javascript:` pseudo-protocol to supply the parameter for `href` and `src` attributes in HTML tags, such as links. In the process, you have to be careful that the function or statement being invoked by the URL does not return or evaluate to any values. If a value comes back from such an expression, then that value or sometimes the directory of the client's hard disk often replaces the page content. To avoid this possibility, use the `void` operator in front of the function or expression being invoked by the `javascript:` URL.

**Example**

The best way to use this construction is to place the operator before the expression or function and separate them by a space, as in

```
javascript: void doSomething();
```

On occasion, you may have to wrap the expression inside parentheses after the `void` operator. Using parentheses is necessary only when the expression contains operators of a lower precedence than the `void` operator (see the following section, "Operator Precedence"). But don't automatically wrap all expressions in parentheses, because some browsers can experience problems with these. Even so, it is common practice to assign the following URL to the `href` attribute of an a link whose `onclick` event handler does all of the work:

```
href="javascript: void (0)"
```

The `void` operator makes sure the function or expression returns no value that the HTML attribute can use. Such a link's `onclick` event handler should also inhibit the natural behavior of a clicked link (for example, by evaluating to return `false`).

## Operator Precedence

When you start working with complex expressions that hold a number of operators (for example, Listing 32-2), knowing the order in which JavaScript evaluates those expressions is vital. JavaScript assigns different priorities or weights to types of operators in an effort to achieve uniformity in the way it evaluates complex expressions.

In the following expression

```
10 + 4 * 5 // result = 30
```

JavaScript uses its precedence scheme to perform the multiplication before the addition—regardless of where the operators appear in the statement. In other words, JavaScript first multiplies 4 by 5 and then adds that result to 10 to get a result of 30. That may not be the way you want this expression to evaluate. Perhaps your intention was to add the 10 and 4 first and then to multiply that sum by 5. To make that happen, you have to override JavaScript's natural operator precedence. To do that, you must use parentheses to enclose an operator with lower precedence. The following statement shows how you adjust the previous expression to make it behave differently:

```
(10 + 4) * 5 // result = 70
```

That one set of parentheses has a great impact on the outcome. Parentheses have the highest precedence in JavaScript, and if you nest parentheses in an expression, the innermost set evaluates first.

For help in constructing complex expressions, refer to Table 32-10 for JavaScript's operator precedence. My general practice: When in doubt about complex precedence issues, I build the expression with lots of parentheses according to the way I want the internal expressions to evaluate.

**Table 32-10: JavaScript Operator Precedence**

<i>Precedence Level</i>	<i>Operator</i>	<i>Notes</i>
1	()	From innermost to outermost
	[]	Array index value
2	function()	Any remote function call
	!	Boolean Not
	~	Bitwise Not
	-	Negation
	++	Increment
	--	Decrement
	new	
	typeof	
	void	
	delete	Delete array or object entry
3	*	Multiplication
	/	Division
	%	Modulo
4	+	Addition
	-	Subtraction
5	<<	Bitwise shifts
	>	
	>>	
6	<	Comparison operators
	<=	
	>	
	>=	
7	==	Equality
	!=	
8	&	Bitwise And
9	^	Bitwise XOR
10		Bitwise Or
11	&&	Boolean And
12		Boolean Or
13	?	Conditional expression

*Continued*

**Table 32-10** (continued)

<i>Precedence Level</i>	<i>Operator</i>	<i>Notes</i>
14	= += -= *= /= %= <<= >= >>= &= ^=  =	Assignment operators
15	,	Comma (parameter delimiter)

This precedence scheme is devised to help you avoid being faced with two operators from the same precedence level that often appear in the same expression. When it happens (such as with addition and subtraction), JavaScript begins evaluating the expression from left to right.

One related fact involves a string of Boolean expressions strung together for a condition statement (see Listing 32-2). JavaScript follows what is called *short-circuit evaluation*. As the nested expressions are evaluated left to right, the fate of the entire condition can sometimes be determined before all expressions are evaluated. Anytime JavaScript encounters an And operator, if the left operand evaluates to `false`, the entire expression evaluates to `false` without JavaScript's even bothering to evaluate the right operand. For an Or operator, if the left operand is `true`, JavaScript short-circuits that expression to `true`. This feature can trip you up if you don't perform enough testing on your scripts: If a syntax error or other error exists in a right operand, and you fail to test the expression in a way that forces that right operand to evaluate, you may not know that a bug exists in your code. Users of your page, of course, will find the bug quickly. Do your testing to head bugs off at the pass.

**Note**

Notice, too, that all math and string concatenation is performed prior to any comparison operators. This enables all expressions that act as operands for comparisons to evaluate fully before they are compared.

The key to working with complex expressions is to isolate individual expressions and to try them out by themselves, if you can. See additional debugging tips in Chapter 45 on the CD-ROM.

# Functions and Custom Objects

---

**B**y now, you've seen dozens of JavaScript functions in action and probably have a pretty good feel for the way they work. This chapter provides the `function` object specification and delves into the fun prospect of creating objects in your JavaScript code. (That includes objects that have properties and methods, just like the big boys.)

## Function Object

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>arguments</code>	<code>apply()</code>	
<code>arity</code>	<code>call()</code>	
<code>caller</code>	<code>toString()</code>	
<code>constructor</code>	<code>valueOf()</code>	
<code>length</code>		
<code>prototype</code>		

## Syntax

Creating a function object:

```
function functionName([arg1,...[,argN]]) {  
    statement(s)  
}  
var funcName = new Function(["argName1",...[, "argNameN"],  
    "statement1;...[,statementN]");  
object.eventHandlerName = function([arg1,...[,argN]])  
    {statement(s)}
```

Accessing function object properties and methods:

```
functionObject.property | method([parameters])
```

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

### In This Chapter

Creating function blocks

Passing parameters to functions

Creating your own objects

*functionObject*

## About this object

JavaScript accommodates what other languages might call procedures, subroutines, and functions all in one type of structure: the *custom function*. A function may return a value (if programmed to do so with the `return` keyword), but it does not have to return any value. Except for JavaScript code that executes as the document loads, all deferred processing takes place in functions.

While you can create functions that are hundreds of lines long, I recommend you break up longer processes into shorter functions. Among the reasons for doing so: smaller chunks are easier to write and debug; building blocks make it easier to visualize the entire script; you can make functions generalizable and reusable for other scripts; and other parts of the script or other open frames can use the functions.

Learning how to write good, reusable functions takes time and experience. But the earlier you understand the importance of this concept, the more you will be on the lookout for good examples in other people's scripts on the Web.

## Creating functions

The standard way of defining a function in your script means following a simple pattern and then filling in the details. The formal syntax definition for a function is:

```
function functionName( [arg1] ... [, argN] ) {  
    statement(s)  
}
```

The task of assigning a function name helps you determine the precise scope of activity of the function. If you find that you can't reduce the planned task for the function to a simple one- to three-word name (which is then condensed into one contiguous sequence of characters for the *functionName*), perhaps you're asking the function to do too much. A better idea may be to break the job into two or more functions. As you start to design a function, be on the lookout for functions that you can call from the one you're writing. If you find yourself copying and pasting lines of code from one part of a function to another because you're performing the same operation in different spots within the function, it may be time to break that segment out into its own function.

You can also create what is called an *anonymous function* using the new `Function()` constructor. In reality, you assign a name to this "anonymous" function as follows:

```
var funcName = new Function(["argName1",...[, "argNameN"],  
    "statement1;...[,statementN]");
```

This other way of building a function is particularly helpful when your scripts need to create a function after a document loads. All the components of a function are present in this definition. Each function parameter name is supplied as a string value, separated from each other by commas. The final parameter string consists of the statements that execute whenever the function is called. Separate each JavaScript statement with a semicolon, and enclose the entire sequence of statements inside quotes, as in the following:

```
var willItFit = new Function("width","height",  
    "var sx = screen.availWidth; var sy = screen.availHeight;  
    return (sx >= width && sy >= height)");
```

The `willItFit()` function takes two parameters; the body of the function defines two local variables (`sx` and `sy`) and then returns a Boolean value of `true` if the incoming parameters are smaller than the local variables. In traditional form, this function is defined as follows:

```
function willItFit(width, height) {
    var sx = screen.availWidth;
    var sy = screen.availHeight;
    return (sx >= width && sy >= height);
}
```

Once this function exists in the browser's memory, you can invoke it like any other function:

```
if (willItFit(400,500)) {
    statements to load image
}
```

One last function creation format is available in NN4+, IE4+, and W3C DOM browsers. This advanced technique, called a *lambda expression*, provides a shortcut for creating a reference to an anonymous function (truly anonymous because the function has no name that you can reference later). The common application of this technique is to assign function references to event handlers when the NN event object also must be passed. The following is an example of how to assign an anonymous function to an `onchange` event handler for a form control:

```
document.forms[0].age.onchange = function(event)
{isNumber(document.forms[0].age)}
```

## Nesting functions

NN4+, IE4+, and W3C browsers also provide for nesting functions inside one another. In all prior scripting, each function definition is defined at the global level whereby every function is exposed and available to all other scripting. With nested functions, you can encapsulate the exposure of a function inside another and make that nested function private to the enclosing function. Of course I don't recommend reusing names in this fashion, but you can create nested functions with the same name inside multiple global level functions, as the following skeletal structure shows:

```
function outerA() {
    statements
    function innerA() {
        statements
    }
    statements
}
function outerB() {
    statements
    function innerA() {
        statements
    }
    function innerB() {
        statements
    }
    statements
}
```

A good time to apply a nested function is when a sequence of statements need to be invoked in multiple places within a large function but those statements have meaning only within the context of the larger function. In other words, rather than break out the repeated sequence as a separate global function, you keep it all within the scope of the larger function.

You can access a nested function only from statements in its containing function (and in any order). Moreover, all variables defined in the outer function (including parameter variables) are accessible to the inner function; but variables defined in an inner function are not accessible to

**functionObject**

the outer function. See the section, “Variable scope: Globals and locals” later in this chapter for details on how variables are visible to various components of a script.

## Function parameters

The function definition requires a set of parentheses after the *functionName*. If the function does not rely on any information arriving with it when invoked, the parentheses can be empty. But when some kind of data is arriving with a call to the function, you need to assign names to each parameter. Virtually any kind of value can be a parameter: strings, numbers, Booleans, and even complete object references such as a form or form element. Choose names for these variables that help you remember the content of those values; also, avoid reusing existing object names as variable names because it’s easy to get confused when objects and variables with the same name appear in the same statements. You must avoid using JavaScript keywords (including the reserved words listed in Appendix B) and any global variable name defined elsewhere in your script. (See more about global variables in the following sections.)

JavaScript is forgiving about matching the number of parameters in the function definition with the number of parameters passed along from the calling statement. If you define a function with three parameters and the calling statement specifies only two, the third parameter variable value in that function is assigned a `null` value. For example:

```
function oneFunction(a, b, c) {  
    statements  
}  
oneFunction("George", "Gracie");
```

In the preceding example, the values of `a` and `b` inside the function are “George” and “Gracie”, respectively; the value of `c` is `null`.

At the opposite end of the spectrum, JavaScript also doesn’t balk if you send more parameters from the calling statement than the number of parameter variables specified in the function definition. In fact, the language includes a mechanism—the `arguments` property—that you can add to your function to gather any extraneous parameters that should read your function.

## Properties

### arguments

**Value:** Array of arguments.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

When a function receives parameter values from the statement that invokes the function, those parameter values are silently assigned to the `arguments` property of the function object. This property is an array of the values, with each parameter value assigned to a zero-based index entry in the array—whether or not parameters are defined for it. You can find out how many parameters are sent by extracting `functionName.arguments.length`. For example, if four parameters are passed, `functionName.arguments.length` returns 4. Then, you can use array notation (`functionName.arguments[i]`) to extract the values of any parameter(s) you want.

Theoretically, you never have to define parameter variables for your functions by extracting the desired arguments array entry instead. Well-chosen parameter variable names, however, are much more readable, so I recommend them over the `arguments` property in most cases. But you may run into situations in which a single function definition needs to handle multiple calls to the function when each call may have a different number of parameters. The function knows how to handle any arguments over and above the ones given names as parameter variables.

## Example

See Listings 33-1 and 33-2 for a demonstration of both the `arguments` and `caller` properties.

### arity

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

See the discussion of the `length` property later in this chapter.

### caller

**Value:** Function object reference.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari-

When one function invokes another, a chain is established between the two primarily so that a returned value knows where to go. Therefore, a function invoked by another maintains a reference to the function that called it. Such information is automatically stored in a function object as the `caller` property. This relationship reminds me a bit of a subwindow's `opener` property, which points to the window or frame responsible for the subwindow's creation. The value is valid only while the called function is running at the request of another function; when a function isn't running, its `caller` property is `null`.

The value of the `caller` property is a reference to a function object, so you can inspect its `arguments` and `caller` properties (in case it was called by yet another function). Thus, a function can look back at a calling function to see what values it was passed.

The `functionName.caller` property reveals the contents of an entire function definition if the current function was called from another function (including an event handler). If the call for a function comes from a regular JavaScript statement not originating from inside a function, the `functionName.caller` property is `null`.

## Example

To help you grasp all that these two properties yield, study Listing 33-1.

### Listing 33-1: A Function's arguments and caller Properties

```

<html>
  <head>
    <title></title>
    <script type="text/javascript">
      function hansel(x,y) {
        var args = hansel.arguments;
        document.write("<p>hansel.caller is " + hansel.caller + "<br />");
        document.write("hansel.arguments.length is " +
          hansel.arguments.length + "<br />");
        for (var i = 0; i < args.length; i++) {
          document.write("argument " + i + " is " + args[i] + "<br />");
        }
        document.write("<\/p>");
      }
    <\/script>
  <\/head>
<\/html>

```

*Continued*

**functionObject.caller****Listing 33-1 (continued)**

```

    function gretel(x,y,z) {
        today = new Date();
        thisYear = today.getFullYear();
        hansel(x,y,z,thisYear);
    }
</script>
</head>
<body>
    <script type="text/javascript">
        hansel(1, "two", 3);
        gretel(4, "five", 6, "seven");
    </script>
</body>
</html>

```

When you load this page, the following results appear in the browser window (although the caller property values show undefined for Safari):

```

hansel.caller is null
hansel.arguments.length is 3
argument 0 is 1
argument 1 is two
argument 2 is 3

```

```

hansel.caller is function gretel(x, y, z) { today = new Date(); thisYear =
today.getFullYear(); hansel(x, y, z, thisYear); }
hansel.arguments.length is 4
argument 0 is 4
argument 1 is five
argument 2 is 6
argument 3 is 2004 (or whatever the current year is)

```

As the document loads, the `hansel()` function is called directly in the body script. It passes three arguments, even though the `hansel()` function defines only two. The `hansel.arguments` property picks up all three arguments just the same. The main body script then invokes the `gretel()` function, which, in turn, calls `hansel()` again. But when `gretel()` makes the call, it passes four parameters. The `gretel()` function picks up only three of the four arguments sent by the calling statement. It also inserts another value from its own calculations as an extra parameter to be sent to `hansel()`. The `hansel.caller` property reveals the entire content of the `gretel()` function, whereas `hansel.arguments` picks up all four parameters, including the year value introduced by the `gretel()` function.

**constructor**

(See `string.constructor` in Chapter 27)

**length**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

As the `arguments` property of a function proves, JavaScript is very forgiving about matching the number of parameters passed to a function with the number of parameter variables defined

***functionObject.apply()***

for the function. But a script can examine the `length` property of a function object to see precisely how many parameter variables are defined for a function. A reference to the property starts with the function name representing the object. For example, consider the following function definition shell:

```
function identify(name, rank, serialNum) {
    ...
}
```

A script statement anywhere outside of the function can read the number of parameters with the reference:

```
identify.length
```

The value of the property in the preceding example is 3. The `length` property supercedes the NN-only `arity` property.

## prototype

(See `Array.prototype` in Chapter 30)

## Methods

```
apply([thisObj[, argumentsArray]])
call([thisObj[, arg1[, arg2[...argN]]]])
```

**Returns:** Nothing.

**Compatibility:** WinIE5.5+, MacIE-, NN6+, Moz1+, Safari1+

The `apply()` and `call()` methods of a function object invoke the function. This may seem redundant to the normal way in which script statements invoke functions by simply naming the function, following it with parentheses, passing parameters, and so on. The difference with these methods is that you can invoke the function if your script has only a reference to the function. For example, if your script defines a function via the `new Function()` constructor (or other anonymous shortcut supported by the browser), you receive a reference to the function as a result of the constructor. To invoke the function later using only that reference (presumably preserved in a global variable), use either the `apply()` or `call()` method. Both of these methods achieve the same result, but choosing one method over the other depends on the form in which the function's parameters are conveyed (more about that in a moment).

The first parameter of both methods is a reference to the object that the function treats as the current object. For garden-variety functions defined in your script, use the keyword `this`, which means that the function's context becomes the current object (just like a regular function). In fact, if there are no parameters to be sent to the function, you can omit parameters to both methods altogether.

The object reference comes into play when the function being invoked is one that is normally defined as a method to a custom object. (I cover some of these concepts later in this chapter, so you may need to return here after you are familiar with custom objects.)

## Example

Consider the following code that generates a custom object and assigns a method to the object to display an alert about properties of the object:

```
// function to be invoked as a method from a 'car' object
function showCar() {
    alert(this.make + " : " + this.color);
}
```

**functionObject.apply()**

```

}
// 'car' object constructor function
function car(make, color) {
    this.make = make;
    this.color = color;
    this.show = showCar;
}
// create instance of a 'car' object
var myCar = new car("Ford", "blue");

```

The normal way of getting the `myCar` object to display an alert about its properties is:

```
myCar.show();
```

At that point, the `showCar()` function runs, picking up the current `car` object as the context for the `this` references in the function. In other words, when the `showCar()` function runs as a method of the object, the function treats the object as the “current object.”

With the `call()` or `apply()` methods, however, you don’t have to bind the `showCar()` function to the `myCar` object. You can omit the statement in the `car()` constructor that assigns the `showCar` function to a method name for the object. Instead, a script can invoke the `showCar()` method and instruct it to treat `myCar` as the current object:

```
showCar.call(myCar);
```

The `showCar()` function operates just as before, and the object reference in the `call()` method’s first parameter slot is treated as the current object for the `showCar()` function.

As for succeeding parameters, the `apply()` method’s second parameter is an array of values to be passed as parameters to the current function. The order of the values must match the order of parameter variables defined for the function. The `call()` method, on the other hand, enables you to pass individual parameters in a comma-delimited list. Your choice depends on how the parameters are carried along in your script. If they’re already in array form, use the `apply()` method; otherwise, use the `call()` method. The (ECMA) recommended way to invoke a function through this mechanism when no parameters need to be passed is via the `call()` method.

**toString()****valueOf()**

**Returns:** String.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

Scripts rarely, if ever, summon the `toString()` and `valueOf()` methods of a function object. They work internally to allow debugging scripts to display a string version of the function definition. For example, when you enter the name of a function defined in The Evaluator (see Chapter 13) into the top text box, JavaScript automatically converts the function to a string so that its “value” can be displayed in the Results box. Using these methods or parsing the text they return has little, if any, practical application.

## Function Application Notes

Understanding the ins and outs of JavaScript functions is the key to successful scripting, especially for complex applications. Additional topics covered in this chapter include the ways to invoke functions, variable scope in and around functions, recursion, and the design of reusable functions.

## Invoking functions

A function doesn't perform any work until a script calls it by name or reference. Scripts invoke functions (that is, get functions to do something) via four routes: document object event handlers; JavaScript statements; href attributes pointing to a javascript: URL; and the more recent call() and apply() methods of function objects. The one approach not discussed at length yet in this book is the javascript: URL (some say pseudo-URL).

Several HTML tags have href attributes that normally point to Internet URLs for navigating to another page or loading a MIME file that requires a helper application or plug-in. These HTML tags are usually tags for clickable objects, such as links and client-side image map areas.

A JavaScript-enabled browser has a special, built-in URL pseudo-protocol—javascript:—that lets the href attribute point to a JavaScript function or method rather than to a URL out on the Net. For example, it is common practice to use the javascript: URL to change the contents of two frames from a single link. Because the href attribute is designed to point to only a single URL, you'd be out of luck without a convenient way to put multiframe navigation into your hands. Implement multiframe navigation by writing a function that sets the location.href properties of the two frames; then invoke that function from the href attribute. The following example shows what the script may look like:

```
function loadPages() {
    parent.frames[1].location.href = "page2.html";
    parent.frames[2].location.href = "instrux2.html";
}
...
<a href="javascript:loadPages()">Next</a>
```

**Note**

These kinds of function invocations can include parameters, and the functions can do anything you want. One potential side effect to watch out for occurs when the function returns a value (perhaps the function is also invoked from other script locations where a returned value is expected). Because the href attribute sets the target window to whatever the attribute evaluates to, the returned value is assigned to the target window—probably not what you want.

To prevent the assignment of a returned value to the href attribute, prefix the function call with the void operator:

```
<a href="javascript:void loadPages()">
```

If you don't want the href attribute to do anything (that is, let the onclick event handler do all the work), assign a blank function after the operator:

```
<a href="javascript:void (0)">
```

Experienced programmers of many other languages recognize this operator as a way of indicating that no values are returned from a function or procedure. The operator has that precise functionality here, but in a nontraditional location.

## Variable scope: Globals and locals

A variable can have two scopes in JavaScript. As you might expect, any variable initialized within the main flow of a script (not inside a function) is a *global variable* in that any statement in the same document's script can access it by name. You can, however, also initialize variables inside a function (in a var statement) so the variable name applies only to statements inside that function. By limiting the scope of the variable to a single function, you can reuse the same variable name in multiple functions thereby enabling the variables to carry very different information in each function. Listing 33-2 demonstrates the various possibilities.

## Listing 33-2: Variable Scope Workbench Page

```
<html>
  <head>
    <title>Variable Scope Trials</title>
    <script type="text/javascript">
      var headGlobal = "Gumby";
      function doNothing() {
        var headLocal = "Pokey";
        return headLocal;
      }
    </script>
  </head>
  <body>
    <script type="text/javascript">
      // two global variables
      var aBoy = "Charlie Brown";
      var hisDog = "Snoopy";
      function testValues() {
        var hisDog = "Gromit"; // initializes local version of "hisDog"
        var page = "";
        page += "headGlobal is: " + headGlobal + "<br />";
        // page += "headLocal is: " + headLocal + "<br />" // won't run:
        // ...headLocal not defined
        page += "headLocal value returned from head function is: " +
          doNothing() + "<br />";
        page += " aBoy is: " + aBoy + "<br />"; // picks up global
        page += "local version of hisDog is: " + hisDog + "<br />"; // "sees"
        // ...only local version
        document.write(page);
      }
      testValues();
      document.write("global version of hisDog is intact: " + hisDog);
    </script>
  </body>
</html>
```

In this page, you define a number of variables—some global, others local—that are spread out in the document's Head and Body sections. When you load this page, it runs the `testValues()` function, which accounts for the current values of all the variable names. The script then follows up with one more value extraction that was masked in the function. The results of the page look like this:

```
headGlobal is: Gumby
headLocal value returned from head function is: Pokey
aBoy is: Charlie Brown
local version of hisDog is: Gromit
global version of hisDog is intact: Snoopy
```

Examine the variable initialization throughout this script. In the Head, you define the first variable (`headGlobal`) as a global style outside of any function definition. The `var` keyword for the global variable is optional but often helpful for enabling you to see at a glance where you initialize your variables. You then create a short function, which defines a variable (`headLocal`) that only statements in the function can use.

In the `Body`, you define two more global variables: `aBoy` and `hisDog`. Inside the `Body`'s function (for purposes of demonstration), you reuse the `hisDog` variable name. By initializing `hisDog` with the `var` statement inside the function, you tell JavaScript to create a separate variable whose scope is only within the function. This initialization does not disturb the global variable of the same name. It can, however, make things confusing for you as the script author.

Statements in this script attempt to collect the values of variables scattered around the script. Even from within this script, JavaScript has no problem extracting global variables directly—including the one defined in the `Head`. But JavaScript cannot get the local variable defined in the other function—that `headLocal` variable is private to its own function. Trying to run a script that references that variable value will result in an error message saying that the variable name is not defined. In the eyes of everyone else outside of the `doNothing()` function, that's true. If you really need that value, you can have the function return the value to a calling statement as you do in the `testValues()` function.

Near the end of the function, the script reads the `aBoy` global value without a hitch. But because you initialized a separate version of `hisDog` inside that function, only the localized version is available to the function. If you reassign a global variable name inside a function, you cannot access the global version from inside that function.

As proof that the global variable—whose name was reused inside the `testValues()` function—remains untouched, the script writes that value to the end of the page for all to see. Charlie Brown and his dog are reunited.

A benefit of this variable-scoping scheme is that you can reuse “throw-away” variable names in any function you like. For instance, you can use the `i` loop counting variable in every function that employs loops. (In fact, you can reuse it in multiple `for` loops of the same function because the `for` loop reinitializes the value at the start of the loop.) If you pass parameters to a function, you can assign to those parameter variables the same names to aid in consistency. For example, a common practice is to pass an entire form object reference as a parameter to a function (using a `this.form` parameter in the event handler). For every function that catches one of these objects, you can use the variable name `form` in the parameter:

```
function doSomething(form) {
    statements
}
...

```

If five buttons on your page pass their form objects as parameters to five different functions, each function can assign `form` (or whatever you want to use) to that parameter value.

I recommend reusing variable names only for these “throwaway” variables. In this case, the variables are all local to functions, so the possibility of a mix-up with global variables does not exist. But the thought of reusing a global variable name as, say, a special case inside a function sends shivers up my spine. Such a tactic is doomed to cause confusion and error.

Some programmers devise naming conventions to avoid reusing global variables as local variables. A popular scheme puts a lowercase “g” in front of any global variable name. In the example from Listing 33-2, you can name the global variables

```
gHeadGlobal
gABoy
gHisDog
```

Then, if you define local variables, don't use the leading “g.” A similar scheme involves using an underscore character (`_`) instead of a `g` in front of global variable names. Any scheme you employ to prevent the reuse of variable names in different scopes is fine as long as it does the job.

In a multiframe or multiwindow environment, your scripts can also access global variables from any other document currently loaded into the browser. For details about this level of access, see Chapter 16.

Variable scoping rules apply equally to nested functions in NN4+, IE4+, and W3C browsers. Any variables defined in an outer function (including parameter variables) are exposed to all functions nested inside. But if you define a new local variable inside a nested function, that variable is not available to the outer function. Instead, you can return a value from the nested function to the statement in the outer function that invokes the nested function.

## Parameter variables

When a function receives data in the form of parameters, remember that the values may be copies of the data (in the case of run-of-the-mill data values) or references to real objects (such as a form object). In the latter case, you can change the object's modifiable properties in the function when the function receives the object as a parameter, as shown in the following example:

```
function validateCountry (form) {
    if (form.country.value == "") {
        form.country.value = "USA";
    }
}
```

Therefore, whenever you pass an object reference as a function parameter, be aware that the changes you make to that object in its “passed” form affect the real object.

As a matter of style, if my function needs to extract properties or results of methods from passed data (such as object properties or string substrings), I like to do that at the start of the function. I initialize as many variables as needed for each piece of data used later in the function. This task enables me to assign meaningful names to the data chunks, rather than rely on potentially long references within the working part of the function (such as using a variable like `inputStr` instead of `form.entry.value`).

## Recursion in functions

Functions can call themselves — a process known as *recursion*. The classic example of programmed recursion is the calculation of the factorial (the factorial for a value of 4 is  $4 * 3 * 2 * 1$ ), shown in Listing 33-3.

In the third line of this function, the statement calls itself, passing along a parameter of the next lower value of *n*. As this function executes, diving ever deeper into itself, JavaScript watches intermediate values and performs the final evaluations of the nested expressions. Be sure to test any recursive function carefully. In particular, make sure that the recursion is finite: that a limit exists for the number of times it can recurse. In the case of Listing 33-3, that limit is the initial value of *n*. Failure to watch out for this limit may cause the recursion to overpower the limits of the browser's memory and even lead to a crash.

### Listing 33-3: A JavaScript Function Utilizing Recursion

```
function factorial(n) {
    if (n > 0) {
        return n * (factorial(n-1));
    } else {
```

```
    return 1;
  }
}
```

---

## Turning functions into libraries

As you start writing functions for your scripts, be on the lookout for ways to make functions generalizable (written so that you can reuse the function in other instances, regardless of the object structure of the page). The likeliest candidates for this kind of treatment are functions that perform specific kinds of validation checks (see examples in Chapter 43 on the CD-ROM), data conversions, or iterative math problems.

To make a function generalizable, don't let it make any references to specific objects by name. Object names generally change from document to document. Instead, write the function so that it accepts a named object as a parameter. For example, if you write a function that accepts a `text` object as its parameter, the function can extract the object's data or invoke its methods without knowing anything about its enclosing form or name. Look again, for example, at the `factorial()` function in Listing 33-4—but now as part of an entire document.

### Listing 33-4: Calling a Generalizable Function

```
<html>
  <head>
    <title>Variable Scope Trials</title>
    <script type="text/javascript">
      function factorial(n) {
        if (n > 0) {
          return n * (factorial(n - 1));
        } else {
          return 1;
        }
      }
    </script>
  </head>
  <body>
    <form>
      Enter an input value: <input type="text" name="input" value="0" />
      <p><input type="button" value="Calc Factorial"
        onclick="this.form.output.value =
          factorial(this.form.input.value)" /></p>
      <p>Results: <input type="text" name="output" /></p>
    </form>
  </body>
</html>
```

---

This function is designed to be generalizable, accepting only the input value (`n`) as a parameter. In the form, the `onClick` event handler of the button sends only the input value from one of the form's fields to the `factorial()` function. The returned value is assigned to the output field of the form. The `factorial()` function is totally ignorant about forms, fields, or buttons in this document. If I need this function in another script, I can copy and paste it into that script knowing that it has been pretested. Any generalizable function is part of my personal library of scripts—from which I can borrow—and saves me time in future scripting tasks.

You cannot always generalize a function. Somewhere along the line in your scripts, you must have references to JavaScript or custom objects. But if you find that you're frequently writing functions that perform the same kind of actions, see how you can generalize the code and put the results in your library of ready-made functions. You should also consider placing these reusable library functions in an external `.js` library file. See Chapter 13 for details on this convenient way to share utility functions among many documents.

## Custom Objects

In all the previous chapters of this book, you've seen how conveniently the browser document object models organize all the information about the browser window and its document. What may not be obvious from the scripting you've done so far is that JavaScript enables you to create your own objects in memory—objects with properties and methods. These objects are not user-interface elements on the page but rather the kinds of objects that may contain data and script functions (behaving as methods) whose results the user can see displayed in the browser window.

You actually had a preview of this power in Chapter 30's discussion about arrays. An array, you recall, is an ordered collection of data. An object typically contains different kinds of data. It doesn't have to be an ordered collection of data—although your scripts can use objects in constructions that strongly resemble arrays. Moreover, you can attach any number of custom functions as methods for that object. You are in total control of the object's structure, data, and behavior.

### An example – planetary objects

Building on your familiarity with the planetary data array created in Chapter 30, this chapter shows you how convenient it is to use the data when it is constructed in the form of custom objects. The application goal for the extended example in this section is to present a pop-up list of the nine planets of the solar system and display data about the selected planet. From a user-interface perspective (and for more exposure to multiframe environments), the resulting data displays in a separate frame of a two-frame window. This means your object method builds HTML on the fly and plugs it into the display frame. If you implement this application strictly for IE4+, NN6+, and W3C browsers, you can apply the same data to reconstruct the displayed table data for each user selection. The example as shown, however, is fully backward compatible for all scriptable browsers.

In this chapter, instead of building arrays to hold the data, you build objects—one object for each planet. The design of your object has five properties and one method. The properties of each planet are: name, diameter, distance from the sun, year length, and day length. To assign more intelligence to these objects, you give each of them the capability to display their data in the lower frame of the window. You can conveniently define one function that knows how to behave with any of these planet objects, rather than having to define nine separate functions.

Listing 33-5 shows the source code for the document that creates the frameset for your planetary explorations; Listing 33-6 shows the entire HTML page for the object-oriented planet document, which appears in the top frame.

#### Listing 33-5: Framesetting Document for a Two-Frame Window

```
<html>
  <head>
    <title>Solar System Viewer</title>
```

```

    <script type="text/javascript">
    function blank() {
        return "<html><body></body></html>";
    }
    </script>
</head>
<frameset rows="50%,50%"
onload="Frame1.doDisplay(Frame1.document.forms[0].planetsList)">
    <frame name="Frame1" src="lst33-06.htm" />
    <frame name="Frame2" src="javascript:parent.blank()" />
</frameset>
</html>

```

One item to point out in Listing 33-5 is that because the lower frame isn't filled until the upper frame's document loads, you need to assign some kind of URL for the `src` attribute of the second frame. Rather than add the extra transaction and file burden of a blank HTML document, here you use the `javascript: URL` to invoke a function. In this instance, I want the value returned from the function (a blank HTML page) to be reflected into the target frame (no `void` operator here). This method provides the most efficient way of creating a blank frame in a frameset.

### Listing 33-6: Object-Oriented Planetary Data Presentation

```

<html>
<head>
    <title>Our Solar System</title>
    <script type="text/javascript">
    // method definition
    function showPlanet() {
        var result = "<html><body><center><table border='2'>";
        result += "<caption align='top'>Planetary data for: <b>" + this.name +
            "</b></caption>";
        result += "<tr><td align='right'>Diameter:</td><td>" + this.diameter +
            "</td></tr>";
        result += "<tr><td align='right'>Distance from Sun:</td><td>" +
            this.distance + "</td></tr>";
        result += "<tr><td align='right'>One Orbit Around Sun:</td><td>" +
            this.year + "</td></tr>";
        result += "<tr><td align='right'>One Revolution (Earth
            Time):</td><td>" + this.day + "</td></tr>";
        result += "</table></center></body></html>";
        // display results in a second frame of the window
        parent.Frame2.document.write(result);
        parent.Frame2.document.close();
    }

    // definition of planet object type;
    // 'new' will create a new instance and stuff parameter data into object
    function planet(name, diameter, distance, year, day) {
        this.name = name;
        this.diameter = diameter;
        this.distance = distance;
        this.year = year;
    }

```

*Continued*

## Listing 33-6 (continued)

```

        this.day = day;
        this.showPlanet = showPlanet; // make showPlanet() function a method
        // ...of planet
    }

    // create new planet objects, and store in a series of variables
    var Mercury = new planet("Mercury", "3100 miles", "36 million miles",
        "88 days", "59 days");
    var Venus = new planet("Venus", "7700 miles", "67 million miles",
        "225 days", "244 days");
    var Earth = new planet("Earth", "7920 miles", "93 million miles",
        "365.25 days", "24 hours");
    var Mars = new planet("Mars", "4200 miles", "141 million miles",
        "687 days", "24 hours, 24 minutes");
    var Jupiter = new planet("Jupiter", "88,640 miles", "483 million miles",
        "11.9 years", "9 hours, 50 minutes");
    var Saturn = new planet("Saturn", "74,500 miles", "886 million miles",
        "29.5 years", "10 hours, 39 minutes");
    var Uranus = new planet("Uranus", "32,000 miles",
        "1.782 billion miles", "84 years", "23 hours");
    var Neptune = new planet("Neptune", "31,000 miles",
        "2.793 billion miles", "165 years", "15 hours, 48 minutes");
    var Pluto = new planet("Pluto", "1500 miles", "3.67 billion miles",
        "248 years", "6 days, 7 hours");

    // called from push button to invoke planet object method
    function doDisplay(popup) {
        i = popup.selectedIndex;
        eval(popup.options[i].text + ".showPlanet()");
    }
</script>
</head>
<body>
    <h1>The Daily Planet</h1>
    <hr />
    <form>
        <p>Select a planet to view its planetary data: <select
            name='planetsList' onchange='doDisplay(this)'\>
                <option>Mercury</option>
                <option>Venus</option>
                <option selected="selected">Earth</option>
                <option>Mars</option>
                <option>Jupiter</option>
                <option>Saturn</option>
                <option>Uranus</option>
                <option>Neptune</option>
                <option>Pluto</option>
            </select></p>
        </form>
    </body>
</html>

```

The first task in the Head is to define the function that becomes a method in each of the objects. You must do this task before scripting any other code that adopts the function as its method. Failure to define the function ahead of time results in an error — the function name is not defined. If you compare the data extraction methodology with the function in the array version, notice that the parameter for the index value is gone and the reference to each property begins with `this`. Later, I return to the custom method after giving you a look at the rest of the Head code.

Next comes the object constructor function, which performs several important tasks. For one, everything in this function establishes the structure of your custom object: the properties available for data storage and retrieval and any methods that the object can invoke. The name of the function is the name you use later to create new instances of the object. Therefore, choosing a name that truly reflects the nature of the object is important. And, because you probably want to stuff some data into the function's properties to get one or more instances of the object loaded and ready for the page's user, the function definition includes parameters for each of the properties defined in this object definition.

Inside the function, you use the `this` keyword to assign data that comes in as parameters to labeled names for both the incoming parameter variables and the properties. That's primarily for convenience (and is very common practice), but you can assign any variable and property names you want and connect them any way you like. In the `planet()` constructor function, five property slots are reserved for every instance of the object whether or not any data actually is placed in every property (any unassigned slot has a value of `null`).

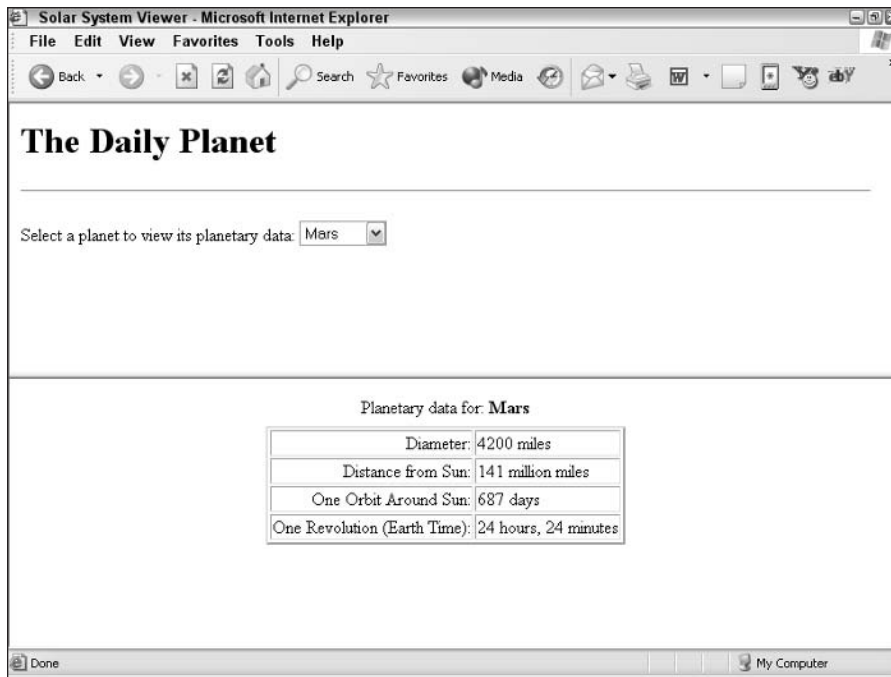

The last entry in the `planet()` constructor function is a reference to the `showPlanet()` function defined earlier. Notice that the assignment statement doesn't refer to the function with its parentheses — just to the function name. When JavaScript sees this assignment statement, it looks back through existing definitions (those functions defined ahead of the current location in the script) for a match. If it finds a function (as it does here), JavaScript knows to assign the function to the identifier on the left side of the assignment statement. In doing this task with a function, JavaScript automatically sets up the identifier as a method name for this object. As you do in every JavaScript method you encounter, you must invoke a method by using a reference to the object, a period, and the method name followed by a set of parentheses. You see that syntax in a minute.

The next long block of statements creates the individual objects according to the definition established in the `planet()` constructor. Similar to an array, an assignment statement and the keyword `new` create an object. I assign names that are not only the real names of planets (the `Mercury` object name is the `Mercury planet` object) but that also can come in handy later when the `doDisplay()` function extracts names from the pop-up list in search of a particular object's data.

The act of creating a new object sets aside space in memory (associated with the current document) for this object and its properties. In this script, you create nine object spaces, each with a different set of properties. Notice that no parameter is sent (or expected at the function) that corresponds to the `showPlanet()` method. Omitting that parameter here is fine because the specification of that method in the object definition means that the script automatically attaches the method to every version (instance) of the planet object that it creates.

The last function definition, `doDisplay()`, is invoked whenever the user makes a choice from the list of planets in the upper frame. This function is also invoked via the frameset's `onload` event handler so that an initial table is displayed from the default selected item (see Figure 33-1). Invoking the function from the upper frame's `onload` event handler can cause problems (such as the failure of the other frame) if the frameset is not completely loaded.

**Figure 33-1:** An external and internal face-lift for an earlier application.

The `onchange` event handler in the `select` list passes that `select` element's reference to the `doDisplay()` function. In that function, the `select` object is assigned to a variable called `popup` to help you visualize that the object is the pop-up list. The first statement extracts the index value of the selected item. Using that index value, the script extracts the text. But things get a little tricky because you need to use that text string as a variable name—the name of the planet—and append it to the call to the `showPlanet()` method. To make the disparate data types come together, use the `eval()` function. Inside the parentheses, extract the string for the planet name and concatenate a string that completes the reference to the object's `showPlanet()` method. The `eval()` function evaluates that string, which turns it into a valid method call. Therefore, if the user selects Jupiter from the pop-up list, the method call becomes `Jupiter.showPlanet()`.

Now it's time to look back to the `showPlanet()` function/method definition at the top of the script. When that method runs in response to a user selection of the planet Jupiter, the method's only scope is of the Jupiter object. Therefore, all references to `this.propertyName` in `showPlanet()` refer to Jupiter only. The only possibility for `this.name` in the Jupiter object is the value assigned to the `name` property for Jupiter. The same goes for the rest of the properties extracted in the function/method.

## Creating an array of objects

In Listing 33-6, each of the planet objects is assigned to a global variable whose name is that of the planet. If the idea of custom objects is new to you, this idea probably doesn't sound so bad because it's easy to visualize each variable representing an object. But, as shown in the `doDisplay()` function, accessing an object by name requires use of the `eval()` function to

convert a string representation to a valid object reference. While it's not too important in this simple example, the `eval()` function is not particularly efficient in JavaScript. If you find yourself using an `eval()` function, look for ways to improve efficiency such that you can reference an object by string. The way to accomplish that streamlining for this application is to place the objects in an array whose index values are the planet names.

To assign the custom objects in Listing 33-6 to an array, first create an empty array and then assign the result of each object constructor call to an entry in the array. The modified code section looks like the following (formatted to fit this printed page):

```
// create array
var planets = new Array();
// populate array with new planet objects
planets["Mercury"] =
    new planet("Mercury","3100 miles", "36 million miles",
    "88 days", "59 days");
planets["Venus"] =
    new planet("Venus", "7700 miles", "67 million miles",
    "225 days", "244 days");
planets["Earth"] =
    new planet("Earth", "7920 miles", "93 million miles",
    "365.25 days", "24 hours");
planets["Mars"] =
    new planet("Mars", "4200 miles", "141 million miles",
    "687 days", "24 hours, 24 minutes");
planets["Jupiter"] =
    new planet("Jupiter", "88,640 miles", "483 million miles",
    "11.9 years", "9 hours, 50 minutes");
planets["Saturn"] =
    new planet("Saturn", "74,500 miles", "886 million miles",
    "29.5 years", "10 hours, 39 minutes");
planets["Uranus"] =
    new planet("Uranus", "32,000 miles", "1.782 billion miles",
    "84 years", "23 hours");
planets["Neptune"] =
    new planet("Neptune", "31,000 miles", "2.793 billion miles",
    "165 years", "15 hours, 48 minutes");
planets["Pluto"] =
    new planet("Pluto", "1500 miles", "3.67 billion miles",
    "248 years", "6 days, 7 hours");
```

The supreme advantage to this approach comes in a modified `doDisplay()` function, which can use the string value from the `select` element directly without any conversion to an object reference:

```
// called from push button to invoke planet object method
function doDisplay(popup) {
    i = popup.selectedIndex;
    planets[popup.options[i].text].showPlanet();
}
```

The presence of so many similar objects cries out for their storage as an array. Because the names play a key role in their choice for this application, the named index values work best; in other situations, you may prefer to use numeric indexes to facilitate looping through the array.

## Adding a custom method

You're approaching advanced subject matter at this point, so I merely mention and briefly demonstrate an additional power of defining and using custom objects. A custom object can

have a reference to another custom object as a property. Let's extend the planet example to help you understand the implications.

Say that you want to beef up the planet page with a photo of each planet. Each photo has a URL for the photo file; each photo also contains other information, such as the copyright notice and a reference number, which displays on the page for the user. One way to handle this additional information is to create a separate object definition for a photo database. Such a definition may look like this:

```
function photo(name, URL, copyright, refNum) {
    this.name = name;
    this.URL = URL;
    this.copyright = copyright;
    this.refNum = refNum;
}
```

You then need to create individual photo objects for each picture. One such definition may look like this:

```
mercuryPhoto = new photo("Planet Mercury", "/images/merc44.gif",
    "(c)1990 NASA", 28372);
```

Attaching a photo object to a planet object requires modifying the planet constructor function to accommodate one more property. The new planet constructor looks like this:

```
function planet(name, diameter, distance, year, day, photo) {
    this.name = name;
    this.diameter = diameter;
    this.distance = distance;
    this.year = year;
    this.day = day;
    this.showPlanet = showPlanet;
    this.photo = photo; // add photo property
}
```

Once the photo objects are created, you can then create each planet object by passing one more parameter—a photo object you want associated with that object:

```
// create new planet objects, and store in a series of variables
Mercury = new planet("Mercury", "3100 miles", "36 million miles",
    "88 days", "59 days", mercuryPhoto);
```

To access a property of a photo object, your scripts then have to assemble a reference that works its way through the connection with the planet object:

```
copyrightData = Mercury.photo.copyright;
```

The potential of custom objects of this type is enormous. For example, you can embed all the copy elements and image URLs for an online catalog in a single document. As the user selects items to view (or cycles through them in sequence), a new JavaScript-written page displays the information in an instant. This requires only the image to be downloaded—unless the image was precached, as described in the image object discussion in Chapter 18. In this case, everything works instantaneously—no waiting for page after page of catalog.

If, by now, you think you see a resemblance between this object-within-an-object construction and a relational database, give yourself a gold star. Nothing prevents multiple objects from having the same subobject as their properties—like multiple business contacts having the same company object property.

## More ways to create objects

The examples in Listings 33-5 and 33-6 show a way of creating objects that works with all scriptable browsers. If your audience is limited to users with more modern browsers, additional ways of creating custom objects exist.

From NN3+ and IE4+ onward (including W3C browsers), you can use the `new Object()` constructor to generate a blank object. From that point on, you can define property and method names by simple assignment, as in the following:

```
var Earth = new Object();
Earth.diameter = "7920 miles";
Earth.distance = "93 million miles";
Earth.year = "365.25";
Earth.day = "24 hours";
Earth.showPlanet = showPlanet; // function reference
```

When you create a lot of like-structured objects, the custom object constructor shown in Listing 33-6 is more efficient. But for single objects, the `new Object()` constructor is more efficient.

For more modern browsers, you can also benefit from a shortcut literal syntax for creating a new object. You can set pairs of property names and their values inside a set of curly braces, and you can assign the whole construction to a variable that becomes the object name. The following script shows how to organize this kind of object constructor:

```
var Earth = {diameter:"7920 miles", distance:"93 million miles", year:"365.25",
            day:"24 hours", showPlanet:showPlanet};
```

Colons link name-value pairs, and commas separate multiple name-value pairs. The value portion of a name-value pair can even be an array (using the `[...]` constructor shortcut) or a nested object (using another pair of curly braces). In fact, you can nest arrays and objects to your heart's content to create exceedingly complex objects. All in all, this is a very compact way to embed data in a page for script manipulation. If your CGI, XML, and database skills are up to the task, consider using a server program to convert XML data into this compact JavaScript version with each XML record being its own JavaScript object. For multiple records, assign the curly-braced object definitions to an array entry. Then your scripts on the client can iterate through the data and generate the HTML to display the data in a variety of forms and sorted according to different criteria (thanks to the JavaScript array-sorting powers).

## Defining object property getters and setters

A future version of the ECMA-262 language specification will likely include a pair of facilities called *getter* and *setter*. Until such time as the formal syntax is finalized, you can begin to experiment with this technique in NN6+/Moz1+ using temporary syntax that adheres to the likely format (but intentionally uses different keywords until the standard is adopted). When the standard is adopted, a subsequent version of NN/Moz will include the standard keywords.

I introduced the idea of creating a getter and setter for an object briefly in Chapter 14, where the NN6 syntax style extended properties of some W3C DOM objects to include some of the Microsoft-specific (and very convenient) DOM syntax. Most notably, you can define a getter for any container to return an array of nested elements just like the IE-only `document.all` collection.

The purpose of a getter is to assign a new property to the prototype of an object and to define how the value returned by the property should be evaluated. A setter does the same, but it also defines how a new value assigned to the property should apply the value to the object. Both

definitions are written in the form of anonymous functions, such that reading or writing an object's property value can include sophisticated processing for either operation.

Getters and setters are assigned to the `prototype` property of an object, thus enabling you to customize native and DOM objects. The NN6 syntax fashions getters, setters, and methods of an object's prototype with the following syntax:

```
object.prototype.__defineGetter__("propName", function)
object.prototype.__defineSetter__("propName", function)
```

Note that the underscores before and after the method names are actually pairs of underscore characters (that is, `_`, `_`, `defineGetter`, `_`, `_`). This double underscore was chosen as a syntax that the ECMA standard will not use, so it will not conflict with the eventual syntax for this facility.

The first parameter of the method is the name of the property for which the getter or setter is defined. This can be an existing property name that you want to override. The second parameter can be a function reference; but more likely it will be an anonymous function defined in place. By using an anonymous function, you can take advantage of the context of the object for which the property is defined. For each property, define both a getter and setter—even if the property is meant to be read-only or write-only.

To see how this mechanism works, let's use the getter and setter shown in Chapter 14 to add an `innerText` property to HTML elements in NN6+. This property is read/write, so functions are defined for both the getter and setter. The getter definition is as follows:

```
HTMLElement.prototype.__defineGetter__("innerText", function () {
    var rng = document.createRange();
    rng.selectNode(this);
    return rng.toString();
})
```

The modified object is the basic `HTMLElement` object—the object that NN6+ uses to create instances of every HTML element for the page. After the preceding statement executes, every HTML element on the page inherits the new `innerText` property. Each time the `innerText` property is read for an element, the anonymous function in this getter executes. Thus, after a text range object is created, the range is set to the node that is the current element. This is an excellent example of how the context of the current object allows the use of the `this` keyword to refer to the very same object. Finally, the string version of the selected range is returned. It is essential that a getter function include a `return` statement and that the returned value is of the desired data type. Also take notice of the closing of the function's curly brace and the getter method's parenthesis.

By executing this function each time the property is read, the getter always returns the current state of the object. If content of the element has changed since the page loaded, you are still assured of getting the current text inside the element. This is far superior to simply running the statements inside this function once as the page loads to capture a static view of the element's text.

The corresponding setter definition is as follows:

```
HTMLElement.prototype.__defineSetter__("innerText", function (txt) {
    var rng = document.createRange();
    rng.selectNodeContents(this);
    rng.deleteContents();
    var newText = document.createTextNode(txt);
    this.appendChild(newText);
    return txt;
})
```

To assign a value to an object's property, the setter function requires that a parameter variable receive the assigned value. That parameter variable plays a role somewhere within the function definition. For this particular setter, the current object (`this`) also manipulates the text range object. The contents of the current element are deleted, and a text node comprising the text passed as a parameter is inserted into the element. To completely simulate the IE behavior of setting the `innerText` property, the text is returned. While setters don't always return values, this one does so that the expression that assigns a value to the `innerText` property evaluates to the new text.

If you want to create a read-only property, you still define a setter for the property but you also assign an empty function, as in:

```
Node.prototype.__defineSetter__("all", function() {})
```

This prevents assignment statements to a read-only property from generating errors. A write-only property should also have a getter that returns `null` or an empty string, as in:

```
HTMLElement.prototype.__defineGetter__("outerHTML", function() {return ""})
```

Because the getter and setter syntax shown here is unique to NN6, you must obviously wrap such statements inside object detection or browser version detection statements. And, to reiterate, this syntax will change in future browser versions once ECMA adopts the formal syntax.

## Using custom objects

There is no magic to knowing when to use a custom object instead of an array in your application. The more you work with and understand the way custom objects work, the more likely you will think about your data-carrying scripts in these terms — especially if an object can benefit from having one or more methods associated with it. This avenue is certainly not one for beginners, but I recommend that you give custom objects more than a casual perusal once you gain some JavaScripting experience.

## Object-Oriented Concepts

As stated several times throughout this book, JavaScript is object-based rather than object-oriented. Instead of adhering to the class, subclass, and inheritance schemes of object-oriented languages such as Java, JavaScript uses what is called *prototype inheritance*. This scheme works not only for native and DOM objects but also for custom objects.

### Adding a prototype

A custom object is frequently defined by a constructor function, which typically parcels out initial values to properties of the object, as in the following example:

```
function car(plate, model, color) {
    this.plate = plate;
    this.model = model;
    this.color = color;
}
var car1 = new car("AB 123", "Ford", "blue");
```

NN4+, IE4+, and W3C browsers offer a handy shortcut, as well, to stuff default values into properties if none are provided (the supplied value is `null`, `0`, or an empty string). The `OR` operator (`|`) can let the property assignment statement apply the passed value, if present,

or a default value you hard-wire into the constructor. Therefore, you can modify the preceding function to offer default values for the properties:

```
function car(plate, model, color) {
    this.plate = plate || "missing";
    this.model = model || "unknown";
    this.color = color || "unknown";
}
var car1 = new car("AB 123", "Ford", "");
```

After the preceding statements run, the `car1` object has the following properties:

```
car1.plate    // value = "AB 123"
car1.model    // value = "Ford"
car1.color    // value = "unknown"
```

If you then add a new property to the constructor's prototype property, as in

```
car.prototype.companyOwned = true;
```

any `car` object you already created or are about to create automatically inherits the new `companyOwned` property and its value. You can still override the value of the `companyOwned` property for any individual `car` object. But if you don't override the property for instances of the `car` object, the `car` objects whose `companyOwned` property is not overridden automatically inherit any change to the `prototype.companyOwned` value. This has to do with the way JavaScript looks for prototype property values.

## Prototype inheritance

Each time your script attempts to read or write a property of an object, JavaScript follows a specific sequence in search of a match for the property name. The sequence is as follows:

1. If the property has a value assigned to the current (local) object, this is the value to use.
2. If there is no local value, check the value of the property's prototype of the object's constructor.
3. Continue up the prototype chain until either a match of the property is found (with a value assigned to it) or the search reaches the native `Object` object.

Therefore, if you change the value of a constructor's `prototype` property and you do not override the property value in an instance of that constructor, JavaScript returns the current value of the constructor's `prototype` property.

## Nested objects and prototype inheritance

When you begin nesting objects, especially when one object invokes the constructor of another, there is an added wrinkle to the prototype inheritance chain. Let's continue with the `car` object defined earlier. In this scenario, consider the `car` object to be akin to a root object that has properties shared among two other types of objects. One of the object types is a company fleet vehicle, which needs the properties of the root `car` object (`plate`, `model`, `color`) but also adds some properties of its own. The other object that shares the `car` object is an object representing a car parked in the company garage—an object that has additional properties regarding the parking of the vehicle. This explains why the `car` object is defined on its own.

Now look at the constructor function for the parking record, along with the constructor for the basic car object:

```
function car(plate, model, color) {
    this.plate = plate || "missing";
    this.model = model || "unknown";
    this.color = color || "unknown";
}
function carInLot(plate, model, color, timeIn, spaceNum) {
    this.timeIn = timeIn;
    this.spaceNum = spaceNum;
    this.carInfo = car;
    this.carInfo(plate, model, color);
}
```

The `carInLot` constructor not only assigns values to its unique properties (`timeIn` and `spaceNum`) but it also includes a reference to the `car` constructor arbitrarily assigned to a property called `carInfo`. This property assignment is merely a conduit that allows property values intended for the `car` constructor to be passed within the `carInLot` constructor function. To create a `carInLot` object, use a statement like the following:

```
var car1 = new carInLot("AA 123", "Ford", "blue", "10:02AM", "31");
```

After this statement, the `car1` object has the following properties and values:

```
car1.timeIn      // value = "10:02AM"
car1.spaceNum    // value = "31"
car1.carInfo     // value = reference to car object constructor function
car1.plate       // value = "AA 123"
car1.model       // value = "Ford"
car1.color       // value = "blue"
```

Let's say that five `carInLot` objects are created in the script (`car1` through `car5`). The prototype wrinkle comes into play if, for example, you assign a new property to the `car` constructor prototype:

```
car.prototype.companyOwned = true;
```

Even though the `carInLot` objects use the `car` constructor, the instances of `carInLot` objects do not have a prototype chain back to the `car` object. As the preceding code stands, even though you've added a `companyOwned` property to the `car` constructor, no `carInLot` object inherits that property (even if you were to create a new `carInLot` object after defining the new prototype property for `car`). To get the `carInLot` instances to inherit the prototype `companyOwned` property, you must explicitly connect the prototype of the `carInLot` constructor to the `car` constructor prior to creating instances of `carInLot` objects:

```
carInLot.prototype = new car();
```

The complete sequence, then, is as follows:

```
function car(plate, model, color) {
    this.plate = plate || "missing";
    this.model = model || "unknown";
    this.color = color || "unknown";
}
function carsInLot(plate, model, color, timeIn, spaceNum) {
    this.timeIn = timeIn;
    this.spaceNum = spaceNum;
    this.carInfo = car;
    this.carInfo(plate, model, color);
}
```

**objectObject**

```
carsInLot.prototype = new car();
var car1 = new carsInLot("123ABC", "Ford", "blue", "10:02AM", "32");
car1.prototype.companyOwned = true;
```

After this stretch of code runs, the `car1` object has the following properties and values:

```
car1.timeIn           // value = "10:02AM"
car1.spaceNum        // value = "31"
car1.carInfo         // value = reference to car object constructor function
car1.plate           // value = "AA 123"
car1.model           // value = "Ford"
car1.color           // value = "blue"
car1.companyOwned    // value = true
```

NN4+ provides one extra, proprietary bit of syntax in this prototype world. The `__proto__` property (that's with double underscores before and after the word "proto") returns a reference to the object that is next up the prototype chain. For example, if you inspect the properties of `car1.__proto__` after the preceding code runs, you see that the properties of the object next up the prototype chain are as follows:

```
car1.__proto__.plate // value = "AA 123"
car1.__proto__.model // value = "Ford"
car1.__proto__.color // value = "blue"
car1.__proto__.companyOwned // value = true
```

This property can be helpful in debugging custom objects and prototype inheritance chain challenges, but the property is not part of the ECMA standard. Therefore, I discourage you from using the property in your production scripts.

## Object Object

<b>Properties</b>	<b>Methods</b>
constructor	hasOwnProperty()
prototype	isPrototypeOf()
	propertyIsEnumerable()
	toLocaleString()
	toString()
	valueOf()

## Syntax

Creating an object object:

```
function constructorName([arg1,...[,argN]]) {
    statement(s)
}
var objName = new constructorName(["argName1",...[, "argNameN"]);
var objName = new Object();
var objName = {propName1:propVal1[, propName2:propVal2[,...N]}
```

Accessing an object object properties and methods:

```
objectReference.property | method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

## About this object

While it might sound like doubletalk, the `Object` object is a vital native object in the JavaScript environment. It is the root object on which all other native objects — such as `Date`, `Array`, `String`, and the like — are based. This object also provides the foundation for creating custom objects, as described earlier in this chapter.

By and large, your scripts do not access the properties of the native `Object` object. The same is true for many of its methods, such as `toString()` and `valueOf()`, which internally allow debugging alert dialog boxes (and The Evaluator) to display something when referring to an object or its constructor.

You can use a trio of methods to perform some inspection of the prototype environment of an object instance. They are of interest primarily to advanced scripters who are building extensive, simulated object-oriented applications.

## Methods

### `hasOwnProperty("propName")`

**Returns:** Boolean.

**Compatibility:** WinIE5.5+, MacIE-, NN6+, Moz1+, Safari-

The `hasOwnProperty()` method returns `true` if the current object instance has the property defined in its constructor or in a related constructor function. But if this property is defined externally, as via assignment to the object's prototype property, the method returns `false`.

Using the example of the `car` and `carInLot` objects from earlier in this chapter, the following expressions evaluate to `true`:

```
car1.hasOwnProperty("spaceNum");  
car1.hasOwnProperty("model");
```

Even though the `model` property is defined in a constructor that is invoked by another constructor, the property belongs to the `car1` object. The following statement, however, evaluates to `false`:

```
car1.hasOwnProperty("companyOwned");
```

This property is defined by way of the prototype of one of the constructor functions and is not a built-in property for the object instance.

### `isPrototypeOf(objRef)`

**Returns:** Boolean.

**Compatibility:** WinIE5.5+, MacIE-, NN6+, Moz1+, Safari-

The `isPrototypeOf()` method is intended to reveal whether or not the current object has a prototype relation with an object passed as a parameter. In practice, the IE and NN/Moz versions of this method operate differently and return different results.

***object*Object.propertyIsEnumerable()**

`propertyIsEnumerable("propName")`

**Returns:** Boolean.

**Compatibility:** WinIE5.5+, MacIE-, NN6+, Moz1+, Safari-

In the terminology of the ECMA-262 language specification, a value is enumerable if constructions such as the `for-in` property inspection loop (see Chapter 31) can inspect it. Enumerable properties include values such as arrays, strings, and virtually every kind of object. According to the ECMA specification, this method is not supposed to work its way up the prototype chain.

# Global Functions and Statements

---

In addition to all the objects and other language constructs described in the preceding chapters of this reference part of the book, several language items need to be treated on a global scale. These items apply to no particular objects (or any object), and you can use them anywhere in a script. If you read earlier chapters, you were introduced to many of these functions and statements. This chapter serves as a convenient place to highlight these all-important items that are otherwise easily forgotten. At the end of the chapter, note the brief introduction to several objects that are built into the Windows-only versions of Internet Explorer.

This chapter begins with coverage of the following global functions and statements that are part of the core JavaScript language:

<i>Functions</i>	<i>Statements</i>
<code>decodeURI()</code>	<code>//</code> and <code>/*...*/</code> (comment)
<code>decodeURIComponent()</code>	<code>const</code>
<code>encodeURI()</code>	<code>var</code>
<code>encodeURIComponent()</code>	
<code>escape()</code>	
<code>eval()</code>	
<code>isFinite()</code>	
<code>isNaN()</code>	
<code>Number()</code>	
<code>parseFloat()</code>	
<code>parseInt()</code>	
<code>toString()</code>	
<code>unescape()</code>	
<code>unwatch()</code>	
<code>watch()</code>	

Global functions are not tied to the document object model. Instead, they typically enable you to convert data from one type to another type. The list of global statements is short, but a couple of them appear extensively in your scripting.

## In This Chapter

Converting strings into object references

Creating URL-friendly strings

Adding comments to scripts

`decodeURI()`

## Functions

```
decodeURI("encodedURI")
decodeURIComponent("encodedURIComponent")
encodeURI("URIString")
encodeURIComponent("URIComponentString")
```

**Returns:** String.

**Compatibility:** WinIE5.5+, MacIE-, NN6+, Moz1+, Safari-

The ECMA-262 Edition 3 standard, as implemented in IE5.5+, NN6+, and Mozilla, provides utility functions that perform a more rigorous conversion of strings to valid URI strings and vice versa than was achieved earlier via the `escape()` and `unescape()` functions (described later in this chapter). The purpose of the encoding functions is to convert any string to a version that you can use as a Uniform Resource Identifier, such as a Web page address or an invocation of a server CGI script. While Latin alphanumeric characters pass through the encoding process untouched, you must use the encoding functions to convert some symbols and other Unicode characters to a form (hexadecimal representations of the character numbers) that the Internet can pass from place to place. The space character, for example, must be encoded to its hex version: `%20`.

Perhaps the biggest difference between the `encodeURI()` and `escape()` functions (and their `decodeURI()` and `unescape()` counterparts) is that the more modern versions do not encode a wide range of symbols that are perfectly acceptable as URI characters according to the syntax recommended in RFC2396 (<http://www.ietf.org/rfc/rfc2396.txt>). Thus, the following characters are not encoded via the `encodeURI()` function:

```
; / ? : @ & = + $ , - _ . ! ~ * ' ( ) #
```

Use the `encodeURI()` and `decodeURI()` functions only on complete URIs. Applicable URIs can be relative or absolute, but these two functions are wired especially so symbols that are part of the protocol (`://`), search string (`?` and `=`, for instance), and directory-level delimiters (`/`) are not encoded. The `decodeURI()` function should work with URIs that arrive from servers as page locations, but be aware that some server CGIs encode spaces into plus symbols (`+`) that are not decoded back to spaces by the JavaScript function. If the URIs your script needs to decode contain plus symbols in place of spaces, you need to run your decoded URI through a string replacement method to finish the job (regular expressions come in handy here). If you are decoding URI strings that your scripts encoded, use the decode functions only on URIs that were encoded via the corresponding encode function. Do not attempt to decode a URI that was created via the old `escape()` function because the conversion processes work according to different rules.

The difference between a URI and a URI component is that a *component* is a single piece of a URI, generally not containing delimiter characters. For example, if you use the `encodeURIComponent()` function on a complete URI, almost all of the symbols (other than things such as periods) are encoded into hexadecimal versions — including directory delimiters. Therefore, you should use the component-level conversion functions only on quite granular pieces of a URI. For example, if you assemble a search string that has a name-value pair, you can use the `encodeURIComponent()` function separately on the name and on the value. But if you use that function on the pair that is already in the form `name=value`, the function encodes the equal symbol to a hexadecimal equivalent.

`escape()`

## Example

Use The Evaluator (Chapter 13) to experiment with the differences between encoding a full URI and a component and encoding and escaping a URI string. For example, compare the results of the following three statements:

```
escape("http://www.giantco.com/index.html?code=42")
encodeURIComponent("http://www.giantco.com/index.html?code=42")
encodeURIComponent("http://www.giantco.com/index.html?code=42")
```

Because the sample URI string is valid as is, the `encodeURIComponent()` version makes no changes. Experiment further by making the search string value into a string with a space, and see how each function treats that character.

```
escape("URIStrIng" [,1])
unescape("escapedURIStrIng")
```

**Returns:** String.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

If you watch the content of the Location field in your browser, you may occasionally see URLs that include a lot of % symbols plus some numbers. The format you see is *URL encoding* (more accurately called *URI encoding*—Uniform Resource Identifier rather than Uniform Resource Locator). This format allows even multiple word strings and nonalphanumeric characters to be sent as one contiguous string of a very low, common denominator character set. This encoding turns a character, such as a space, into its hexadecimal equivalent value preceded by a percent symbol. For example, the space character (ASCII value 32) is hexadecimal 20, so the encoded version of a space is %20.

All characters, including tabs and carriage returns, can be encoded in this way and sent as a simple string that can be decoded on the receiving end for reconstruction. You can also use this encoding to preprocess multiple lines of text that must be stored as a character string in databases. To convert a plain-language string to its encoded version, use the `escape()` method. This function returns a string consisting of the encoded version. For example:

```
var theCode = escape("Hello there");
// result: "Hello%20there"
```

Most, but not all, non-alphanumeric characters are converted to escaped versions with the `escape()` function. One exception is the plus sign, which URLs use to separate components of search strings. If you must encode the plus symbol, too, then add the optional second parameter to the function to make the plus symbol convert to its hexadecimal equivalent (2B):

```
var a = escape("Adding 2+2");
// result: "Adding%202+2"
var a = escape("Adding 2+2",1);
// result: "Adding%202%2B2"
```

To convert an escaped string back into plain language, use the `unescape()` function. This function returns a string and converts all URL-encoded strings—including those encoded with the optional parameter.

The `escape()` function operates in a way that is approximately midway between the newer functions `encodeURIComponent()` and `encodeURIComponent()`. The `escape()` function is best used on portions of URIs, such as the search string. If your scripts bounce back and forth between escaped and unescaped strings, be sure to balance the functions of the same type; use `unescape()` only on URI strings that are encoded via the `escape()` function.

**escape()**

Finally, be aware of slightly different behavior with regard to the @ symbol in various browsers. This character is not encoded in IE, but it is encoded (to %40) in NN.

**eval("string")**

**Returns:** Object reference.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Expression evaluation, as you probably are well aware by now, is an important concept to grasp in scripting with JavaScript (and programming in general). An expression evaluates to some value. But occasionally you need to force an additional evaluation on an expression to receive the desired results. The `eval()` function acts on a string value to force an evaluation of that string expression. Perhaps the most common application of the `eval()` function is to convert a string version of an object reference to a genuine object reference.

**Example**

The `eval()` function can evaluate any JavaScript statement or expression stored as a string. This includes string equivalents of arithmetic expressions, object value assignments, and object method invocation. I do not recommend that you rely on the `eval()` function, however, because this function is inherently inefficient (from the standpoint of performance). Fortunately, you may not need the `eval()` function to get from a string version of an object's name to a valid object reference. For example, if your script loops through a series of objects whose names include serial numbers, you can use the object names as array indices rather than use `eval()` to assemble the object references. The inefficient way to set the value of a series of fields named `data0`, `data1`, and so on, is as follows:

```
function fillFields() {
    var theObj;
    for (var i = 0; i < 10; i++) {
        theObj = eval("document.forms[0].data" + i);
        theObj.value = i;
    }
}
```

A more efficient way is to perform the concatenation within the index brackets for the object reference:

```
function fillFields() {
    for (var i = 0; i < 10; i++) {
        document.forms[0].elements["data" + i].value = i;
    }
}
```

**Tip**

Whenever you are about to use an `eval()` function, look for ways to use string index values of arrays of objects instead. The W3C DOM makes it even easier with the help of the `document.getElementById()` method, which takes a string as a parameter and returns a reference to the named object.

**isFinite(number)**

**Returns:** Boolean.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

It is unlikely that you will ever need the `isFinite()` function, but its purpose is to advise whether a number is beyond the absolute minimum or maximum values that JavaScript can handle. If a number is outside of that range, the function returns `false`. The parameter to the function must be a number data type.

## isNaN(*expression*)

**Returns:** Boolean.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

For those instances in which a calculation relies on data coming from a text field or other string-oriented source, you frequently need to check whether the value is a number. If the value is not a number, the calculation may result in a script error.

### Example

Use the `isNaN()` function to test whether a value is a number prior to passing the value onto the operation. The most common use of this function is to test the result of a `parseInt()` or `parseFloat()` function. If the strings submitted for conversion to those functions cannot be converted to a number, the resulting value is `NaN` (a special symbol indicating “not a number”). The `isNaN()` function returns `true` if the value is not a number.

A convenient way to use this function is to intercept improper data before it can do damage, as follows:

```
function calc(form) {
    var inputValue = parseInt(form.entry.value);
    if (isNaN(inputValue)) {
        alert("You must enter a number to continue.");
    } else {
        statements for calculation
    }
}
```

Probably the biggest mistake scripters make with this function is failing to observe the case of all the letters in the function name. The trailing uppercase “N” is easy to miss.

## Number("string")

## parseFloat("string")

## parseInt("string" [,radix])

**Returns:** Number.

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

All three of these functions convert a string value into a numeric value. The `parseInt()` and `parseFloat()` functions are compatible across all versions of all browsers; the `Number()` function was introduced in NN4 and IE4.

Use the `Number()` function when your script is not concerned with the precision of the value and prefers to let the source string govern whether the returned value is a floating-point number or an integer. The function takes a single parameter—a string to convert to a number value.

The `parseFloat()` function also lets the string source value determine whether the returned value is a floating-point number or an integer. If the source string includes any non-zero value to the right of the decimal, the result is a floating-point number. But if the string value were, say, "3.00", the returned value would be an integer value.

An extra, optional parameter for `parseInt()` enables you to define the number base for use in the conversion. If you don't specify a radix parameter, JavaScript tries to look out for you; but in doing so, JavaScript may cause some difficulty for you. The primary problem arises when the string parameter for `parseInt()` starts with a zero, which a text box entry or database field might do. In JavaScript, numbers starting with zero are treated as octal (base-8) numbers. Therefore, `parseInt("010")` yields the decimal value 8.

**parseFloat()**

When you apply the `parseInt()` function, always specify the radix of 10 if you are working in base-10 numbers. You can, however, specify any radix value from 2 through 36. For example, to convert a binary number string to its decimal equivalent, assign a radix of 2 as follows:

```
var n = parseInt("011",2);
// result: 3
```

Similarly, you can convert a hexadecimal string to its decimal equivalent by specifying a radix of 16:

```
var n = parseInt("4F",16);
// result: 79
```

**Example**

Both `parseInt()` and `parseFloat()` exhibit a very useful behavior: If the string passed as a parameter starts with at least one number followed by, say, letters, the functions do their jobs on the numeric part of the string and ignore the rest. This is why you can use `parseFloat()` on the `navigator.appVersion` string to extract just the reported version number without having to parse the rest of the string. For example, NN6 for Windows reports a `navigator.appVersion` value as

```
5.0 (Windows; en-US)
```

But you can get just the numeric part of the string via `parseFloat()`:

```
var ver = parseFloat(navigator.appVersion);
```

Because the result is a number, you can perform numeric comparisons to see, for instance, whether the version is greater than or equal to 4.

**toString([radix])**

**Returns:** String.

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

Every JavaScript core language object and every DOM document object has a `toString()` method associated with it. This method is designed to render the contents of the object in as meaningful a way as possible. Table 34-1 shows the result of applying the `toString()` method on each of the convertible core language object types.

---

**Table 34-1: toString() Method Results for Object Types**

---

<i>Object Type</i>	<i>Result</i>
String	The same string
Number	String equivalent (but numeric literals cannot be converted)
Boolean	"true" or "false"
Array	Comma-delimited list of array contents (with no spaces after commas)
Function	Decompiled string version of the function definition

---

Many DOM objects can be converted to a string. For example, a `location` object returns its URL. But when an object has nothing suitable to return for its content as a string, it usually returns a string in the following format:

[object objectType]

## Example

The `toString()` method is available on all versions of all browsers. By setting the optional `radix` parameter between 2 and 16, you can convert numbers to string equivalents in different number bases. Listing 34-1 calculates and draws a conversion table for decimal, hexadecimal, and binary numbers between 0 and 20. In this case, the source of each value is the value of the index counter variable each time the `for` loop's statements execute.

### Listing 34-1: Using `toString()` with Radix Values

```
<html>
  <head>
    <title>Number Conversion Table</title>
  </head>
  <body>
    <b>Using toString() to convert to other number bases:</b>
    <hr />
    <table border="1">
      <tr>
        <th>Decimal</th>
        <th>Hexadecimal</th>
        <th>Binary</th>
        <script type="text/javascript">
          var content = "";
          for (var i = 0; i <= 20; i++) {
            content += "<tr>";
            content += "<td>" + i.toString(10) + "<\td>";
            content += "<td>" + i.toString(16) + "<\td>";
            content += "<td>" + i.toString(2) + "<\td><\tr>";
          }
          document.write(content);
        </script>
      </tr>
    </table>
  </body>
</html>
```

The `toString()` method of user-defined objects does not convert the object into a meaningful string, but you can create your own method to do just that. For example, if you want to make your custom object's `toString()` method behave like an array's method, define the action of the method and assign that function to a property of the object (as shown in Listing 34-2).

### Listing 34-2: Creating a Custom `toString()` Method

```
<html>
  <head>
    <title>Custom toString()</title>
    <script type="text/javascript">
      function customToString() {
        var dataArray = new Array();
```

*Continued*

**toString()****Listing 34-2 (continued)**

```

        var count = 0;
        for (var i in this) {
            dataArray[count++] = this[i];
            if (count > 2) {
                break;
            }
        }
        return dataArray.join(",");
    }
    var book = {title:"The Aeneid", author:"Virgil", pageCount:543};
    book.toString = customToString;
</script>
</head>
<body>
    <b>A user-defined toString() result:</b>
    <hr />
    <script type="text/javascript">
        document.write(book.toString());
    </script>
</body>
</html>

```

When you run Listing 34-2, you can see how the custom object's `toString()` handler extracts the values of all elements of the object. You can customize how the data should be labeled and/or formatted.

**unwatch(*property*)****watch(*property*, *handler*)**

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

To supply the right kind of information to external debuggers, JavaScript in NN4+ implements two global functions that belong to every object—including user-defined objects. The `watch()` function keeps an eye on a desired object and property. If that property is set by assignment, the function invokes another user-defined function that receives information about the property name, its old value, and its new value. The `unwatch()` function turns off the watch functionality for a particular property.

## Statements

```
//
/* ... */
```

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Comments are statements that the JavaScript interpreter (or server-side compiler) ignores. However, these statements enable authors to leave notes about how things work in their scripts. While lavish comments are useful to authors during a script's creation and maintenance, the full content of a client-side comment is downloaded with the document. Every

**const**

byte of non-operational content of the page takes a bit more time to download. Still, I recommend lots of comments — particularly as you create a script.

JavaScript offers two styles of comments. One style consists of two forward slashes (no spaces between them). JavaScript ignores any characters to the right of those slashes on the same line, even if they appear in the middle of a line. You can stack as many lines of these single-line comments as is necessary to convey your thoughts. I typically place a space between the second slash and the beginning of my comment. The following are examples of valid, one-line comment formats:

```
// this is a comment line usually about what's to come
var a = "Fred"; // a comment about this line
// You may want to capitalize the first word of a comment
// sentence if it runs across multiple lines.
//
// And you can leave a completely blank line, like the one above.
```

For longer comments, it is usually more convenient to enclose the section in the other style of comment. The following comment opens with a forward slash and asterisk (`/*`) and ends with an asterisk and forward slash (`*/`). JavaScript ignores all statements in between — including multiple lines. If you want to comment out briefly a large segment of your script for debugging purposes, it is easiest to bracket the segment with these comment symbols. To make these comment blocks easier to find, I generally place these symbols on their own lines as follows:

```
/*
some
  commented-out
  statements
*/
```

If you are developing rather complex documents, you might find using comments a convenient way to help you organize segments of your scripts and make each segment easier to find. For example, you can define a comment block above each function and describe what the function is about, as in the following example.

```
/*-----
  calculate()
  Performs a mortgage calculation based on
  parameters blah, blah, blah. Called by blah
  blah blah.
-----*/
function calculate(form) {
  statements
}
```

**const**

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `const` keyword initializes a constant. Unlike a variable, whose data is subject to change while a page loads, a constant's value cannot be modified once it is assigned. It is common practice in many programming languages to define constant identifiers with all uppercase letters, usually with underscore characters to delimit multiple words. This style makes it easier to see a constant's application later in the program.

**Example**

Listing 34-3 shows how you can use a constant in NN6+/Moz1+. The page conveys temperature data for several cities. (Presumably, this data is updated on the server and fashioned

**const**

into an array of data when the user requests the page.) For temperatures below freezing, the temperature is shown in a distinctive text style. Because the freezing temperature is a constant reference point, it is assigned as a constant.

**Listing 34-3: Using the const Keyword**

```
<html>
  <head>
    <title>const(ant)</title>
    <style type="text/css">
      .cold {font-weight:bold; color:blue}
    </style>
    <script type="text/javascript">
      const FREEZING_F = 32;
      var cities = ["London", "Moscow", "New York", "Tokyo", "Sydney"];
      var tempsF = [33, 12, 20, 40, 75];
      function showData() {
        var tableData = "";
        for (var i = 0; i < cities.length; i++) {
          tableData += "<tr><td>" + cities[i] + "<\td><td ";
          tableData += (tempsF[i] < FREEZING_F) ? "class='cold'" : "";
          tableData += ">" + tempsF[i] + "<\td><\tr>";
        }
        document.getElementById("display").innerHTML = tableData;
      }
    </script>
  </head>
  <body onload="showData()">
    <h1>The const keyword</h1>
    <hr />
    <table id="temps">
      <tr>
        <th>City</th>
        <th>Temperature</th>
      </tr>
      <tbody id="display"></tbody>
    </table>
  </body>
</html>
```

The `const` keyword likely will be adopted in the next version of the ECMA-262 standard and will become part of the JavaScript vernacular in future browsers.

**var**

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

Before using any variable, you should declare it (and optionally initialize it with a value) via the `var` statement. If you omit the `var` keyword, the variable is automatically assigned as a global variable within the current document. To keep a variable local to a function, you must declare or initialize the variable with the `var` keyword inside the function's braces.

If you assign no value to a variable, it evaluates to `null`. Because a JavaScript variable is not limited to one variable type during its lifetime, you don't need to initialize a variable to an

**ActiveXObject**

empty string or zero unless that initial value helps your scripting. For example, if you initialize a variable as an empty string, you can then use the add-by-value operator (+) to append string values to that variable in a future statement in the document.

To save statement lines, you can declare and/or initialize multiple variables with a single `var` statement. Separate each `varName=value` pair with a comma, as in

```
var name, age, height; // declare as null
var color = "green", temperature = 85.6; // initialize
```

Variable names (also known as identifiers) must be one contiguous string of characters, and the first character must be a letter. Many punctuation symbols are also banned, but the underscore character is valid and often is used to separate multiple words in a long variable name. All variable names (like most identifiers in JavaScript) are case-sensitive, so you must name a particular variable identically throughout the variable's scope.

## WinIE Objects

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

Microsoft prides itself on the integration between Web browser functionality and the Windows operating system. The linkage between browser and OS is most apparent in IE's facilities for accessing ActiveX objects. Microsoft has fashioned several such objects for access to scripters — again, provided the deployment is intended only for Windows versions of Internet Explorer. Some objects also exist as a way to expose some Visual Basic Script (VBScript) functionality to JavaScript. Because these objects are more within the realm of Windows and ActiveX programming, the details and quirks of working with them from WinIE is best left to other venues. But in case you are not familiar with these facilities, the following discussions introduce the basic set of WinIE objects. You can find more details at the Microsoft Developer Network (MSDN) Web site at <http://msdn.microsoft.com/>.

The objects mentioned here are the `ActiveXObject`, `Dictionary`, `Enumerator`, and `VBArray` objects. Microsoft documents these objects as if they are part of the native JScript language. However, you can be sure that they will remain proprietary certainly to Internet Explorer, if not exclusively for Windows-only versions.

## ActiveXObject

`ActiveXObject` is a generic object that allows your script to open and access what Microsoft sometimes calls *automation objects*. An automation object is an executable program that might run on the client or be served from a server. This can include local applications, such as applications from the Microsoft Office suite, executable DLLs (dynamic-link libraries), and so on.

Use the constructor for the `ActiveXObject` to obtain a reference to the object according to the following syntax:

```
var objRef = new ActiveXObject(appName.className[, remoteServerName]);
```

This JScript syntax is the equivalent of the VBScript `CreateObject()` method. You need to know a bit about Windows programming to determine the application name and the classes or types available for that application. For example, to obtain a reference to an Excel worksheet, use this constructor:

```
var mySheet = new ActiveXObject("Excel.Sheet");
```

Once you have a reference to the desired object, you must also know the names of the properties and methods of the object you'll be addressing. You can access much of this information via Microsoft's developer tools, such as Visual Studio .NET or the tools that come with Visual

**ActiveXObject**

Basic .NET. These tools enable you to query an object to discover its properties and methods. Unfortunately, an `ActiveXObject`'s properties are not enumerable through a typical JavaScript `for-in` property inspector.

Accessing an `ActiveXObject`, especially one on the client, involves some serious security considerations. The typical security setup for an IE client prevents scripts from accessing client applications, at least not without asking the user if it's okay to do so. While it's foolhardy to state categorically that you cannot perform surreptitious inspection or damage to a client without the user's knowledge (hackers find holes from time to time), it is highly unlikely. In a corporate environment, where some level of access to all clients is desirable, the client may be set up to accept instructions to work with ActiveX objects when they come from trusted sources. The bottom line is that unless you are well versed in Windows programming, don't expect the `ActiveXObject` to become some kind of magic portal that enables you to invade the privacy or security of unsuspecting users.

**Dictionary**

While the `Dictionary` object is very helpful to VBScript authors, JavaScript already provides the equivalent functionality natively. A `Dictionary` object behaves very much like a JavaScript array that has string index values (similar to a Java hash table), although numeric index values are also acceptable in the `Dictionary`. Indexes are called *keys* in this environment. VBScript arrays do not have this facility natively, so the `Dictionary` object supplements the language for the sake of convenience. Unlike a JavaScript array, however, you must use the various properties and methods of the `Dictionary` object to add, access, or remove items from it.

You create a `Dictionary` object via `ActiveXObject` as follows:

```
var dict = new ActiveXObject("Scripting.Dictionary");
```

You must create a separate `Dictionary` object for each array. Table 34-2 lists the properties and methods of the `Dictionary` object. After you create a blank `Dictionary` object, populate it via the `Add()` method for each entry. For example, the following statements create a `Dictionary` object to store U.S. state capitals:

```
var stateCaps = new ActiveXObject("Scripting.Dictionary");
stateCaps.Add("Illinois", "Springfield");
```

You can then access an individual item via the `Key` property (which, thanks to its VBScript heritage, looks more like a JavaScript method). One convenience of the `Dictionary` object is the `Keys()` method, which returns an array of all the keys in the dictionary — something that a string-indexed JavaScript array could use.

---

**Table 34-2: Dictionary Object Properties and Methods**

---

<i>Property</i>	<i>Description</i>
Count	Integer number of entries in the dictionary (read-only)
Item("key")	Reads or writes a value for an entry whose name is <i>key</i>
Key("key")	Assigns a new key name to an entry
<i>Method</i>	<i>Description</i>
Add("key", value)	Adds a value associated with a unique key name
Exists("key")	Returns Boolean <i>true</i> if <i>key</i> exists in dictionary

<b>Method</b>	<b>Description</b>
Items()	Returns VBAArray of values in dictionary
Keys()	Returns VBAArray of keys in dictionary
Remove("key")	Removes <i>key</i> and its value
RemoveAll()	Removes all entries

## Enumerator

An `Enumerator` object provides JavaScript with access to collections that otherwise do not allow direct access to their items via index number or name. This object isn't necessary when working with DOM collections, such as `document.all`, because you can use the `item()` method to obtain a reference to any member of the collection. But if you are scripting ActiveX objects, some of these objects' methods or properties may return collections that cannot be accessed through this mechanism or the JavaScript `for-in` property inspection technique. Instead, you must wrap the collection inside an `Enumerator` object.

To wrap a collection in an `Enumerator`, invoke the constructor for the object, passing the collection as the parameter:

```
var myEnum = new Enumerator(someCollection);
```

This enumerator instance must be accessed via one of its four methods to position a "pointer" to a particular item and then extract a copy of that item. In other words, you don't access a member directly (that is, by diving into the collection with an item number to retrieve). Instead, you move the pointer to the desired position and then read the item value. As you can see from the list of methods in Table 34-3, this object is truly intended for looping through the collection. Pointer control is limited to positioning it at the start of the collection and incrementing its position along the collection by one:

```
myEnum.moveFirst();
for (; !myEnum.atEnd(); myEnum.moveNext()) {
    val = myEnum.item();
    // more statements that work on value
}
```

**Table 34-3: Enumerator Object Methods**

<b>Method</b>	<b>Description</b>
atEnd()	Returns <code>true</code> if pointer is at end of collection
item()	Returns value at current pointer position
moveFirst()	Moves pointer to first position in collection
moveNext()	Moves pointer to next position in collection

## VBAArray

The `VBAArray` object provides JavaScript access to Visual Basic *safe arrays*. Such an array is read-only and is commonly returned by ActiveX objects. Such arrays can be composed in

**VBArry**

VBScript sections of client-side scripts. Visual Basic arrays by their very nature can have multiple dimensions. For example, the following code creates a three-by-two VB array:

```
<script type="text/vbscript">
Dim myArray(2, 1)
myArray(0, 0) = "A"
myArray(0, 1) = "a"
myArray(1, 0) = "B"
myArray(1, 1) = "b"
myArray(2, 1) = "C"
myArray(2, 2) = "c"
</script>
```

Once you have a valid VB array, you can convert it to an object that the JScript interpreter can't choke on:

```
<script type="text/javascript">
var theVBArry = new VBArry(myArray);
</script>
```

Global variables from one script language block can be accessed by another block, even in a different language. But at this point, the array is not in the form of a JavaScript array yet. You can either convert it to such via the `VBArry.toArray()` method or access information about the `VBArry` object through its other methods (described briefly in Table 34-4). Once you convert a `VBArry` to a JavaScript array, you can then iterate through the values just like any JavaScript array.

---

**Table 34-4: VBArry Object Methods**

---

<i>Method</i>	<i>Description</i>
<code>dimensions()</code>	Returns number of dimensions of the original array
<code>getItem(dim1[, dim2[...dimN]])</code>	Returns value at array location defined by dimension addresses
<code>lbound(dim)</code>	Returns lowest index value for a given dimension
<code>toArray()</code>	Returns JavaScript array version of <code>VBArry</code>
<code>ubound(dim)</code>	Returns highest index value for a given dimension

---

When you use the `toArray()` method and the source array has multiple dimensions, values from dimensions after the first “row” are simply appended to the JavaScript array with no nesting structure.

# Body Text Objects

---

A large number of HTML elements fall into a catchall category of elements whose purposes are slightly more targeted than contextual elements covered in Chapter 15. In this group are some very widely used elements, such as the `h1` through `h6` header elements, plus several elements that are not yet widely used because their full support may be lacking in even some of the most modern browsers. In this chapter, you find all sorts of text-related objects, excluding those objects that act as form controls (text boxes and such, which are covered in Chapter 23). For the most part, properties, methods, and event handlers of this chapter's objects are the generic ones covered in Chapter 15. Only those items that are unique to each object are covered in this chapter (as will be the case in all succeeding chapters).

Beyond the HTML element objects covered in this chapter, you also meet the `TextRange` object, first introduced in IE4, and the corresponding `Range` object from the W3C DOM. This object is a very powerful one for scripters because it allows scripts to work very closely with body content — not in terms of, for example, the `innerText` or `nodeValue` properties of elements, but rather in terms of the text as it appears on the page in what users see as paragraphs, lists, and the like. The `TextRange` and `Range` objects essentially give your scripts cursor control over running body text for functions, such as cutting, copying, pasting, and applications that extend from those basic operations — search and replace, for instance. Bear in mind that everything you read in this chapter requires at minimum the dynamic object models of IE4+ and NN6+/W3C; some items require IE5+. Unfortunately, the IE `TextRange` object is not implemented in MacIE5.

## blockquote and q Element Objects

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

For HTML element properties, methods, and event handlers, see Chapter 15.

---

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
cite		

---

### In This Chapter

Objects that display running body text in documents

Using the NN/Mozilla `Range` and IE `TextRange` objects

Scripting search-and-replace actions

**blockquote**

## Syntax

Accessing `blockquote` or `q` element object properties or methods:

```
(IE4+)      [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

## About these objects

The `blockquote` element is a special-purpose text container. Browsers typically start the content on its own line in the body and indent on both the left and right margins approximately 40 pixels. An inline quotation can be encased inside a `q` element, which does not force the quoted material to start on the next line.

From an object point of view, the only property that distinguishes these two objects from any other kind of contextual container is the `cite` property, which comes from the HTML 4.0 `cite` attribute. This attribute simply provides a URL reference for the citation and does not act as an `src` or `href` attribute to load an external document.

## Property

### `cite`

**Value:** String.

Read/Write

**Compatibility:** WinIE6, MacIE5+, NN6+, Moz1+, Safari1+

The `cite` property can contain a URL (as a string) that points to the source of the quotation in the `blockquote` or `q` element. Future browsers may provide some automatic user interface link to the source document, but none of the browsers that support the `cite` property do anything special with this information.

## br Element Object

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>clear</code>		

## Syntax

Accessing `br` element object properties or methods:

```
(IE4+)      [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

## About this object

The `br` element forces a carriage return and line feed for rendered content on the page. This element does not provide the same kind of vertical spacing that goes between paragraphs in a series of `p` elements. Only one attribute (`clear`) distinguishes this element from generic HTML elements and objects.

## Property

`clear`

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `clear` property defines how any text in an element following the `br` element wraps around a floating element (for example, an image set to float along the right margin). While recent browsers expose this property, the attribute on which it is based is deprecated in the HTML 4.0 specification in an effort to encourage the use of the `clear` stylesheet attribute for a `br` element.

Values for the `clear` property can be one of the following strings: `all`, `left`, or `right`.

**Related Items:** `clear` stylesheet property.

## font Element Object

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
color		
face		
size		

## Syntax

Accessing font element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])  
(IE5+/W3C) [window.]document.getElementById("elemID").property |  
method([parameters])
```

## About this object

In a juxtaposition of standards implementations, the `font` element is exposed as an object only in browsers that also support Cascading Style Sheets as the preferred way to control font faces, colors, and sizes. This doesn't mean that you shouldn't use `font` elements in your page with modern browsers — using this element may be necessary for a single page that

**font**

needs to be backward compatible with older browsers. But it does present a quandary for scripters who want to use scripts to modify font characteristics of body text after the page has loaded. A good rule of thumb to follow is to use the `font` element (and script the `font-HTML` element object's properties) when the page must work in all browsers; use stylesheets (and their scriptable properties) on pages that will be running exclusively in IE4+ and NN6+/W3C.

## Properties

**color**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

A `font` object's text color can be controlled via the `color` property. Values can be either hexadecimal triplets (for example, #FFCCFF) or the plain-language color names recognized by most browsers. In either case, the values are case-insensitive strings.

### Example

Listing 35-1 contains a page that demonstrates changes to the three `font` element object properties: `color`, `face`, and `size`. Along the way, you can see an economical use of the `setAttribute()` method to do the work for all of the property changes. This page loads successfully in all browsers, but the `select` lists make changes to the text only in IE4+ and NN6+/W3C.

A `p` element contains a nested `font` element that encompasses three words whose appearance is controlled by three `select` lists. Each list controls one of the three `font` object properties, and their `name` attributes are strategically assigned the names of the properties (as you see in a moment). `value` attributes for `option` elements contain strings that are to be assigned to the various properties. Each `select` element invokes the same `setFontAttr()` function, passing a reference to itself so that the function can inspect details of the element.

The first task of the `setFontAttr()` function is to make sure that only browsers capable of treating the `font` element as an object get to the meat of the function. The test for the existence of `document.all` and the `myFONT` element blocks all older browsers from changing the font characteristics.

For suitably equipped browsers, the function next extracts the string from the `value` property of the `select` object that was passed to the function. If a selection is made (meaning other than the first, empty one), the single nested statement uses the `setAttribute()` method to assign the value to the attribute whose name matches the name of the `select` element.

**Note**

An odd bug in MacIE5 doesn't let the rendered color change when changing the `color` property. But the setting is valid, as proven by selecting any of the other two property choices.

### Listing 35-1: Dynamically Changing Font Properties

```
<html>
  <head>
    <title>Font Object Properties</title>
    <script type="text/javascript">
      // one function does all!
```

**font.face**

```

function setFontAttr(select) {
    var choice = select.options[select.selectedIndex].value;
    if (choice) {
        document.getElementById("myFONT").setAttribute(select.name,
            choice);
    }
}
</script>
</head>
<body>
<h1>Font Object Properties</h1>
<br />
<p>This may look like a simple sentence, but <font id="myFONT">THESE
    THREE WORDS</font> are contained by a FONT element.</p>
<form>
    Select a text color: <select name="color"
        onchange="setFontAttr(this)">
        <option></option>
        <option value="red">Red</option>
        <option value="green">Green</option>
        <option value="blue">Blue</option>
        <option value="#FA8072">Some Hex Triplet Value</option>
    </select><br />
    Select a font face: <select name="face" onchange="setFontAttr(this)">
        <option></option>
        <option value="Helvetica">Helvetica</option>
        <option value="Times">Times</option>
        <option value="Comic Sans MS, sans-serif">Comic Sans MS,
            sans-serif</option>
        <option value="Courier, monospace">Courier, monospace</option>
        <option value="Zapf Dingbats, serif">Zapf Dingbats, serif</option>
    </select><br />
    Select a font size: <select name="size" onchange="setFontAttr(this)">
        <option></option>
        <option value="3">3 (Default)</option>
        <option value="+1">Increase Default by 1</option>
        <option value="-1">Decrease Default by 1</option>
        <option value="1">Smallest</option>
        <option value="7">Biggest</option>
    </select>
</form>
</body>
</html>

```

**Related Items:** color stylesheet attribute.

**face**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

A font object's font face is controllable via the `face` property. Just as the `face` attribute (and the corresponding `font-family` stylesheet attribute), you can specify one or more font names in a comma-delimited string. Browsers start with the leftmost font face and look for a match in the client computer's system. The first matching font face that is found in the client system is applied to the text surrounded by the `font` element. You should list the most specific fonts first,

**font.face**

and generally allow the generic font faces (`sans-serif`, `serif`, and `monospace`) to come last; that way you exert at least some control over the look of the font on systems that don't have your pretty fonts. If you know that Windows displays a certain font you like and the Macintosh has something that corresponds to that font but with a different name, you can specify both names in the same property value. The browser skips over font face names not currently installed on the client.

**Example**

See Listing 35-1 for an example of values that can be used to set the `face` property of a `font` element object. While you will notice visible changes to most choices on the page, the font face selections may not change from one choice to another, since that all depends on the fonts that are installed on your PC.

**Related Items:** `font-family` style sheet attribute.

**size**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The size of text contained by a `font` element can be controlled via the `size` property. Unlike the more highly recommended `font-size` stylesheet attribute, the `size` property of the `font` element object (and its corresponding `SIZE` attribute) are restricted to the relative font size scale imposed by early HTML implementations: a numbering scale from 1 to 7.

Values for the `size` property are strings, even though most of the time they are single numeral values. You can also specify a size relative to the default value by including a plus or minus sign before the number. For example, if the default font size (as set by the browser's user preferences) is 3, you can bump up the size of a text segment by encasing it inside a `font` element and then setting its `size` property to "+2".

For more accurate font sizing using units, such as pixels or points, use the `font-size` stylesheet attribute.

**Example**

See Listing 35-1 for an example of values that can be used to set the `size` property of a `font` element object. Notice that incrementing or decrementing the `size` property is applied only to the size assigned to the `size` attribute of the element (or the default, if none is specified) and not the current setting adjusted by script.

**Related Items:** `font-size` style sheet attribute.

## h1...h6 Element Objects

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>align</code>		

## Syntax

Accessing h1 through h6 element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

## About these objects

The so-called “heading” elements (denoted by h1, h2, h3, h4, h5, and h6) provide shortcuts for formatting up to six different levels of headings and subheadings. While you can simulate the appearance of these headings with p elements and stylesheets, the heading elements very often contain important contextual information about the structure of the document. With the IE5+ and NN6+/W3C powers of inspecting the node hierarchy of a document, a script can generate its own table of contents or outline of a very long document by looking for elements whose nodeName properties are in the hn family. Therefore, it is a good idea to continue using these elements for contextual purposes, even if you intend to override the default appearance by way of stylesheet templates.

As for the scriptable aspects of these six objects, they are essentially the same as the generic contextual objects with the addition of the align property. Because each hn element is a block-level element, you can use stylesheets to set their alignment rather than the corresponding attribute or property. The choice is up to you.

## Property

align

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

String values of the align property control whether the heading element is aligned with the left margin (left), center of the page (center), or right margin (right). The corresponding align attribute is deprecated in HTML 4.0 in favor of the text-align stylesheet attribute.

**Related Items:** text-align stylesheet attribute.

## hr Element Object

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
align		
color		
noShade		
width		

**hr**

## Syntax

Accessing `hr` element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

## About this object

The `hr` element draws a horizontal rule according to size, dimension, and alignment characteristics normally set by the attributes of this element. Stylesheets can also specify many of those settings, the latter route being recommended for pages that will be loaded exclusively in pages that support CSS. In IE4+ and NN6+/W3C DOM browsers, your scripts can modify the appearance of an `hr` element either directly through element object properties or through stylesheet properties. To reference a specific `hr` element by script, you must assign an `id` attribute to the element—a practice that you are probably not accustomed to observing.

## Properties

**align****Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

An `hr` object's horizontal alignment can be controlled via the `align` property. String values enable you to set it to align with the left margin (`left`), the center of the page (`center`), or right margin (`right`). By default, the element is centered.

## Example

Listing 35-2 contains a page that demonstrates the changes to the five `hr` element object properties: `align`, `color`, `noShade`, `size`, and `width`. Along the way, you can see an economical use of the `setAttribute()` method to do the work for all of the property changes. This page loads successfully in all browsers, but the `select` lists make changes to the text only in IE4+ and NN6+/W3C DOM browsers (because they treat the element as an object).

An `hr` element (whose `id` is `myHR`) is displayed with the browser default settings (100% width, centered, and its “magic” color). Each list controls one of the five `hr` object properties, and their `name` attributes are strategically assigned the names of the properties (as you see in a moment). `value` attributes for `option` elements contain strings that are to be assigned to the various properties. Each `select` element invokes the same `setHRAttr()` function, passing a reference to itself so that the function can inspect details of the element.

The first task of the `setHRAttr()` function is to make sure that only browsers capable of treating the `hr` element as an object get to the meat of the function. As the page loads, the `document.all` property is set for NN6+/W3C using a normalization technique described in Chapter 14.

For suitably equipped browsers, the function next reads the string from the `value` property of the `select` object that is passed to the function. If a selection is made (that is, other than the first, empty one), the single, nested statement uses the `setAttribute()` method to assign the value to the attribute whose name matches the name of the `select` element.

**Listing 35-2: Controlling hr Object Properties**

```
<html>
  <head>
    <title>hr Object Properties</title>
    <script type="text/javascript">
      // one function does all!
      function setHRAttr(select) {
        var choice = select.options[select.selectedIndex].value;
        if (choice) {
          document.getElementById("myHR").setAttribute(select.name, choice);
        }
      }
    </script>
  </head>
  <body>
    <h1>hr Object Properties</h1>
    <br />
    <p>Here is the hr element you will be controlling:</p>
    <hr id="myHR" />
    <form>
      Select an alignment: <select name="align" onchange="setHRAttr(this)">
        <option></option>
        <option value="left">Left</option>
        <option value="center">Center</option>
        <option value="right">Right</option>
      </select><br />
      Select a rule color (IE only): <select name="color"
      onchange="setHRAttr(this)">
        <option></option>
        <option value="red">Red</option>
        <option value="green">Green</option>
        <option value="blue">Blue</option>
        <option value="#FA8072">Some Hex Triplet Value</option>
      </select><br />
      Select a rule shading: <select name="noShade"
      onchange="setHRAttr(this)">
        <option></option>
        <option value="true">No Shading</option>
        <option value="false">Shading</option>
      </select><br />
      Select a rule height: <select name="size" onchange="setHRAttr(this)">
        <option></option>
        <option value="2">2 (Default)</option>
        <option value="4">4 Pixels</option>
        <option value="10">10 Pixels</option>
      </select><br />
      Select a rule width: <select name="width" onchange="setHRAttr(this)">
        <option></option>
        <option value="100%">100% (Default)</option>
        <option value="80%">80%</option>
        <option value="300">300 Pixels</option>
      </select>
    </form>
  </body>
</html>
```

**hr.align**

**Related Items:** `text-align` stylesheet attribute.

**color**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

An `hr` object's `color` can be controlled via the `color` property. Values can be either hexadecimal triplets (for example, `#FFCCFF`) or the plain-language color names recognized by most browsers. In either case, the values are case-insensitive strings. If you change the color from the default, the default shading (3-D effect) of the rule disappears. I have yet to find the magic value that lets you return the color to the browser default after it has been set to another color.

**Example**

See Listing 35-2 earlier in this chapter for an example of values that can be used to set the `color` property of an `hr` element object.

**Related Items:** `color` stylesheet attribute.

**noShade**

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

A default `hr` element is displayed with a kind of three-dimensional effect, called *shading*. You can turn shading off under script control by setting the `noShade` property to `true`. But be aware that in IE4+, the `noShade` property is a one-way journey: You cannot restore shading after it is removed. Moreover, default shading is lost if you assign a different color to the rule.

**Example**

See Listing 35-2 earlier in this chapter for an example of values that can be used to set the `noShade` property of an `hr` element object. Because of the buggy behavior associated with setting this property, adjusting the property in the example has unexpected (and usually undesirable) consequences.

**Related Items:** `color` stylesheet attribute.

**size**

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The size of an `hr` element is its vertical thickness, as controlled via the `size` property. Values are integers, representing the number of pixels occupied by the rule. Safari 1.0 does not change the element's rendered size via this property.

**Example**

See Listing 35-2 earlier in this chapter for an example of values that can be used to set the `size` property of an `hr` element object.

**width**

**Value:** Integer or string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**label.accessKey**

The width of an `hr` element is controlled via the `width` property. By default, the element occupies the entire width of its parent container (usually the Body).

You can specify width as either an absolute number of pixels (as an integer) or as a percentage of the width of the parent container. Percentage values are strings that include a trailing percent character (%).

### Example

See Listing 35-2 earlier in this chapter for an example of values that can be used to set the `width` property of an `hr` element object.

**Related Items:** `width` stylesheet attribute.

## label Element Object

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
accessKey		
form		
htmlFor		

### Syntax

Accessing `label` element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

### About this object

The `label` element lets you assign a contextual relationship between a form control (text field, radio button, select list, and so on) and the otherwise freestanding text that is used to label the control on the page. This element does not control the rendering or physical relationship between the control and the label—the HTML source code order does that.

Wrapping a form control label inside a `label` element is important if scripts will be navigating the element hierarchy of a page's content and the relationship between a form control and its label is important to the results of the document parsing.

### Properties

`accessKey`

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE5+, NN6+, Moz1+, Safari1+

For most other HTML element objects, the `accessKey` property description is covered in the generic element property descriptions of Chapter 15. The function of the property for the

**label.accessKey**

`label` object is the same as the IE implementation for all other elements. The single-character string value is the character key to be used in concert with the OS- and browser-specific modifier key (for example, Ctrl in IE for Windows) to bring focus to the form control associated with the label. This value is best set initially via the `accesskey` attribute for the `label` element.

**Related Items:** `accessKey` property of generic elements.

**form**

**Value:** Form object reference.

Read-Only

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `form` property of a `label` element object returns a reference to the form object that contains the form control with which the label is associated. This property can be useful in a node parsing script that wants to retrieve the form container from the perspective of the label rather than from the form control. The form object reference returned from the `label` element object is the same form object reference returned by the `form` property of any form control object.

**Related Items:** `form` property of `input` element objects.

**htmlFor**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `htmlFor` property is a string that contains the `id` of the form control element with which the label is associated. This value is normally set via the `htmlfor` attribute in the `label` element's tag. Modifying this property does not alter the position or rendering of the label, but it does change the relationships between label and control.

## marquee Element Object

**Compatibility:** WinIE4+, MacIE4+, NN7+, Moz1+, Safari-

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>behavior</code>	<code>start()</code>	<code>onbounce</code>
<code>bgColor</code>	<code>stop()</code>	<code>onfinish</code>
<code>direction</code>		<code>onstart</code>
<code>height</code>		
<code>hspace</code>		
<code>loop</code>		
<code>scrollAmount</code>		
<code>scrollDelay</code>		
<code>trueSpeed</code>		
<code>vspace</code>		
<code>width</code>		

## Syntax

Accessing marquee element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+) [window.]document.getElementById("elemID").property |
method([parameters])
```

## About this object

The marquee element is a Microsoft proprietary element that displays scrolling text within a rectangle specified by the `width` and `height` attributes of the element. Text that scrolls in the element goes between the element's `start` and `end` tags. The IE4+ object model exposes the element and many properties to the object model for control by script. The element and some of its scriptability is implemented in NN7+/Moz1+.

## Properties

### behavior

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `behavior` property controls details in the way scrolled text moves within the scrolling space. Values for this property are one of the following three strings: `alternate`, `scroll`, and `slide`. NN7/Moz allows only `alternate`. When set to `alternate`, scrolling alternates between left and right (or up and down, depending on the `direction` property setting). A value of `scroll` means that the text marches completely to and through the space before appearing again. And a value of `slide` causes the text to march into view until the last character is visible. When the `slide` value is applied as a property (instead of as an attribute value in the tag), the scrolling stops when the text reaches an edge of the rectangle. Default behavior for the marquee element is the equivalent of `scroll`.

## Example

Listing 35-3 contains a page that demonstrates the changes to several marquee element object properties: `behavior`, `bgColor`, `direction`, `scrollAmount`, and `scrollDelay`. NN7+/Moz do not react to all property settings. See the description of Listing 35-1 for details on the attribute setting script.

### Listing 35-3: Controlling marquee Object Properties

```
<html>
  <head>
    <title>marquee Object Properties</title>
    <script type="text/javascript">
      // one function does all!
      function setMARQUEEAttr(select) {
        var choice = select.options[select.selectedIndex].value;
        if (choice) {
          document.getElementById("myMARQUEE").setAttribute(select.name,
            choice);
        }
      }
    </script>
  </head>
</html>
```

*Continued*

**marquee.behavior****Listing 35-3 (continued)**

```

    </script>
</head>
<body>
  <h1>marquee Object Properties</h1>
  <br />
  <hr />
  <marquee id="myMARQUEE" width="400" height="24">This is the marquee
  element object you will be controlling.</marquee>
  <form>
    <input type="button" value="Start Marquee"
    onclick="document.getElementById('myMARQUEE').start()" /> <input
    type="button" value="Stop Marquee"
    onclick="document.getElementById('myMARQUEE').stop()" /><br />
    Select a behavior: <select name="behavior"
    onchange="setMARQUEEAttr(this)">
      <option></option>
      <option value="alternate">Alternate</option>
      <option value="scroll">Scroll</option>
      <option value="slide">Slide</option>
    </select><br />
    Select a background color: <select name="bgColor"
    onchange="setMARQUEEAttr(this)">
      <option></option>
      <option value="red">Red</option>
      <option value="green">Green</option>
      <option value="blue">Blue</option>
      <option value="#FA8072">Some Hex Triplet Value</option>
    </select><br />
    Select a scrolling direction: <select name="direction"
    onchange="setMARQUEEAttr(this)">
      <option></option>
      <option value="left">Left</option>
      <option value="right">Right</option>
      <option value="up">Up</option>
      <option value="down">Down</option>
    </select><br />
    Select a scroll amount: <select name="scrollAmount"
    onchange="setMARQUEEAttr(this)">
      <option></option>
      <option value="4">4</option>
      <option value="6">6 (Default)</option>
      <option value="10">10</option>
    </select><br />
    Select a scroll delay: <select name="scrollDelay"
    onchange="setMARQUEEAttr(this)">
      <option></option>
      <option value="50">Short</option>
      <option value="85">Normal</option>
      <option value="125">Long</option>
    </select>
  </form>
</body>
</html>

```

**Related Items:** direction property of marquee object.

**marquee.hspace****bgColor**

**Value:** Hexadecimal triplet or color name string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `bgColor` property determines the color of the background of the `marquee` element's rectangular space. To set the color of the text, either surround the `marquee` element with a `font` element or apply the `color` stylesheet attribute to the `marquee` element. Values for all color properties can be either the common HTML hexadecimal triplet value (for example, "#00FF00") or any of the Netscape color names (a list is available at <http://developer.netscape.com/docs/manuals/htmlguid/colortab.htm>).

**Example**

See Listing 35-3 earlier in this chapter for an example of how to apply values to the `bgColor` property.

**direction**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN7+, Moz1+, Safari-

The `direction` property lets you get or set the horizontal or vertical direction in which the scrolling text moves. Four possible string values are `left`, `right`, `down`, `up`. NN7/Moz observe `left` and `right` only. The default value is `left`.

**Example**

See Listing 35-3 earlier in this chapter for an example of how to apply values to the `direction` property.

**Related Items:** `behavior` property of `marquee` object.

**height****width**

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN7+, Moz1+, Safari-

The `height` and `width` properties enable you to get or set the pixel size of the rectangle occupied by the element. NN7/Moz implement `width` only. You can adjust each property independently of the other, but like most attribute-inspired properties of IE objects, if no `height` or `width` attributes are defined in the element's tag, you cannot use these properties to get the size of the element as rendered by default.

**hspace****vspace**

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `hspace` and `vspace` properties let you get or set the amount of blank margin space surrounding the `marquee` element. Adjustments to the `hspace` property affect both the left and right (horizontal) margins of the element; `vspace` governs both top and bottom (vertical) margins. Margin thicknesses are independent of the height and width of the element.

**marquee.loop****loop****Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `loop` property allows you to discover the number of times the `marquee` element was set to repeat its scrolling according to the `loop` attribute. Although this property is read/write, modifying it by script does not cause the text to loop only that number of times more before stopping. Treat this property as read-only.

**scrollAmount****scrollDelay****Value:** Integers.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN7+, Moz1+, Safari-

The `scrollAmount` and `scrollDelay` properties control the perceived speed and scrolling smoothness of the `marquee` element text. The number of pixels between redrawings of the scrolling text is controlled by the `scrollAmount` property. The smaller the number, the less jerky the scrolling is (the default value is 6). At the same time, you can control the time in milliseconds between each redrawing of the text with the `scrollDelay` property. The smaller the number, the more frequently redrawing is performed (the default value is 85 or 90, depending on the operating system). Thus, a combination of low `scrollAmount` and `scrollDelay` property values presents the smoothest (albeit slow) perceived scrolling.

**Example**

See Listing 35-3 earlier in this chapter for an example of how to apply values to the `scrollAmount` and `scrollDelay` properties.

**Related Items:** `trueSpeed` property of `marquee` object.

**trueSpeed****Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

IE has a built-in regulator that prevents `scrollDelay` attribute or `scrollDelay` property settings below 60 from causing the `marquee` element text to scroll too quickly. But if you genuinely want to use a speed faster than 60 (meaning, a value lower than 60), then also set the `trueSpeed` property to `true`.

**Related Items:** `scrollDelay` property of `marquee` object.

## Methods

**start()****stop()****Returns:** Nothing.**Compatibility:** WinIE4+, MacIE4+, NN7+, Moz1+, Safari-

Scripts can start or stop (pause) a `marquee` element via the `start()` and `stop()` methods. Neither method takes parameters, and you are free to invoke them as often as you like after the page loads. Be aware that the `start()` method does not trigger the `onstart` event handler for the object.

### Example

See Listing 35-3 earlier in this chapter for examples of both the `start()` and `stop()` methods, which are invoked in event handlers of separate controlling buttons on the page. Notice, too, that when you have the behavior set to `slide`, stopping and restarting the `marquee` does not cause the scroll action to start from a blank region.

## Event Handlers

### `onbounce`

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `onbounce` event handler fires only when the `marquee` element has its `behavior` set to `alternate`. In that back-and-forth mode, each time the text reaches a boundary and is about to start its return trip, the `onbounce` event fires. If you truly want to annoy your users, you could have the `onbounce` event handlers play a sound at each bounce (I'm kidding—please don't do this).

**Related Items:** `behavior` property of `marquee` object.

### `onfinish`

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `onfinish` event handler fires only when the `marquee` element has its `loop` set to a specific value of 1 or greater. After the final text loop has completed, the `onfinish` event fires.

**Related Items:** `loop` property of `marquee` object.

### `onstart`

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `onstart` event handler fires as the `marquee` element begins its scrolling, but only as a result of the page loading. The `start()` method does not trigger this event handler.

**Related Items:** `start()` method of `marquee` object.

## Range Object

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

## Syntax

Creating a Range object:

```
var rangeRef = document.createRange();
```

Accessing Range object properties or methods:

```
(NN6+/Moz1+) rangeRef.property | method([parameters])
```

## About this object

The Range object is the W3C DOM (Level 2) version of what Microsoft had implemented earlier as its TextRange object. A number of important differences (not the least of which is an almost entirely different property and method vocabulary) distinguish the behaviors and capabilities of these two similar objects. Although Microsoft participated in the W3C DOM Level 2 working groups, no participant from the company is credited on the DOM specification chapter regarding the Range object. Because the W3C version has not been implemented as of IE6, it is unknown if or when IE will eventually implement the W3C version. In the meantime, see the WinIE TextRange object section later in this chapter for comparisons between the two objects. Neither the W3C DOM Range nor Microsoft TextRange objects are implemented in MacIE5.

The purpose of the W3C DOM Range object is to provide hooks to a different “slice” of content (most typically a portion of a document’s content) that is not necessarily restricted to the node hierarchy (tree) of a document. While a Range object can be used to access and modify nodes and elements, it can also transcend node and element boundaries to encompass arbitrary segments of a document’s content. The content contained by a range is sometimes referred to as a *selection*, but this does not mean that the text is highlighted on the page, such as a user selection. Instead, the term “selection” here means a segment of the document’s content that can be

## Range

addressed as a unit, separate from the node tree of the document. As soon as the range is created, a variety of methods let scripts examine, modify, remove, replace, and insert content on the page.

A range object (meaning, an instance of the static `Range` object) has a start point and an end point, which together define the boundaries of the range. The points are defined in terms of an offset count of positions within a container. These counts are usually character positions within text nodes (ignoring any HTML tag or attribute characters), but when both boundaries are at the edges of the same node, the offsets may also be counts of nodes within a container that surrounds both the start and end points. An example helps clarify these concepts.

Consider the following simplified HTML document:

```
<html>
  <body>
    <p>This paragraph has an <em>emphasized</em> segment.</p>
  </body>
</html>
```

You can create a range that encompasses the text inside the `em` element from several points of view, each with its own offset counting context:

1. *From the `em` element's only child node (a text node).* The offset of the start point is zero, which is the location of the insertion point in front of the first character (lowercase “e”); the end point offset is 10, which is the character position (zero-based) following the lowercase “d”.
2. *From the `em` element.* The point of view here is that of the child text node inside the `em` element. Only one node exists here, and the offset for the start point is 0, while the offset for the end point is 1.
3. *From the `p` element's child nodes (two text nodes and an element node).* You can set the start point of a range to the very end (counting characters) of the first child text node of the `p` element; you can then set the end point to be in front of the first character of the last child text node of the `p` element. The resulting range encompasses the text within the `em` element.
4. *From the `p` element.* From the point of view of the `p` element, the range can be set with an offset starting with 1 (the second node nested inside the `p` element) and ending with 2 (the start of the third node).

Although these different points of view provide a great deal of flexibility, they also can make it more difficult to imagine how you can use this power. The W3C vocabulary for the `Range` methods, however, helps you figure out what kind of offset measure to use.

A range object's start point could be in one element, and its end point in another. For example, consider the following HTML:

```
<p>And now to introduce our <em>very special</em> guest:</p>
```

If the text shown in boldface indicates the content of a range object, you can see that the range crosses element boundaries in a way that would make HTML element or node object properties difficult to use for replacing that range with some other text. The W3C specification provides guidelines for browser makers on how to handle the results of removing or inserting HTML content that crosses node borders.

An important aspect of the `Range` object is that the size of a range can be zero or more characters. Start and end points always position themselves between characters. When the start point and end point of a range are at the same location, the range acts like a text insertion pointer.

## Range

## Working with ranges

To create a range object, use the `document.createRange()` method and assign the range object returned by this method to a variable that you can use to control the range:

```
var rng = document.createRange();
```

With an active range stored in a variable, you can use many of the object's methods to adjust the start and end points of the range. If the range is to consist of all of the contents of a node, you have two convenience methods that do so from different points of view: `selectNode()` and `selectNodeContents()`. The sole parameter passed with both methods is a reference to the node whose contents you want to turn into a range. The difference between the two methods is how the offset properties of the range are calculated as a result (see the discussion about these methods later in the chapter for details). Another series of methods (`setStartBefore()`, `setStartAfter()`, `setEndBefore()`, and `setEndAfter()`) let you adjust each end point individually to a position relative to a node boundary. For the most granular adjustment of boundaries, the `setStart()` and `setEnd()` methods let you specify a reference node (where to start counting the offset) and the offset integer value.

If you need to select an insertion point (for example, to insert some content into an existing node), you can position either end point where you want it, and then invoke the `collapse()` method. A parameter determines whether the collapse should occur at the range's start or end point.

A suite of other methods lets your scripts work with the contents of a range directly. You can copy (`cloneContents()`), delete (`deleteContents()`, `extractContents()`), insert a node (`insertNode()`), and even surround a range's contents with a new parent node (`surroundContents()`). Several properties let your scripts examine information about the range, such as the offset values, the containers that hold the offset locations, whether the range is collapsed, and a reference to the next outermost node that contains both the start and end points.

Mozilla adds a proprietary method to the Range object (which is actually a method of an object that is built around the Range object) called `createContextualFragment()`. This method lets scripts create a valid node (of type `DocumentFragment`) from arbitrary strings of HTML content — a feature that the W3C DOM does not (yet) offer. This method was devised at first as a substitute for what eventually became the NN6+/Moz `innerHTML` property.

Using the Range object can be a bit tedious, because it often requires a number of script statements to execute an action. Three basic steps are generally required to work with a Range object:

1. Create the text range.
2. Set the start and end points.
3. Act on the range.

As soon as you are comfortable with this object, you will find it provides a lot of flexibility in scripting interaction with body content. For ideas about applying the Range object in your scripts, see the examples that accompany the descriptions of individual properties and methods in the following sections.

Note

The Evaluator (Chapter 13) automatically initializes a W3C DOM Range object in browsers that support the feature. You can access the object via the `rng` global variable to work with examples in the following sections.

## Properties

### collapsed

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `collapsed` property reports whether a range has its start and end points set to the same position in a document. If the value is `true`, the range's start and end containers are the same and the offsets are also the same. You can use this property to verify that a range is in the form of an insertion pointer just prior to inserting a new node:

```
if (rng.collapsed) {
    rng.insertNode(someNewNodeReference);
}
```

### Example

Use The Evaluator's predefined `rng` object to experiment with the `collapsed` property. Reload the page and set the range to encompass a node:

```
rng.selectNode(document.body)
```

Enter `a.collapsed` into the top text box. The expression returns `false` because the end points of the range are not the same.

**Related Items:** `endContainer`, `endOffset`, `startContainer`, `startOffset` properties; `Range.collapse()` method.

### commonAncestorContainer

**Value:** Node object reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `commonAncestorContainer` property returns a reference to the document tree node that both the start and end points have in common. It is not uncommon for a range's start point to be in one node and the end point to be in another. Yet a more encompassing node most likely contains both of those nodes, perhaps even the `document.body` node. The W3C DOM specification also calls the shared ancestor node the *root node* for the range (a term that may make more sense to you).

### Example

Use The Evaluator's predefined `rng` object to experiment with the `commonAncestorContainer` property. Reload the page. Now set the start point to the beginning of the contents of the `myEM` element and set the end point to the end of the surrounding `myP` element:

```
rng.setStartBefore(document.getElementById("myEM").firstChild)
rng.setEndAfter(document.getElementById("myP").lastChild)
```

Verify that the text range is set to encompass content from the `myEM` node (the word "all") and end of `myP` nodes (note that Safari 1.0 returns the wrong data here):

```
rng.toString()
```

Verify, too, that the two end point containers are different nodes:

```
rng.startContainer.tagName
rng.endContainer.tagName
```

**Range.commonAncestorContainer**

Finally, see what node contains both of these two end points:

```
rng.commonAncestorContainer.id
```

The result is the `myP` element, which both the `myP` and `myEM` nodes have in common.

**Related Items:** `endContainer`, `endOffset`, `startContainer`, `startOffset` properties; all “set” and “select” methods of the `Range` object.

**endContainer****startContainer**

**Value:** Node object reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `endContainer` and `startContainer` properties return a reference to the document tree node that contains the range’s end point and start point, respectively. Be aware that the object model calculates the container, and the container may not be the reference you used to set the start and end points of a range. For example, if you use the `selectNode()` method to set the start and end points of a range to encompass a particular node, the containers of the end points are most likely the next outermost nodes. Thus, if you want to expand a range to the start of the node that contains the current range’s start point, you can use the value returned by the `startContainer` property as a parameter to the `setStartBefore()` method:

```
rng.setStartBefore(rng.startContainer)
```

**Example**

Use The Evaluator’s predefined `rng` object to experiment with the `endContainer` and `startContainer` properties. Reload the page and set the range to encompass the `myEM` element:

```
rng.selectNode(document.getElementById("myEM"))
```

Inspect the containers for both the start and end points of the selection:

```
rng.startContainer.id  
rng.endContainer.id
```

The range encompasses the entire `myEM` element, so the start and end points are outside of the element. Therefore, the container of both start and end points is the `myP` element that also surrounds the `myEM` element.

**Related Items:** `commonAncestor`, `endOffset`, `startOffset` properties; all “set” and “select” methods of the `Range` object.

**endOffset****startOffset**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `endOffset` and `startOffset` properties return an integer count of the number of characters or nodes for the location of the range’s end point and start point, respectively. These counts are relative to the node that acts as the container node for the position of the boundary (see the `Range.endContainer` and `Range.startContainer` properties earlier in this chapter).

**Range.endOffset**

When a boundary is at the edge of a node (or perhaps “between” nodes is a better way to say it), the integer returned is the offset of nodes (zero-based) within the boundary’s container. But when the boundary is in the middle of a text node, the integer returned is an index of the character position within the text node. The fact that each boundary has its own measuring system (nodes versus characters, relative to different containers) can get confusing if you’re not careful, because conceivably the integer returned for an end point could be smaller than that for the start point. Consider the following nested elements:

```
<p>This paragraph has an <em>emphasized</em> segment.</p>
```

The next script statements set the start of the range to a character within the first text node and the end of the range to the end of the `em` node:

```
var rng = document.createRange();
rng.setStart(document.getElementById("myP").firstChild, 19);
rng.setEndAfter(document.getElementById("myEM"));
```

Using boldface to illustrate the body text that is now part of the range and the pipe (|) character to designate the boundaries as far as the nodes are concerned, here is the result of the preceding script execution:

```
<p id="myP">This paragraph has |an <em id="myEM">emphasized</em>| segment.</p>
```

Because the start of the range is in a text node (the first child of the `p` element), the range’s `startOffset` value is 19, which is the zero-based character position of the “a” of the word “an.” The end point, however, is at the end of the `em` element. The system recognizes this point as a node boundary, and thus counts the `endOffset` value within the context of the end container: the `p` element. The `endOffset` value is 2 (the `p` element’s text node is node index 0; the `em` element is node index 1; and the position of the end point is at the start of the `p` element’s final text node, at index 2).

For the `endOffset` and `startOffset` values to be of any practical use to a script, you must also use the `endContainer` and `startContainer` properties to read the context for the offset integer values.

## Example

Use The Evaluator’s predefined `rng` object to experiment with the `endOffset` and `startOffset` properties, following similar paths you just saw in the description. Reload the page and set the range to encompass the `myEM` element and then move the start point outward to a character within the `myP` element’s text node:

```
rng.selectNode(document.getElementById("myEM"))
rng.setStart(document.getElementById("myP").firstChild, 7)
```

Inspect the node types of the containers for both the start and end points of the selection:

```
rng.startContainer.nodeType
rng.endContainer.nodeType
```

The `startContainer` node type is 3 (text node), while the `endContainer` node type is 1 (element). Now inspect the offsets for both the start and end points of the selection:

```
rng.startOffset
rng.endOffset
```

**Related Items:** `endContainer`, `startContainer` properties; all “set” and “select” methods of the `Range` object.

**Range.cloneContents()****Methods**`cloneContents()``cloneRange()`

**Returns:** DocumentFragment node reference; Range object reference.

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1+, Safari1+

The `cloneContents()` method (available in NN7+) takes a snapshot copy of the contents of a Range object and returns a reference to that copy. The copy is stored in the browser's memory, but is not part of the document tree. The `cloneRange()` method (available in NN6+) performs the same action on an entire range and stores the range copy in the browser's memory. A range's contents can consist of portions of multiple nodes and may not be surrounded by an element node; that's why its data is of the type `DocumentFragment` (one of the W3C DOM's node types). Because a `DocumentFragment` node is a valid node, it can be used with other document tree methods where nodes are required as parameters. Therefore, you can clone a text range to insert a copy elsewhere in the document.

In contrast, the `cloneRange()` method deals with range objects. While you are always free to work with the contents of a range object, the `cloneRange()` method returns a reference to a range object, which acts as a kind of wrapper to the contents (just as it does when the range is holding content in the main document). You can use the `cloneRange()` method to obtain a copy of one range to compare the end points of another range (via the `Range.compareBoundaryPoints()` method).

**Example**

Use The Evaluator's predefined `rng` object in NN7+/Moz/Safari to see the `cloneContents()` method in action. Begin by reloading the page and setting the range to the `myP` paragraph element:

```
rng.selectNode(document.getElementById("myP"))
```

Next, clone the original range and preserve the copy in variable `b`:

```
b = rng.cloneContents()
```

Move the original range so that it is an insertion point at the end of the body by first expanding it to encompass the entire body and then collapse it to the end:

```
rng.selectNode(document.body)
rng.collapse(false)
```

Now, insert the copy at the very end of the body:

```
rng.insertNode(b)
```

If you scroll to the bottom of the page, you see a copy of the text in NN7/Moz. Safari 1.0 appears to miscalculate the range's boundary points after `collapse()`, causing a DOM hierarchy error when invoking `insertNode()`. But you can also use `appendChild()` or `insertBefore()` on any element node to put the cloned range into the document tree.

See the description of the `compareBoundaryPoints()` method later in this chapter to see an example of the `cloneRange()` method.

**Related Items:** `compareBoundaryPoints()`, `extractContents()` methods.

**Range.compareBoundaryPoints()**

`collapse([startBoolean])`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

Use the `collapse()` method to shrink a range from its current size down to a single insertion point between characters. Collapsing a range becomes more important than you may think at first, especially in a function that is traversing the body or large chunk of text. For example, in a typical looping word-counting script, you create a text range that encompasses the body fully. To begin counting words, you can first collapse the range to the insertion point at the very beginning of the range. Next, use the `expand()` method to set the range to the first word of text (and increment the counter if the `expand()` method returns `true`). At that point, the text range extends around the first word. You want the range to collapse at the end of the current range so that the search for the next word starts after the current one. Use `collapse()` once more, but this time with a twist of parameters.

The optional parameter of the `collapse()` method is a Boolean value that directs the range to collapse itself either at the start or end of the current range. The default behavior is the equivalent of a value of `true`, which means that unless otherwise directed, a `collapse()` method shifts the text range to the point in front of the current range. This method works great at the start of a word-counting script, because you want the text range to collapse to the start of the text. But for subsequent movements through the range, you want to collapse the range so that it is after the current range. Thus, you include a `false` parameter to the `collapse()` method.

### Example

See Listings 35-11 and 15-14 to see the `collapse()` method at work (albeit with the IE `TextRange` object).

**Related Items:** `Range.setEnd()`, `Range.setStart()` methods.

`compareBoundaryPoints(typeInteger, sourceRangeRef)`

**Returns:** Integer (-1, 0, or 1).

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

Generating multiple range objects and assigning them to different variables is not a problem. You can then use the `compareBoundaryPoints()` method to compare the relative positions of start and end points of both ranges. One range is the object you use to invoke the `compareBoundaryPoints()` method, and the other range is the second parameter of the method. The order in which you reference the two ranges influences the results, based on the value assigned to the first parameter.

Values for the first parameter can be one of four constant values that are properties of the static `Range` object: `Range.START_TO_START`, `Range.START_TO_END`, `Range.END_TO_START`, and `Range.END_TO_END`. What these values specify is which point of the current range is compared with which point of the range passed as the second parameter. For example, consider the following body text that has two text ranges defined within it:

It was the **best of times**.

The first text range (assigned in our discussion here to variable `rng1`) is shown in boldface, while the second text range (`rng2`) is shown in bold-italic. In other words, `rng2` is nested inside `rng1`. We can compare the position of the start of `rng1` against the position of the start of `rng2` by using the `Range.START_TO_START` value as the first parameter of the `compareBoundaryPoints()` method:

```
var result = rng1.compareBoundaryPoints(Range.START_TO_START, rng2);
```

**Range.compareBoundaryPoints**

The value returned from the `compareBoundaryPoints()` method is an integer of one of three values. If the positions of both points under test are the same, then the value returned is 0. If the start point of the (so-called source) range is before the range on which you invoke the method, the value returned is -1; in the opposite positions in the code, the return value is 1. Therefore, from the example above, because the start of `rng1` is before the start of `rng2`, the method returns -1. If you change the statement to invoke the method on `rng2`, as in

```
var result = rng2.compareBoundaryPoints(Range.START_TO_START, rng1);
```

the result is 1.

In practice, this method is helpful in knowing if two ranges are the same, if one of the boundary points of both ranges is the same, or if one range starts where the other ends.

**Example**

The page rendered by Listing 35-4 lets you experiment with text range comparisons in NN6+/Moz. The bottom paragraph contains a `span` element that has a `Range` object assigned to its nested text node after the page loads (in the `init()` function). That fixed range becomes a solid reference point for you to use while you select text in the paragraph.

After you make a selection, all four versions of the `compareBoundaryPoints()` method run to compare the start and end points of the fixed range against your selection. One column of the results table shows the raw value returned by the `compareBoundaryPoints()` method, while the third column puts the results into plain language.

To see how this page works, begin by selecting the first word of the fixed text range (carefully drag the selection from the first red character). You can see that the starting positions of both ranges are the same, because the returned value is 0. Because all of the invocations of the `compareBoundaryPoints()` method are on the fixed text range, all comparisons are from the point of view of that range. Thus, the first row of the table for the `START_TO_END` parameter indicates that the start point of the fixed range comes before the end point of the selection, yielding a return value of -1.

Other selections to make include:

- ♦ Text that starts before the fixed range and ends inside the range
- ♦ Text that starts inside the fixed range and ends beyond the range
- ♦ Text that starts and ends precisely at the fixed range boundaries
- ♦ Text that starts and ends before the fixed range
- ♦ Text that starts after the fixed range

Study the returned values and the plain language results and see how they align with the selection you made.

**Listing 35-4: Lab for NN6+/Moz compareBoundaryPoints() Method**

```

```

compareNode (*nodeReference*)**Returns:** Integer (0, 1, 2, or 3).**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

**Range.createContextualFragment()**

The `compareNode()` method returns an integer code that indicates the relative position of the specified node with respect to the range. The node is passed as the only parameter to the method, and the value returned indicates the relative location of the node. The following four constants may be returned from the `compareNode()` method, and correspond to integer values in the range 0–3: `Range.NODE_BEFORE`, `Range.NODE_AFTER`, `Range.NODE_BEFORE_AND_AFTER`, `Range.NODE_INSIDE`. The first two values explain themselves, but the third value (`Range.NODE_BEFORE_AND_AFTER`) indicates that the node begins before the range and ends after the range. The final value (`Range.NODE_INSIDE`), on the other hand, indicates that the node is contained in its entirety by the range.

**Related Items:** `comparePoint()` method.

**comparePoint(*nodeReference*, *offset*)**

**Returns:** Integer (-1, 0, or 1).

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `comparePoint()` method returns an integer code that indicates the relative position of the specified node at a certain offset with respect to the range. The node (as an object reference) and its offset (an integer count of an element's nodes or a text node's characters) are passed as parameters to the method, and the value returned indicates the relative location of the node. This location is specified with respect to the point (node and offset), not the range. The location of the node is indicated by the integer values -1, 0, and 1, where -1 indicates that the point comes before the start of the range, 0 indicates that the point is located within the range, and 1 reveals that the point comes after the end of the range.

**Related Items:** `compareNode()` method.

**createContextualFragment("text")**

**Returns:** W3C DOM document fragment node.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `createContextualFragment()` method provides a way, within the context of the W3C DOM Level 2 node hierarchy to create a string of HTML text (with or without HTML tags, as needed) for insertion or appendage to existing node trees. During the development of the NN6 browser, this method filled a gap that was eventually filled by Netscape's adoption of the Microsoft proprietary `innerHTML` property. The method obviates the need for tediously assembling a complex HTML element via a long series of `document.createElement()` and `document.createTextNode()` methods for each segment, plus the assembly of the node tree prior to inserting it into the actual visible document. The existence of the `innerHTML` property of all element objects, however, reduces the need for the `createContextualFragment()` method, while allowing more code to be shared across browser brands.

The parameter to the `createContextualFragment()` method is any text, including HTML tags. To invoke the method, however, you need to have an existing range object available. Therefore, the sequence used to generate a document fragment node is

```
var rng = document.createRange();
rng.selectNode(document.body); // any node will do
var fragment = rng.createContextualFragment("<h1>Howdy</h1>");
```

As a document fragment, the node is not part of the document node tree until you use the fragment as a parameter to one of the tree modification methods, such as `Node.insertBefore()` or `Node.appendChild()`.

**Range.createContextualFragment****Example**

Use The Evaluator's predefined `rng` object to replace an existing document tree node with the fragment. Begin by creating the fragment from The Evaluator's built-in range:

```
b = rng.createContextualFragment("<span style='font-size:22pt'>a bunch of  
</span>")
```

This fragment consists of a `span` element node with a text node nested inside. At this point, you can inspect the properties of the document fragment by entering `b` into the bottom text box.

To replace the `myEM` element on the page with this new fragment, use the `replaceChild()` method on the enclosing `myP` element:

```
document.getElementById("myP").replaceChild(b, document.getElementById("myEM"))
```

The fragment now becomes a legitimate child node of the `myP` element and can be referenced like any node in the document tree. For example, if you enter the following statement into the top text box of The Evaluator, you can retrieve a copy of the text node inside the new `span` element:

```
document.getElementById("myP").childNodes[1].firstChild.nodeValue
```

**Related Items:** Node object (Chapter 15).

**deleteContents()**

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `deleteContents()` method removes all contents of the current range from the document tree. After deletion, the range collapses to an insertion point where any surrounding content (if any) cinches up to its neighbors.

Some alignment of a range's boundaries forces the browser to make decisions about how element boundaries inside the range are treated after the deletion. An easy deletion is one for which the range boundaries are symmetrical. For example, consider the following HTML with a range highlighted in bold:

```
<p>One paragraph with an <em>emphasis</em> inside.</p>
```

After you delete the contents of this range, the text node inside the `em` element disappears, but the `em` element remains in the document tree (with no child nodes). Similarly, if the range is defined as being the entire second child node of the `p` element, as follows

```
<p>One paragraph with an <em>emphasis</em> inside.</p>
```

then deleting the range contents removes both the text node and the `em` element node, leaving the `p` element with a single, unbroken text node as a child (although in the previous case, an extra space would be between the words "an" and "inside" because the `em` element does not encompass a space on either side).

When range boundaries are not symmetrical, the browser does its best to maintain document tree integrity after the deletion. Consider the following HTML and range:

```
<p>One paragraph with an <em>emphasis</em> inside.</p>
```

After deleting this range's contents, the document tree for this segment looks like the following:

```
<p>One paragraph <em>phasis</em> inside.</p>
```

The range collapses to an insertion point just before the `<em>` tag. But notice that the `em` element persisted to take care of the text still under its control. Many other combinations of range

**Range.detach()**

boundaries and nodes are possible, so be sure that you check out the results of a contents deletion for asymmetrical boundaries before applying the deletion.

**Example**

Use The Evaluator's predefined `rng` object to experiment with deleting contents of both a text node and a complete element node. Begin by adjusting the text range to the text node inside the `myEM` element (enter the third statement, which wraps below, as one continuous expression):

```
rng.setStart(document.getElementById("myEM").firstChild, 0)
rng.setEnd(document.getElementById("myEM").lastChild,
            document.getElementById("myEM").lastChild.length)
```

Verify the makeup of the range by entering `a` into the bottom text box and inspect its properties. Both containers are text nodes (they happen to be the same text node), and offsets are measured by character positions.

Now, delete the contents of the range:

```
rng.deleteContents()
```

The italicized word “all” is gone from the tree, but the `myEM` element is still there. To prove it, put some new text inside the element:

```
document.getElementById("myEM").innerHTML = "a band of "
```

The italic style of the `em` element applies to the text, as it should.

Next, adjust the range boundaries to include the `myEM` element tags, as well:

```
rng.selectNode(document.getElementById("myEM"))
```

Inspect the `Range` object's properties again by entering `rng` into the bottom text box. The container nodes are the `p` element that surrounds the `em` element; the offset values are measured in nodes. Delete the range's contents:

```
rng.deleteContents()
```

Not only is the italicized text gone, but the `myEM` element is gone, too. The `myP` element now has two child nodes: the two text nodes that used to flank the `em` element. The following entries into the top text box of The Evaluator verify this fact:

```
document.getElementById("myP").childNodes.length
document.getElementById("myP").childNodes[0].nodeValue
```

To combine the two sibling text nodes into one, invoke the `normalize()` method of the container:

```
document.getElementById("myP").normalize()
```

Check the number of child nodes again to verify the results.

**Related Items:** `Range.extractContents()` method.

**detach()**

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `detach()` method instructs the browser to release the current range object from the object model. In the process, the range object is nulled out to the extent that an attempt to access the object results in a script error. You can still assign a new range to the same variable if you like. You are not required to detach a range when you're finished with it, and the browser

**Range.detach**

resources employed by a range are not that large. But it is good practice to “clean up after yourself,” especially when a script repetitively creates and manages a series of new ranges.

**Related Items:** `document.createRange()` `method.extractContents()`

**extractContents()**

**Returns:** `DocumentFragment` node reference.

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1+, Safari1+

The `extractContents()` method deletes the contents of the range and returns a reference to the document fragment node that is held in the browser memory, but which is no longer part of the document tree. A range’s contents can consist of portions of multiple nodes and may not be surrounded by an element node; that’s why its data is of the type `DocumentFragment` (one of the W3C DOM’s node types). Because a `DocumentFragment` node is a valid node, it can be used with other document tree methods where nodes are required as parameters. Therefore, you can extract a text range from one part of a document to insert elsewhere in the document.

**Example**

Use The Evaluator’s predefined `rng` object in NN7+/Moz/Safari to see how the `extractContents()` method works. Begin by setting the built-in range object to contain the text of the `myP` paragraph element.

```
rng.selectNode(document.getElementById("myP"))
```

Next, extract the original range’s content and preserve the copy in variable `b`:

```
b = a.extractContents()
```

Now, insert the extracted fragment at the very end of the body:

```
document.body.appendChild(b)
```

If you scroll to the bottom of the page, you see a copy of the text.

**Related Items:** `cloneContents()`, `deleteContents()` methods.

**insertNode(*nodeReference*)**

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1+, Safari1+

The `insertNode()` method inserts a node at the start point of the current range. The node being inserted may be an element or text fragment node, and its source can be any valid node creation mechanism, such the `document.createTextNode()` method or any node extraction method.

**Example**

Listing 35-5 demonstrates the `insertNode()` method plus some additional items from the `selection` object. The example even includes a rudimentary undo buffer for scripted changes to a text range. In the page generated by this listing, users can select any text in a paragraph and have the script automatically convert the text to all uppercase characters. The task of replacing a selection with other text requires several steps, starting with the selection, which is retrieved via the `window.getSelection()` method. After making sure the selection contains some text (that is, the selection isn’t collapsed), the selection is preserved as a range object so that the starting text can be stored in a global variable (as a property of the `undoBuffer` global variable object). After that, the selection is deleted from the document tree, leaving the selection as a

**Range.insertNode()**

collapsed insertion point. A copy of that selection in the form of a range object is preserved in the `undoBuffer` object so that the undo script knows where to reinsert the original text. A new text node is created with an uppercase version of the original text, and, finally, the `insertNode()` method is invoked to stick the converted text into the collapsed range.

Undoing this operation works in reverse. Original locations and strings are copied from the `undoBuffer` object. After creating the range with the old start and end points (which represent a collapsed insertion point), the resurrected text (converted to a text node) is inserted into the collapsed range. For good housekeeping, the `undoBuffer` object is restored to its unused form.

**Listing 35-5: Inserting a Node into a Range**

```
<html>
  <head>
    <title>NN Selection Object Replacement</title>
    <script type="text/javascript">
      var undoBuffer = {rng:{}, txt:""};

      function convertSelection() {
        var sel, grossRng, netRng, newText;
        try {
          sel = window.getSelection();
          if (!sel.isCollapsed) {
            grossRng = sel.getRangeAt(0);
            undoBuffer.txt = grossRng.toString();
            undoBuffer.rng.startContainer = grossRng.startContainer;
            undoBuffer.rng.startOffset = grossRng.startOffset;
            undoBuffer.rng.endContainer = grossRng.endContainer;
            undoBuffer.rng.endOffset = grossRng.endOffset;
            sel.deleteFromDocument();
            netRng = sel.getRangeAt(0);
            newText = document.createTextNode(undoBuffer.txt.toUpperCase());
            netRng.insertNode(newText);
            netRng.commonAncestorContainer.parentNode.normalize();
          }
        }
        catch(err) {
          alert("Vital Range or Selection object services are not yet
implemented " +
              "in this browser.");
        }
      }

      function undoConversion() {
        var rng, oldText;
        if (undoBuffer.rng) {
          rng = document.createRange();
          rng.setStart(undoBuffer.rng.startContainer,
undoBuffer.rng.startOffset);
          rng.setEnd(undoBuffer.rng.endContainer, undoBuffer.rng.endOffset);
          rng.extractContents();
          oldText = document.createTextNode(undoBuffer.txt);
          rng.insertNode(oldText);
          undoBuffer.rng = {};
        }
      }
    </script>
  </head>
</html>

```

**intersectsNode(*nodeReference*)****Returns:** Boolean.**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `intersectsNode()` method returns a Boolean value that indicates whether (`true`) or not (`false`) any part of the range overlaps the node whose reference is passed as the method's parameter.

**Related Items:** `compareNode()` method.**isPointInRange(*nodeReference*, *offset*)****Returns:** Boolean.**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `isPointInRange()` method returns a Boolean value that indicates whether (`true`) or not (`false`) the specified node (a node object reference) and offset (integer count of an element's nodes or a text node's characters) are located entirely within the range.

**selectNode(*nodeReference*)****selectNodeContents(*nodeReference*)****Returns:** Nothing.**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

The `selectNode()` and `selectNodeContents()` methods are convenience methods for setting both end points of a range to surround a node or a node's contents. The kind of node you supply as the parameter to either method (text node or element node) has a bearing on the range's container node types and units of measure for each (see the container- and offset-related properties of the `Range` object earlier in this chapter).

Starting with the `selectNode()` method, if you specify an element node as the one to select, the start and end container node of the new range is the next outermost element node; offset values count nodes within that parent element. If you specify a text node to be selected, the

**Range.setEnd()**

container node for both ends is the parent element of that text node; offset values count the nodes within that parent.

With the `selectNodeContents()` method, the start and end container nodes are the very same element specified as the parameter; offset values count the nodes within that element. If you specify a text node's contents to be selected, the text node is the start and end parent, but the range is collapsed at the beginning of the text.

By and large, you specify element nodes as the parameter to either method, allowing you to set the range to either encompass the element (via `selectNode()`) or just the contents of the element (via `selectNodeContents()`).

**Example**

Use The Evaluator's predefined `rng` object to see the behavior of both the `selectNode()` and `selectNodeContents()` methods work. Begin by setting the range object's boundaries to include the `myP` element node:

```
rng.selectNode(document.getElementById("myP"))
```

Enter `a` into the bottom text box to view the properties of the range. Notice that because the range has selected the entire paragraph node, the container of the range's start and end points is the `body` element of the page (the parent element of the `myP` element).

Now change the range so that it encompasses only the contents of the `myP` element:

```
rng.selectNodeContents(document.getElementById("myP"))
```

Click the List Properties button to view the current properties of the range. The container of the range's boundary points is the `p` element that holds the element's contents.

**Related Items:** `setEnd()`, `setEndAfter()`, `setEndBefore()`, `setStart()`, `setStartAfter()`, `setStartBefore()` methods.

`setEnd(nodeReference, offset)`

`setStart(nodeReference, offset)`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

You can adjust the start and end points of a text range independently via the `setStart()` and `setEnd()` methods. While not as convenient as the `selectNode()` or `selectNodeContents()` methods, these two methods give you the ultimate in granularity over precise positioning of a range boundary.

The first parameter to both methods is a reference to a node. This reference can be an element or text node, but your choice here also influences the kind of measure applied to the integer offset value supplied as the second parameter. When the first parameter is an element node, the offset counts are in increments of child nodes inside the specified element node. But if the first parameter is a text node, the offset counts are in increments of characters within the text node.

When you adjust the start and end points of a range with these methods, you have no restrictions to the symmetry of your boundaries. One boundary can be defined relative to a text node, while the other relative to an element node — or vice versa.

To set the end point of a range to the last node or character within a text node (depending on the unit of measure for the `offset` parameter), you can use the `length` property of the units being measured. For example, to set the end point to the end of the last node within an element

**Range.setEnd()**

(perhaps there are multiple nested elements and text nodes within that outer element), you can use the first parameter reference to help you get there:

```
rng.setEnd(document.getElementById("myP"),
           document.getElementById("myP").childNodes.length);
```

These kinds of expressions get lengthy, so you may want to make a shortcut to the reference to simplify the values of the parameters, as shown in this version that sets the end point to after the last character of the last text node of a `p` element:

```
var nodeRef = document.getElementById("myP").lastChild;
rng.setEnd(nodeRef, nodeRef.nodeValue.length);
```

In both previous examples with the `length` properties, the values of those properties are always pointing to the node or character position after the final object because the index values for those objects' counts are zero-based. Also bear in mind that if you want to set a range end point at the edge of a node, you have four other methods to choose from (`setEndAfter()`, `setEndBefore()`, `setStartAfter()`, and `setStartBefore()`). The `setEnd()` and `setStart()` methods are best used when an end point needs to be set at a location other than at a node boundary.

**Example**

Use The Evaluator's predefined `rng` object to experiment with both the `setStart()` and `setEnd()` methods. For the first range, set the start and end points to encompass the second node (the `myEM` element) inside the `myP` element:

```
rng.setStart(document.getElementById("myP"), 1)
rng.setEnd(document.getElementById("myP"), 2)
```

The text encompassed by the range consists of the word "all" plus the trailing space that is contained by the `myEM` element. Prove this by entering the following statement into the top text box (Safari 1.0 returns an incorrect value):

```
rng.toString()
```

If you then click the Results box to the right of the word "all," you see that the results contain the trailing space. Yet, if you examine the properties of the range (enter `a` into the bottom text box), you see that the range is defined as actually starting before the `myEM` element and ending after it.

Next, adjust the start point of the range to a character position inside the first text node of the `myP` element:

```
rng.setStart(document.getElementById("myP").firstChild, 11)
```

Click the List Properties button to see that the `startContainer` property of the range is the text node, and that the `startOffset` measures the character position. All end boundary properties, however, have not changed. Enter `rng.toString()` in the top box again to see that the range now encompasses text from two of the nodes inside the `myP` element.

You can continue to experiment by setting the start and end points to other element and text nodes on the page. After each adjustment, verify the properties of the a range object and the text it encompasses (via `rng.toString()`).

**Related Items:** `selectNode()`, `selectNodeContents()`, `setEndAfter()`, `setEndBefore()`, `setStartAfter()`, `setStartBefore()` methods.

```
setEndAfter(nodeReference)  
setEndBefore(nodeReference)  
setStartAfter(nodeReference)  
setStartBefore(nodeReference)
```

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

You can adjust the start and end points of a text range relative to existing node boundaries via your choice of these four methods. The “before” and “after” designations are used to specify which side of the existing node boundary the range should have for its boundary. For example, using `setStartBefore()` and `setEndAfter()` with the same element node as a parameter is the equivalent of the `selectNode()` method on that element. You may also specify a text node as the parameter to any of these methods. But because these methods work with node boundaries, the offset values are always defined in terms of node counts, rather than character counts. At the same time, however, the boundaries do not need to be symmetrical, so that one boundary can be inside one node and the other boundary inside another node.

## Example

Use The Evaluator’s predefined `rng` object to experiment with all four methods. For the first range, set the start and end points to encompass the `myEM` element inside the `myP` element:

```
rng.setStartBefore(document.getElementById("myEM"))  
rng.setEndAfter(document.getElementById("myEM"))
```

The text encompassed by the range consists of the word “all” plus the trailing space that is contained by the `myEM` element. Prove this by entering the following statement into the top text box (Safari 1.0 returns an incorrect value):

```
rng.toString()
```

Next, adjust the start point of the range to the beginning of the first text node of the `myP` element:

```
rng.setStartBefore(document.getElementById("myP").firstChild)
```

Enter `rng` into the bottom text box to see that the `startContainer` property of the range is the `p` element node, while the `endContainer` property points to the `em` element.

You can continue to experiment by setting the start and end points to before and after other element and text nodes on the page. After each adjustment, verify the properties of the `a` range object and the text it encompasses (via `rng.toString()`).

**Related Items:** `selectNode()`, `selectNodeContents()`, `setEnd()`, `setStart()` methods.

## surroundContents(*nodeReference*)

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1+, Safari1+

The `surroundContents()` method surrounds the current range with a new parent element. Pass the new parent element as a parameter to the method. No document tree nodes or elements are removed or replaced in the process, but the current range becomes a child node of the new node; if the range coincides with an existing node, then the relationship between that node and its original parent becomes that of grandchild and grandparent. An application of this method may be to surround user-selected text with a `span` element whose class renders the content with a special font style or other display characteristic based on a stylesheet selector for that class name.

**Range.surroundContents()**

When the element node being applied as the new parent has child nodes itself, those nodes are discarded before the element is applied to its new location. Therefore, for the most predictable results, using content-free element nodes as the parameter to the `surroundContents()` method is best.

**Example**

Listing 35-6 demonstrates how the `surroundContents()` method wraps a range inside a new element. As the page loads, a global variable (`newSpan`) stores a `span` element that is used as a prototype for elements to be used as new surrounding parent nodes. When you select text in either of the two paragraphs, the selection is converted to a range. The `surroundContents()` method then wraps the range with the `newSpan` element. Because that `span` element has a class name of `hilite`, the element and its contents pick up the stylesheet properties as defined for that class selector.

**Note**

NN7 and Mozilla (at least through version 1.4) exhibit a bug in this method when used with a range derived from a `selection` object or when the range is not aligned with element boundaries. Until this bug is fixed, Listing 35-6 will follow its exception execution track.

**Listing 35-6: Using the Range.surroundContents() Method**

```
<html>
  <head>
    <title>Range.surroundContents() Method</title>
    <style type="text/css">
      .hilite {background-color:yellow; color:red; font-weight:bold}
    </style>
    <script type="text/javascript">
      var newSpan = document.createElement("span");
      newSpan.className = "hilite";

      function highlightSelection() {
        var sel, rng;
        try {
          sel = window.getSelection();
          if (!sel.isCollapsed) {
            rng = sel.getRangeAt(0);
            rng.surroundContents(newSpan.cloneNode(false));
          }
        }
        catch(err) {
          alert("Vital Range or Selection object services are not yet
implemented in
this browser.");
        }
      }
    </script>
  </head>
  <body>
    <h1>Range.surroundContents() Method</h1>
    <hr />
    <p onmouseup="highlightSelection()">These paragraphs contain text that
you can select. Selections are surrounded by span elements that share
a stylesheet class selector for special font and display
characteristics.</p>
```

## selection

```

    <p onmouseup="highlightSelection()">Lorem ipsum dolor sit amet,
    consectetur adipiscing elit, sed do eiusmod tempor incididunt ut
    labore et dolore magna aliqua. Ut enim adminim veniam, quis nostrud
    exercitation ullamco laboris nisi ut aliquip ex ea commodo
    consequat.</p>
  </body>
</html>

```

**Related Items:** `Range.insertNode()` method.

## toString()

**Returns:** String.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

Use the `toString()` method to retrieve a copy of the body text that is contained by the current text range. The text returned from this method is ignorant of any HTML tags or node boundaries that exist in the document tree. You also use this method to get the text of a user selection, after it has been converted to a text range. Safari 1.0 commonly returns text beyond the range, even though the range's property values reflect correct characteristics.

## Example

Use The Evaluator's predefined `rng` object to see the results of the `toString()` method. Enter the following sequence of statements into the top text box:

```

rng.selectNode(document.getElementById("myP"))
rng.toString()

```

If you type only `rng` into the top text box, you see the text contents of the range, but don't be fooled. Internal workings of The Evaluator attempt to evaluate any expression entered into that text field. Assigning a range object to a text box forces an internal application of the `toString()` method (just as the `Date` object does when you create a new object instance in The Evaluator).

**Related Items:** `Selection.getRangeAt()`, `Range.extractContents()` methods.

# selection Object

## Syntax

Accessing `selection` object properties or methods:

```
(IE4+)      [window.]document.selection.property | method()
(NN6+/Moz) window.selection.property | method()
```

## About this object

The `selection` object provides scripted access to any body text or text in a form text control that is selected either by the user or by script. A `selection` object of one character or more is always highlighted on the page, and only one `selection` object can be active at any given instant.

Take advantage of the `selection` object when your page invites a user to select text for some operation that utilizes the selected text. The best event to use for working with a selection is the `onmouseup` event handler. This event fires on every release of the mouse, and your script can investigate the `document.selection` object to see if any text has been selected (using the selection's `type` property).

If you intend to perform some action on a selection, you may not be able to trigger that action by way of a button or link. In some browser versions and operating systems, clicking one of these elements automatically deselects the body selection.

One important difference between the IE and NN selections is that the NN6+/Moz `selection` object works only on body text, and not on selections inside text-oriented form controls. An NN6/Moz `selection` object has relationships with the document's node tree in that the object defines itself by the nodes (and offsets within those nodes) that encase the start and end points of a selection. When a user drags a selection, the node in which the selection starts is called the *anchor* node; the node holding the text at the point of the selection release is called the *focus* node; for double- or triple-clicked selections, the direction between anchor and focus nodes is in the direction of the language script (for example, left-to-right in Latin-based script families). In many ways, an NN6+/Moz `selection` object behaves just as the W3C DOM `Range` object, complete with methods to collapse and extend the selection. Unlike a range, however, the text encompassed by a `selection` object is highlighted on the page. If your scripts need to work with the nodes inside a selection, the `getRangeAt()` method of the `selection` object returns a range object whose boundary points coincide with the selection's boundary points.

## Properties

anchorNode

focusNode

**Value:** Node reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

These two properties return a reference to the node where the user started (`anchorNode`) and ended (`focusNode`) the selection. If the selection is modified via the `addRange()` method, these properties point to the node boundaries of the most recently added range.

**Related Items:** `anchorOffset` and `focusOffset` properties.

anchorOffset

focusOffset

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

These two properties return an integer count of the number of characters or nodes from the beginning of the selection to the anchor node (`anchorOffset`) and focus node (`focusOffset`). The count represents characters for text nodes, and nodes for element nodes. If the selection is modified via the `addRange()` method, these properties point to the node offsets of the most recently added range.

**Related Items:** `anchorNode` and `focusNode` properties.

isCollapsed

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `isCollapsed` property returns a Boolean value indicating whether or not the anchor and focus boundaries of the selection are the same. If they are the same (`true`), it means the selection has zero length between two characters (or before the first or after the last character of the document).

**Related Items:** `anchorNode` and `focusNode` properties.

rangeCount

**Value:** Integer.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `rangeCount` property returns an integer count of the range objects contained within the selection. A manual user selection always results in a single range being selected, but the `addRange()` method can result in multiple ranges being contained by the selection.

**Related Items:** `getRangeAt()` method.

**selection.type**

## type

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `type` property returns `Text` whenever a selection exists on the page. Otherwise the property returns `None`. A script can use this information to determine if a selection is made on the page:

```
if (document.selection.type == "Text") {
    // process selection
    ...
}
```

Microsoft indicates that this property can sometimes return `Control`, but that terminology is associated with an edit mode outside the scope of this book.

**Example**

Listing 35-7 contains a page that demonstrates several features of the IE `selection` object. When you make a selection with the Deselect radio button selected, you see the value of the `selection.type` property (in the status bar) before and after the selection is deselected. After the selection goes away, the `type` property returns `None`.

**Listing 35-7: Using the document.selection Object**

```
<html>
  <head>
    <title>selection Object</title>
    <script type="text/javascript">
      function processSelection() {
        if (document.choices.process[0].checked) {
          status = "Selection is type: " + document.selection.type;
          setTimeout("emptySelection()", 2000);
        } else if (document.choices.process[1].checked) {
          var rng = document.selection.createRange();
          document.selection.clear();
        }
      }
      function emptySelection() {
        document.selection.empty();
        status = "Selection is type: " + document.selection.type;
      }
    </script>
  </head>
  <body>
    <h1>IE selection Object</h1>
    <hr />
    <form name="choices">
      <input type="radio" name="process" checked="checked" />De-select after
      two seconds<br />
      <input type="radio" name="process" />Delete selected text.
    </form>
```

**selection.clear()**

```
<p onmouseup="processSelection()">Lorem ipsum dolor sit amet,
consectetur adipisicing elit, sed do eiusmod tempor incididunt ut
labore et dolore magna aliqua. Ut enim adminim veniam, quis nostrud
exercitation ullamco laboris nisi ut aliquip ex ea commodo consequat.
Duis aute irure dolor in reprehenderit involuptate velit esse cillum
dolore eu fugiat nulla pariatur.</p>
</body>
</html>
```

---

**Related Items:** `TextRange.select()` method.

## typeDetail

**Value:** See text.

Read-Only

**Compatibility:** WinIE5.5+, MacIE-, NN-, Moz-, Safari-

The `typeDetail` property serves as a placeholder for applications that use the IE browser component, in which case the property can serve as a means of providing additional selection type information.

**Related Items:** `type` property.

## Methods

### `addRange(rangeRef)`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `addRange()` method is used to highlight a selection on a page based upon a `Range` object. You can add multiple ranges to a selection by making repeated calls to the `addRange()` method.

**Related Items:** `removeRange()` method.

### `clear()`

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

Use the `clear()` method to delete the current selection from the document. To the user, the `clear()` method has the same effect as setting the `TextRange.text` property to an empty string. The difference is that you can use the `clear()` method without having to generate a text range for the selection. After you delete a selection, the `selection.type` property returns `None`.

## Example

See Listing 35-7 earlier in this chapter to see the `selection.clear()` method at work.

**Related Items:** `selection.empty()` method.

**selection.collapse**`collapse(nodeRef, offset)`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `collapse()` method collapses the current selection to a location specified by the two parameters, which consist of a node reference and an offset. The `nodeRef` parameter is a text or element node in the document tree to which the collapsed selection is to be moved, while the `offset` parameter is an integer count of characters or nodes within the target node where the collapsed selection should be moved.

**Related Items:** `collapseToEnd()` and `collapseToStart()` methods.

`collapseToEnd()`  
`collapseToStart()`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

These methods collapse the current selection to a location at the start (`collapseToStart()`) or end (`collapseToEnd()`) of the selection. After the collapse, any previously highlighted selection returns to normal display and the selection contains only one range.

**Related Items:** `collapse()` method.

`containsNode(nodeRef, entirelyFlag)`

**Returns:** Boolean.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `containsNode()` method returns a Boolean value indicating whether or not the specified node is contained in the selection. The `nodeRef` parameter is the node you are checking for selection containment, while the `entirelyFlag` parameter specifies whether or not the node must be contained in its entirety (passing `null` for the `entirelyFlag` parameter is usually sufficient).

`createRange()`

**Returns:** `TextRange` object.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

To generate a text range for a user selection in IE, invoke the `createRange()` method of the selection object. I'm not sure why the method for the selection object is called `createRange()` while text ranges for other valid objects are created with a `createTextRange()` method. The result of both methods is a full-fledged `TextRange` object.

**Example**

See Listings 15-36 and 15-45 to see the `selection.createRange()` method turn user selections into text ranges.

**Related Items:** `TextRange` object.

`deleteFromDocument()`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `deleteFromDocument()` method deletes the current selection from the document tree.

**Related Items:** `removeRange()` method.

`selection.removeRange()`

## `empty()`

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `empty()` method deselects the current IE selection. After deselection, the `selection` type property returns `None`. The action of the `empty()` method is the same as the `UnSelect` command invoked via the `execCommand()` method for a document. If the selection was made from a `TextRange` object (via the `TextRange.select()` method), the `empty()` method affects only the visible selection and not the text range.

### Example

See Listing 35-7 earlier in this chapter to view the `selection.empty()` method at work.

**Related Items:** `selection.clear()` method.

## `extend(nodeRef, offset)`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `extend()` method extends the boundary of the selection to the specified node (`nodeRef`) and `offset` (`offset`) within that node. The start of the boundary (anchor node) remains unaffected by this method; only the end of the boundary (focus node) is altered.

## `getRangeAt(rangeIndex)`

**Returns:** Range object.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `getRangeAt()` method obtains the range at the specified zero-based index (`rangeIndex`) within the selection. You can use the `rangeCount` property to determine how many ranges are contained within the selection.

**Related Items:** `rangeCount` property.

## `removeAllRanges()`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `removeAllRanges()` method empties the selection by removing all of the ranges from it. Upon calling this method, the selection collapses and the `rangeCount` property goes to zero; the document tree remains unaffected.

**Related Items:** `removeRange()` method.

## `removeRange(rangeRef)`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `removeRange()` method removes the specified range (`rangeRef`) from the selection, but not from the document tree.

**Related Items:** `removeAllRanges()` method.

**selection.selectAllChildren()****selectAllChildren(*elementNodeRef*)****Returns:** Nothing.**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `selectAllChildren()` method forces the selection to encompass the specified node (`elementNodeRef`) and all of its children. Calling this method on an element node results in the anchor and focus nodes being set to that node.

**toString()****Returns:** String.**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `toString()` method returns a string representation of the selection, which is the body content from the selection minus tags and attributes.

## Text and TextNode Objects

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

## Syntax

Accessing `Text` and `TextNode` object properties or methods:

```
(IE5+/W3C) [window.]document.getElementById("id").TextNodeRef.property | method()
```

## About this object

Discussing the `Text` object of the W3C DOM (as implemented in NN6+/Moz) in the same breath as the IE5+ `TextNode` object is a little tricky. Conceptually, they are the same kind of object in that they are the document tree objects — text nodes — that contain an HTML element's text (see Chapter 14 for details on the role of the text node in the document object hierarchy). Generating a new text node by script is achieved the same way in both object models: `document.createTextNode()`. What makes the discussion of the two objects tricky is that while the W3C DOM version comes from a strictly object-oriented specification (in which a text node is an instance of a `CharacterData` object, which, in turn is an instance of the generic `Node` object), the IE object model is not quite as complete. For example, while the W3C DOM `Text` object inherits all of the properties and methods of the `CharacterData` and `Node` definitions, the IE `TextNode` object exposes only those properties and method that Microsoft deems appropriate.

No discrepancy in terminology gets in the way as to what to call these objects because their object names never become part of the script. Instead script statements always refer to text nodes by other means, such as through a child node-related property of an element object or as a variable that receives the result of the `document.createTextNode()` method.

Although both objects share a number of properties and one method, the W3C DOM `Text` object contains a few methods that have “data” in their names. These properties and methods are inherited from the `CharacterData` object in the DOM specification. They are discussed as a group in the section about object methods in this chapter. In all cases, check the browser version support for each property and method described here.

## Properties

data

**Value:** String.

Read/Write

**Compatibility:** WinIE5+, MacIE5+, NN6+, Moz1+, Safari1+

The `data` property contains the string comprising the text node. Its value is identical to the `nodeValue` property of a text node. See the description of the `nodeValue` property in Chapter 15.

## Example

In the example for the `nodeValue` property used in a text replacement script (in Chapter 1 of this book), you can substitute the `data` property for `nodeValue` to accomplish the same result.

**Related Items:** `nodeValue` property of all element objects (Chapter 15).

**TextNode.appendData()****Methods**

```
appendData("text")
deleteData(offset, count)
insertData(offset, "text")
replaceData(offset, count, "text")
substringData(offset, count)
```

**Returns:** See text.

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

These five methods of the W3C DOM `Text` object provide scripted manipulation of the text inside a text node. Methods that modify the node's data automatically change the values of both the `data` and `nodeValue` properties.

The purposes of these methods are obvious for the most part. Any method that requires an *offset* parameter uses this integer value to indicate where in the existing text node the deletion, insertion, or replacement starts. Offsets are zero-based, meaning that to indicate the action should take place starting with the first character, specify a zero for the parameter. A *count* parameter is another integer, but one that indicates how many characters are to be included. For example, consider a text node that contains the following data:

```
abcdefgh
```

This node could be a node of an element on the page or a node that has been created and assigned to a variable but not yet inserted into the page. To delete the first three characters of that text node, the statement is

```
textNodeReference.deleteData(0,3)
```

This leaves the text node content as

```
defgh
```

As for the `replaceData()` method, the length of the text being put in place of the original chunk of text need not match the *count* parameter. The *count* parameter, in concert with the *offset* parameter, defines what text is to be removed and replaced by the new text.

The `substringData()` method is similar to the JavaScript core language `String.substr()` method in that both require parameters indicating the offset within the string to start reading and for how many characters. You get the same result with the `substringData()` method of a text node as you do from a `nodeValue.substr()` method when both are invoked from a valid text node object.

Of all five methods discussed here, only `substringData()` returns a value: a string.

**Example**

The page created by Listing 35-8 is a working laboratory that you can use to experiment with the five data-related methods in NN6+/Moz/Safari. The text node that invokes the methods is a simple sentence in a `p` element. Each method has its own clickable button, followed by two or three text boxes into which you enter values for method parameters. Don't be put off by the length of the listing. Each method's operation is confined to its own function and is fairly simple.

**TextNode.appendData()**

Each of the data-related methods throws exceptions of different kinds. To help handle these errors gracefully, the method calls are wrapped inside a `try/catch` construction. All caught exceptions are routed to the `handleError()` function where details of the error are inspected and friendly alert messages are displayed to the user. See Chapter 39 on the CD-ROM for details on the `try/catch` approach to error handling in W3C DOM-capable browsers.

**Listing 35-8: Text object Data Method Laboratory**

```
<html>
  <head>
    <title>Data Methods of a W3C Text Object</title>
    <script type="text/javascript">
      function doAppend(form) {
        var node = document.getElementById("myP").firstChild;
        var newString = form.appendStr.value;
        try {
          node.appendData(newString);
        }
        catch(err) {
          handleError(err);
        }
      }

      function doDelete(form) {
        var node = document.getElementById("myP").firstChild;
        var offset = form.deleteOffset.value;
        var count = form.deleteCount.value;
        try {
          node.deleteData(offset, count);
        }
        catch(err) {
          handleError(err);
        }
      }

      function doInsert(form) {
        var node = document.getElementById("myP").firstChild;
        var offset = form.insertOffset.value;
        var newString = form.insertStr.value;
        try {
          node.insertData(offset, newString);
        }
        catch(err) {
          handleError(err);
        }
      }

      function doReplace(form) {
        var node = document.getElementById("myP").firstChild;
        var offset = form.replaceOffset.value;
        var count = form.replaceCount.value;
        var newString = form.replaceStr.value;
```

*Continued*

**TextNode.appendData()****Listing 35-8 (continued)**

```

        try {
            node.replaceData(offset, count, newString);
        } catch(err) {
            handleError(err);
        }
    }
}

function showSubstring(form) {
    var node = document.getElementById("myP").firstChild;
    var offset = form.substrOffset.value;
    var count = form.substrCount.value;
    try {
        alert(node.substringData(offset, count));
    }
    catch(err) {
        handleError(err);
    }
}

// error handler for these methods
function handleError(err) {
    switch (err.name) {
        case "NS_ERROR_DOM_INDEX_SIZE_ERR":
            alert("The offset number is outside the allowable range.");
            break;
        case "NS_ERROR_DOM_NOT_NUMBER_ERR":
            alert("Make sure each numeric entry is a valid number.");
            break;
        default:
            alert("Double-check your text box entries.");
    }
}
</script>
</head>
<body>
    <h1>Data Methods of a W3C Text Object</h1>
    <hr />
    <p id="myP" style="font-weight:bold; text-align:center">
So I called myself Pip, and became to be called Pip.</p>
    <form name="choices">
        <p><input type="button" onclick="doAppend(this.form)"
            value="appendData()" /> String:<input type="text" name="appendStr"
            size="30" /></p>
        <p><input type="button" onclick="doDelete(this.form)"
            value="deleteData()" /> Offset:<input type="text"
            name="deleteOffset" size="3" /> Count:<input type="text"
            name="deleteCount" size="3" /></p>
        <p><input type="button" onclick="doInsert(this.form)"
            value="insertData()" /> Offset:<input type="text"
            name="insertOffset" size="3" /> String:<input type="text"
            name="insertStr" size="30" /></p>
        <p><input type="button" onclick="doReplace(this.form)"
            value="replaceData()" /> Offset:<input type="text"
            name="replaceOffset" size="3" /> Count:<input type="text"
            name="replaceCount" size="3" /> String:<input type="text"
            name="replaceStr" size="30" /></p>
    </form>

```

**TextNode.splitText()**

```

<p><input type="button" onclick="showSubstring(this.form)"
  value="substringData()" /> Offset:<input type="text"
  name="substrOffset" size="3" /> Count:<input type="text"
  name="substrCount" size="3" /></p>
</form>
</body>
</html>

```

**Related Items:** `appendChild()`, `removeChild()`, `replaceChild()` methods of element objects (Chapter 15).

**splitText(*offset*)**

**Returns:** Text or TextNode object.

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `splitText()` method performs multiple actions with one blow. The *offset* parameter is an integer indicating the zero-based index position within the text node at which the node is to divide into two nodes. After you invoke the method on the current text node, the current node consists of the text from the beginning of the node up to the *offset* position. The method returns a reference to the text node whose data starts with the character after the dividing point and extends to the end of the original node. Users won't notice any change in the rendered text: This method influences only the text node structure of the document. Using this method means, for example, that an HTML element that starts with only one text node will have two after the `splitText()` method is invoked. The opposite action (combining contiguous text node objects into a single node) is performed by the NN6+ `normalize()` method (see Chapter 15).

**Example**

Use The Evaluator (Chapter 13) to see the `splitText()` method in action. Begin by verifying that the `myEM` element has but one child node, and that its `nodeValue` is the string "all":

```
document.getElementById("myEM").childNodes.length
document.getElementById("myEM").firstChild.nodeValue
```

Next, split the text node into two pieces after the first character:

```
document.getElementById("myEM").firstChild.splitText(1)
```

Two text nodes are now inside the element:

```
document.getElementById("myEM").childNodes.length
```

Each text node contains its respective portion of the original text:

```
document.getElementById("myEM").firstChild.nodeValue
document.getElementById("myEM").lastChild.nodeValue
```

If you are using NN6+/Moz/Safari, now bring the text nodes back together:

```
document.getElementById("myEM").normalize()
document.getElementById("myEM").childNodes.length
```

At no time during these statement executions does the rendered text change.

**Related Items:** `normalize()` method (Chapter 15).

## TextRange

## Syntax

**Creating a TextRange object:**

```
var rangeRef = document.body.createTextRange();
var rangeRef = buttonControlRef.createTextRange();
var rangeRef = textControlRef.createTextRange();
var rangeRef = document.selection.createRange();
```

**Accessing TextRange object properties or methods:**

```
(IE4+) rangeRef.property | method([parameters])
```

## About this object

Unlike most of the objects covered in Part III of the book, the IE4+ `TextRange` object is not tied to a specific HTML element. The `TextRange` object is, instead, an abstract object that represents text content anywhere on the page (including text content of a text-oriented form control) between a start point and an end point (collectively, the *boundaries* of the range). The user may not necessarily know that a `TextRange` object exists, because no requirement exists to force a `TextRange` object to physically select text on the page (although the `TextRange` object can be used to assist scripts in automating the selection of text; or a script may turn a user selection into a `TextRange` object for further processing).

The purpose of the `TextRange` object is to give scripts the power to examine, modify, remove, replace, and insert content on the page. Start and end points of an IE `TextRange` object are defined exclusively in terms of character positions within the element that is used to create the range (usually the `body` element, but also button- and text-related form control elements). Character positions of body text do not take into account source code characters that may define HTML elements. This factor is what distinguishes a `TextRange`'s behavior from, for instance, the various properties and methods of HTML elements that let you modify or copy elements and their text (for example, `innerText` and `outerText` properties). A `TextRange` object's start point can be in one element, and its end point in another. For example, consider the following HTML:

```
<p>And now to introduce our <em>very special</em> guest:</p>
```

If the text shown in boldface indicates the content of a `TextRange` object, you can see that the range crosses element boundaries in a way that makes HTML element object properties difficult to use for replacing that range with some other text. Challenges still remain in this example, however. Simply replacing the text of the range with some other text forces your script (or the browser) to reconcile the issue of what to do about the nested `em` element, because the `TextRange` object handles only its text. (Your word processing program must address the same kind of issue when you select a phrase that starts in italic but ends in normal font, and then you paste text into that selection.)

An important aspect of the `TextRange` object is that the size of the range can be zero or more characters. Start and end points always position themselves between characters. When the start point and end point of a range are at the same location, the range acts as a text insertion pointer. In fact, when the `TextRange` object represents text inside a text-related form control, the `select()` method of the `TextRange` object can be used to display the text insertion pointer where your script desires. Therefore, through the `TextRange` object you can script your forms to always display the text insertion pointer at the end of existing text in a text box or text area when the control receives focus.

## Working with text ranges

To create a `TextRange` object, use the `createTextRange()` method with the `document.body` object or any button- or text-related form control object. If you want to convert a block of selected text to a text range, use the special `createRange()` method of the `document.selection` object. Regardless of how you create it, the range encompasses the entire text of the object used to generate the range. In other words, the start point is at the very beginning of the text and the end point is at the very end. Note that when you create a `TextRange` object from the `body` element, text that is inside text-related form controls is not part of the text of the `TextRange` (just as text field content isn't selected if you select manually the entire text of the page).

## TextRange

After you create a `TextRange` object (assigned to a variable), the typical next steps involve some of the many methods associated with the object that help narrow the size of the range. Some methods (`move()`, `moveEnd()`, `moveStart()`, and `setEndPoint()`) offer manual control over the intra-character position for the start and end points. Parameters of some of these methods understand concepts, such as words and sentences, so not every action entails tedious character counts. Another method, `moveToElementText()`, automatically adjusts the range to encompass a named element. The oft-used `collapse()` method brings the start and end points together at the beginning or end of the current range—helpful when a script must iterate through a range for tasks, such as word counting or search and replace. The `expand()` method can extend a collapsed range to encompass the whole word, whole sentence, or entire range surrounding the insertion point. Perhaps the most powerful method is `findText()`, which allows scripts to perform single or global search-and-replace operations on body text.

After the range encompasses the desired text, several other methods let scripts act on the selection. The types of operations include scrolling the page to make the text represented by the range visible to the user (`scrollIntoView()`) and selecting the text (`select()`) to provide visual feedback to the user that something is happening (or to set the insertion pointer at a location in a text form control). An entire library of additional commands are accessed through the `execCommand()` method for operations, such as copying text to the clipboard and a host of formatting commands that can be used in place of stylesheet property changes. To swap text from the range with new text accumulated by your script, you can modify the `text` property of the range.

Using the `TextRange` object can be a bit tedious, because it often requires a number of script statements to execute an action. Three basic steps are generally required to work with a `TextRange` object:

1. Create the text range.
2. Set the start and end points.
3. Act on the range.

As soon as you are comfortable with this object, you will find it provides a lot of flexibility in scripting interaction with body content. For ideas about applying the `TextRange` object in your scripts, see the examples that accompany the following descriptions of individual properties and methods.

## About browser compatibility

The `TextRange` object is available only for 32-bit versions of IE4 and later. There is no support for the `TextRange` object in MacIE.

The W3C DOM and NN6+ implement a slightly different concept of text ranges in what they call the `Range` object. In many respects, the fundamental way of working with a `Range` object is the same as for a `TextRange` object: create, adjust start and end points, and act on the range. But the W3C version (like the W3C DOM itself) is more conscious of the node hierarchy of a document. Properties and methods of the W3C `Range` object reflect this node-centric point of view, so that most of the terminology for the `Range` object differs from that of the IE `TextRange` object. As of this writing, it is unknown if or when IE will implement the W3C `Range` object.

At the same time, the W3C `Range` object lacks a couple of methods that are quite useful with the IE `TextRange` object—notably `findText()` and `select()`. On the other hand, the `Range` object, as implemented in NN6+/Moz, works on all OS platforms and is also implemented in Apple Safari for Mac OS X.

**TextRange.boundingHeight**

The bottom-line question, then, is whether you can make range-related scripts work in both browsers. While the basic sequence of operations is the same for both objects, the scripting vocabulary is quite different. Table 35-1 presents a summary of the property and method behaviors that the two objects have in common and their respective vocabulary terms (sometimes the value of a property in one object is accessed via a method in the other object). Notice that the ways of moving individual end points are not listed in the table because the corresponding methods for each object (for example, `moveStart()` in `TextRange` versus `setStart()` in `Range`) use very different spatial paradigms.

---

**Table 35-1: TextRange versus Range Common Denominators**

---

<i>TextRange Object</i>	<i>Range Object</i>
<code>text</code>	<code>toString()</code>
<code>collapse()</code>	<code>collapse()</code>
<code>compareEndpoints()</code>	<code>compareEndpoints()</code>
<code>duplicate()</code>	<code>clone()</code>
<code>moveToElementText()</code>	<code>selectContents()</code>
<code>parentElement()</code>	<code>commonParent</code>

---

To blend text range actions for both object models into a single scripted page, you have to include script execution branches for each category of object model or create your own API to invoke library functions that perform the branching. On the IE side of things, too, you have to script around actions that can cause script errors when run on MacOS and other non-Windows versions of the browser.

## Properties

`boundingHeight`

`boundingLeft`

`boundingTop`

`boundingWidth`

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

Every text range has physical dimension and location on the page, even if you cannot see the range reflected graphically with highlighting. Even a text insertion pointer (meaning a collapsed text range) has a rectangle whose height equals the line height of the body text in which the insertion point resides; its width, however, is zero.

The pixel dimensions of the rectangle of a text range can be retrieved via the `boundingHeight` and `boundingWidth` properties of the `TextRange` object. When a text range extends across multiple lines, the dimensions of the rectangle are equal to the smallest single rectangle that can contain the text (a concept identical to the bounding rectangle of inline body text, as described in the `TextRectangle` object later in this chapter). Therefore, even a range consisting of one character at the end of one line and another character at the beginning of the next, force the bounding rectangle to be as wide as the paragraph element.

```

        <tr>
            <td class="propName">boundingTop</td>
            <td class="count" id="B3">&nbsp;&nbsp;&nbsp;</td>
        </tr>
        <tr>
            <td class="propName">boundingLeft</td>
            <td class="count" id="B4">&nbsp;&nbsp;&nbsp;</td>
        </tr>
        <tr>
            <td class="propName">offsetTop</td>
            <td class="count" id="B5">&nbsp;&nbsp;&nbsp;</td>
        </tr>
        <tr>
            <td class="propName">offsetLeft</td>
            <td class="count" id="B6">&nbsp;&nbsp;&nbsp;</td>
        </tr>
    </table>
    <hr />
    <p onmouseup="setAndShowRangeData()">Lorem ipsum dolor sit amet,
    consectetur adipiscing elit, sed do eiusmod tempor incididunt ut
    labore et dolore magna aliqua. Ut enim adminim veniam, quis nostrud
    exercitation ullamco laboris nisi ut aliquip ex ea commodo consequat.

    expedit.</p>
</body>
</html>

```

**Related Items:** `offsetLeft`, `offsetTop` properties of element objects (Chapter 15).

## htmlText

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `htmlText` property returns the HTML of the text contained by a text range. If a range's start and end points are at the very edges of an element's text, the HTML tag for that element becomes part of the `htmlText` property value. Also, if the range starts in one element and ends partway in another, the tags that influence the text of the end portion become part of the `htmlText`. This property is read-only, so you cannot use it to insert or replace HTML in the text range (see the `pasteHTML()` method and various insert commands associated with the `execCommand()` method in the following section).

## Example

Use The Evaluator (Chapter 13) to investigate values returned by the `htmlText` property. Use the top text box to enter the following statements and see the values in the Results box.

Begin by creating a `TextRange` object for the entire body and store the range in local variable `a`:

```
a = document.body.createTextRange()
```

Next, use the `findText()` method to set the start and end points of the text range around the word "all," which is an `em` element inside the `myP` paragraph:

```
a.findText("all")
```

**TextRange.htmlText**

The method returns `true` (see the `findText()` method) if the text is found and the text range adjusts to surround it. To prove that the text of the text range is what you think it is, examine the `text` property of the range:

```
a.text
```

Because the text range encompasses all of the text of the element, the `htmlText` property contains the tags for the element as well:

```
a.htmlText
```

If you want to experiment by finding other chunks of text and looking at both the `text` and `htmlText` properties, first restore the text range to encompass the entire body with the following statement:

```
a.expand("textEdit")
```

You can read about the `expand()` method later in this chapter. In other tests, use `findText()` to set the range to “for all” and just “for al.” Then, see how the `htmlText` property exposes the `em` element’s tags.

**Related Items:** `text` property.

**text**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

Use the `text` property to view or change the string of visible characters that comprise a text range. The browser makes some decisions for you if the range you are about to change has nested elements inside. By and large, the nested element (and any formatting that may be associated with it) is deleted, and the new text becomes part of the text of the container that houses the start point of the text range. By the same token, if the range starts in the middle of one element and ends in the parent element’s text, the tag that governs the start point now wraps all of the new text.

**Example**

See Listing 35-11 later in this chapter for the `findText()` method to see the `text` property used to perform the replace action of a search-and-replace function.

**Related Items:** `htmlText` property.

**Methods****collapse([startBoolean])**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

Use the `collapse()` method to shrink a text range from its current size down to a single insertion point between characters. This method becomes more important than you may think at first, especially in a function that is traversing the body or large chunk of text. For example, in a typical looping word-counting script, you create a text range that encompasses the full body (or text in a `textarea`). When the range is created, its start point is at the very beginning of the text, and its end point is at the very end. To begin counting words, you can first collapse the range to the insertion point at the very beginning of the range. Next, use the `expand()` method to set the range to the first word of text (and increment the counter if the

**TextRange.compareEndpoints()**

`expand()` method returns `true`). At that point, the text range extends around the first word. What you want is for the range to collapse at the end of the current range so that the search for the next word starts after the current one. Use `collapse()` once more, but this time with a twist of parameters.

The optional parameter of the `collapse()` method is a Boolean value that directs the range to collapse itself either at the start or end of the current range. The default behavior is the equivalent of a value of `true`, which means that unless otherwise directed, a `collapse()` method shifts the text range to the point in front of the current range. That works great as an early step in the word-counting example, because you want the text range to collapse to the start of the text before doing any counting. But for subsequent movements through the range, you want to collapse the range so that it is after the current range. Thus, you include a `false` parameter to the `collapse()` method.

**Example**

See Listings 35-11 and 15-14 to see the `collapse()` method at work.

**Related Items:** `Range.collapse()`, `TextRange.expand()` methods.

**compareEndpoints("type", rangeRef)**

**Returns:** Integer (-1, 0, or 1).

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

Generating multiple `TextRange` objects and assigning them to different variables is no problem. You can then use the `compareEndpoints()` method to compare the relative positions of start and end points of two ranges. One range is the object that you use to invoke the `compareEndpoints()` method, and the other range is the second parameter of the method. The order doesn't matter, because the first parameter of the method determines which points in each range you will be comparing.

Values for the first parameter can be one of four explicit strings: `StartToEnd`, `StartToStart`, `EndToStart`, and `EndToEnd`. What these values specify is which point of the current range is compared with which point of the range passed as the second parameter. For example, consider the following body text that has two text ranges defined within it:

It was the **best of times**.

The first text range (assigned in our discussion here to variable `rng1`) is shown in boldface, while the second text range (`rng2`) is shown in bold-italic. In other words, `rng2` is nested inside `rng1`. We can compare the position of the start of `rng1` against the position of the start of `rng2` by using the `StartToStart` parameter of the `compareEndpoints()` method:

```
var result = rng1.compareEndpoints("StartToStart", rng2);
```

The value returned from the `compareEndpoints()` method is an integer of one of three values. If the positions of both points under test are the same, the value returned is 0. If the first point is before the second, the value returned is -1; if the first point is after the second, the value is 1. Therefore, from the example above, because the start of `rng1` is before the start of `rng2`, the method returns -1. If you changed the statement to invoke the method on `rng2`, as in

```
var result = rng2.compareEndpoints("StartToStart", rng1);
```

the result would be 1.

In practice, this method is helpful in knowing if two ranges are the same, if one of the boundary points of both ranges is the same, or if one range starts where the other ends.

**TextRange.compareEndpoints()****Example**

The page rendered by Listing 35-10 lets you experiment with text range comparisons. The bottom paragraph contains a `span` element that has a `TextRange` object assigned to its text after the page loads (in the `init()` function). That fixed range becomes a solid reference point for you to use while you select text in the paragraph. After you make a selection, all four versions of the `compareEndpoints()` method run to compare the start and end points of the fixed range against your selection. One column of the results table shows the raw value returned by the `compareEndpoints()` method, while the third column puts the results into plain language.

To see how this page works, begin by selecting the first word of the fixed text range (double-click the word). You can see that the starting positions of both ranges are the same, because the returned value is 0. Because all of the invocations of the `compareEndpoints()` method are on the fixed text range, all comparisons are from the point of view of that range. Thus, the first row of the table for the `StartToEnd` parameter indicates that the start point of the fixed range comes before the end point of the selection, yielding a return value of -1.

Other selections to make include:

- ♦ Text that starts before the fixed range and ends inside the range
- ♦ Text that starts inside the fixed range and ends beyond the range
- ♦ Text that starts and ends precisely at the fixed range boundaries
- ♦ Text that starts and ends before the fixed range
- ♦ Text that starts after the fixed range

Study the returned values and the plain language results and see how they align with the selection you make.

</body>
</html>

```

**Related Items:** `Range.compareEndpoints()` method.

**duplicate()**

**Returns:** `TextRange` object.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `duplicate()` method returns a `TextRange` object that is a snapshot copy of the current `TextRange` object. In a way, a non-intuitive relationship exists between the two objects. If you alter the `text` property of the copy without moving the start or end points of the original, the original takes on the new text. But if you move the start or end points of the original, the `text` and `htmlText` of the original obviously change, while the copy retains its properties from the time of the duplication. Therefore, this method can be used to clone text from one part of the document to other parts.

**Example**

Use The Evaluator (Chapter 13) to see how the `duplicate()` method works. Begin by creating a new `TextRange` object that contains the text of the `myP` paragraph element:

```
a = document.body.createTextRange()
a.moveToElementText(myP)
```

Next, clone the original range and preserve the copy in variable `b`:

```
b = a.duplicate()
```

The method returns no value, so don't be alarmed by the "undefined" that appears in the Results box. Move the original range so that it is an insertion point at the end of the body by first expanding it to encompass the entire body, and then collapse it to the end:

```
a.expand("textedit")
a.collapse(false)
```

Now, insert the copy at the very end of the body:

```
a.text = b.text
```

**TextRange.execCommand()**

If you scroll to the bottom of the page, you'll see a copy of the text.

**Related Items:** `Range.clone()`, `TextRange.isEqual()` methods.

`execCommand("commandName" [, UIFlag[, value]])`

**Returns:** Boolean.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

IE4+ for Win32 operating systems lets scripts access a very large number of commands that act on insertion points, abstract text ranges, and selections that are made with the help of the `TextRange` object. Access to these commands is through the `execCommand()` method, which works with `TextRange` objects and the document object (see the `document.execCommand()` method discussion in Chapter 18 and list of document- and selection-related commands in Table 18-3).

The first, required parameter is the name of the command that you want to execute. Only a handful of these commands offer unique capabilities that aren't better accomplished within the IE object model and stylesheet mechanism. Of particular importance is the command that lets you copy a text range into the Clipboard. Most of the rest of the commands modify styles or insert HTML tags at the position of a collapsed text range. These actions are better handled by other means, but they are included in Table 35-2 for the sake of completeness only (see Table 18-3 for additional commands).

**Table 35-2: TextRange.execCommand() Commands**

<i>Command</i>	<i>Parameter</i>	<i>Description</i>
Bold	None	Encloses the text range in a <b> tag pair
Copy	None	Copies the text range into the Clipboard
Cut	None	Copies the text range into the Clipboard and deletes it from the document or text control
Delete	None	Deletes the text range
InsertButton	ID String	Inserts a <button> tag at the insertion point, assigning the parameter value to the id attribute
InsertFieldset	ID String	Inserts a <fieldset> tag at the insertion point, assigning the parameter value to the id attribute
InsertHoritontalRule	ID String	Inserts an <hr> tag at the insertion point, assigning the parameter value to the id attribute
InsertIFrame	ID String	Inserts an <iframe> tag at the insertion point, assigning the parameter value to the id attribute
InsertInputButton	ID String	Inserts an <input type="button"> tag at the insertion point, assigning the parameter value to the id attribute
InsertIntpuCheckbox	ID String	Inserts an <input type="checkbox"> tag at the insertion point, assigning the parameter value to the id attribute
InsertInputFileUpload	ID String	Inserts an <input type="FileUpload"> tag at the insertion point, assigning the parameter value to the id attribute
InsertInputHidden	ID String	Inserts an <input type="hidden"> tag at the insertion point, assigning the parameter value to the id attribute

*Continued*

**TextRange.execCommand()****Table 35-2** (continued)

<b>Command</b>	<b>Parameter</b>	<b>Description</b>
InsertInputImage	ID String	Inserts an <code>&lt;input type="image"&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
InsertInputPassword	ID String	Inserts an <code>&lt;input type="password"&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
InsertInputRadio	ID String	Inserts an <code>&lt;input type="radio"&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
InsertInputReset	ID String	Inserts an <code>&lt;input type="reset"&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
InsertInputSubmit	ID String	Inserts an <code>&lt;input type="submit"&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
InsertInputText	ID String	Inserts an <code>&lt;input type="text"&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
InsertMarquee	ID String	Inserts a <code>&lt;marquee&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
InsertOrderedList	ID String	Inserts an <code>&lt;ol&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
InsertParagraph	ID String	Inserts a <code>&lt;p&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
InsertSelectDropdown	ID String	Inserts a <code>&lt;select type="select-one"&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
InsertSelectListbox	ID String	Inserts a <code>&lt;select type="select-multiple"&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
InsertTextArea	ID String	Inserts an empty <code>&lt;textarea&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
InsertUnorderedList	ID String	Inserts a <code>&lt;ul&gt;</code> tag at the insertion point, assigning the parameter value to the <code>id</code> attribute
Italic	None	Encloses the text range in an <code>&lt;i&gt;</code> tag pair
OverWrite	Boolean	Sets the text input control mode to <code>overwrite</code> ( <code>true</code> ) or <code>insert</code> ( <code>false</code> )
Paste	None	Pastes the current Clipboard contents into the insertion point or selection
PlayImage	None	Begins playing dynamic images if they are assigned to the <code>dynsrc</code> attribute of the <code>img</code> element
Refresh	None	Reloads the current page
StopImage	None	Stops playing dynamic images if they are assigned to the <code>dynsrc</code> attribute of the <code>img</code> element
Underline	None	Encloses the text range in a <code>&lt;u&gt;</code> tag pair

An optional second parameter is a Boolean flag to instruct the command to display any user interface artifacts that may be associated with the command. The default is `false`. For the third parameter, some commands require an attribute value for the command to work. For example, to insert a new paragraph at an insertion point, you pass the identifier to be assigned to the `id` attribute of the `p` element. The syntax is

**TextRange.expand()**

```
myRange.execCommand("InsertParagraph", true, "myNewP");
```

The `execCommand()` method returns Boolean `true` if the command is successful; `false` if not successful. Some commands can return values (for example, finding out the font name of a selection), but these values are accessed through the `queryCommandValue()` method.

Although the commands in Table 35-2 work on text ranges, even the commands that work on selections (Table 18-3) can frequently benefit from some preprocessing with a text range. Consider, for example, a function whose job it is to find every instance of a particular word in a document and set its background color to a yellow highlight. Such a function utilizes the powers of the `findText()` method of a text range to locate each instance. Then the `select()` method selects the text in preparation for applying the `BackColor` command. Here is a sample:

```
function hiliteIt(txt) {
    var rng = document.body.createTextRange();
    for (var i = 0; rng.findText(txt); i++) {
        rng.select();
        rng.execCommand("BackColor", "false", "yellow");
        rng.execCommand("Unselect");
        // prepare for next search
        rng.collapse(false);
    }
}
```

This example is a rare case that makes the `execCommand()` method way of modifying HTML content more efficient than trying to wrap some existing text inside a new tag. The downside is that you don't have control over the methodology used to assign a background color to a span of text (in this case, IE wraps the text in a `<font>` tag with a `style` attribute set to `background-color:yellow`—probably not the way you'd do it on your own).

### Example

Use The Evaluator (Chapter 13) to see how to copy a text range's text into the client computer's Clipboard. Begin by setting the text range to the `myP` element:

```
a = document.body.createTextRange()
a.moveToElementText(myP)
```

Now use `execCommand()` to copy the range into the Clipboard:

```
a.execCommand("Copy")
```

To prove that the text is in the Clipboard, click the bottom text field and choose Paste from the Edit menu (or type `Ctrl+V`).

**Related Items:** Several query command methods of the `TextRange` object.

### `expand("unit")`

**Returns:** Boolean.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The single `expand()` method can open any range—collapsed or not—to the next largest character, word, or sentence or to the entire original range (for example, encompassing the text of the body element if the range was generated by `document.body.createTextRange()`). The parameter is a string designating which unit to expand outward to: `character`, `word`, `sentence`, or `textedit`. If the operation is successful, the method returns `true`; otherwise it returns `false`.

**TextRange.expand()**

When operating from an insertion point, the `expand()` method looks for the word or sentence that encloses the point. The routine is not very smart about sentences, however. If you have some text prior to a sentence that you want to expand to, but that text does not end in a period, the `expand()` routine expands outward until it can find either a period or the beginning of the range. Listing 15-14 demonstrates a workaround for this phenomenon. When expanding from an insertion point to a character, the method expands forward to the next character in language order. If the insertion point is at the end of the range, it cannot expand to the next characters, and the `expand()` method returns `false`.

It is not uncommon in an extensive script that needs to move the start and end points all over the initial range to perform several `collapse()` and `expand()` method operations from time to time. Expanding to the full range is a way to start some range manipulation with a clean slate, as if you just created the range.

**Example**

You can find examples of the `expand()` method in Listing 15-14.

**Related Items:** `TextRange.collapse()` method.

**findText("searchString" [, searchScope, flags])**

**Returns:** Boolean.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

One of the most useful methods of the `TextRange` object is `findText()`, whose default behavior is to look through a text range starting at the range's start point up to the end of the range in search of a case-insensitive match for a search string. If an instance is found in the range, the start and end points of the range are cinched up to the found text and the method returns `true`; otherwise it returns `false`, and the start and end points do not move. Only the rendered text is searched and not any of the tags or attributes.

Optional parameters let you exert some additional control over the search process. You can restrict the distance from a collapsed range to be used for searching. The `searchScope` parameter is an integer value indicating the number of characters from the start point. The larger the number, the more text of the range is included in the search. Negative values force the search to operate backward from the current start point. If you want to search backward to the beginning of the range, but you don't know how far away the start of the range is, you can specify an arbitrarily huge number that would encompass the text.

The optional `flags` parameter lets you set whether the search is to be case-sensitive and/or to match whole words only. The parameter is a single integer value that uses bit-wise math to calculate the single value that accommodates one or both settings. The value for matching whole words is 2; the value for matching case is 4. If you want only one of those behaviors, then supply just the desired number. But for both behaviors, use the bit-wise XOR operator (the `^` operator) on the values to reach a value of 6.

The most common applications of the `findText()` method include a search-and-replace action and format changes to every instance of a string within the range. This iterative process requires some extra management of the process. Because searching always starts with the range's current start point, advancing the start point to the end of the text found in the range is necessary. This advancing allows a successive application of `findText()` to look through the rest of the range for another match. And because `findText()` ignores the arbitrary end point of the current range and continues to the end of the initial range, you can use the `collapse(false)` method to force the starting point to the end of the range that contains the first match.

**TextRange.findText()**

A repetitive search can be accomplished by a `while` or `for` repeat loop. The Boolean returned value of the `findText()` method can act as the condition for continuing the loop. If the number of times the search succeeds is not essential to your script, a `while` loop works nicely:

```
while (rng.findText(searchString)) {
    ...
    rng.collapse(false);
}
```

Or you can use a `for` loop counter to maintain a count of successes, such as a counter of how many times a string appears in the body:

```
for (var i = 0; rng.findText(searchString); i++) {
    ...
    rng.collapse(false);
}
```

Some of the operations you want to perform on a range (such as many of the commands invoked by the `execCommand()` method) require that a selection exists for the command to work. Be prepared to use the `select()` method on the range after the `findText()` method locates a matching range of text.

## Example

Listing 35-11 implements two varieties of text search-and-replace operation, while showing you how to include extra parameters for case-sensitive and whole-word searches. Both approaches begin by creating a `TextRange` for the entire body, but they immediately shift the starting point to the beginning of the `div` element that contains the text to search.

One search-and-replace function prompts the user to accept or decline replacement for each instance of a found string. The `select()` and `scrollIntoView()` methods are invoked to help the user see what is about to be replaced. Notice that even when the user declines to accept the replacement, the text range is collapsed to the end of the found range so that the next search can begin after the previously found text. Without the `collapse()` method, the search can get caught in an infinite loop as it keeps finding the same text over and over (with no replacement made). Because no counting is required, this search-and-replace operation is implemented inside a `while` repeat loop.

The other search-and-replace function goes ahead and replaces every match and then displays the number of replacements made. After the loop exits (because there are no more matches), the loop counter is used to display the number of replacements made.

### Listing 35-11: Two Search-and-Replace Approaches (with Undo)

```
<html>
  <head>
    <title>TextRange.findText() Method</title>
    <script type="text/javascript">
      // global range var for use with Undo
      var rng;

      // return findText() third parameter arguments
      function getArgs(form) {
        var isCaseSensitive = (form.caseSensitive.checked) ? 4 : 0;
        var isWholeWord = (form.wholeWord.checked) ? 2 : 0;
        return isCaseSensitive ^ isWholeWord;
      }
    </script>
  </head>
  <body>
    <div id="text">
      ...
    </div>
  </body>
</html>
```

*Continued*

**TextRange.findText()****Listing 35-11 (continued)**

```

    }

    // prompted search and replace
    function sAndR(form) {
        var srchString = form.searchString.value;
        var replString = form.replaceString.value;
        if (srchString) {
            var args = getArgs(form);
            rng = document.body.createTextRange();
            rng.moveToElementText(rights);
            clearUndoBuffer();
            while (rng.findText(srchString, 10000, args)) {
                rng.select();
                rng.scrollIntoView();
                if (confirm("Replace?")) {
                    rng.text = replString;
                    pushUndoNew(rng, srchString, replString);
                }
                rng.collapse(false);
            }
        }
    }

    // unprompted search and replace with counter
    function sAndRCount(form) {
        var srchString = form.searchString.value;
        var replString = form.replaceString.value;
        var i;
        if (srchString) {
            var args = getArgs(form);
            rng = document.body.createTextRange();
            rng.moveToElementText(rights);
            for (i = 0; rng.findText(srchString, 10000, args); i++) {
                rng.text = replString;
                pushUndoNew(rng, srchString, replString);
                rng.collapse(false);
            }
            if (i > 1) {
                clearUndoBuffer();
            }
        }
        document.getElementById("counter").innerText = i;
    }

    // BEGIN UNDO BUFFER CODE
    // buffer global variables
    var newRanges = new Array();
    var origSearchString;

    // store original search string and bookmarks of each replaced range
    function pushUndoNew(rng, srchString, replString) {
        origSearchString = srchString;
        rng.moveStart("character", -replString.length);
        newRanges[newRanges.length] = rng.getBookmark();
    }

```

**TextRange.findText()**

```

// empty array and search string global
function clearUndoBuffer() {
    document.getElementById("counter").innerText = "0";
    origSearchString = "";
    newRanges.length = 0;
}

// perform the undo
function undoReplace() {
    if (newRanges.length && origSearchString) {
        for (var i = 0; i < newRanges.length; i++) {
            rng.moveToBookmark(newRanges[i]);
            rng.text = origSearchString;
        }
        document.getElementById("counter").innerText = i;
        clearUndoBuffer();
    }
}
</script>
</head>

```

---

Having a search-and-replace function available in a document is only one-half of the battle. The other half is offering the facilities to undo the changes. To that end, Listing 35-11 includes an undo buffer that accurately undoes only the changes made in the initial replacement actions.

**TextRange.findText()**

The undo buffer stores its data in two global variables. The first, `origSearchString`, is simply the string used to perform the original search. This variable is the string that has to be put back in the places where it had been replaced. The second global variable is an array that stores `TextRange` bookmarks (see `getBookmark()` later in this chapter). These references are string values that don't mean much to humans, but the browser can use them to re-create a range with its desired start and end point. Values for both the global search string and bookmark specifications are stored in calls to the `pushUndoNew()` method each time text is replaced.

A perhaps unexpected action of setting the `text` property of a text range is that the start and end points collapse to the end of the new text. Because the stored bookmark must include the replaced text as part of its specification, the start point of the current range must be adjusted back to the beginning of the replacement text before the bookmark can be saved. Thus, the `pushUndoNew()` function receives the replacement text string so that the `moveStart()` method can be adjusted by the number of characters matching the length of the replacement string.

After all of the bookmarks are stored in the array, the undo action can do its job in a rather simple `for` loop inside the `undoReplace()` function. After verifying that the undo buffer has data stored in it, the function loops through the array of bookmarks and replaces the bookmarked text with the old string. The benefit of using the bookmarks rather than using the replacement function again is that only those ranges originally affected by the search-and-replace operation are touched in the undo operation. For example, in this document if you replace a case-sensitive “states” with “States” two replacements are performed. At that point, however, the document has four instances of “States,” two of which existed before. Redoing the replacement function by inverting the search-and-replace strings would convert all four back to the lowercase version — not the desired effect.

**Related Items:** `TextRange.select()` method.

**getBookmark()**

**Returns:** Bookmark string.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

In the context of a `TextRange` object, a bookmark is not to be confused with the kinds of bookmarks you add to a browser list of favorite Web sites. Instead, a bookmark is a string that represents a definition of a text range, including its location in a document, its text, and so on. Viewing the string is futile, because it contains string versions of binary data, so the string means nothing in plain language. But a bookmark allows your scripts to save the current state of a text range so that it may be restored at a later time. The `getBookmark()` method returns the string representation of a snapshot of the current text range. Some other script statement can adjust the `TextRange` object to the exact specifications of the snapshot with the `moveToBookmark()` method (described later in this chapter).

**Example**

Listing 35-11 earlier in this chapter shows how the `getBookmark()` method is used to preserve specifications for text ranges so that they can be called upon again to be used to undo changes made to the text range. The `getBookmark()` method is used to save the snapshots, while the `moveToBookmark()` method is used during the undo process.

**Related Items:** `TextRange.moveToBookmark()` method.

## inRange(*otherRangeRef*)

**Returns:** Boolean.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

You can compare the physical stretches of text contained by two different text ranges via the `inRange()` method. Typically, you invoke the method on the larger of two ranges and pass a reference to the smaller range as the sole parameter to the method. If the range passed as a parameter is either contained by or equal to the text range that invokes the method, the method returns `true`; otherwise the method returns `false`.

### Example

Use The Evaluator (Chapter 13) to see the `inRange()` method in action. The following statements generate two distinct text ranges, one for the `myP` paragraph element and the other for the `myEM` element nested within:

```
a = document.body.createTextRange()  
a.moveToElementText(myP)  
b = document.body.createTextRange()  
b.moveToElementText(myEM)
```

Because the `myP` text range is larger than the other, invoke the `inRange()` method on it, fully expecting the return value of `true`:

```
a.inRange(b)
```

But if you switch the references, you see that the larger text range is not “in” the smaller one:

```
b.inRange(a)
```

**Related Items:** `TextRange.isEqual()` method.

## isEqual(*otherRangeRef*)

**Returns:** Boolean.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

If your script has references to two independently adjusted `TextRange` objects, you can use the `isEqual()` method to test whether the two objects are identical. This method tests for a very literal equality, requiring that the text of the two ranges be character-for-character and position-for-position equal in the context of the original ranges (for example, body or text control content). To see if one range is contained by another, use the `inRange()` method instead.

### Example

Use The Evaluator (Chapter 13) to try the `isEqual()` method. Begin by creating two separate `TextRange` objects, one for the `myP` element and one for `myEM`:

```
a = document.body.createTextRange()  
a.moveToElement(myP)  
b = document.body.createTextRange()  
b.moveToElement(myEM)
```

Because these two ranges encompass different sets of text, they are not equal, as the results show from the following statement:

```
a.isEqual(b)
```

But if you now adjust the first range boundaries to surround the `myEM` element, both ranges are the same values:

**TextRange.isEqual()**

```
a.moveToElement(myEM)
a.isEqual(b)
```

**Related Items:** `TextRange.inRange()` method.

**move("unit" [, count])**

**Returns:** Integer.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `move()` method performs two operations. First, the method collapses the current text range to become an insertion point at the location of the previous end point. Next, it moves that insertion point to a position forward or backward any number of character, word, or sentence units. The first parameter is a string specifying the desired unit (`character`, `word`, `sentence`, or `textedit`). A value of `textedit` moves the pointer to the beginning or end of the entire initial text range. If you omit the second parameter, the default value is 1. Otherwise you can specify an integer indicating the number of units the collapsed range should be moved ahead (positive integer) or backward (negative). The method returns an integer revealing the exact number of units the pointer is able to move — if you specify more units than are available, the returned value lets you know how far it can go.

Bear in mind that the range is still collapsed after the `move()` method executes. Expanding the range around desired text is the job of other methods.

You can also use the `move()` method in concert with the `select()` method to position the flashing text insertion pointer within a text box or textarea. Thus, you can script a text field, upon receiving focus or the page loading, to have the text pointer waiting for the user at the end of existing text. A generic function for such an action is shown in the following:

```
function setCursorToEnd(elem) {
    if (elem) {
        if (elem.type && (elem.type == "text" || elem.type == "textarea")) {
            var rng = elem.createTextRange();
            rng.move("textedit");
            rng.select();
        }
    }
}
```

You can then invoke this method from a text field's `onfocus` event handler:

```
<input type="text" ... onfocus="setCursorToEnd(this)" />
```

The function previously shown includes a couple of layers of error checking, such as making sure that the function is invoked with a valid object as a parameter and that the object has a `type` property whose value is one capable of having a text range made for its content.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `move()` method. To see how the method returns just the number of units it moves the pointer, begin by creating a text range and set it to enclose the `myP` element:

```
a = document.body.createTextRange()
a.moveToElementText(myP)
```

Now enter the following statement to collapse and move the range backward by 20 words:

```
a.move("word", -20)
```

**TextRange.moveEnd()**

Continue to click the Evaluate button and watch the returned value in the Results box. The value shows 20 while it can still move backward by 20 words. But eventually the last movement will be some other value closer to zero. And after the range is at the beginning of the body element, the range can move no more in that direction, so the result is zero.

**Related Items:** `TextRange.moveEnd()`, `TextRange.moveStart()` methods.

```
moveEnd("unit" [, count])  
moveStart("unit" [, count])
```

**Returns:** Integer.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `moveEnd()` and `moveStart()` methods are similar to the `move()` method, but they each act only on the end and starting points of the current range, respectively. In other words, the range does not collapse before the point is moved. These methods allow you to expand or shrink a range by a specific number of units by moving only one of the range's boundaries.

The first parameter is a string specifying the desired unit (`character`, `word`, `sentence`, or `textedit`). A value of `textedit` moves the pointer to the beginning or end of the entire initial text range. Therefore, if you want the end point of the current range to zip to the end of the body (or text form control), use `moveEnd("textedit")`. If you omit the second parameter, the default value is 1. Otherwise you can specify an integer indicating the number of units the collapsed range is to move ahead (positive integer) or backward (negative). Moving either point beyond the location of the other forces the range to collapse and move to the location specified by the method. The method returns an integer revealing the exact number of units the pointer is able to move—if you specify more units than are available, the returned value lets you know how far it can go.

## Example

Use The Evaluator (Chapter 13) to experiment with the `moveEnd()` and `moveStart()` methods. Begin by creating a text range and set it to enclose the `myEM` element:

```
a = document.body.createTextRange()  
a.moveToElementText(myEM)
```

To help you see how movements of the pointers affect the text enclosed by the range, type a into the bottom text box and view all the properties of the text range. Note especially the `htmlText` and `text` properties.

Now enter the following statement to move the end of the range forward by one word:

```
a.moveEnd("word")
```

Click the List Properties button to see that the text of the range now includes the word following the `em` element. Try each of the following statements in the top text box and examine both the integer results and (by clicking the List Properties button) the properties of the range after each statement:

```
a.moveStart("word", -1)  
a.moveEnd("sentence")
```

Notice that for a sentence, a default unit of 1 expands to the end of the current sentence. And if you move the start point backward by one sentence, you'll see that the lack of a period-ending sentence prior to the `myP` element causes strange results.

**TextRange.moveEnd()**

Finally, force the start point backward in increments of 20 words and watch the results as the starting point nears and reaches the start of the `body`:

```
a.moveStart("word", -20)
```

Eventually the last movement will be some other value closer to zero. And as soon as the range is at the beginning of the `body` element, the range can move no more in that direction, so the result is zero.

**Related Items:** `TextRange.move()` method.

**moveToBookmark("bookmarkString")**

**Returns:** Boolean.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

If a snapshot of a text range specification has been preserved in a variable (with the help of the `getBookmark()` method), the `moveToBookmark()` method uses that bookmark string as its parameter to set the text range to exactly the way it appeared when the bookmark was originally obtained. If the method is successful, it returns a value of `true`, and the text range is set to the same string of text as originally preserved via `getBookmark()`. It is possible that the state of the content of the text range has been altered to such an extent that resurrecting the original text range is not feasible. In that case, the method returns `false`.

**Example**

Listing 35-11 earlier in this chapter shows how to use the `moveToBookmark()` method to restore a text range so that changes that created the state saved by the bookmark can be undone. The `getBookmark()` method is used to save the snapshots, while the `moveToBookmark()` method is used during the undo process.

**Related Items:** `TextRange.getBookmark()` method.

**moveToElementText(elementObjRef)**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The fastest way to cinch up a text range to the boundaries of an HTML element on the page is to use the `moveToElementText()` method. Any valid reference to the HTML element object is accepted as the sole parameter — just don't try to use a string version of the object ID unless it is wrapped in the `document.getElementById()` method (IE5+). When the boundaries are moved to the element, the range's `htmlText` property contains the tags for the element.

**Example**

A majority of examples for other `TextRange` object methods in this chapter use the `moveToElementText()` method. Listings 35-10 and 35-11 earlier in this chapter show the method within an application context.

**Related Items:** `TextRange.parentElement()` method.

**moveToPoint(x, y)**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

**TextRange.parentElement()**

The `moveToPoint()` method shrinks the current text range object to an insertion point and then moves it to a position in the current browser window or frame. You control the precise position via the  $x$  (horizontal) and  $y$  (vertical) pixel coordinates specified as parameters. The position is relative to the visible window, and not the document, which may have been scrolled to a different position. Invoking the `moveToPoint()` method is the scripted equivalent of the user clicking that spot in the window. Use the `expand()` method to flesh out the collapsed text range to encompass the surrounding character, word, or sentence.

 **Note**

Using the `moveToPoint()` method on a text range defined for a text form control may cause a browser crash. The method appears safe with the `document.body` text ranges, even if the  $x,y$  position falls within the rectangle of a text control. Such a position, however, does not drop the text range into the form control or its content.

**Example**

Use The Evaluator (Chapter 13) to see the `moveToPoint()` method in action. Begin by creating a text range for the entire body element:

```
a = document.body.createTextRange()
```

Now, invoke the `moveToPoint()` method to a location 100,100, which turns out to be in the rectangle space of the Results textarea:

```
a.moveToPoint(100,100)
```

If you type `a` into the bottom text box and view the properties, both the `htmlText` and `text` properties are empty because the insertion point represents no visible text content. But if you gradually move, for example, the start point backward one character at a time, you will see the `htmlText` and `text` properties begin to fill in with the body text that comes before the `textarea` element, namely the “Results:” label and the `<br>` tag between it and the `textarea` element. Enter the following statement into the top text box and click the Evaluate button several times:

```
a.moveStart("character", -1)
```

Enter `a` into the bottom text box after each evaluation to list the properties of the range.

**Related Items:** `TextRange.move()`, `TextRange.moveStart()`, `TextRange.moveEnd()` methods.

**parentElement()**

**Returns:** Element object reference.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `parentElement()` method returns a reference to the next outermost HTML element container that holds the text range boundaries. If the text range boundaries are at the boundaries of a single element, the `parentElement()` method returns that element’s reference. But if the boundaries straddle elements, the object returned by the method is the element that contains the text of the least-nested text portion. In contrast to the `expand()` and various `move`-related methods, which understand text constructs, such as words and sentences, the `parentElement()` method is concerned solely with element objects. Therefore, if a text range is collapsed to an insertion point in body text, you can expand it to encompass the HTML element by using the `parentElement()` method as a parameter to `moveToElementText()`:

```
rng.moveToElementText(rng.parentElement());
```

**TextRange.parentElement()****Example**

Use The Evaluator (Chapter 13) to experiment with the `parentElement()` method. Begin by setting the text range to the `myEM` element:

```
a = document.body.createTextRange()  
a.moveToElementText(myEM)
```

To inspect the object returned by the `parentElement()` method, enter the following statement in the lower text box:

```
a.parentElement()
```

If you scroll down to the `outerHTML` property, you see that the parent of the text range is the `myEM` element, tag and all.

Next, extend the end point of the text range by one word:

```
a.moveEnd("word")
```

Because part of the text range now contains text of the `myP` object, the `outerHTML` property of `a.parentElement()` shows the entire `myP` element and tags.

**Related Items:** `TextRange.expand()`, `TextRange.move()`, `TextRange.moveEnd()`, `TextRange.moveStart()` methods.

**pasteHTML("HTMLText")**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

While the `execCommand()` method offers several commands that insert HTML elements into a text range, it is probably more convenient to simply paste fully formed HTML into the current text range (assuming you need to be working with a text range instead of even more simply setting new values to an element object's `outerHTML` property). Provide the HTML to be inserted as a string parameter to the `pasteHTML()` method.

Use the `pasteHTML()` method with some forethought. Some HTML that you may attempt to paste into a text range may force the method to wrap additional tags around the content you provide to ensure the validity of the resulting HTML. For example, if you were to replace a text range consisting of a portion of text of a `p` element with, for instance, an `li` element, the `pasteHTML()` method has no choice but to divide the `p` element into two pieces, because a `p` element is not a valid container for a solo `li` element. This division can greatly disrupt your document object hierarchy, because the divided `p` element assumes the same ID for both pieces. Existing references to that `p` element will break, because the reference now returns an array of two like-named objects.

**Example**

Use The Evaluator (Chapter 13) to experiment with the `pasteHTML()` method. The goal of the following sequence is to change the `<em>` tag to a `<span>` tag whose `style` attribute sets the color of the original text that was in the `em` element.

Begin by creating the text range and setting the boundaries to the `myEM` element:

```
a = document.body.createTextRange()  
a.moveToElementText(myEM)
```

**TextRange.select()**

While you can pass the HTML string directly as a parameter to `pasteHTML()`, storing the HTML string in its own temporary variable may be more convenient (and more easily testable), such as:

```
b = "<span style='color:red'>" + a.text + "</span>"
```

Notice that we concatenate the text of the current text range, because it has not yet been modified. Now we can paste the new HTML string into the current text range:

```
a.pasteHTML(b)
```

At this point the `em` element is gone from the object model, and the `span` element is in its place. Prove it to yourself by looking at the HTML for the `myP` element:

```
myP.innerHTML
```

As noted earlier, the `pasteHTML()` method is not the only way to insert or replace HTML in a document. This method makes excellent sense when the user selects some text in the document to be replaced, because you can use the `document.selection.createRange()` method to get the text range for the selection. But if you're not using text ranges for other related operations, consider the other generic object properties and methods available to you.

**Related Items:** `outerHTML` property; `insertAdjacentHTML()` method.

```
queryCommandEnabled("commandName")  
queryCommandIndeterm("commandName")  
queryCommandState("commandName")  
queryCommandSupported("commandName")  
queryCommandText("commandName")  
queryCommandValue("commandName")
```

**Returns:** See `document.queryCommandEnabled()` in Chapter 18.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

See descriptions under `document.queryCommandEnabled()` in Chapter 18.

**select()**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `select()` method selects the text inside the boundaries of the current text range. For some operations, such as prompted search and replace, it is helpful to show the user the text of the current range to highlight what text is about to be replaced. In some other operations, especially several commands invoked by `execCommand()`, the operation works only on a text selection in the document. Thus, you can use the `TextRange` object facilities to set the boundaries, followed by the `select()` method to prepare the text for whatever command you like. Text selected by the `select()` method becomes a `selection` object (covered earlier in this chapter).

**Example**

See Listing 35-11 earlier in this chapter for an example of the `select()` method in use.

**Related Items:** `selection` object.

**TextRange.setEndPoint()**

`setEndPoint("type", otherRangeRef)`

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

In contrast to the `moveEnd()` method, which adjusts the end point of the current range with respect to characters, words, sentences, and the complete range, the `setEndPoint()` method sets a boundary of the current range (not necessarily the ending boundary) relative to a boundary of another text range whose reference is passed as the second parameter. The first parameter is one of four types that control which boundary of the current range is to be adjusted and which boundary of the other range is the reference point. Table 35-3 shows the four possible values and their meanings.

**Table 35-3: setEndPoint() Method Types**

Type	Description
StartToEnd	Moves the start point of the current range to the end of the other range
StartToStart	Moves the start point of the current range to the start of the other range
EndToStart	Moves the end point of the current range to the start of the other range
EndToEnd	Moves the end point of the current range to the end of the other range

Note that the method moves only one boundary of the current range at a time. If you want to make two ranges equal to each other, you have to invoke the method twice, once with `StartToStart` and once with `EndToEnd`. At that instant, the `isEqual()` method applied to those two ranges returns `true`.

Setting a boundary point with the `setEndPoint()` method can have unexpected results when the revised text range straddles multiple elements. Don't be surprised to find that the new HTML text for the revised range does not include tags from the outer element container.

## Example

Use The Evaluator (Chapter 13) to experiment with the `setEndPoint()` method. Begin by creating two independent text ranges, one for the `myP` element and one for `myEM`:

```
a = document.body.createTextRange()
a.moveToElementText(myP)
b = document.body.createTextRange()
b.moveToElementText(myEM)
```

Before moving any end points, compare the HTML for each of those ranges:

```
a.htmlText
b.htmlText
```

Now, move the start point of the `a` text range to the end point of the `b` text range:

```
a.setEndPoint("StartToEnd", b)
```

If you now view the HTML for the `a` range,

```
a.htmlText
```

**TextRectangle**

you see that the `<p>` tag of the original a text range is nowhere to be found. This demonstration is a good lesson to use the `setEndPoint()` method primarily if you are concerned only with visible body text being inside ranges, rather than an element with its tags.

**Related Items:** `TextRange.moveEnd()`, `TextRange.moveStart()`, `TextRange.moveToElementText()` methods.

## TextRectangle Object

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
bottom		
left		
right		
top		

### Syntax

Accessing `TextRectangle` object properties:

```
(IE5+) [window.]document.getElementById("elemID").
    getBoundingClientRect().property
(IE5+) [window.]document.getElementById("elemID").
    getClientRects()[i].property
```

### About this object

The IE5+ `TextRectangle` object exposes to scripts a concept that is described in the HTML 4.0 specification, whereby an element's rendered text occupies a rectangular space on the page just large enough to contain the text. For a single word, the rectangle is as tall as the line height for the font used to render the word and no wider than the space occupied by the text. But for a sequence of words that wraps to multiple lines, the rectangle is as tall as the line height times the number of lines and as wide as the distance between the leftmost and rightmost character edges, even if it means that the rectangle encloses some other text that is not part of the element.

If you extract the `TextRectangle` object for an element by way of, for example, the `getBoundingClientRect()` method, be aware that the object is but a snapshot of the rectangle when the method was invoked. Resizing the page may very well alter dimensions of the actual rectangle enclosing the element's text, but the `TextRectangle` object copy that you made previously does not change its values to reflect the element's physical changes. After a window resize or modification of body text, any dependent `TextRectangle` objects should be recopied from the element.

**TextRectangle.bottom**

## Properties

bottom

left

right

top

**Values:** Integers.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The screen pixel coordinates of its four edges define every `TextRectangle` object. These coordinates are relative to the window or frame displaying the page. Therefore, if you intend to align a positioned element with an inline element's `TextRectangle`, your position assignments must take into account the scrolling of the body.

To my eye, the left edge of a `TextRectangle` does not always fully encompass the left-most pixels of the rendered text. You may have to fudge a few pixels in the measure when trying to align a real element with the `TextRectangle` of another element.

## Example

Listing 35-12 lets you click one of four nested elements to see how the `TextRectangle` is treated. When you click one of the elements, that element's `TextRectangle` dimension properties are used to set the size of a positioned element that highlights the space of the rectangle. Be careful not to confuse the visible rectangle object that you see on the page with the abstract `TextRectangle` object that is associated with each of the clicked elements.

An important part of the listing is the way the action of sizing and showing the positioned element is broken out as a separate function (`setHighlighter()`) from the one that is the `onclick` event handler function (`handleClick()`). This is done so that the `onresize` event handler can trigger a script that gets the current rectangle for the last element clicked, and the positioned element can be sized and moved to maintain the highlight of the same text. As an experiment, try removing the `onresize` event handler from the `<body>` tag and watch what happens to the highlighted rectangle after you resize the browser window: the rectangle that represents the `TextRectangle` remains unchanged and loses track of the abstract `TextRectangle` associated with the actual element object.

### Listing 35-12: Using the TextRectangle Object Properties

```
<html>
  <head>
    <title>TextRectangle Object</title>
    <script type="text/javascript">
      // preserve reference to last clicked elem so resize can re-use it
      var lastElem;
      // TextRectangle left tends to be out of registration by a couple of
      // pixels
      var rectLeftCorrection = 2;

      // process mouse click
```

**TextRectangle.bottom**

```

function handleClick() {
    var elem = event.srcElement;
    if (elem.className && elem.className == "sample") {
        // set hiliter element only on a subset of elements
        lastElem = elem;
        setHiliter();
    } else {
        // otherwise, hide the hiliter
        hideHiliter();
    }
}

function setHiliter() {
    if (lastElem) {
        var textRect = lastElem.getBoundingClientRect();
        hiliter.style.pixelTop = textRect.top + document.body.scrollTop;
        hiliter.style.pixelLeft = textRect.left +
            document.body.scrollLeft - rectLeftCorrection;
        hiliter.style.pixelHeight = textRect.bottom - textRect.top;
        hiliter.style.pixelWidth = textRect.right - textRect.left;
        hiliter.style.visibility = "visible";
    }
}

function hideHiliter() {
    hiliter.style.visibility = "hidden";
    lastElem = null;
}
</script>
</head>
<body onclick="handleClick()" onresize="setHiliter()">
<h1>TextRectangle Object</h1>
<hr />
<p>Click on any of the four colored elements in the paragraph below and
watch the highlight rectangle adjust itself to the element's
TextRectangle object.</p>

**Original DOM Compatibility Guide**

Baseline browsers for this section are NN2, WinIE3.1, and MacIE3.01. An item with no notation is compatible back to that level, and is not supported in later versions of the browser. Notations indicate the browser and version in which the property, method, or event handler was introduced.

Event (E) for the window and navigator objects (whose features are all browser-specific) cover only through NN4 (and IE4 when they matched a new NN4 feature). Notations are as follows:  
 N2 — New in NN2  
 N4 — New in NN4  
 J2 — New in IE3, ScriptCall ver.2  
 IE4 — New in IE4, all OSes  
 (S) — Requires signed scripts (NN)  
 A — Active window and navigator object notations are:  
 W4 — IE4+/Windows only  
 W5 — IE5+/Windows only  
 W6,5 — IE5+/Windows only  
 W6,5 — IE5+/Mac only  
 M4 — IE4+/Mac only  
 M5 — IE5+/Mac only  
 N6 — New in NN6 & Mozilla  
 Except for items marked N4-only, which are supported in all browsers, the notation N4+ and/or W3C DOM object models. "N4-only" means that no methods or events exist for the current object through IE3 and NN4.

IE4+ DHTML DOM Compatibility Guide

The baseline browser for this section is MSIE 4. An item with no notation is compatible back to that level for all OS versions. Notations as follows:  
 W4 — Windows only  
 MS — IE5+/Windows only  
 IE5.5 — IE5.5+/Windows only  
 M5 — IE5+/Mac  
 All HTML element objects share items from "All HTML" box on Page 1. "(None)" means no special methods or events for the current object. This Quick Reference does not contain listings for Microsoft's separate XML DOM.

TextNode		IE5	35

# JavaScript Reserved Words

---

**E**very programming language has a built-in vocabulary of keywords that you cannot use for the names of variables and the like. Because a JavaScript function is an object that uses the function name as an identifier for the object, you cannot employ reserved words for function names either. Netscape's list of reserved words closely echoes that of the Java language; thus, many of the keywords in the list do not — at least yet — apply to JavaScript. Remember that JavaScript keywords are case-sensitive. Although you may get away with using these words in other cases, it may lead to unnecessary confusion for someone reading your scripts.

# Answers to Tutorial Exercises

---

**T**his appendix provides answers to the tutorial exercises that appear in Part II of this book (Chapters 4 through 12).

## Chapter 4 Answers

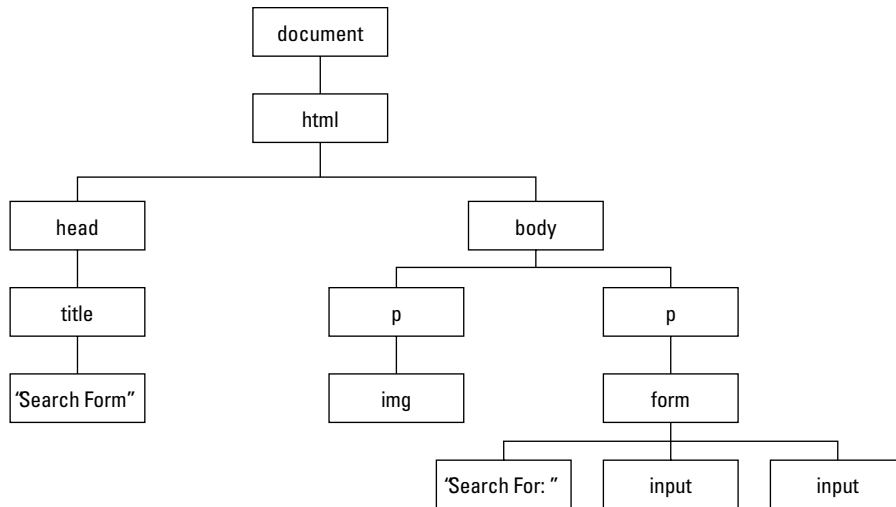

1. The music jukebox (a) and temperature calculator (d) are good client-side JavaScript applications. Even though the jukebox relies on server storage of the music files, you can create a more engaging and responsive user interface of buttons, swappable images, and information from a plugin, such as Windows Media Player or QuickTime. The temperature calculator is a natural, because all processing is done instantaneously on the client, rather than having to access the server for each conversion.

The Web site visit counter (b) that accumulates the number of different visitors to a Web site is a server-side CGI application, because the count must be updated and maintained on the server. At best, a client-side counter could keep track of the number of visits the user has made to a site and report to the user how many times he or she has been to the site. The storage requires scripting the cookie (see Chapter 16). A chat room application (c) done properly requires server facilities to open up communication channels among all users connected simultaneously. Client-side scripting by itself cannot create a live chat environment.

2.
  - a. Valid, because it is one contiguous word. InterCap spelling is fine.
  - b. Valid, because an underscore character is acceptable between words.
  - c. Not valid, because an identifier cannot begin with a numeral.
  - d. Not valid, because no spaces are allowed.
  - e. Not valid, because apostrophes and most other punctuation are not allowed.

3. The diagram is shown below. The paragraph element reference is:

```
document.getElementById("formPar")
```

4. In common:

- Both are types of nodes, derived from the basic DOM node
- Both may be children of parent nodes that act as containers

Different:

- An element node is created by a tag, while a text node has no tag associated with it
- A text node cannot be a parent to any other node, but an element node can be either a parent (branch node) or end node (leaf node)

5. 

```
<input type="button" name="Hi" value="Howdy" onclick="alert('Hello to you, too!')" />
```

## Chapter 5 Answers

1. 

```
<script type="text/javascript">
<!--
document.write("Hello, world.");
// -->
</script>
```
2. 

```
<html>
<body>
<script type="text/javascript">
```

```

<!--
document.write("Hello, world.");
// -->
</script>
</body>
</html>

```

3. `<html>`  
`<body>`  
`<script type="text/javascript">`  
`<!--`  
`// write a welcome message to the world`  
`document.write("Hello, world.");`  
`// -->`  
`</script>`  
`</body>`  
`</html>`

4. My answer is written so that both event handlers call separate functions. You can also have each event handler invoke the `alert()` method inline. If you prefer to follow the XHTML format, include a space and forward slash character before the right angle bracket of the `input` element's tag.

```

<html>
<head>
<title>An onload script</title>
<script type="text/javascript">
<!--
function done() {
    alert("The page has finished loading.");
}
function alertUser() {
    alert("Ouch!");
}
// -->
</script>
</head>
<body onload="done()">
Here is some body text.
<form>
    <input type="button" name="oneButton" value="Press Me!"
onclick="alertUser()">
</form>
</body>
</html>

```

5. a. The page displays two text fields.
- b. The user enters text into the first field and either clicks or tabs out of the field to trigger the `onchange` event handler.
- c. The function displays an all-uppercase version of one field into the other.

## Chapter 6 Answers

- Valid.
  - Not valid. The variable needs to be a single word, such as `howMany` or `how_many`.
  - Valid. The trailing semicolon is missing, but because it is optional for a one-line statement, browsers accept the statement as written.
  - Not valid. The variable name cannot begin with a numeral. If the variable needs a number to help distinguish it from other similar variables, then put the numeral at the end: `address1`.
- 4
  - 40
  - "4020"
  - "Robert"
- The functions are `parseInt()` and `parseFloat()`. Strings to be converted are passed as parameters to the functions:  
`parseInt(document.getElementById("entry").value)`.
- Both text field values are strings that must be converted to numbers before they can be arithmetically added together. You can use the `parseFloat()` functions either on the variable assignment expressions (for example, `var value1 = parseFloat(document.getElementById("inputA").value)`) or in the addition expression (`document.getElementById("output").value = parseFloat(value1) + parseFloat(value2)`).
- Concatenate means to join together two strings to become one string.

## Chapter 7 Answers

- The following answer shows the HTML markup portion in XHTML, where elements not acting as containers (notably the `input` elements) include a space and forward slash to simulate XHTML's required close tag.

```
<html>
<head>
<script type="text/javascript">
var USStates = new Array(51);

stateEntered[20] = 1788;
stateEntered[21] = 1788;
stateEntered[22] = 1837;
stateEntered[23] = 1858;
stateEntered[24] = 1817;
stateEntered[25] = 1821;
stateEntered[26] = 1889;
stateEntered[27] = 1867;
stateEntered[28] = 1864;
stateEntered[29] = 1788;
stateEntered[30] = 1787;
stateEntered[31] = 1912;
stateEntered[32] = 1788;
stateEntered[33] = 1789;
stateEntered[34] = 1889;
stateEntered[35] = 1803;
stateEntered[36] = 1907;
stateEntered[37] = 1859;
stateEntered[38] = 1787;
stateEntered[39] = 1790;
stateEntered[40] = 1788;
stateEntered[41] = 1889;
stateEntered[42] = 1796;
stateEntered[43] = 1845;
stateEntered[44] = 1896;
stateEntered[45] = 1791;
stateEntered[46] = 1788;
stateEntered[47] = 1889;
stateEntered[48] = 1863;
stateEntered[49] = 1848;
stateEntered[50] = 1890;

function getStateDate() {
    var selectedState = document.getElementById("entry").value;
    for ( var i = 0; i < USStates.length; i++) {
        if (USStates[i] == selectedState) {
            break;
        }
    }
}
```

```

        alert("That state entered the Union in " + stateEntered[i] + ".");
    }
</script>
</head>
<body>
<form name="entryForm">
Enter the name of a state:
<input type="text" name="entry" />
<input type="button" value="Look Up Entry Date"
onclick="getStateDate()" />
</form>
</body>
</html>

```

2. Several problems plague this function definition. Parentheses are missing from the first `if` construction's condition statement. Curly braces are missing from the second nested `if...else` construction. A mismatch of curly braces also exists for the entire function. The following is the correct form (changes and additions in boldface):

```

function format(ohmage) {
    var result;
    if (ohmage >= 10e6) {
        ohmage = ohmage / 10e6;
        result = ohmage + " Mohms";
    } else {
        if (ohmage >= 10e3) {
            ohmage = ohmage / 10e3;
            result = ohmage + " Kohms";
        } else {
            result = ohmage + " ohms";
        }
    }
    alert(result);
}

```

3. Here is one possibility:

```

for (var i = 1; i < tomatoes.length; i++) {
    if (tomatoes[i].looks == "mighty tasty") {
        break;
    }
}
var myTomato = tomatoes[i]

```

4. The new version defines a different local variable name for the dog.

```

<html>
<head>
<script type="text/javascript">
var aBoy = "Charlie Brown"; // global
var hisDog = "Snoopy"; // global
function demo() {
    var WallacesDog = "Gromit"; // local version of hisDog
}

```

```

    var output = WallacesDog + " does not belong to " + aBoy +
    ".<br>";
    document.write(output);
}
</script>
<body>
<script type="text/javascript">
demo(); // runs as document loads
document.write(hisDog + " belongs to " + aBoy + ".");
</script>
</body>
</html>

```

- 5.** The application uses three parallel arrays and is structured very much like the solution to question 1. Learn to reuse code whenever you can.

```

<html>
<head>
<script type="text/javascript">
var planets = new Array(4);
planets[0] = "Mercury";
planets[1] = "Venus";
planets[2] = "Earth";
planets[3] = "Mars";

var distance = new Array(4);
distance[0] = "36 million miles";
distance[1] = "67 million miles";
distance[2] = "93 million miles";
distance[3] = "141 million miles";

var diameter = new Array(4);
diameter[0] = "3100 miles";
diameter[1] = "7700 miles";
diameter[2] = "7920 miles";
diameter[3] = "4200 miles";

function getPlanetData() {
    var selectedPlanet = document.getElementById("entry").value;
    for ( var i = 0; i < planets.length; i++) {
        if (planets[i] == selectedPlanet) {
            break;
        }
    }
    var msg = planets[i] + " is " + distance[i];
    msg += " from the Sun and ";
    msg += diameter[i] + " in diameter.";
    document.getElementById("output").value = msg;
}
</script>
</head>
<body>

```

```
<form name="entryForm">
Enter the name of a planet:
<input type="text" name="entry" id="entry" />
<input type="button" value="Look Up a Planet"
onclick="getPlanetData()" />
<br />
<input type="text" size="70" name="output" id="output" />
</body>
</html>
```

## Chapter 8 Answers

- Close, but no cigar. Array references are always plural:  
`window.document.forms[0]`
  - Not valid: `self` refers to a window and `entryForm` must refer to a form. Where's the document? It should be `self.document.entryForm.entryField.value`.
  - Valid. This reference points to the name property of the third form in the document.
  - Not valid. The uppercase "D" in the method name is incorrect.
  - Valid, assuming that `newWindow` is a variable holding a reference to a subwindow.

2. `window.status = "Welcome to my Web page."`

3. `document.write("<h1>Welcome to my Web page.</h1>")`

4. A script in the Body portion invokes a function that returns the text entered in a `prompt()` dialog box.

```
<html>
<head>
<script type="text/javascript">
function askName() {
    var name = prompt("What is your name, please?","");
    return name;
}
</script>
</head>
<body>
<script type="text/javascript">
document.write("Welcome to my web page, " + askName() + ".");
</script>
</body>
</html>
```

5. The URL can be derived from the `href` property of the `location` object.

```
<html>
<head>
<script type="text/javascript">
```

```
function showLocation() {
    alert("This page is at: " + location.href);
}
</script>
</head>
<body onload="showLocation()">
Blah, blah, blah.
</body>
</html>
```

## Chapter 9 Answers

1. For Listing 9-1, pass the text input element object because that's the only object involved in the entire transaction.

```
<html>
<head>
<title>Text Object value Property</title>
<script type="text/javascript">
function upperMe(field) {
    field.value = field.value.toUpperCase();
}
</script>
</head>
<body>
<form onsubmit="return false">
<input type="text" name="convertor" value="sample"
onchange="upperMe(this)">
</form>
</body>
</html>
```

For Listing 9-2, the button invokes a function that communicates with a different element in the form. Pass the form object.

```
<html>
<head>
<title>Checkbox Inspector</title>
<script type="text/javascript">
function inspectBox(form) {
    if (form.checkThis.checked) {
        alert("The box is checked.");
    } else {
        alert("The box is not checked at the moment.");
    }
}
</script>
</head>
<body>
<form>
<input type="checkbox" name="checkThis">Check here<br>
```

```

<input type="button" value="Inspect Box"
onclick="inspectBox(this.form)">
</form>
</body>
</html>

```

For Listing 9-3, again the button invokes a function that looks at other elements in the form. Pass the form object.

```

<html>
<head>
<title>Extracting Highlighted Radio Button</title>
<script type="text/javascript">
function fullName(form) {
    for (var i = 0; i < form.stooges.length; i++) {
        if (form.stooges[i].checked) {
            break;
        }
    }
    alert("You chose " + form.stooges[i].value + ".");
}
</script>
</head>

<body>
<form>
<p>Select your favorite Stooge:
<input type="radio" name="stooges" value="Moe Howard" checked>Moe
<input type="radio" name="stooges" value="Larry Fine"> Larry
<input type="radio" name="stooges" value="Curly Howard"> Curly<br>
<input type="button" name="Viewer" value="View Full Name..."
onclick="fullName(this.form)"></p>
</form>
</body>
</html>

```

For Listing 9-4, all action is triggered by and confined to the `select` object. Pass only that object to the function.

```

<html>
<head>
<title>Select Navigation</title>
<script type="text/javascript">
function goThere(list) {
    location = list.options[list.selectedIndex].value;
}
</script>
</head>

<body>
<form>
Choose a place to go:

```

```

<select name="urlList" onchange="goThere(this)">
  <option selected value="index.html">Home Page
  <option value="store.html">Shop Our Store
  <option value="policies">Shipping Policies
  <option value="http://www.google.com">Search the Web
</select>
</form>
</body>
</html>

```

**2. Here are the most likely ways to reference the text box object:**

```

document.getElementById("email")
document.forms[0].elements[0]
document.forms["subscription"].elements[0]
document.subscription.elements[0]
document.forms[0].elements["email"]
document.forms["subscription"].elements["email"]
document.subscription.elements["email"]
document.forms[0].email
document.forms["subscription"].email
document.subscription.email

```

**The reference `document.all.email` (or any reference starting with `document.all`) works only in Internet Explorer and other browsers that emulate IE, but not in Mozilla or Safari, as requested. Other valid references may include the W3C DOM `getElementsByTagName()` method. Since the question indicates that there is only one form on the page, the text box is the first input element in the page, indicating that `document.body.getElementsByTagName("input")[0]` would be valid for this page.**

**3. The `this` keyword refers to the text input object, so that `this.value` refers to the value property of that object.**

```

function showText(txt) {
  alert(txt);
}

```

**4. `document.accessories.accl.value = "Leather Carrying Case";`**

```
document.forms[1].accl.value = "Leather Carrying Case";
```

**5. The `select` object invokes a function that does the job.**

```

<html>
<head>
<title>Color Changer</title>
<script type="text/javascript">
function setColor(list) {
  var newColor = list.options[list.selectedIndex].value;
  document.bgColor = newColor;
}
</script>
</head>

```

```

<body>
<form>
Select a background color:
<select onchange="setColor(this)">
<option value="red">Stop
<option value="yellow">Caution
<option value="green">Go
</select>
</form>
</body>
</html>

```

## Chapter 10 Answers

1. Use `string.indexOf()` to see if the field contains the "@" symbol.

```

<html>
<head>
<title>E-mail @ Validator</title>
<script type="text/javascript">
function checkAddress(form) {
    if (form.email.value.indexOf("@") == -1) {
        alert("Check the e-mail address for accuracy.");
        return false;
    }
    return true;
}
</script>
</head>

<body>
<form onsubmit="return checkAddress(this)">
Enter your e-mail address:
<input type="text" name="email" size="30"><br>
<input type="submit">
</form>
</body>
</html>

```

2. Remember that the substring goes up to, but does not include, the index of the second parameter. Spaces count as characters.

```

myString.substring(0,3)    // result = "Int"
myString.substring(11,17) // result = "plorer"
myString.substring(5,12)  // result = "net Exp"

```

3. The missing `for` loop is in boldface. You could also use the increment operator on the count variable (`++count`) to add 1 to it for each letter "e."

```

function countE(form) {
    var count = 0;
    var inputString = form.mainstring.value.toLowerCase();

```

```

    for (var i = 0; i < inputString.length; i++) {
        if (inputString.charAt(i) == "e") {
            count += 1;
        }
    }
    var msg = "The string has " + count;
    msg += " instances of the letter e.";
    alert(msg);
}

```

**4. The formula for the random throw of one die is in the chapter.**

```

<html>
<head>
<title>Roll the Dice</title>
<script type="text/javascript">
function roll(form) {
    form.die1.value = Math.floor(Math.random() * 6) + 1
    form.die2.value = Math.floor(Math.random() * 6) + 1
}
</script>
</head>

<body>
<form>
<input type="text" name="die1" size="2">
<input type="text" name="die2" size="2"><br>
<input type="button" value="Roll the Dice" onclick="roll(this.form)">
</form>
</body>
</html>

```

**5. If you used the `Math.round()` method in your calculations, that is fine for your current exposure to the `Math` object. Another method, `Math.ceil()`, may be more valuable because it rounds up any fractional value.**

```

<html>
<head>
<title>Waiting for Santa</title>
<script type="text/javascript">
function daysToXMAS() {
    var oneDay = 1000 * 60 * 60 * 24;
    var today = new Date();
    var XMAS = new Date("December 25, 2001");
    var diff = XMAS.getTime() - today.getTime();
    return Math.ceil(diff/oneDay);
}
</script>
</head>

<body>
<script type="text/javascript">

```

```
document.write(daysToXMAS() + " days until Christmas.");
</script>
</body>
</html>
```

## Chapter 11 Answers

1. `onload="parent.currCourse = 'history101'"`

2.

3. All three frames are siblings, so references include the parent.

```
parent.mechanics.location.href = "french201M.html";
parent.description.location.href = "french201D.html";
```

4. A script in one of the documents is attempting to reference the `selector` object in one of the frames but the document has not fully loaded, causing the object to not yet be in the browser's object model. Rearrange the script so that it fires in response to the `onload` event handler of the framesetting document.

5. From the subwindow, the `opener` property refers back to the frame containing the `window.open()` method. To extend the reference to the frame's parent, the reference includes both pieces: `opener.parent.location`.

## Chapter 12 Answers

1. As the document loads, the `<img>` tag creates a document image object. A memory image object is created with the `new Image()` constructor. Both objects have the same properties, and assigning a URL to the `src` property of a memory object loads the image into the browser's image cache.

2. `var janeImg = new Image(100,120);`

```
janeImg.src = "jane.jpg";
```

3. `document.images["people"].src = janeImg.src;`

4. Surround `<img>` tags with `<a>` tags, and use the link's `onclick`, `onmouseover`, and `onmouseout` event handlers. Set the image's `border` attribute to zero if you don't want the link highlight to appear around the image.

5. The following works in all W3C DOM-compatible browsers. The order of the first two statements may be swapped without affecting the script.

```
var newElem = document.createElement("a");
var newText = document.createTextNode("Next Page");
newElem.href = "page4.html";
newElem.appendChild(newText);
document.getElementById("forwardLink").appendChild(newElem);
```

# JavaScript and DOM Internet Resources

---

**A**s an online technology, JavaScript has plenty of support online for scripters. Items recommended here were taken as a snapshot of Internet offerings in late 2003. But beware! Sites change. URLs change. Be prepared to hunt around for these items if the information provided here becomes out-of-date by the time you read this.

## Support and Updates for This Book

The most up-to-date list of errata and other notes of interest pertaining to this edition of the *JavaScript Bible* can be found at the official Support Center, located at:

<http://www.dannyg.com/support/index.html>

If you are experiencing difficulty with the example listings in this book, first check with the Support Center to see if your question has been answered. As mentioned earlier, you are encouraged to enter the tutorial listings yourself to get used to typing JavaScript (and HTML) code. If, after copying the examples from Part II, you can't make something work (and a fix hasn't already been posted to the Support Center), send the file you've typed to me via e-mail, along with a description of what's not working for you. Also tell me the browser version and operating system that you're using. My e-mail address is [dannyg@dannyg.com](mailto:dannyg@dannyg.com). Regretfully, I am unable to answer general questions about JavaScript or how to apply examples from the book to your own projects.

## Newsgroups

The best places to get quick answers to your pressing questions are online newsgroups. Here are the top JavaScript-related newsgroups:

On most news servers:

`comp.lang.javascript`

On `news://msnews.microsoft.com`:

```
microsoft.public.scripting.jscript
microsoft.public.windows.inetexplorer.ie5.programming.dhtml
microsoft.public.windows.inetexplorer.ie5.programming.dhtml.scripting
microsoft.public.inetsdk.programming.scripting.jscript
```

On `news://secnews.netscape.com`:

```
netscape.public.mozilla.dom
netscape.public.mozilla.jseng
```

Before you post a question to a newsgroup, however, read about FAQs in the following section and also use the extremely valuable newsgroup archive search facility of Google Groups. Visit the Google Groups search page at:

<http://groups.google.com/>

Enter the keyword or phrase into the top text box, but then also try to narrow your search by limiting the newsgroup(s) to search. For example, if you have a question about weird behavior you are experiencing with the `borderCollapse` style property in IE, enter `borderCollapse` into the search field, and then try narrowing the search to a specific newsgroup (forum) such as `comp.lang.javascript`.

If you post a question to a newsgroup, you will most likely get a quick and intelligent response if you also provide either some sample code that's giving you a problem, or a link to a temporary file on your server that others can check out. Visualizing a problem you've spent days on is very hard for others. Be as specific as possible, including the browser(s) on which the code must run and the nature of the problem.

## FAQs

One situation that arises with a popular and accessible technology, such as JavaScript and DHTML authoring, is that the same questions get asked over and over, as newcomers arrive on the scene daily. Rather than invoke the ire of newsgroup users, look through existing FAQ files to see if your concern has already been raised and answered. Here are some of the best JavaScript FAQ sites:

```
javascript.faqts.com
developer.irt.org/script/script.htm
```

For less-frequently asked questions — but previously asked and answered in a public form — use the Google Groups search, described earlier in this appendix.

## Online Documentation

Locations of Web sites that dispense official documentation for one browser or another are extremely fluid. Therefore, the following information contains links only to top-level areas of appropriate Web sites, along with tips on what to look for after you are at the site.

Microsoft has condensed its developer documentation into a massive site called MSDN (Microsoft Developer Network). The place to begin is:

<http://msdn.microsoft.com/workshop/>

This page is the portal to many technologies, but the one most applicable to JavaScript and client-side scripting is one labeled “Web Development.” Within that heading you’ll find a section named “Scripting.” Here you’ll find plenty of documentation and technical articles for Microsoft scripting technologies, including JScript (Microsoft’s flavor of JavaScript).

For Netscape browser technologies, start at:

<http://developer.netscape.com/docs/>

You can also find some interesting future-oriented developer documentation at:

<http://www.mozilla.org/docs>

Finally, you can read the industry standards for HTML, CSS, and ECMAScript technologies online. Be aware that these documents are primarily intended for developers of tools that we use—browsers, WYSIWYG editors, and so forth—to direct them on how their products should respond to tags, stylesheets, scripts, and so on. Reading these documents has frequently been cited as a cure for insomnia.

<http://www.ecma-international.org/publications/standards/ECMA-262.HTM>

<http://www.w3.org/TR/html4>

<http://www.w3.org/Markup>

<http://www.w3.org/TR/REC-CSS2>

<http://www.w3.org/DOM/>

Please note that just because a particular item is described in an industry standard doesn’t mean that it is implemented in any or all browsers. In the real world, we must develop for the way the technologies are actually implemented in browsers.

## World Wide Web

The number of Web sites devoted to JavaScript tips and tricks is mind-boggling. Many sites come and go in the middle of the night, leaving no trace of their former existence. If you are looking for more example code for applications not covered in this book, perhaps the best place to begin your journey is through the traditional search engines. Narrowing your search through careful keyword choice is vital. In addition to the Netscape and (heavily Windows-oriented) Microsoft developer Web sites (plus numerous online articles of mine listed at <http://www.dannyg.com/pubs/index.html>), a couple other venerable sites are:

<http://builder.com>

<http://www.webreference.com>

These sites are by no means the only worthwhile JavaScript and DHTML destinations on the Web. Sometimes having too many sources is as terrifying as having not enough. The links and newsgroups described in this appendix should take you a long way.

# What's on the CD-ROM

---

**T**he accompanying Windows–Macintosh CD-ROM contains additional chapters including many more JavaScript examples, electronic versions of the Quick Reference shown in Appendix A for printing in several formats, a complete, searchable version of the entire book, and the Adobe Acrobat Reader.

## System Requirements

To derive the most benefit from the example listings, you should have both Netscape Navigator 7 (or later) and Internet Explorer 6 (or later) installed on your computer. Although many scripts run in these and other browsers, several scripts demonstrate features that are available on only a limited range of browsers. To write scripts, you can use a simple text editor, word processor, or dedicated HTML editor.

To use the Adobe Acrobat Reader (version 6.0), you need the following:

- ◆ For Windows 98, Windows ME, Windows NT4.0 (with SP6), Windows 2000 (with SP2), Windows XP Pro/Home, or Windows XP Table PC Edition, you should be using a Pentium computer with 32MB of RAM and 60MB of hard disk space.
- ◆ Macintosh users require a PowerPC, OS X v10.2.2 or later, at least 32MB of RAM, and 70MB of disk space.

## Disc Contents

When you view the contents of the CD-ROM, you will see files tailored for your operating system. The contents include the following items.

### JavaScript listings for text editors

Starting with Part III of the book, almost all example listings are on the CD-ROM in the form of complete HTML files, which you can load into a browser to see the language item in operation. A directory called Listings contains the example files, with nested folders named for each chapter. Each HTML file's name is keyed to the listing number in the book. For example, the file for Listing 15-1 is named `lst15-01.htm`. Note that no listing files are provided for the tutorial chapters of Part II, because you are encouraged to enter HTML and scripting code manually.

For your convenience, the `_index.html` file in the `Listings` folder provides a front-end table of contents to the HTML files for the book's program listings. Open that file from your browser whenever you want to access the program listing files. If you intend to access that index page frequently, you can bookmark it in your browser(s). Using the index file to access the listing files can be very important in some cases, because several individual files must be opened within their associated framesets to work properly. Accessing the files through the `_index.html` file ensures that you open the frameset. The `_index.html` file also shows browser compatibility ratings for all the listings. This saves you time from opening listings that are not intended to run on your browser. To examine and modify the HTML source files, open them from your favorite text editor program (for Windows editors, be sure to specify the `.htm` file extension in the Open File dialog box).

You can open all example files directly from the CD-ROM, but if you copy them to your hard drive, access is faster and you will be able to experiment with modifying the files more readily. Copy the folder named `Listings` from the CD-ROM to any location on your hard drive.

## JavaScript and Browser Object Quick Reference from Appendix A (Adobe Acrobat format)

If you like the quick reference in Appendix A, you can print it out on two sides of seven sheets of paper with the help of the Adobe Acrobat Reader, included with the CD-ROM. You can choose from four versions, depending on the type of layout you prefer and kind of printer you use. Open the `JS Object Reference` folder and read the file `Choose a Version.txt` for details on each Quick Reference printout type. Then read the "howtoprt" file for your desired version to understand details about Page Setup settings, paper feed options, and assembly after printing.

## Adobe Acrobat Reader

The Adobe Acrobat Reader is a helpful program that enables you to view the reference example sections for Parts III and IV of the book, the Quick Reference from Appendix A, and the searchable version of this book, all of which are in `.pdf` format on the CD-ROM. To install and run Adobe Acrobat Reader, follow these steps:

### For Windows

1. Start Windows Explorer and then open the Acrobat folder on the CD-ROM.
2. In the Acrobat folder, double-click the lone executable file and follow the instructions presented on-screen for installing Adobe Acrobat Reader.

### For Macintosh

1. Open the Acrobat folder on the CD-ROM.
2. In the Acrobat folder, double-click the Adobe Acrobat Reader disk image icon (`AdbeRdXX_enu_full.dmg`), this will mount the disk image on your computer, then open the mounted image and copy the Adobe Reader folder to the Applications directory of your computer.

## Acrobat version of book with topical references

In many places throughout the reference chapters of Parts III and IV, you see notations directing you to the CD-ROM for a particular topic being discussed. All of these topics are located in the chapters as they appear in complete Adobe Acrobat form on the CD-ROM. A single PDF file is located on the CD-ROM, and it serves as an electronic version of the entire book, complete with full topics that are listed as CD-ROM references in the printed book. For the fastest access to these topics, copy the entire PDF file for the book to your hard disk.

Like any Acrobat document, the PDF version of the book is searchable. Current versions of Acrobat should automatically load the Acrobat index file (with the .pdx extension) to supply indexed search capabilities (which is much faster than Acrobat's Find command).

To begin an actual search, click the Search icon (binoculars in front of a sheet of paper). Enter the text for which you're searching. To access the index and search facilities in future sessions, the CD-ROM must be in your CD-ROM drive; unless, of course, you've copied both the .pdx and .pdf files to your hard drive.

## Troubleshooting

If you have difficulty installing or using the CD-ROM programs, try the following solutions:

- ♦ **Turn off any anti-virus software that you may have running.** Installers sometimes mimic virus activity and can make your computer incorrectly believe that a virus is infecting it. (Be sure to turn the antivirus software back on later.)
- ♦ **Close all running programs.** The more programs you're running, the less memory is available to other programs. Installers also typically update files and programs; if you keep other programs running, installation may not work properly.

If you still have trouble with the CD-ROM, please call the Wiley Product Technical Support phone number: (800) 762-2974. Outside the United States, call 1(317) 572-3994. You can also contact Wiley Product Technical Support through the Internet at: <http://www.wiley.com/techsupport>. Wiley Publishing will provide technical support only for installation and other general quality control items; for technical support on the applications themselves, consult the program's vendor or author.

To place additional orders or to request information about other Wiley products, please call (800) 225-5945.

# HTML Directive Objects

---

Thanks to the modern browser's desire to expose all HTML elements to the document object model, we can now (in IE4+ and W3C DOM browsers) access a variety of objects that represent many HTML elements that are normally invisible to the human viewer of a page. These elements are called *directive elements* because they predominantly contain instructions for the browser — instructions that direct the browser to locate associated content on the page, link in external specifications, treat content as executable script statements, and more.

As you browse through the objects of this chapter, you may wonder why they have so many properties that normally indicate that the elements occupy space on the rendered page. After all, how can a meta element have dimension or position on the page when it has no renderable content? The reason is that modern browsers internally employ some form of object-oriented behavior that lets all HTML elements — rendered or not — inherit the same set of properties, methods, and event handlers that any generic element has (see Chapter 15). The logical flaw is that unrendered elements can have properties and methods that don't genuinely apply to them. In such cases, their property values may be zero, an empty string, or an empty array. Yet the properties and methods exist in the objects just the same. Therefore, despite the large number of objects covered in this chapter, there are relatively few properties and methods that are not shared already with all HTML elements (as covered in Chapter 15).

## HTML Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

### In This Chapter

Accessing non-displayed element objects

Linking operating-system specific stylesheet definitions

HTML, head, link, title, meta, base, and script elements

## html

## Syntax

Accessing `html` element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.body.parentNode.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
(IE4+) [window.]document.body.parentElement.property | method([parameters])
```

## About this object

The `html` element is the big wrapper around all other elements of the page. In the object tree, the `html` element sits between the all-encompassing `document` object and the element's most common children, the `head` and `body` elements. Other than one deprecated property (`version`), the `html` element object offers nothing of importance to the scripter — with one possible exception. When your script needs to use methods on the child nodes of the `html` element, you must invoke most of those methods from the point of view of the `html` element. Therefore, you should know how to create a reference to the `html` element object (shown in the preceding “Syntax” section) just in case you need it.

## Property

### version

**Value:** String.

Read-Only

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `version` property is an artifact of an “ancient” way an HTML document used to specify the HTML version of its content. These days, the preferred way to declare the HTML version for a document is through a Document Type Declaration (DTD) statement that precedes the `<html>` tag. An example of a modern DTD statement that accommodates HTML 4 plus deprecated elements and attributes as well as frameset support is

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.0 Frameset//EN"
"http://www.w3.org/TR/REC-html40/frameset.dtd">
```

See <http://www.w3.org/TR/REC-html40/struct/global.html#h-7.2> for several other possibilities. A DTD statement does not affect the `version` property of an `html` element object.

## head Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
profile		

## Syntax

Accessing head element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

## About this object

The purpose of the `head` element is primarily to act as a container for most of the other HTML directive elements. Other than as a reference point to the child elements nested within, the `head` element object rarely comes into play when scripting a document.

## Property

### profile

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `profile` property is the script version of the optional `profile` attribute of a `head` element. While the attribute and property are supported in many browsers, they are not used in practice yet. You can find details about the attribute at <http://www.w3.org/TR/REC-html40/struct/global.html#profiles>.

**Related Items:** `meta` element object.

## base Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
href		
target		

## Syntax

Accessing base element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**base**

## About this object

The `base` element enables the page author to specify a default server directory and/or link target for the entire page. If you omit the `base` element from the HTML, browsers use the current page's path as the base URL and the current window or frame as the default target. Occasionally, a page generated entirely by way of `document.write()` has difficulty establishing the same base URL as the document that generates the content, particularly if the primary page is written out by a server script (in Perl or in another language). Including a `<base>` tag in the dynamically written new page solves the problem; the new page can fetch images or other external elements via relative URLs within the page.

The two distinctive properties of the `base` element object are rarely scripted, if ever.

## Properties

### href

**Value:** URL string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `href` property is generally an absolute URL to the directory you wish to declare as the default directory for the page. Even though browsers automatically set the `base href` to the document's own directory, this object and property do not have any values unless you explicitly set them in a `<base>` tag. In IE, changing this property after a page loads causes the page to re-resolve all relative URLs on the page to the new `base href`. Therefore, if images have relative URLs assigned to their `src` properties (either by way of the tag attribute or script), a change to the `base` element's `href` property forces the browser to look for those same relative URLs in the new directory. If the files aren't there, the images show up broken on the page.

### target

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `target` property governs the default window or frame that is to receive any content coming from a server in response to a click on a link or any other element that has its own `target` attribute. Valid values include the name of any frame (as assigned to the `name` attribute of the `<frame>` tag) or window (as defined by the second attribute of the `window.open()` method). You can also assign standard HTML targets (`_blank`, `_parent`, `_self`, and `_top`) to this property as strings.

## basefont Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
color		
face		
size		

## Syntax

Accessing `basefont` element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

## About this object

The `basefont` element enables authors to define a font face, size, and color for an entire section of an HTML document—or the entire document. Although page authors still frequently use the `basefont` element, font control in modern browsers should fall in the hands of stylesheets. (The element is deprecated in HTML 4.0.) The paradox of this is that the `basefont` element is accessible as a scriptable object only in browsers that support stylesheets. Even so, I recommend avoiding dynamic font changes by way of the `basefont` element and use scripts to control stylesheets instead.

**Note**

The `basefont` element has no end tag, so IE's `outerHTML` property consists of all HTML in the document starting with the element itself.

The three distinctive properties of the `basefont` element object are rarely, if ever, scripted.

## Properties

`color`  
`face`  
`size`

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

These three properties define the characteristics of font rendering for all content following the element's tag in the document. Color specifications can be hexadecimal triplets or Netscape color names (a list is available at <http://developer.netscape.com/docs/manuals/htmlguid/colortab.htm>). Font faces can include a list of comma-separated font face names. And because this is HTML as opposed to stylesheet fonts, the `size` property is in terms of the 1 through 7 scale of font sizes. You can also use relative sizes (for example, +1).

## isindex Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
alt		
border		
checked		

*Continued*

**isindex**

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
complete		
dynsrc		
form		
height		
hspace		
indeterminate		
loop		
lowsrc		
maxLength		
name		
prompt		
readOnly		
size		
start		
status		
value		
vrml		
vspace		
width		

## Syntax

Accessing `isindex` element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])  
(IE5+/W3C) [window.]document.getElementById("elemID").property |  
method([parameters])
```

## About this object

The `isindex` element is a holdover from the early beginnings of HTML. It offered the first text input field prior to the addition of `form` and `input` elements to the HTML specification. IE treats this element as if it were an `input` element, so `isindex` takes on all possible input element properties (including those of buttons). This element is deprecated in HTML 4.0 and should not be part of your development vocabulary. Use forms and genuine `input` elements instead (see Chapters 21–24).

## link Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
charset		onload
disabled		
href		
hreflang		
media		
rel		
rev		
sheet		
styleSheet		
target		
type		

## Syntax

Accessing `link` element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

## About this object

The `link` element (not to be confused with the `a` element that is often referred to as a “link” element when it contains an `href` attribute pointing to another document) has many potential uses in pointing to external documents that relate to the current document. Its most common usage today is for linking an external stylesheet specification to the document. In fact, it’s not uncommon for sophisticated site designs to use `document.write()` to generate the `<link>` tag so that operating-system–specific stylesheets are applied to the page. In the following code fragment (which goes inside a document’s head element), the page loads a Macintosh-specific stylesheet when the page is running on a Macintosh; otherwise, it loads a Windows-specific stylesheet:

```
<script type="text/javascript">
var isMac = navigator.userAgent.indexOf("Mac") != -1;
var linkTagStart = "<link rel='stylesheet' type='text/css' href='";
var linkTagEnd = ".css'>";
if (isMac) {
    document.write(linkTagStart + "mac" + linkTagEnd;
} else {
    document.write(linkTagStart + "windows" + linkTagEnd;
}
</script>
```

Although it may appear that the `link` element can load a variety of content into a page, do not use it for multimedia (in which case you should use the `embed` or `object` elements) or external HTML (where you should use an `iframe` element).

**link**

Many of the properties of the `link` element object are script representations of HTML 4.0 attributes for the element. However, browsers don't take full advantage of the possibilities available from the `link` element yet. (For example, a browser can provide arrows to the previous and next documents in a series, as specified by the `rev` and `rel` attributes. But so far, no browser implements this.) Properties unique to this object offer scripted access (in various browser versions) to attribute values of the `link` element. Therefore, this chapter does not spend a lot of time on properties that are not in current use.

## Properties

### charset

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `charset` property advises the browser about the character encoding of the content that will arrive from the external document (assuming you also have the `href` attribute set). Values for this property must match the encoding naming conventions defined in an industry standard registry (<http://www.iana.org/assignments/character-sets>).

### disabled

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

By changing the `disabled` property (default is `false`), you can turn externally linked content on and off. For example, you can define two different stylesheet links in a document that has two `<link>` tags with one's `disabled` attribute set. You can switch between the two stylesheets by setting the `disabled` property of one to `true` and the other to `false`.

### href

**Value:** String.

See Text

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Another way to swap stylesheets is to modify the value of a single `link` element object's `href` property (although the property is read-only in MacIE4+). The property's value is a URL string.

### hrefLang

**Value:** String.

Read/Write

**Compatibility:** WinIE6+, MacIE6+, NN6+, Moz1+, Safari1+

The `hrefLang` property is an advisory for the browser (if the browser takes advantage of it) about the written language used for the content to which the `link` element's `href` attribute points. Values for this property must be in the form of the standard language codes (for example, `en-us` for U.S. English).

### media

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE-, NN6+, Moz1+, Safari1+

**link.target**

The `media` property is an advisory for the browser about the target output device intended for the content to which the `link` element's `href` attribute points. This is an outgrowth of HTML 4.0 efforts to make way for future browsers and content that can be optimized for devices such as printers, handheld computers, and audio digitizers. The W3C specifies a preliminary set of constant string values for this property's equivalent attribute. So far, browsers (at most) recognize all (default), print, and screen.

**rel****rev**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `rel` and `rev` properties are intended to define relationships in the forward and back directions with respect to the current document. Browsers have yet to exploit most of the potential of these attributes and properties. For the most part, the attributes solely direct the browser to treat the external content as a stylesheet definition file.

A long list of values is predefined for these properties, based on the corresponding attribute values specified in HTML 4.0. If the browser does not respond to a particular value, the value is simply ignored. You can string together multiple values in a space-delimited list inside a single string. Accepted values are as follows:

alternate	contents	index	start
appendix	copyright	next	stylesheet
bookmark	glossary	prev	subsection
chapter	help	section	

**sheet**

**Value:** Object.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

When a `link` element loads an external stylesheet, the W3C DOM `sheet` property of the `link` element object provides scripted access to the stylesheet rules that belong to that external file. Use properties of the `sheet` object to access specifics about the imported rules.

**styleSheet**

**Value:** Object.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

When a `link` element loads an external stylesheet, the IE-specific `styleSheet` property of the `link` element object provides scripted access to the stylesheet rules that belong to that external file. Use properties of the `styleSheet` object (see Chapter 26) to access specifics about the imported rules.

**target**

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

**link.target**

In the context of using `link` elements to point to other content associated with the current document (for example, the next and previous documents within a series), the `target` property can advise the browser which frame or window to use to display that content. For example, a suitably equipped browser can display a glossary in a separate window. No browsers currently implement these extended features of the `link` element, so the property is provided in browsers only for compatibility with the W3C standards. If the property were truly functional, it would accept values in the form of a string name for a frame or one of the window constants (`_blank`, `_parent`, `_self`, or `_top`).

## type

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `type` property specifies the `mime type` for the content that will arrive from the external document to which the element's `href` attribute points. `link` elements are used primarily for Cascading Style Sheets, so the property value is `text/css`.

## Event handlers

## onload

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `onload` event handler fires when the external content pointed to by the `link` element's `href` attribute completes loading. WinIE5 fires this event handler even if the loading does not succeed, so use this event handler with care.

## meta Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
charset		
content		
httpEquiv		
name		
url		

## Syntax

Accessing meta element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

## About this object

In computer terminology, *metadata* usually consists of extra information about the primary data of a document or information collection. In HTML documents, metadata can be additional hidden information about the document, such as the name of the author and keywords. If the browser is suitably equipped, metadata can also include some instructions, such as when to reload the page by itself. `meta` elements add all of this metadata to HTML documents. Both fact and folklore surround the application of `meta` elements within pages. One fact is that Internet search engine robots used to scour pages for certain kinds of keyword meta tags to help place your page within relevant categories when Web surfers are looking for specific content (but thanks to keyword loading by unscrupulous Web sites, search engines now rarely consider `meta` keywords). More on the folklore side is that browsers always respond to `meta` element wording that prevents browsers from copying pages into the cache — when in fact, this behavior is not universal among browsers.

Complete details about `meta` element usage is beyond the scope of this JavaScript book, but you should be aware of one widely accepted composition that enables you to set a page to reload itself (or another page) at a fixed time interval. This is especially useful if your page retrieves very timely information from a database. The format is

```
<meta http-equiv="refresh" content="n,url=url" />
```

`n` is the number of seconds to delay before reloading the page, and `url` is the complete URL of the page to be reloaded. Note that you can specify any page you like. This allows for a kind of slide show to be sequenced in a freestanding kiosk, because each page's `meta` element points to the next page in the series after a fixed amount of time.

Unique properties for the `meta` element object mimic the HTML attributes for the `<meta>` tag. Browsers read most attributes only at load time, which means that scripted changes to values after the page loads have no effect. These properties are rarely, if ever, accessed from a script, so I mention them here only briefly.

## Properties

### charset

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `charset` property advises the browser about the character encoding of the content for the page. Values for this property must match the encoding naming conventions defined in an industry standard registry (<http://www.iana.org/assignments/character-sets>).

### content

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

For many applications of the `meta` element, the `content` property contains the primary value associated with the element. For example, search engines look for a `meta` element whose `name` attribute is "keywords". The value of the `content` attribute is a comma-delimited string of keywords that the search engine reads and indexes in its own database. The `content` property simply represents the `content` attribute string. Changing the values by script obviously does nothing to alter the tag values of the page on the server.

**meta.httpEquiv****httpEquiv****Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

A `meta` element can simulate and extend the transmission of server instructions to the browser — instructions that normally arrive in the form of `http` headers. These header supplements are supplied in `meta` elements via the `http-equiv` attribute, which is represented in the object model by the `httpEquiv` property. Common values include `refresh` and `expires`. Each of these also requires a `content` attribute that provides necessary details for carrying out the instructions. If you assign a string value to the `httpEquiv` property, be sure the `content` property has a suitable string assigned to it.

**name****Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

A `meta` element that includes genuine metadata about the page (for example, author or keywords) usually has a `name` attribute that identifies what the metadata is (analogous to the name of a name-value pair). The `name` and `content` properties go hand in hand because the `content` string usually must be in a particular form for an external process (for example, a search engine) to read the data successfully. Values for the `name` attribute are rarely case-sensitive.

**url****Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

If a `meta` element needs to point to a document on the Internet for any reason, the URL of that document is assigned to the `url` attribute of the element. You can modify the value via the `url` property of a `meta` element object. I recommend a complete URL string for the `url` property value.

## script Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
defer		
event		
htmlFor		
src		
text		
type		

## Syntax

Accessing `script` element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])  
(IE5+/W3C) [window.]document.getElementById("elemID").property |  
method([parameters])
```

## About this object

The `<script>` tag is well known to scripters, and modern browsers (IE4+ and W3C DOM-compatible) treat the `script` element as an object that, itself, can be scripted. The circularity of this description isn't as far-fetched as it sounds. Although scripting an existing script is a rarity in practice, it is not out of the question to generate a new `script` element after the page loads. If you use W3C DOM syntax to create a new `script` element, you then need to assign values to the properties that are normally set via the tag's attributes. Thus, scripting a script does make sense.

Unless you have experience with IE's option of binding event handlers to `<script>` tags (see Chapter 14), some of the properties described next will be foreign to you. Even so, these properties are now a part of the W3C DOM specification, so they are implemented in IE5+/NN6+/Mozilla/Safari as well.

## Properties

### defer

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The default process of loading a page that contains scripts is to wait for any immediate script execution to complete before the rest of the page loads. But if you include a `defer` attribute in the tag, modern browsers (except Safari 1.0) continue to load the rest of the page without waiting for immediate scripts to run. The `defer` property enables you to inspect or set that property; its default value is `false`. Once a page loads, any change you make to an existing `script` element's `defer` property has no effect.

### event

#### htmlFor

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Internet Explorer enables you to bind events to script statements when you specify both a `for` and `event` attribute in the `<script>` tag. Statements inside the tag execute only when the object named by the `for` attribute receives the event named by the `event` attribute. You can examine the `event` attribute by way of the `script` element object's `event` property, and you can view the `for` attribute through the `htmlFor` property. Both properties simply mimic whatever values are assigned to their respective attributes, such as `onclick()` and `myDIV`.

**script.src**

## src

**Value:** String.

See Text

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `src` property is a string of the URL of an external `.js` script file to be linked into a page. You can change this property in IE after you load the external script, but the old script does not go away from the page. If the new script defines the same variable and function names, the new versions overwrite the old. Other browsers may not load a new external script.

## text

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The full text of a `script` element is available for reading through the `text` property. Although IE5+ may give the impression that you can modify this property, the script that loads with the page is what is stored in the browser's memory. Thus, the original script statements continue to work even though the object's property is different.

## type

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `type` attribute was added to the `<script>` tag in HTML 4.0 to help resolve the conflict that the deprecated `language` attribute created for all HTML elements. The value of the attribute (and thus the `type` property) is a `mime type string`. For JavaScript, that value is `text/javascript`.

## title Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
text		

## Syntax

Accessing `title` element object properties or methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

## About this object

Before the `title` element was accessible to scripting as an object, the prescribed way to get to the content of the page's `<title>` tag was through the `document.title` property. Although that property is still available for backward compatibility, scripts written exclusively for newer browsers should access the `text` property of the `title` element object. As a useful exercise, you can modify Listing 18-17 (loaded via Listing 18-16) to use the IE4+ or W3C DOM syntax to retrieve and display the document's title.

## Property

`text`

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `text` property represents the text between the start and end tags of the `title` element object (Safari 1.0 returns an empty string). This is simply a convenience property because the text can be referenced by other ways in IE4+ (`innerText` property), NN6+ (`innerHTML`), and W3C DOM (`firstChild.nodeValue`) syntaxes. For backward compatibility with earlier browsers, you can alternatively use the `document.title` property.

**Related Items:** `document.title` property.

# Table and List Objects

---

**T**ables are incredibly popular HTML constructions. When you consider that a lot of CGI programs search SQL databases and display data gathered from SQL tables, it's not unusual to find the table concept carried over from data storage to data display. Spreadsheet programs certainly put the notion of tabular display into the minds of most computer users.

One of the truly beneficial properties of tables in HTML is that they pack a lot of page organization and alignment punch in just a few tags and attributes. Even if you're not a graphics designer or a dedicated HTML jockey, you can get rows and columns of text and images to line up perfectly on the page. This behavior also lures many page designers to sculpt elaborately detailed pages out of what appear to be positioned elements. Earlier browsers didn't offer positioning facilities, so borderless tables were torqued into performing all kinds of placement tricks with the help of precisely sized, transparent images creating the illusion of white space between carefully placed elements. If you use some of the WYSIWYG authoring tools for HTML pages, you may not realize how much table-related HTML code is generated for you as you use the tool to drag an image to a particular location on the page.

Using tables to specify design and page layout is giving way to CSS techniques that achieve a similar look with less code. This trend is driven by Web standards goals of using HTML markup to denote context rather than layout. Even so, many Web pages need to display genuinely columnar data—a purpose for which HTML tables are still ideally suited. The first part of this chapter focuses on the scriptable aspects of `table` element objects and the shopping list of elements that support tables. All of these objects became scriptable objects starting with IE4 and NN6/W3C DOM-compatible browsers. Later in the chapter, I discuss element objects that create formatted lists in pages.

## The Table Object Family Hierarchy

The repertoire of table-related elements expanded a bit with the HTML 4.0 specification, and the W3C DOM built upon that foundation. While most of this discussion is best left to HTML texts, the structure of a full-fledged table and the relationships among the elements—particularly the parent-child relationships—may affect your scripting and event handling.

### In This Chapter

Modifying table cell content

Adding and deleting table rows

`table`, `caption`, `tbody`, `tfoot`, `thead`, `col`, `colgroup`, `th`, `tr`, and `td` element objects

`ol`, `ul`, `li`, and `dl` list element objects

You are probably very familiar with the most basic table structure that predates HTML 4.0. Such a table (in a 2×2 layout) can have the following form:

```
<table>
  <tr>
    <td></td>
    <td></td>
  </tr>
  <tr>
    <td></td>
    <td></td>
  </tr>
</table>
```

If you want to place a row of cells at the top of each column such that the contents of the cells act as headers for each column, add such a row as follows:

```
<table>
  <tr>
    <th></th>
    <th></th>
  </tr>
  <tr>
    <td></td>
    <td></td>
  </tr>
  <tr>
    <td></td>
    <td></td>
  </tr>
</table>
```

You can also include a caption associated with the table. Its tag goes immediately after the table element's start tag:

```
<table>
  <caption></caption>
  <tr>
    <th></th>
    <th></th>
  </tr>
  <tr>
    <td></td>
    <td></td>
  </tr>
  <tr>
    <td></td>
    <td></td>
  </tr>
</table>
```

In line with its emphasis on providing contextual tags, HTML 4.0 includes three tags that enable you to define groups of table rows according to whether they are the header, body, or footer of the table (`thead`, `tbody`, and `tfoot` elements, respectively). A table footer, for example, can display column totals. The only seemingly illogical rule about these elements is that you should define the `tfoot` element and its row contents before the `tbody` element(s) in the table. Even with this source code placement, the `tfoot` row appears at the bottom of the table.

Some browsers produce visual dividers between these sections (WinIE5+ does a nice job of this). Moreover, you can have multiple `tbody` sections within a table. Some browsers render dividers between these `tbody` sections (again, WinIE5+ does it well). Regardless of the built-in divider support, these contextual groupings also enable you to assign stylesheets to HTML tag selectors rather than having to dream up a scheme of class and `id` names tied to stylesheet rules. Building upon the skeletal table shown thus far, you add the `thead` and `tbody` elements like this:

```
<table>
  <caption></caption>
  <thead>
    <tr>
      <th></th>
      <th></th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td></td>
      <td></td>
    </tr>
    <tr>
      <td></td>
      <td></td>
    </tr>
  </tbody>
</table>
```

That's the extent of table-oriented HTML containers. The remaining two elements, `colgroup` and `col`, provide a different "slice" of the table for stylesheets and other visual groupings. One of the most obvious purposes of these two elements is to assign a width or other style to all cells in a particular column or group of columns. You can also use these elements to group adjacent columns so that dividers are drawn between groups of columns — if the browser (such as WinIE5+) supports dividers between column groups — without specifying global table borders. You can see an example of the HTML for a complex table in the HTML 4.0 specification (<http://www.w3.org/tr/REC-html40/struct/tables.html#h-11.5>). Elsewhere on that same page, you can find the formal specification for all table-related tags and attributes as defined by the W3C.

## Populating table cells

Source material for a table's content can come from many different places. Most of the tables you see on the Web are hard-coded in the HTML. That is, the content of the table is fixed inside a static HTML file on the server.

But tables may also convey content from live databases or content that changes more frequently than the Web site's author manually updates other content. The source and your Web development infrastructure (not to mention your technical skills) dictate other avenues for populating tables.

After hard-coded HTML files, the next most common way to generate tables is through server-based CGI programs. These programs (written in Perl, C, and many other languages, including server-side JavaScript on those few servers that support it) generally compose a query for the database and then repackage the data returned from the database into HTML-formatted pages.

A more client-side-oriented approach is to let JavaScript apply the `document.write()` method to compose the table's tags as the page loads. Data for the cells can come from JavaScript arrays defined at the beginning of the document or defined in external `.js` library files that are linked in as the page loads. In the newest browsers, the data may come from blocks of XML-formatted data stuffed into the document. These solutions can work in situations where you need to update the table data periodically, but the table delivered to the client does not reflect the instantaneous state of a database. For example, a daily batch program on a server can capture the day's sales totals and write out a `.js` text file to a known place on the server. The file consists entirely of JavaScript array definitions. When the HTML page loads, the current `.js` file is automatically loaded into the page, and `document.write()` statements compose the table's HTML from the data supplied in the arrays. Although the script that assembles the HTML for the tables might appear formidable to a nonscripeter, a nonscripeter can also manually update the array data by following a template format supplied by the programmer.

Finally, if your page visitors run IE4+, you can take advantage of a Microsoft-specific technology called *data binding*. Data binding invokes the powers of one or more ActiveX controls that come with the IE browser (simulated in MacIE). These objects (collectively called Data Source Objects) let HTML pages access ODBC databases and structured text files (MacIE works only with text files). As the page loads, the table fills with data pulled live from the database. You can see an example of data binding in Chapter 15 under the description of the data binding property: `dataFld`. The HTML file carries tags for only one row of cells, but data binding fills in the rest of the rows and cells.

## Modifying table cell content

You can modify the HTML content of a table cell directly in IE4+ and W3C DOM-compatible browsers. Some tricks with positioned elements in NN4 can, under some circumstances, make it appear to the user as if the table content is being modified.

By far, the most compatible way to modify a table cell's content in IE4+ and W3C DOM browsers is via the `td` element's `innerHTML` property (a Microsoft invention that is not sanctioned by the W3C DOM Level 2 but is supported elsewhere as a de facto standard). Even if the content is simply text that is to inherit the style format of the surrounding `td` element, you can still use the `innerHTML` property. If the size of the new content affects the dimensions of the cell's column width or row height, the browser reflows the rest of the table content around the new content.

If you prefer to follow the W3C DOM form of modifying an element's content (for IE5+ and NN6+/Mozilla/Safari), you can generate the new content via the `document.createElement()` or `document.createTextNode()` sequence and assign that new content to the cell by way of the `td` element's `replaceChild()` method.

The situation for NN4 is quite gnarled because the content you replace must be within its own layer (either a `layer` element or positioned container element, such as a `div` or `span`). No matter how you create the layer in your HTML, you must overcome the problem that a layer floats in its own plane and must be positioned precisely where the table cell is. Table cells are not objects in NN4, so you must create a positioning context in the cell by first creating a relative-positioned layer that can contain nothing more than an “invisible” nonbreaking space character (`&nbsp;`). The layer displaying the content must be absolute-positioned with respect to that relative-positioned layer. Nesting of layers in NN4 causes headaches, especially when scripts reference the deeply nested content — content that is, essentially, an HTML document inside the nested layer.

Listing 37-1 shows a synthesis of different techniques to effect cell content replacement, including script code branches that emulate the appearance of replacement in NN4. The table represents only one line of what might be an order form for several products. As the user makes a selection of the quantity, the extended total is displayed in the rightmost column.

You can find the key features of the NN4 implementation in the script that dynamically writes the table cell content within the HTML as the page loads. The cell begins with a relative-positioned `span` element. This `span` is positioned at the top left of the table cell, as planned. That spot now is the positioning context for the absolute-positioned `span` nested inside it. This second `span` is the layer whose document contains the displayed content. The content, itself, is yet another `span` element because it simplifies the application of a stylesheet rule (to display the total in red) when you replace the content. Because a newly written NN4 layer does not inherit the stylesheet of its next outermost layer, you must apply the style as part of the new content.

The initial `span` content contains a series of nonbreaking space characters that force NN4 to open space for eventual replacement content. Recall that an NN4 page does not reflow the page to accommodate resized content. This means that whatever you intend to insert in the table cell can be no larger than the original space allocated for it.

Although the page shown in Listing 37-1 consists of only one row of data, the scripts and naming conventions are intended to be carried out among multiple rows. The product name appears in several object names and `ids` in each row, and the scripts count on the convention being followed throughout. In fact, the regularity of the namings can allow the content for a table's row to form a script function that is invoked for each table row. The product code name can be passed as the parameter, and all object names and `ids` can be assembled in that function. The regularity of table content often lends itself to script-generated construction.

**Note**

For NN4, when the table gets complicated, you will have more success defining the absolute-positioned elements outside of the table entirely. They should be defined on their own at the bottom of the `body`. You can still position them with respect to the relative-positioned elements in the table, but all such layers are now only one level deep within the main document.

### Listing 37-1: Replacing Table Cell Content

```
<html>
  <head>
    <title>Modifying Table Cell Content</title>
    <style type="text/css">
      .absoluteWrap {position:absolute}
      .relativeWrap {position:relative}
      .total {color:red}
    </style>
    <script type="text/javascript">
      var Ver4 = parseInt(navigator.appVersion) == 4;
      var Ver4Up = parseInt(navigator.appVersion) >= 4;
      var Nav4 = ((navigator.appName == "Netscape") && Ver4);
      var modifiable;

      // calculate and display a row's total
```

*Continued*

## Listing 37-1 (continued)

```

function showTotal(qtyList) {
    var qty = qtyList.options[qtyList.selectedIndex].value;
    var prodID = qtyList.name;
    var total = "US$" + (qty * parseFloat(qtyList.form.elements[prodID +
        "Price"].value));
    var newCellHTML = "<span class='total'>" + total + "</span>";

    if(Nav4) {
        document.layers[prodID + "TotalWrapper"].document.layers[prodID +
            "Total"].document.write(newCellHTML);
        document.layers[prodID + "TotalWrapper"].document.layers[prodID +
            "Total"].document.close();
    } else if (modifiable) {
        if (document.all) {
            document.all(prodID + "Total").innerHTML = newCellHTML;
        } else {
            document.getElementById(prodID + "Total").innerHTML =
                newCellHTML;
        }
    }
}

// initialize global flag for browsers capable of modifiable content
function init() {
    modifiable = (Ver4Up && document.body && document.body.innerHTML);
}

// display content for all products (e.g., in case of Back navigation)
function showAllTotals(form) {
    for (var i = 0; i < form.elements.length; i++) {
        if (form.elements[i].type == "select-one") {
            showTotal(form.elements[i]);
        }
    }
}
</script>
</head>
<body onload="init(); showAllTotals(document.orderForm)">
<h1>Modifying Table Cell Content</h1>
<hr />
<form name="orderForm">
    <table border="1">
        <colgroup width="150"></colgroup>
        <colgroup width="100"></colgroup>
        <colgroup width="50"></colgroup>
        <colgroup width="100"></colgroup>
        <tr>
            <th>Product Description</th>
            <th>Price Each</th>
            <th>Quantity</th>
            <th>Total</th>
        </tr>
        <tr>
            <td>Wonder Widget 9000</td>
            <td>US$125.00</td>
            <td><select name="ww9000" onchange="showTotal(this)">

```

**Note**

IE5 for the Macintosh offers unpredictable results when inserting rows of a table via these methods. The browser does behave when modifying the HTML elements by accumulating the HTML for a row as a string and then adding the row to the table via IE DOM methods such as `insertAdjacentHTML()`. If your pages must modify the composition of tables after the page loads—and your audience includes Mac IE5 users—use the element and node insertion techniques rather than the methods shown in Table 37-1 and techniques described next.

---

**Table 37-1: IE4+ and NN6+/W3C Table Modification Methods**

---

<i>table</i>	<i>thead, tbody, tfoot</i>	<i>tr</i>
<code>insertRow()</code>	<code>insertRow()</code>	<code>insertCell()</code>
<code>deleteRow()</code>	<code>deleteRow()</code>	<code>deleteCell()</code>
<code>createTHead()</code>		
<code>deleteTHead()</code>		
<code>createTFoot()</code>		
<code>deleteTFoot()</code>		
<code>createCaption()</code>		
<code>deleteCaption()</code>		

---

The basic sequence for inserting a row into a table entails the following steps:

1. Invoke `insertRow()` and capture the returned reference to the new, unpopulated row.
2. Use the reference to the row to invoke `insertCell()` for each cell in the row, capturing the returned reference to each new, unpopulated cell.
3. Assign values to properties of the cell, including its content.

The following code fragment appends a new row to a table (`myTABLE`) and supplies information for the two cells in that row:

```
// parameter of -1 appends to table
// (you can use document.all.myTABLE.insertRow(-1) for IE4+ only)
var newRow = document.getElementById("myTABLE").insertRow(-1);
// parameter of 0 inserts at first cell position
var newCell = newRow.insertCell(0);
newCell.innerHTML = "Mighty Widget 2000";
// parameter of 1 inserts at second cell position
newCell = newRow.insertCell(1);
newCell.innerHTML = "Release Date TBA";
```

A key point to note about this sequence is that the `insertRow()` and `insertCell()` methods do their jobs before any content is handed over to the table. In other words, you first create the HTML space for the content and then add the content.

Listing 37-2 presents a living environment that adds and removes `thead`, `tr`, and `tfoot` elements to an empty table in the HTML. The only subelement inside the `table` element is a `tbody` element, which directs the insertion of table rows so as not to disturb any existing `thead` or `tfoot` elements. You can also see how to add or remove a caption from a table via caption-specific methods.

Each table row consists of the hours, minutes, seconds, and milliseconds of a time stamp generated when you add the row. The color of any freshly added row in the `tbody` is a darker color than the normal `tbody` rows. This is so you can see what happens when you specify an index value to the `insertRow()` method. Some of the code here concerns itself with enabling and disabling form controls and updating `select` elements, so don't be deterred by the length of Listing 37-2.

### Listing 37-2: Inserting/Removing Row Elements

```
<html>
  <head>
    <title>Modifying Table Cell Content</title>
    <style type="text/css">
      thead {background-color:lightyellow; font-weight:bold}
      tfoot {background-color:lightgreen; font-weight:bold}
      #myTABLE {background-color:bisque}
    </style>
    <script type="text/javascript">
      var theTable, theTableBody;
      function init() {
        theTable = (document.all) ? document.all.myTABLE :
          document.getElementById("myTABLE");
        theTableBody = theTable.tBodies[0];
      }
      function appendRow(form) {
        insertTableRow(form, -1);
      }

      function addRow(form) {
        insertTableRow(form, form.insertIndex.value);
      }

      function insertTableRow(form, where) {
        var now = new Date();
        var nowData = [now.getHours(), now.getMinutes(), now.getSeconds(),
          now.getMilliseconds()];
        clearBGColors();
        var newCell;
        var newRow = theTableBody.insertRow(where);
        for (var i = 0; i < nowData.length; i++) {
          newCell = newRow.insertCell(i);
          newCell.innerHTML = nowData[i];
          newCell.style.backgroundColor = "salmon";
        }
        updateRowCounters(form);
      }

      function removeRow(form) {
        theTableBody.deleteRow(form.deleteIndex.value);
        updateRowCounters(form);
      }
    </script>
  </head>
</html>
```

*Continued*

                value="Delete Caption" disabled="disabled"
                onclick="removeCaption(this.form)" /></td>
        </tr>
    </table>
</fieldset>
</form>
<hr />
<table id="myTABLE" cellpadding="10" border="1">
    <tbody></tbody>
</table>
</body>
</html>

```

## Modifying table columns

Unlike the table row-oriented elements, such as `tbody`, the `col` and `colgroup` elements are not containers of cells. Instead, these elements serve as directives for the rendering of columns within a table. But through scripting, you can add or remove one or more columns from a table on the fly. There is no magic to it; you simply insert or delete the same-indexed cell from every row of the table.

Listing 37-3 demonstrates adding and removing a left-hand column of a table. The table presents the four longest rivers in Africa, and the new column provides the numeric ranking. Thanks to the regularity of this table, the values for the rankings can be calculated dynamically. Note, too, that the `className` property of each new table cell is set to a class that has a stylesheet rule defined for it. Instead of inheriting the style of the table, the cells obey the more specific background color and font weight rules defined for the cells.

**Listing 37-3: Modifying Table Columns**

```
<html>
  <head>
    <title>Modifying Table Columns</title>
    <style type="text/css">
      thead {background-color:lightyellow; font-weight:bold}
      .rankCells {background-color:lightgreen; font-weight:bold}
      #myTABLE {background-color:bisque}
    </style>
    <script type="text/javascript">
      var theTable, theTableBody;
      function init() {
        theTable = (document.all) ? document.all.myTABLE :
          document.getElementById("myTABLE");
        theTableBody = theTable.tBodies[0];
      }

      function insertColumn(form) {
        var oneRow, newCell, rank;
        if (theTable.tHead) {
          oneRow = theTable.tHead.rows[0];
          newCell = oneRow.insertCell(0);
          newCell.innerHTML = "Ranking";
        }
        rank = 1;
        for (var i = 0; i < theTableBody.rows.length; i++) {
          oneRow = theTableBody.rows[i];
          newCell = oneRow.insertCell(0);
          newCell.className = "rankCells";
          newCell.innerHTML = rank++;
        }
        form.addColumn.disabled = true;
        form.removeColumn.disabled = false;
      }

      function deleteColumn(form) {
        var oneRow;
        if (theTable.tHead) {
          oneRow = theTable.tHead.rows[0];
          oneRow.deleteCell(0);
        }
        for (var i = 0; i < theTableBody.rows.length; i++) {
          oneRow = theTableBody.rows[i];
          oneRow.deleteCell(0);
        }
        form.addColumn.disabled = false;
        form.removeColumn.disabled = true;
      }
    </script>
  </head>
  <body onload="init()">
    <h1>Modifying Table Columns</h1>

```

## W3C DOM table object classes

If you ever read the W3C DOM Level 2 specification, notice that the objects defined for tables do not align themselves fully with the actual elements defined in the HTML 4.0 specification. That's not to say the DOM scoffs at the HTML spec; rather, the needs of a DOM with respect to tables differ a bit. For example, as far as the W3C DOM is concerned, the `thead`, `tbody`, and `tfoot` are all regarded as table sections and are thus known as `HTMLTableSectionElement` objects. In other words, in the W3C DOM, there is no particular distinction among the types of table section elements. They're all lumped together, and they bear the same properties and methods. With their strong adherence to the W3C DOM, Mozilla-based browsers and Safari stick to the W3C DOM object constructions.

When you work in both the IE and W3C DOMs at the same time, it's helpful to know the relationships between the object naming conventions used in each. Table 37-2 provides a quick cross-reference between the object types in both DOMs. None of the terminology in Table 37-2 affects the way scripts construct references to elements or the way elements are nested within one another. The containment hierarchy is driven by the HTML element containment — and that remains the same regardless of DOM exposure.

**Table 37-2: Table Object Classifications**

<i>W3C DOM (NN6+/Mozilla/Safari)</i>	<i>IE4+ and HTML</i>
<code>HTMLTableElement</code>	<code>table</code>
<code>HTMLTableCaptionElement</code>	<code>caption</code>
<code>HTMLTableColElement</code>	<code>col, colgroup</code>
<code>HTMLTableSectionElement</code>	<code>tbody, tfoot, thead</code>
<code>HTMLTableRowElement</code>	<code>tr</code>
<code>HTMLTableCellElement</code>	<code>td, th</code>

Although the following object-specific discussions list the objects according to their HTML tag name, I group these objects according to the W3C DOM classifications because element objects that share a classification also share the same properties, methods, and event handlers.

## table Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>align</code>	<code>createCaption()</code>	<code>onscroll</code>
<code>background</code>	<code>createTFoot()</code>	
<code>bgColor</code>	<code>createThead()</code>	
<code>border</code>	<code>deleteCaption()</code>	
<code>borderColor</code>	<code>deleteRow()</code>	
<code>borderColorDark</code>	<code>deleteTFoot()</code>	

*Continued*

**table**

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
borderColorLight	deleteTHead()	
caption	firstPage()	
cellPadding	insertRow()	
cells	lastPage()	
cellSpacing	moveRow()	
cols	nextPage()	
datePageSize	previousPage()	
frame	refresh()	
height		
rows		
rules		
summary		
tBodies		
tFoot		
tHead		
width		

## Syntax

Accessing table element object properties and methods:

```
(IE4+)      [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

The `table` element object is the outermost container of table-related information. The HTML element has a large number of attributes, most of which are echoed by their counterpart properties in the object model. You rarely will modify these properties if the values are set in the tag's attributes. However, if you construct a new `table` element object for insertion into the page, use these properties to assign values to the equivalents of the element's attributes.

A number of additional properties return collections of cell, row, and row section objects; still more properties return references to other, singular objects within the table (such as the `caption` element object). For example, if your script needs to iterate through all rows within just the `tbody` elements (in other words, without affecting the rows in the `thead` element), your script can perform a nested `for` loop to access each row:

```
var oneTBody, oneRow;
for (var i = 0; i < tableRef.tBodies.length; i++) {
    oneTBody = tableRef.tBodies[i];
    for (var j = 0; j < oneTBody.rows.length; j++) {
        oneRow = oneTBody.rows[j];
        // more stuff working on each row
    }
}
```

**table.background**

For a simple table that does not define table row sections, you can iterate through the `rows` collection property of a `table` element object. You can even access cells directly; but it may be easier to keep track of cells in a loop by going through them row by row (via the `cells` property of each `tr` element object).

A large number of methods enable you to modify the structure of a table (as described earlier in this chapter), but they primarily work with rows. Column modifications require a different approach, as also demonstrated earlier.

## Properties

### align

**Value:** String (center, left, right).

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `align` property controls the horizontal alignment of the table with respect to the next outermost container that provides positioning context. Most typically, the next outermost positioning container is the `body` element. Modifications to this property on an existing table cause the surrounding content to reflow on the page. Be sure you test the consequences of any modification with a variety of browser window sizes.

### Example

Use The Evaluator (Chapter 13) to see the `align` property at work. The default value (`left`) is in force when the page loads. But you can shift the table to right-align with the `body` by entering the following statement into the top text box for IE5+ and NN6+/Mozilla/Safari:

```
document.getElementById("myTable").align = "right"
```

**Related Item:** `style.align` property.

### background

**Value:** URL string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

Only IE4+ makes a provision for assigning a background image to a table, and the `background` property controls that value. You can swap out an image by assigning a new URL to the `background` property. The image appears in front of any background color assigned to the table. Thus, you can assign attributes for both characteristics so that there is at least a background color (and an image for IE users).

### Example

Treat the `background` property of a table like you do the `src` property of an `img` element object. If you precache an image, you can assign the `src` property of the precached image object to the `background` property of the table for quick image changing. Such an assignment statement looks like the following:

```
document.all.myTable.background = imgArray["myTableAlternate"].src;
```

**Related Item:** `IMG.src` property.

**table.bgColor**

## bgColor

**Value:** Color value string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `bgColor` attribute controls the background color of a table (the `bgColor` attribute). Colors assigned to the entire table are overridden if colors are assigned to row, row groups, or cells within the table. If you set the `bgColor` property, the `backgroundColor` style property is not affected. Assign values in any acceptable color string format, such as hexadecimal triplets (for example, “#FCFC00”) or the generally recognized plain-language names (for example, “cornflowerblue”).

**Example**

Use The Evaluator (Chapter 13) to assign a color to the table. After looking at the table to see its initial state, enter the following IE5+/W3C statement into the top text box:

```
document.getElementById("myTable").bgColor = "lightgreen"
```

When you look at the table again, you see that only some of the cells turned to green. This is because colors also are assigned to table elements nested inside the outermost table element, and the color specification closest to the actual element wins the context.

**Related Item:** `style.backgroundColor` property.

## border

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `border` property controls the thickness of the table’s borders. Values indicate the number of pixels thick the border should be. A value of zero removes all visible borders surrounding the table. Different browsers render table cell borders differently depending on background colors and other visual attributes of tables and table elements. Be sure to verify the appearance on as many browsers and operating systems as possible.

**Example**

To remove all traces of an outside border of a table (and, in some combinations of attributes of other table elements, borders between cells), use the following statement (in IE5+/W3C syntax):

```
document.getElementById("myTable").border = 0;
```

**Related Item:** `borderColor` property.

## borderColor

## borderColorDark

## borderColorLight

**Value:** Color value string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

IE4+ provides attributes and corresponding properties to control the border colors of a table. When table borders have enough thickness to display a three-dimensional raised look, the appearance is created by generating two dark and two light edges (simulating a light source coming from the upper-left or lower-right corner). If you want to do a better job of specifying the color combinations for the light and dark edges, you can control them individually via the `borderColorLight` and `borderColorDark` properties, respectively. You can assign colors in

**table.cellPadding**

any valid color value (hexadecimal triplet or plain-language name); but when you read the property, the value is returned as a hexadecimal triplet (for example, "#008000").

**Example**

Assuming that you have set the initial light and dark color attributes of a table, the following function swaps the light and dark colors to shift the light source to the opposite corner:

```
function swapColors(tableRef) {
  var oldLight = tableRef.borderColorLight;
  tableRef.borderColorLight = tableRef.borderColorDark;
  tableRef.borderColorDark = oldLight;
}
```

Although you can easily invoke this function over and over by ending it with a `setTimeout()` method that calls this function after a fraction of a second, the results are very distracting to the person trying to read your page. Please don't do it.

**Related Item:** `td.borderColor` property.

**caption**

**Value:** `caption` element object reference.

Read/Write (see text)

**Compatibility:** WinIE4+, MacIE5+, NN6+, Moz1+, Safari1+

The `caption` property returns a reference to the `caption` element object that is nested inside the current table. If there is no `caption` element, the value is `null`. You can use this property as a shortcut reference to the `caption` element if you need to read or modify that element's properties. The property is read/write in NN6+/Moz, provided you create a valid `caption` element object and assign that new object to the `caption` property.

**Example**

The following example, for use with The Evaluator (Chapter 13) in NN6+/Moz, demonstrates the sequence of assigning a new `caption` element object to a table. Although the table in The Evaluator already has a `caption` element, the following statements replace it with an entirely new one. Enter each of the following statements into the top text box, starting with the one that saves a long reference into a variable for multiple use at the end:

```
t = document.getElementById("myTable")
a = document.createElement("caption")
b = document.createTextNode("A Brand New Caption")
a.appendChild(b)
t.replaceChild(a, t.caption)
```

A view of the table shows that the new `caption` has replaced the old one because a table can have only one `caption` element.

**Related Item:** `caption` element object.

**cellPadding****cellSpacing**

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `cellPadding` property is a table-wide specification for the blank space inserted between the edge of a table cell and the content of the cell. One value affects the padding on all four sides. The effect of cell padding is especially apparent when there are borders between cells; in this case, the padding provides welcome breathing space between the border and content.

**table.cellPadding**

The `cellSpacing` property influences the thickness of borders between cells. If no visible borders are present between cells in a table, you can usually set either `cellpadding` or `cellspacing` to provide the desired blank space between cells.

**Example**

Use The Evaluator (Chapter 13) to adjust the `cellPadding` and `cellSpacing` properties of the demonstrator table. First, adjust the padding (IE5+/W3C syntax):

```
document.getElementById("myTable").cellPadding = 50
```

Now, adjust the cell spacing:

```
document.getElementById("myTable").cellSpacing = 15
```

Notice how `cellSpacing` affected the thickness of inter-cell borders.

**Related Item:** `border` property.

**cells**

**Value:** Array.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `cells` property returns an array (collection) of all `td` and `th` element objects within the entire table. From the perspective of the `table` element object, this “view” encompasses all cells—whether they are inside a table row segment (for example, a `thead`) or in a freestanding row. In the W3C DOM, the `cells` collection is accessible only as a property of a `tr` object. However, a `rows` collection is available from all table container elements, thus enabling you to iterate through all cells of all rows.

**Example**

Use The Evaluator (Chapter 13) with WinIE5+ to have JavaScript calculate the number of columns in the demonstrator table with the help of the `cells` and `rows` properties. Enter the following statement into the top text box:

```
document.all.myTable.cells.length/document.all.myTable.rows.length
```

The result is the number of columns in the table.

**Related Items:** `rows`, `tr.cells` properties.

**cols**

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `cols` property represents the IE-specific `cols` attribute for `table` elements. Specifying this attribute should speed table rendering. If you don't specify the attribute explicitly in your HTML, the property has a value of zero—the property does not tell you dynamically the size of your table. Although this property is read/write, you cannot use this property to add or remove columns from a table. Instead, use the table modification methods discussed later in this section.

**Related Item:** `rows` property.

**table.frame****dataPageSize****Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

When using IE4+ data binding to obtain table data from a data source, there may be more rows or data (records) than you wish to display in one table. If so, you can define the number of rows (records) that constitutes a “page” of data within the table. With this limit installed for the table, you can then use the `firstPage()`, `previousPage()`, `nextPage()`, and `lastPage()` methods to access another page relative to the currently viewed page. While you usually establish this value via the `dataPageSize` attribute of the `table` element, you can adjust it later via the `dataPageSize` property to show more or fewer records per “page” in the table.

**Example**

If you want to change the number of visible rows of linked data in the table to 15, use the following statement:

```
document.all.myTable.dataPageSize = 15;
```

**Related Items:** `dataSrc`, `dataFld` properties; `firstPage()`, `lastPage()`, `nextPage()`, `previousPage()` methods.

**frame****Value:** String constant.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `frame` property enables you to control which side or sides of the table’s border should be displayed. Values for this property can be any of a fixed set of string constants. Table 37-3 lists the acceptable values. Hiding or showing table border edges under script control can have an effect on the layout and placement of both the table and surrounding elements. Note that Safari 1.0 does not change the border rendering when you change this property value.

**Table 37-3: Table frame Property Values**

<b>Value</b>	<b>Description</b>
above	Top edge only
below	Bottom edge only
border	All four sides (same as box)
box	All four sides (same as border)
hsides	Horizontal (top and bottom) edges only
lhs	Left-hand side edge only
rhs	Right-hand side edge only
void	No borders
vsides	Vertical (left and right) edges only

**Example**

Listing 37-4 presents a page that cycles through all possible settings for the `frame` property. The `frame` property value is displayed in the table’s caption.

## Listing 37-4: Cycling Through Table frame Property Values

```

<html>
  <head>
    <title>table.frame Property</title>

    <script type="text/javascript">
      var timeoutID;
      var frameValues = ["box", "above", "rhs", "below", "lhs", "hsides",
        "vsides", "border", "void"];
      function rotateBorder(i) {
        document.getElementById("myTABLE").frame = frameValues[i];
        document.getElementById("myCAPTION").innerHTML = frameValues[i];
        i = (++i == frameValues.length) ? 0 : i;
        timeoutID = setTimeout("rotateBorder(" + i + ")", 2000);
      }
      function stopRotate() {
        clearTimeout(timeoutID);
        document.getElementById("myTABLE").frame = "box";
        document.getElementById("myCAPTION").innerHTML = "box";
      }
    </script>
  </head>
  <body>
    <h1>table.frame Property</h1>
    <hr />
    <form name="controls">
      <fieldset>
        <legend>Cycle Table Edge Visibility</legend>
        <table width="100%" cellspacing="20">
          <tr>
            <td><input type="button" value="Cycle"
              onclick="rotateBorder(0)" /></td>
            <td><input type="button" value="Stop"
              onclick="stopRotate()" /></td>
          </tr>
        </table>
      </fieldset>
    </form>
    <hr />
    <table id="myTABLE" cellpadding="5" border="3" align="center">
      <caption id="myCAPTION">
        Default
      </caption>
      <thead id="myTHEAD">
        <tr>
          <th>River</th>
          <th>Outflow</th>
          <th>Miles</th>
          <th>Kilometers</th>
        </tr>
      </thead>
      <tbody>
        <tr>
          <td>Nile</td>
          <td>Mediterranean</td>
          <td>4160</td>
          <td>6700</td>
        </tr>
      </tbody>
    </table>
  </body>
</html>

```

**table.height**

```
</tr>
<tr>
  <td>Congo</td>
  <td>Atlantic Ocean</td>
  <td>2900</td>
  <td>4670</td>
</tr>
<tr>
  <td>Niger</td>
  <td>Atlantic Ocean</td>
  <td>2600</td>
  <td>4180</td>
</tr>
<tr>
  <td>Zambezi</td>
  <td>Indian Ocean</td>
  <td>1700</td>
  <td>2740</td>
</tr>
</tbody>
</table>
</body>
</html>
```

**Related Items:** border, borderColor, rules properties.

## height width

**Value:** Integer or length string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `height` (IE4+) and `width` (IE4+/W3C) properties represent the `height` and `width` attributes assigned to the `table` element. If no values are assigned to the element in the tag, the properties do not reveal the rendered size of the table (use the `offsetHeight` and `offsetWidth` properties for that information). Values for these properties can be integers representing pixel dimensions or strings containing percentage values, just like the attribute values. Scripts can shrink the dimensions of a table no smaller than the minimum space required to render the cell content. Notice that only the `width` property is W3C DOM-sanctioned (as well as the corresponding property in the HTML 4.0 specification).

### Example

Use The Evaluator (Chapter 13) to adjust the width of the demonstrator table. Begin by increasing the width to the full width of the page:

```
document.getElementById("myTable").width = "100%"
```

To restore the table to its minimum width, assign a very small value to the property:

```
document.getElementById("myTable").width = 50
```

If you have IE4+, you can perform similar experiments with the `height` property of the table.

**Related Items:** `offsetHeight`, `offsetWidth` properties.

**table.rows****rows****Value:** Array of row objects.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `rows` property returns an array (collection) of `tr` element objects in the current table. This array includes rows in the `thead`, `tbody`, and `tfoot` row sections if the table is segmented. You can use the `rows` property to create a cross-browser script that accesses each cell of a table. Such a nested `for` loop looks like the following:

```
var oneCell;
for (var i = 0; i < tableRef.rows.length; i++) {
  for (var j = 0; j < tableRef.rows[i].cells.length; j++) {
    oneCell = tableRef.rows[i].cells[j];
    // more statements working with the cell
  }
}
```

If you want to limit the scope of the `rows` property to rows within a row segment (for example, just in the `tbody`), you can access this property for any of the three types of row segment objects.

**Example**

Use The Evaluator (Chapter 13) to examine the number of rows in the demonstrator table. Enter the following statement into the top text box:

```
document.getElementById("myTable").rows.length
```

In contrast, notice how the `rows` property sees only the rows within the demonstrator table's `tbody` element:

```
document.getElementById("myTbody").rows.length
```

**Related Items:** `tbody.rows`, `tfoot.rows`, `thead.rows` properties.

**rules****Value:** String constant.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

In contrast to the `frame` property, the `rules` property governs the display of borders between cells. Values for this property can be any of a fixed set of string constants. Table 37-4 lists the acceptable values. Hiding or showing table cell border edges under script control can have an effect on the layout and placement of both the table and surrounding elements. Note that Safari 1.0 does not change the `rules` rendering when you change this property value.

**Table 37-4: Table rules Property Values**

<i>Value</i>	<i>Description</i>
<code>all</code>	Borders around every cell
<code>cols</code>	Vertical borders between columns
<code>groups</code>	Vertical borders between column groups; horizontal borders between row groups
<code>none</code>	No borders between cells
<code>rows</code>	Horizontal borders between row groups

## Example

Listing 37-5 presents a page that cycles through all possible settings for the `rules` property. The `rules` property value is displayed in the table's caption. When you run this script, notice the nice border display for this table's combination of `colgroup` and table row segment elements.

### Listing 37-5: Cycling Through Table `rules` Property Values

```
<html>
  <head>
    <title>table.rules Property</title>
    <script type="text/javascript">
      var timeoutID;
      var rulesValues = ["all", "cols", "groups", "none", "rows"];
      function rotateBorder(i) {
        document.getElementById("myTABLE").rules = rulesValues[i];
        document.getElementById("myCAPTION").innerHTML = rulesValues[i];
        i = (++i == rulesValues.length) ? 0 : i;
        timeoutID = setTimeout("rotateBorder(" + i + ")", 2000);
      }
      function stopRotate() {
        clearTimeout(timeoutID);
        document.getElementById("myTABLE").rules = "all";
        document.getElementById("myCAPTION").innerHTML = "all";
      }
    </script>
  </head>
  <body>
    <h1>table.rules Property</h1>
    <hr />
    <form name="controls">
      <fieldset>
        <legend>Cycle Table Rule Visibility</legend>
        <table width="100%" cellpadding="20">
          <tr>
            <td><input type="button" value="Cycle"
              onclick="rotateBorder(0)" /></td>
            <td><input type="button" value="Stop"
              onclick="stopRotate()" /></td>
          </tr>
        </table>
      </fieldset>
    </form>
    <hr />
    <table id="myTABLE" cellpadding="5" border="3" align="center">
      <caption id="myCAPTION">
        Default
      </caption>
      <colgroup span="1">
      </colgroup>
      <colgroup span="3">
      </colgroup>
      <thead id="myTHEAD">
```

*Continued*

## table.rules

## Listing 37-5 (continued)

```

        <th>River</th>
        <th>Outflow</th>
        <th>Miles</th>
        <th>Kilometers</th>
    </tr>
</thead>
<tbody>
    <tr>
        <td>Nile</td>
        <td>Mediterranean</td>
        <td>4160</td>
        <td>6700</td>
    </tr>
    <tr>
        <td>Congo</td>

    </tr>
    <tr>
        <td>Zambezi</td>
        <td>Indian Ocean</td>
        <td>1700</td>
        <td>2740</td>
    </tr>
</tbody>
</table>
</body>
</html>

```

**Related Items:** border, borderColor, frame properties.

## summary

**Value:** String.

Read/Write

**Compatibility:** WinIE6+, MacIE-, NN6+, Moz1+, Safari1+

The `summary` property represents the HTML 4.0 `summary` attribute. The text assigned to this attribute is intended for use by browsers that present a page's content through nonvisual means. For example, a browser equipped to use speech synthesis to read the page aloud can use the text of the `summary` to describe the table for the user.

**Related Item:** `caption` property.

## tBodies

**Value:** Array of `tbody` element objects.

Read-Only

**Compatibility:** WinIE4+, MacIE5+, NN6+, Moz1+, Safari1+

**table.createCaption()**

The `tBodies` property returns an array of all `tbody` elements in the table. Even if you don't specify a `tbody` element, every table contains an implied `tbody` element. Thus, to access a batch of rows of a simple table other than the `thead` and `tfoot` sections, you can use the `tBodies[0]` array notation. From there, you can get the rows of the table body section via the `rows` property.

**Example**

Use The Evaluator (Chapter 13) to access the `tBodies` array and reveal the number of rows in the one `tbody` segment of the demonstrator table. Enter the following statement into the top text box:

```
document.getElementById("myTable").tBodies[0].rows.length
```

**Related Items:** `tFoot`, `tHead` properties.

`tFoot`

`tHead`

**Value:** Row segment element object.

Read/Write (see text)

**Compatibility:** WinIE4+, MacIE5+, NN6+, Moz1+, Safari1+

Each table can have (at most) one `tfoot` and one `thead` element. If you specify one of these for the table, the `tFoot` and `tHead` properties, respectively, return references to those element objects. These properties are read-only in IE, but NN6+/Moz enables you to assign valid `tfoot` and `thead` element objects to these properties in order to insert or replace the elements in the current table. The process for doing this is similar to the sequence described in the `caption` property. For either of these two elements, however, you have to construct the desired number of table cell objects (and row objects if you want multiple rows) for the newly created row segment object. See the discussions of these two objects for details on accessing rows and cells of the segments.

**Related Items:** `tbody`, `tfoot`, `thead` objects.

`width`

(See `height`)

**Methods**

`createCaption()`

`deleteCaption()`

**Returns:** Reference to new `caption` element object; Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `createCaption()` and `deleteCaption()` convenience methods enable you to add or remove a `caption` element object from the current table. When you create a new `caption`, the action simply inserts the equivalent of a blank `caption` element tag into the `table` element (this may not, however, be reflected in the source view of the page). You must populate the `caption` element with text or HTML before it appears on the page. Because the method returns a reference to the newly created object, you can use that reference to assign content to its `innerHTML` property or you can append a child text node.

Because a table can have only one `caption` element nested within, the `deleteCaption()` method belongs to the `table` element object. The method returns no value.

**table.createCaption****Example**

See Listing 37-2 for an example of creating, inserting, and removing a `caption` element object from a table.

**Related Item:** `caption` element object.

```
createTFoot()  
createTHead()  
deleteTFoot()  
deleteTHead()
```

**Returns:** Element references (create methods); Nothing.

**Compatibility:** WinIE4+, MacIE5+, NN6+, Moz1+, Safari1+

These four methods enable you to add or remove `tfoot` and `thead` table row section objects. When you create a `thead` or `tfoot` element, the methods return references to the newly inserted elements. But, as with `createCaption()`, these methods do nothing to display content. Instead, use the returned references to populate the row(s) of the header and footer with cells. Regardless of the number of rows associated with a `thead` or `tfoot` element, the `deleteTFoot()` and `deleteTHead()` methods remove all associated rows and return no values.

Although these methods are available in IE4, you may not have complete write access to the properties of the objects returned by the creation methods. For example, you may not be able to assign a value to the `id` property of the `tfoot` or `thead` element returned by their respective creation methods.

**Example**

See Listing 37-2 for an example of creating, inserting, and removing `tfoot` and `thead` elements object from a table.

**Related Items:** `tfoot`, `thead` element objects.

```
deleteRow(rowIndex)  
insertRow(rowIndex)
```

**Returns:** Nothing; Reference to newly created row.

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `insertRow()` and `deleteRow()` convenience methods assist in adding `tr` elements to, and removing them from, a `table` element. Inserting a row does little more than the equivalent of inserting a pair of empty `tr` element tags into the HTML (although you may not see them in the source view of the page). It is up to the rest of your scripts to assign properties to the row and populate it with new cells (see the `insertCell()` method of the `tr` element object).

Attributes for both methods are zero-based index numbers. In the case of `insertRow()`, the number indicates the row *before* which the new row is to be inserted. To append the row to the end of the table, use `-1` as a shortcut parameter. To delete a row, use the index value for that row. Be aware that if you intend to employ `deleteRow()` to remove all rows from a table (presumably to repopulate the table with a new set), the most efficient way is to use a `while` loop that continues to remove the first row until there are no more:

```
while (tableRef.rows.length > 0) {  
    tableRef.deleteRow(0);  
}
```

## Example

See Listing 37-2 for examples of inserting and deleting table rows.

**Related Item:** `td.insertCell()` method.

## firstPage()

## lastPage()

**Returns:** Nothing.

**Compatibility:** WinIE5+, MacIE5+, NN-, Moz-, Safari-

For tables that are bound to external data sources via IE4+ data binding, the `firstPage()` and `lastPage()` methods zoom to the first and last pages of the data, respectively. You must specify the table's data page size for the Data Source Object to know how many records to assign to a "page" of data. Note that while related methods — `nextPage()` and `previousPage()` — are available in IE4, `firstPage()` and `lastPage()` entered the picture in IE5.

**Related Items:** `dataPageSize`, `dataSrc`, `dataFld` properties; `nextPage()`, `previousPage()` methods.

## moveRow(sourceRowIndex, destinationRowIndex)

**Returns:** Row element object.

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The IE5+ `moveRow()` convenience method enables you to move a row from one position to another within the same table. Both parameters are integer index values. The first parameter is the index of the row you want to move; the second is the index of the row to where you want to move the row. Because no movement takes place when the method is invoked, the removal of the source row does not impact the index count of the destination row. But after the method executes, the row that was in the destination row is now pushed down one row. This method returns a reference to the moved row.

You can accomplish this same functionality in W3C DOM-compatible syntax (for IE5+, NN6+, Mozilla, and Safari) via the `replaceChild()` method of the `table` element.

## Example

If you want to shift the bottom row of a table to the top, you can use the shortcut reference to the last item's index value (-1) for the first parameter:

```
var movedRow = document.all.someTable.moveRow(-1, 0);
```

**Related Item:** `replaceChild()` method.

## nextPage()

## previousPage()

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

For tables that are bound to external data sources via IE4+ data binding, the `nextPage()` and `previousPage()` methods jump ahead and back one page of the data, respectively. You must specify the table's data page size for the Data Source Object to know how many records to assign to a "page" of data. Typically, navigational buttons associated with the table invoke these methods.

**table.nextPage()**

**Related Items:** `dataPageSize`, `dataSrc`, `dataFld` properties; `firstPage()`, `lastPage()` methods.

**refresh()**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

For tables that are bound to external data sources via IE4+ data binding, the `refresh()` method retrieves the current data source data for display in the table. A script can use `setTimeout()` to invoke a function that calls this method at an interval of your choice. If you frequently update the database associated with the table, this method can help keep the table up to date without requiring the client to download the entire page (and perhaps run into cache conflicts).

**Related Items:** `dataPageSize`, `dataSrc`, `dataFld` properties.

## tbody, tfoot, and thead Element Objects

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>align</code>	<code>deleteRow()</code> †	
<code>bgColor</code> †	<code>insertRow()</code> †	
<code>ch</code>	<code>moveRow()</code> †

<code>rows</code> †		
<code>vAlign</code>		

†See table element object.

## Syntax

Accessing tbody, tfoot, and thead element object properties and methods:

```
(IE4+)      [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

Accessing tbody element object properties and methods:

```
(IE4+)      [window.]document.all.tableID.tBodies[i].property |
method([parameters])
(IE5+/W3C) [window.]document.getElementById("tableID").tBodies[i].property |
method([parameters])
```

Accessing tfoot element object properties and methods:

```
(IE4+)      [window.]document.all.tableID.tfoot.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("tableID").tfoot.property |
method([parameters])
```

Accessing thead element object properties and methods:

**tbody.vAlign**

```
(IE4+) [window.]document.all.tableID.tHead.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("tableID").tHead.property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE5, NN6+, Moz1+, Safari1+

## About these objects

Each of these element objects represents a row grouping within a `table` element (an HTML `TableSectionElement` in the syntax of the W3C DOM specification). A table can have only one `thead` and one `tfoot`, but it can have as many `tbody` elements as your table organization requires.

These elements share many properties and methods with the `table` element in that they all contain rows. The benefit of defining table segments is apparent if you use table rules (see the `table.rules` property earlier in this chapter) and if you wish to limit the scope of row activities only to rows within one segment. For instance, if your table has a `thead` that is to remain static, your scripts can merrily loop through the rows of only the `tbody` section without coming anywhere near the row(s) in the `thead`.

## Properties

`ch`

`chOff`

**Value:** One-character string.

Read/Write

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

The `ch` and `chOff` properties represent the optional `char` and `charoff` attributes of table row section elements in the HTML 4.0 specification. As of IE6 and NN7.1, these properties are yet to be implemented in a browser; eventually they will help align cell content within a column or column group similar to the way word processors allow for formatting features such as decimal tabs. For details on these attributes, see <http://www.w3.org/tr/REC-html40/struct/tables.html#adef-char>.

**Related Items:** `col`, `colgroup` objects.

`vAlign`

**Value:** String constant.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Providing the cell-oriented `vAlign` property for a table row section enables you to specify a vertical alignment to apply to all cells within that section rather than specify the `vAlign` attribute for each `td` element. By default, browsers render cell content with a middle vertical alignment within the cell. If you want to modify the setting for an existing table section (or assign it to a new one you create), the values must be one of the following string constants: `baseline`, `bottom`, `middle`, or `top`.

### Example

Use The Evaluator (Chapter 13) to modify the vertical alignment of the content of the `tbody` element in the demonstrator table. Enter the following statement in the top text box to shift the content to the bottom of the cells:

```
document.getElementById("myTBody").vAlign = "bottom"
```

**tbody.vAlign**

Notice that the cells of the `thead` element are untouched by the action imposed on the `tbody` element.

**Related Item:** `td.vAlign` property.

## caption Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>align</code> <code>vAlign</code> <code>tt</code>		
†See <code>table</code> element object.		
††See <code>tbody</code> element object.		

## Syntax

Accessing `caption` element object properties and methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

A `caption` element is a simple HTML container whose only prerequisite is that it must be nested inside a `table` element. That nesting allows the `table` element object to control insertion and removal of a `caption` element at will. You can modify the content of a `caption` element just like you do any HTML element (in DOMs that allow such modification). You can see an example of how the `table` element object uses some of its methods to create and remove a `caption` element in Listing 37-2.

The only properties that lift the `caption` element object above a mere contextual element (described in Chapter 15) are `vAlign` (IE4+) and the W3C DOM-sanctioned `align` (IE4+/NN6+/Mozilla/Safari). I describe these properties and their values for other objects in this chapter.

## col and colgroup Element Objects

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>align</code> <code>ch</code> <code>tt</code> <code>chOff</code> <code>tt</code>		

col

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
Span vAlign†† width		

†See table element object.  
††See tbody element object.

## Syntax

Accessing col and colgroup element object properties and methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About these objects

The purpose of the col and colgroup elements is to allow cells within one or more columns to be treated as a single entity for purposes of stylesheet and other style-related control. In other words, if you want one column of a table to be all boldface, you can assign that stylesheet rule to the col element that encompasses that column. All cells within that column inherit the stylesheet rule definition. Having two different element names allows for the nesting of column groups, which can come in handy for complex tables. For instance, consider a table that reports the forecasted and actual sales for a list of products across four quarters of a year. The left column of the table stands alone with the product item numbers. To the right is one large grouping of eight columns that encompasses the four pairs of forecasted/actual sales pairs. All eight columns of cells are to be formatted with a particular font style to help differentiate the pairs of columns for each quarter. You also want to assign a different background color. Therefore, you designate each pair of columns as its own subgroup within the eight-column master grouping. The colgroup and col tags for this nine-column table are as follows:

```
<col id="productIDs">
<colgroup id="fiscalYear" span="8" width="40">
  <col id="Q1" span="2">
  <col id="Q2" span="2">
  <col id="Q3" span="2">
  <col id="Q4" span="2">
</colgroup>
```

Up in the head section of this document are stylesheet rules similar to the following:

```
<style type="text/css">
#productIDs {font-weight:bold}
#fiscalYear {font-family: Courier, "Courier New", monospace}
#Q1 {background-color: lightyellow}
#Q2 {background-color: pink}
#Q3 {background-color: lightblue}
#Q4 {background-color: lightgreen}
</style>
```

**col**

The HTML code for the column groups demonstrates the two key attributes: `span` and `width`. Both of these attributes are reflected as properties of the objects, and I describe them in the following section. Notice, however, that `col` and `colgroup` elements act cumulatively and in source code order to define the column groups for the table. In other words, if the style of the left-hand column is not important, the table still requires the initial one-column `col` element before the eight-column `colgroup` element. Otherwise, the browser makes the first eight columns the column group. Therefore, it is a good idea to account for every column with `col` and/or `colgroup` elements if you intend to use any column grouping in your table.

From a scripter's point of view, you are more likely to modify styles for a column or column group than you are to alter properties such as `span` or `width`. But, if your scripts generate new tables, you may create new `col` or `colgroup` elements whose properties you definitely should initialize with values.

## Properties

**span**

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `span` property represents the number of columns that the column group should encompass. Don't confuse this property with the `colspan` property of `td` and `th` elements. A `col` or `colgroup` `span` does not have any impact on the rendering or combination of multiple cells into one. It simply draws an imaginary lasso around as many columns as are specified, signifying that these columns can be treated as a group for style purposes (and also for drawing of divider rules, if you set the table's `rules` property to `groups`).

### Example

The following statement assigns a `span` of 3 to a newly created `colgroup` element stored in the variable `colGroupA`:

```
colGroupA.span = 3;
```

**Related Item:** `width` property.

**width**

**Value:** Length string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The only reason the `width` property is highlighted for these objects is that the property (and corresponding attribute) impacts the width of table cells inside the scope of the column grouping. For example, if you assign a width of 50 pixels to a `colgroup` whose `span` attribute is set to 3, all cells in all three columns inherit the 50-pixel width specification. For more details on the values acceptable to this property, see the `table.width` property description earlier in this chapter.

**Related Item:** `table.width` property.

## tr Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

tr

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>

vAlign††		

†See table element object.

††See tbody element object.

## Syntax

Accessing tr element object properties and methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE4+) [window.]document.all.tableID.rows[i].property | method([parameters])
(IE4+) [window.]document.all.tableRowSectionID.rows[i].property |
method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID"). property |
method([parameters])
(IE5+/W3C) [window.]document.getElementById("tableID").rows[i].property |
method([parameters])
(IE5+/W3C)
[window.]document.getElementById("tableRowSectionID").rows[i].property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

Table rows are important objects within the complex nesting of table-related elements and objects. When a table represents server database data, one row usually equals one record. And, although you can employ scripting to add columns to a table, the more common table modifications are to add or delete rows — hence the presence of the table element object's insertRow() and deleteRow() methods.

The primary job of the tr element is to act as a container for td elements. All the cells in a row inherit some attributes and properties that you apply to that row. An array of cell objects is available for iteration via for loops. A tr element object, therefore, also has methods that insert and remove individual cells in that row.

The number of columns in a row is determined by the number of td elements or, more specifically, by the number of columns that the cells intend to span. One row can have four td elements, while the next row can have only two td elements — each of which is defined to

**tr**

occupy two columns. The row of the table with the most `td` elements and column reservations determines the column width for the entire table.

Of the properties just listed, the ones related to border color are available in IE4+ only. In IE4+, the border is drawn around each cell of the row rather than the entire row. The HTML 4.0 specification (and the W3C DOM Level 2 specification by extension) does not recognize border colors for rows alone, nor are stylesheet border rules inherited by the cell children of a row. However, you can define borders for individual cells or classes of cells.

## Properties

**cells**

**Value:** Array of `td` element objects.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `cells` property returns an array (collection) of `td` element objects nested inside the current `tr` object. The `length` property of this array indicates the number of actual `td` elements in the row, which may not be the number of columns if one or more cells occupy multiple columns.

Use the `cells` property in `for` loops to iterate through all cells within a row. Assuming your script has a reference to a single row, the loop should look like the following:

```
for (var i = 0; i < rowRef.cells.length; i++) {
    oneCell = rowRef.cells[i];
    // more statements working with the cell
}
```

### Example

Use The Evaluator (Chapter 13) to retrieve the number of `td` elements in the second row of the demonstrator table. Enter the following statement into the top text box (W3C DOM syntax shown here):

```
document.getElementById("myTable").rows[1].cells.length
```

**Related Items:** `table.rows`, `td.cellIndex` properties.

**height**

**Value:** Integer or length string.

Read/Write

**Compatibility:** WinIE5+, MacIE5+, NN-, Moz-, Safari-

IE5+ enables page authors to predefine a height for a table row; this attribute is echoed by the `height` property. The value can be a number of pixels or a percentage length value. Note that this property does not reveal the rendered height of the row unless you explicitly set the attribute in the HTML. To get the actual height (in IE5+ and NN6+), use the `offsetHeight` property. You cannot adjust the `height` property to be smaller than the table normally renders the row.

### Example

Use The Evaluator (Chapter 13) in IE5+ to expand the height of the second row of the demonstrator table. Enter the following statement into the top text box:

```
document.all.myTable.rows[1].height = 300
```

**tr.deleteCell()**

If you attempt to set the value very low, the rendered height goes no smaller than the default height.

**Related Item:** `offsetHeight` property (Chapter 15).

**rowIndex****sectionRowIndex**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Each row occupies a position within the collection of rows in the table as well as within the collection of rows for a table section (`thead`, `tbody`, or `tfoot`). The `rowIndex` property returns the zero-based index value of the row inside the `rows` collection for the entire table, regardless of table section composition. In contrast, the `sectionRowIndex` property returns the zero-based index value of the row inside its row section container. If the table has no row sections defined for it, a single, all-encompassing `tbody` element is assumed; in this case, the `sectionRowIndex` and `rowIndex` values are equal.

These properties serve in functions that are passed a reference to a row. However, the functions might also need to know the position of the row within the table or section. Although there is no `tr` object property that returns a reference to the next outermost table row section or the table itself, the `parent` and `parent's parent` elements, respectively, can reference these objects.

**Example**

Use The Evaluator (Chapter 13) to explore the `rowIndex` and `sectionRowIndex` property values for the second physical row in the demonstrator table. Enter each of the following statements into the top text box (W3C DOM syntax shown here):

```
document.getElementById("myTable").rows[1].rowIndex  
document.getElementById("myTable").rows[1].sectionRowIndex
```

The result of the first statement is 1 because the second row is the second row of the entire table. But the `sectionRowIndex` property returns 0 because this row is the first row of the `tbody` element in this particular table.

**Related Items:** `table.rows`, `tbody.rows`, `tfoot.rows`, `thead.rows` properties.

**Methods****deleteCell(cellIndex)****insertCell(cellIndex)**

**Returns:** Nothing; Reference to new cell.

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The act of inserting a row into a table is not complete until you also insert cells into the row. The `insertCell()` method does just that, with a parameter indicating the zero-based index of the cell's position among other cells in the row. A value of -1 appends the cell to the end of existing cells in the row.

When you invoke the `insertCell()` method, it returns a reference to the new cell. This gives you the opportunity to adjust other properties of that cell before moving onto the next cell. For example, if you want to insert a cell that has a column span of 2, you adjust the `colSpan` property of the cell whose reference just returned, as in the following:

**tr.deleteCell()**

```
var oneCell = tableRowRef.insertCell(-1);
oneCell.colSpan = 2;
```

Scripts that add rows and cells must make sure that they add the identical number of cells (or cell column spaces) from one row to the next. Otherwise, you have an unbalanced table with ugly blank spaces where you probably don't want them.

To remove a cell from a row, use the `deleteCell()` method. The parameter is a zero-based index value of the cell you want to remove. If all you want to do is replace the content of a cell, apply the new content to the `innerHTML` property of the `td` element. This is smoother and safer than deleting and reinserting a cell because any execution error that occurs in the process results in an unbalanced table. Finally, to rid yourself of all cells in a row, use the `deleteRow()` method of the `table` and `table row section` element objects.

**Example**

See Listing 37-2 for an example of inserting cells during the row insertion process.

**Related Item:** `table.insertRow()` method.

## td and th Element Objects

For HTML element properties, methods, and event handlers, see Chapter 15.

## Syntax

Accessing `td` and `th` element object properties and methods:

```
(IE4+)      [window.]document.all.elemID.property | method([parameters])
(IE4+)      [window.]document.all.tableID.cells[i].property |
method([parameters])
(IE4+)      [window.]document.all.tableRowSectionID.cells[i].property |
method([parameters])
(IE4+)      [window.]document.all.tableRowID.cells[i].property |
method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID"). property |
method([parameters])
(IE5+/W3C) [window.]document.getElementById("tableID").cells[i].property |
method([parameters])
(IE5+/W3C)
[window.]document.getElementById("tableRowSectionID").cells[i].property |
method([parameters])
(IE5+/W3C) [window.]document.getElementById("tableRowID").rows[i].property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About these objects

`td` (table data) and `th` (table header) elements create cells within a table. By common convention, a `th` element is rendered in today's browsers with a distinctive style—usually with a bold font and center alignment—but the context as a table header is a key ingredient of the table. A table cell is as deeply nested as you can get with table-related elements.

Properties of cells that are delivered in the HTML of the page are rarely modified (with the exception of the `innerHTML` property). But you still need full access to properties of cells if your scripts add rows to a table dynamically. After creating each blank table cell object, your scripts can adjust `colSpan`, `rowSpan`, `noWrap`, and other properties that influence the characteristics of that cell within the table.

See the beginning of this chapter for discussions and examples of how to add rows of cells and modify cell content under script control.

## Properties

`abbr`

`axis`

`headers`

**Value:** See text.

Read/Write

**Compatibility:** WinIE6+, MacIE5+, NN6+, Moz1+, Safari1+

These three properties are defined for table cell element objects in the W3C DOM. They all represent attributes for these elements in the HTML 4.0 specification. The purposes of these attributes and properties are geared toward browsers that provide alternate means of rendering content, such as through speech synthesis. Although these properties are definitely valid for W3C browsers, they have no practical effect. For general application, you can ignore these properties—consider them reserved for future use.

**td.cellIndex**

## cellIndex

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `cellIndex` property returns an integer indicating the zero-based count of the current cell within its row. Thus, if a script is passed a reference to a cell, the `cellIndex` property reveals its position within the row. Inserting or deleting cells in the row at lower index values influences the `cellIndex` value after the alteration.

**Example**

You can rewrite the cell addition portion of Listing 37-2 to utilize the `cellIndex` property. The process entails modifying the `insertTableRow()` function so that it uses a `do...while` construction to keep adding cells to match the number of data slots. The function looks like the following (changes shown in boldface):

```
function insertTableRow(form, where) {
    var now = new Date();
    var nowData = [now.getHours(), now.getMinutes(), now.getSeconds(),
        now.getMilliseconds()];
    clearBGColors();
    var newCell;
    var newRow = theTableBody.insertRow(where);
    var i = 0;
    do {
        newCell = newRow.insertCell(i);
        newCell.innerHTML = nowData[i++];
        newCell.style.backgroundColor = "salmon";
    } while (newCell.cellIndex < nowData.length)
    updateRowCounters(form);
}
```

This version is merely for demonstration purposes and is not as efficient as the sequence shown in Listing 37-2. But the `cellIndex` property version can give you some implementation ideas for the property. It also shows how dynamic the property is, even for brand new cells.

**Related Item:** `tr.rowIndex` property.

## colSpan

## rowSpan

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `colSpan` and `rowSpan` properties represent the `colspan` and `rowspan` attributes of table cell elements. Assign values to these properties only when you are creating new table rows and cells — and you are firm in your table cell design. If you fail to assign the correct values to either of these properties, your table cell alignment will get out of whack. Modifying these property values on an existing table is extremely risky unless you are performing other cell manipulation to maintain the balance of rows and columns. Values for both properties are integers greater than or equal to 1.

**Example**

Use The Evaluator (Chapter 13) to witness how modifying either of these properties in an existing table can destroy the table. Enter the following statement into the top text box:

```
document.getElementById("myTable").rows[1].cells[0].colSpan = 3
```

**td.noWrap**

Now that the first cell of the second row occupies the space of three columns, the browser has no choice but to shift the two other defined cells for that row out beyond the original boundary of the table. Experiment with the `rowSpan` property the same way. To restore the original settings, assign 1 to each property.

**Related Item:** `col.span` property.

**height****width**

**Value:** Integer and length string.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Table cells may be specified to be larger than their default rendered size. This usually happens in the `height` and `width` attributes of the cell. Settings of the `width` attribute of a `col` or `colgroup` element (IE4+ and NN6+/W3C) may also govern the width of a cell. A cell's height can be inherited from the `height` attribute setting of a table row or row section (IE4+). Both `height` and `width` attributes are deprecated in HTML 4.0 in favor of the `height` and `width` stylesheet attributes. That said, the `height` and `width` properties of a table cell echo only the settings of the explicit attributes in the cell's tag. If a stylesheet in the element tag governs a cell's dimensions, visit the cell object's `style` property to determine the dimensions. Explicit attributes override stylesheet rules.

Values for these two properties are length values. These can be pixel integers or percentage values as strings. Attempts to set the sizes smaller than their default rendered size results in a cell of default size. Also be aware that enlarging a cell affects the width of the entire column and/or height of the entire row occupied by that cell.

**Example**

Use The Evaluator (Chapter 13) to see the results of setting the `height` and `width` properties of an existing table cell. Enter each of the following statements into the top text box and study the results in the demonstrator table (W3C DOM syntax used here):

```
document.getElementById("myTable").rows[1].cell[1].height = 100
document.getElementById("myTable").rows[2].cell[0].width = 300
```

You can restore both cells to their original sizes by assigning very small values, such as 1 or 0, to the properties. The browser prevents the cells from rendering any smaller than is necessary to show the content.

**Related Items:** `col.width`, `tr.height` properties.

**noWrap**

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The default behavior of a table cell is to wrap text lines within the cell if the text would extend beyond the right edge of the cell as calculated from the width of the entire table. But you can force the table to be wider to accommodate the text in an unwrapped line of text by setting the `noWrap` property (or `nowrap` attribute) of the cell to `true`. The `nowrap` attribute is deprecated in HTML 4.0.

**Example**

The following statement creates a new cell in a row and sets its `noWrap` property to prevent text from word-wrapping inside the cell:

**td.noWrap**

```
newCell = newRow.insertCell(-1);
newCell.noWrap = true;
```

You need to set this property only if the cell must behave differently than the default, word-wrapping style.

**rowSpan**

(See `colSpan`)

**width**

(See `height`)

## ol Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
compact start type		

## Syntax

Accessing `ol` element object properties and methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID"). property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

The `ol` (ordered list) element is a container of `li` (list item) elements. An *ordered list* means that the list items have a sequence and are preceded by a number or letter to signify the position within the sequence. The few element-specific attributes are being deprecated in favor of stylesheet definitions. For the sake of backward compatibility with existing content, however, it is likely that many future generations of browsers will continue to support these deprecated attributes. These attributes are therefore available as properties of the element object.

Most of the special appearance of a list (notably indentation) is handled automatically by the browser's interpretation of how an ordered list should look. You have control over the numbering or lettering schemes and the starting point for those sequences. With CSS you can significantly override the browser's formatting—even eliminating the traditional list appearance via other choices for the `display style` property.

## Properties

### compact

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Although the property is defined for the browsers just shown, the `compact` property (and the deprecated attribute it echoes) has no impact on the density of the listing.

### start

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `start` property governs which number or letter begins the sequence of leading characters for nested `li` items. If the `type` attribute specifies numbers, the corresponding number is used; if it specifies letters, the letter of the alphabet corresponding to the number becomes the starting character. You can change the numbering in the middle of a sequence via the `li.value` property.

It is an extremely rare case that requires you to modify this property for an existing `ol` element. But if your script is creating a new element for a segment of ordered list items that has some other content intervening from an earlier `ol` element, you can use the property to assign a starting value to the `ol` group.

### Example

The following statements generate a new `ol` element and assign a value to the `start` property:

```
var newOL = document.createElement("ol");
newOL.start = 5;
```

**Related Items:** `type`, `li.value` properties.

### type

**Value:** String constant.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

An `ol` element can use any of five different numbering schemes. Each scheme has a `type` code, whose value you can use for the `type` property. The following table shows the property values and examples:

<i>Value</i>	<i>Example</i>
A	A, B, C, ...
a	a, b, c, ...
I	I, II, III, ...
i	i, ii, iii, ...
1	1, 2, 3, ...

**ol.type**

The default value is 1. You are free to adjust the property after the table has rendered, and you can even stipulate a different type for specific `li` elements nested inside (see the `li.type` property). If you want to have further nesting with a different numbering scheme, you can nest the `ol` elements and specify the desired type for each nesting level, as shown in the following HTML example:

```
<ol type="A">
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
    <ol type="a">
      <li>Sub One</li>
      <li>Sub Two</li>
      <li>Sub Three</li>
    </ol>
  <li>Four</li>
</ol>
```

Indenting the HTML is optional, but it may help you to keep the nesting straight.

**Example**

The following statements generate a new `ol` element and assign a value to the `type` property so that the sequence letters are uppercase Roman numerals:

```
var newOL = document.createElement("ol");
newOL.type = "I";
```

**Related Items:** `start`, `UL.type`, `LI.type` properties.

## ul Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
compact†		
type		

†See `ol` element object.

## Syntax

Accessing `ul` element object properties and methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

The `ul` (unordered list) element is a container of `li` (list item) elements. An *unordered list* means that the list items have no sequence and are preceded by symbols that don't signify any

particular order. The few element-specific attributes are being deprecated in favor of stylesheet definitions. For the sake of backward compatibility with existing content, however, it is likely that many future generations of browsers will continue to support these deprecated attributes. These attributes are therefore available as properties of the element object.

Most of the special appearance of a list (notably indentation) is handled automatically by the browser's interpretation of how an ordered list should look. You have control over the three possible characters that precede each item. With CSS you can significantly override the browser's formatting—even eliminating the traditional list appearance via other choices for the `display` style property.

## Properties

### type

**Value:** String constant.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

A `ul` element can use any of three different leading characters. Each character type has a `type` code whose value you can employ for the `type` property. Property values are `circle`, `disc`, and `square`. The difference between a `circle` and `disc` is that the `circle` is unfilled, while the `disc` is solid. The default value is `disc`.

### Example

The following statements generate a new `ul` element and assign a value to the `type` property so that the bullet characters are empty circles:

```
var newUL = document.createElement("ul");
newUL.type = "circle";
```

**Related Items:** `OL.type`, `UL.type` properties.

## li Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
type value		

## Syntax

Accessing `li` element object properties and methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.]document.getElementById("elemID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

An `li` (list item) element contains the HTML that is displayed for each item within an `ol` or `ul` list. Note that you can put any HTML you want inside a list item, including images. Attributes and properties of this element enable you to override the specifications declared in the `ol` or `ul` containers (except in MacIE).

## Properties

### type

**Value:** String constant.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

Because either an `ol` or `ul` container can own an `li` element, the `type` property accepts any of the values that you assign to the `type` properties of both the `ol` and `ul` element objects. See the `ol.type` and `ul.type` properties earlier in this chapter for lists of those values.

Exercise caution, however, if you attempt to mix and match types. For example, if you try to set the `li.type` property of an `li` element to `circle` inside an `ol` element, the results vary from browser to browser. NN6+/Moz, for example, follows your command; however, IE may display some other characters.

### Example

See the examples for the `ol.type` and `ul.type` properties earlier in this chapter.

**Related Items:** `ol.type`, `ul.type` properties.

### value

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `value` property governs which number or letter is used for the current list item inside an ordered list. Employ this attribute and property to override the natural progression. Because these sequence characters can be letters, numbers, or Roman numerals, the integer you specify for this property is converted to the numbering scheme in force by the `li` or `ol` element's `type` property.

### Example

The following statements generate a new `li` element and assign a value to the `start` property:

```
var newLI = document.createElement("li");
newLI.start = 5;
```

**Related Item:** `ol.start` property.

## dl, dt, and dd Element Objects

For HTML element properties, methods, and event handlers, see Chapter 15.

**dir**

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
compact†		
†See <code>ol</code> element object.		

## Syntax

Accessing `dl`, `dt`, and `dd` element object properties and methods:

```
(IE4+)      [window.] document.all.elemID.property | method([parameters])
(IE5+/W3C) [window.] document.getElementById("elemID"). property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About these objects

Three elements — `dl`, `dt`, and `dd` — provide context and (optionally) formatting for definitions in a document. The `dl` element is the outer wrapper signifying a definition list. Each definition term should be inside a `dt` element, while the definition description should be in the nested `dd` element. The HTML for a simple definition list has the following structure:

```
<dl>
  <dt>First term</dt>
  <dd>First term's definition</dd>
  <dt>Second term</dt>
  <dd>Second term's definition</dd>
</dl>
```

Although there are no specific requirements for rendering definition lists by convention, the term and description are usually on different lines with the description indented. With CSS you can significantly override the browser's formatting — even eliminating the traditional list appearance via other choices for the `display style` property.

All three of these elements are treated as element objects, sharing the same properties, methods, and event handlers of generic element objects. The only one of the three that has anything special is the `dl` element, which has a `compact` property. WinIE4+ does respond to this attribute and property by putting the description and term on the same line if the term is shorter than the usual indentation space of the description.

## dir and menu Element Objects

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
compact†		
†See <code>ol</code> element object.		

**dir**

## Syntax

Accessing `dir` and `menu` element object properties and methods:

```
(IE4+) [window.]document.all.elemID.property | method([parameters])  
(IE5+/W3C) [window.]document.getElementById("elemID"). property |  
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About these objects

The `dir` and `menu` elements are treated in modern browsers as if they were `ul` elements for unordered lists of items. Both elements are deprecated in HTML 4.0; yet, because they are acknowledged in that standard, they are also acknowledged in the W3C DOM (and the IE DOM, too). Originally intended to assist in creating single and double columns of text (long since supplanted by tables), usage of these elements has fallen out of favor and is discouraged.

# The Navigator and Other Environment Objects

---

**C**lient-side scripting primarily focuses on the document inside a browser window and the content of the document. As discussed in Chapter 16, the window, too, is an important part of how you apply JavaScript on the client. But stepping out even one more level is the browser application itself. Scripts sometimes need to know about the browser and the computing environment in which it runs so that they can tailor dynamic content for the current browser and operating system.

To that end, browsers provide objects that expose as much about the client computer and the browser as is feasible within accepted principles of preserving a user's privacy. In addition to providing some of the same information that CGI programs on the server receive as environment variables, these browser-level objects in some browsers also include information about how well equipped the browser is with regard to plug-ins and Java. Another object defined for version 4 browsers and on reveals information about the user's video monitor, which may influence the way your scripts calculate information displayed on the page.

The objects in this chapter don't show up on the document object hierarchy diagrams, except as free-standing groups (see Appendix A). The IE4+ object model, however, incorporates these environmental objects as properties of the `window` object. Because the `window` reference is optional, you can omit it and wind up with a cross-browser, compatible script in many cases.

Although these objects were first implemented outside of the object model hierarchy, they are now treated as belonging to the `window` object. As you learn in this chapter, the IE for Windows methodology can be a bit roundabout. And yet the Macintosh version of IE5 adopted the approach initiated by NN3. Go figure.

## In This Chapter

Determining which browser the user has

Branching scripts according to the user's operating system

Detecting plug-in support

**navigator**

## clientInformation Object (IE4+) and navigator Object (All)

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
appCodeName	javaEnabled()	
appMinorVersion	preference()	
appName	taintEnabled()	
appVersion

systemLanguage		
userAgent		
userLanguage		
userProfile		
vendor		
vendorSub		

### Syntax

Accessing `clientInformation` and `navigator` object properties and methods:

```
(All)      navigator.property | method()
(IE4+/NN6+) [window.]navigator.property | method()
(IE4+/NN6+) [window.]clientInformation.property | method()
```

### About this object

In Chapter 16, I repeatedly mention that the `window` object is the top banana of the document object hierarchy. In other programming environments, you likely can find a level higher than the `window` — perhaps referred to as the *application level*. You may think that an object known as the `navigator` object is that all-encompassing object. That is not the case, however.

**navigator.appCodeName**

Although Netscape originally invented the `navigator` object for the Navigator 2 browser, Microsoft Internet Explorer also supports this object in its object model. For those who exhibit partisan feelings toward Microsoft, IE4+ provides an alternate object—`clientInformation`—that acts as an alias to the `navigator` object. You are free to use the IE-specific terminology if your development is intended only for IE browsers. All properties and methods of the `navigator` and `clientInformation` objects are identical. In the rest of this section, all references to the `navigator` object also apply to the `clientInformation` object.

Be aware that the number of properties for this object has grown with virtually every browser version. Moreover, other than some basic items that have been around since the early days, most of the more recent properties are browser-specific. Observe the compatibility ratings for each of the following properties very carefully.

Most of the properties of the `navigator` object deal with the browser program the user runs to view documents. Properties include those for extracting the version of the browser and the platform of the client running the browser. Because so many properties of the `navigator` object are related to one another, I begin this discussion by grouping four of the most popular ones together.

## Properties

`appCodeName`

`appName`

`appVersion`

`userAgent`

**Value:** String.

Read-Only

**Compatibility:** WinIE3+, MacIE3+, NN2+, Moz1+, Safari1+

These four properties reveal just about everything that browser-sniffing code needs to know about the user's browser brand, version, and other tidbits. Of these four, only the last three are particularly valuable. The first property in the list, `appCodeName`, defines a class of client that encompasses essentially every standard browser. The value returned by browsers, `Mozilla`, is the code name of the first browser engine on which NN and IE browsers at one time were based (the NCSA Mosaic browser). This information does nothing to help your scripts distinguish among browser flavors, so you can ignore the property. But the other three properties are the ones with all the goodies.

The `appName` property returns the official name for the browser application. For Netscape and Mozilla browsers, the `appName` value is `Netscape`; for Internet Explorer, the value is `Microsoft Internet Explorer`. The situation is murkier for other browsers. For example, Opera gives users a preference option to have the browser identify itself as IE, NN, or Opera—and the `appName` property value changes accordingly. And Safari 1.0 identifies itself as Netscape in the `appName` property. Thus, the `appName` property is no longer a reliable browser brand determinant.

The `appVersion` and `userAgent` properties provide more meaningful detail. I start with the `appVersion` property because it is revealing and, at times, misleading.

## navigator.appVersion

## Using the appVersion property

A typical `appVersion` property value looks like the following (one from NN7, one from IE6):

```
5.0 (Windows; en-US)
4.0 (compatible; MSIE 6.0; Windows NT 5.1; .NET CLR 1.0.3705)
```

Because most version decisions are based on numeric comparisons (for example, the version is equal to or greater than 4), you frequently need to extract just the number part of the string returned by the `appVersion` property. The cleanest way to do this is via the `parseInt()` or `parseFloat()` methods. Use

```
parseInt(navigator.appVersion)
```

if you are interested only in the number to the left of the decimal; to get the complete leading floating-point number, use

```
parseFloat(navigator.appVersion)
```

All other characters after the leading numbers are ignored.

Also notice that the number does not always accurately represent the version of the browser at hand. For instance, IE6 reports that it is version 4.0. The number is more indicative of a broad generation number rather than a specific browser version number. In other words, the browser exhibits characteristics of the first browsers to wear the `appVersion` of 4 (IE 4.0, it turns out). Although this means that IE6 can use everything that is in the language and object model of IE4, this obviously doesn't help your script to know if the browser is capable of IE6 scripting features.

At the same time, however, buried elsewhere in the `appVersion` string is the wording `MSIE 6.0`—the “true” version of the browser. IE uses this technique to distinguish the actual version number from the generational number. Therefore, for IE, you may have to dig deeper by using string methods such as `indexOf()` to see if the `appVersion` contains the desired string. For example, to see if the browser is a variant of IE6, you can test for just “MSIE 6” as follows:

```
var isIE6x = navigator.appVersion.indexOf("MSIE 6") != -1
```

There is a hazard in doing this kind of testing, however. Going forward, your code will break if future versions of IE have larger version numbers. Therefore, if you want to use IE6 features with an IE8 browser (assuming such a browser becomes available), your testing for the presence of “MSIE 6” fails and the script thinks that it cannot use IE6 features even though they most certainly would be available in IE8. To find out if the current IE browser is the same or newer than a particular version, you must use JavaScript string parsing to deal with the `MSIE x.x` substring of the `appVersion` (or `userAgent`) property. The following example shows one function that extracts the precise IE version name and another function that confirms whether the version is at least IE6.0 for Windows.

```
var ua = navigator.userAgent;
function getIEVersion() {
    var IEOffset = ua.indexOf("MSIE ");
    return parseFloat(ua.substring(IEOffset + 5, ua.indexOf(";", IEOffset)));
}
function qualifyBrowser() {
    var qualified = false;
    if (navigator.appName == "Microsoft Internet Explorer") {
        if (parseInt(getIEVersion()) >= 6) {
            if (ua.indexOf("Windows") != -1) {
                qualified = true;
            }
        }
    }
}
```

**navigator.appVersion**

```
    }  
  }  
  if (!qualified) {  
    var msg = "These scripts are currently certified to run on:\n";  
    msg += " - MS Internet Explorer 6.0 or later for Windows\n";  
    alert(msg);  
  }  
  return qualified;  
}
```

As clever as the preceding code looks, using it assumes that the version string surrounding the MSIE characters will be immutable in the future. We do not have that kind of guarantee, so you have to remain vigilant for possible changes in future versions.

Thus, with each browser generation's pollution of the `appVersion` and `userAgent` properties, the properties become increasingly less useful for browser sniffing—unless you wish to burden your code with a lot of general-purpose sniffing code, very little of which any one browser uses.

Even NN is not free of problems. For example, the main numbering in the `appVersion` property for NN7 is 5 (in other words, the fifth generation of the original Mozilla code). A potentially thornier problem arises due to Netscape's decision to eliminate some nonstandard NN4 DOM features from the NN6 DOM (`layer` objects and some event object behaviors). Many scripters followed the previously recommended technique of “prepare for the future” by using an `appVersion` of 4 as a minimum:

```
var isNN4 = parseInt(navigator.appVersion) >= 4;
```

But any code that relies on the `isNN4` variable to branch to code that talks to the dead-end NN4 objects and properties breaks when it runs in NN6+.

The bottom-line question is, “What do I do for browser version detection?” Unfortunately, there are dozens of answers to that question, depending on what you need browser detection to do and what level of code you produce.

At one end of the spectrum is code that tries to be many things to many browsers, implementing multiple levels of features for many different generations of browser. This is clearly the most difficult tactic, and you have to create quite a long list of variables for the conditions for which you establish branches. Some branches may work on one combination of browsers, while you may need to split other branches differently because the scripted features have more browser-specific implementations.

At the other end of the spectrum is the code that tries to support, say, only IE5+ and other modern browsers with W3C DOM-compatible syntax to the extent that both browser families implement the object model features. Life for this scripter is much easier in that the amount of branching is little or none depending on what the scripts do with the objects.

Between these two extremes, situations call for many different solutions. Object detection (for example, seeing if `document.images` exists before manipulating image objects) is a good solution at times, but not so much for determining the browser version as for knowing whether some code that addresses those objects works. As described in Chapter 14, it is hazardous to use the existence of, say, `document.all` as an indicator that the browser is IE4+. Some other browser in the future may also implement the `document.all` property, but not necessarily all the other IE4+ objects and syntax. Code that thinks it's running in IE4+ just because `document.all` exists can easily break if `document.all` is implemented in another browser but not all the rest of the IE4+ DOM. Using object detection to branch code that addresses the detected objects is, however, very desirable in the long run because it frees your code from getting trapped in the ever-changing browser version game.

**navigator.appVersion**

Don't write off the `appVersion` and `userAgent` properties entirely. The combination of features that you script may benefit from some of the data in that string, especially when the decisions are made in concert with the `navigator.appName` property. A number of other properties can also provide the sufficient clues for your code to perform the branching that your application needs. For instance, it may be very helpful to your scripts to know whether the `navigator.platform` property informs them that they are running in a Windows or Macintosh environment because of the way each operating system renders fonts.

## userAgent property details

The string returned by the `navigator.userAgent` property contains a more complete run-down of the browser. The `userAgent` property is a string similar to the `USER_AGENT` header that the browser sends to the server at certain points during the connection process between client and server.

Unfortunately, there is no standard for the way information in the `userAgent` property is formatted. It may be instructive, however, to view what kinds of values come from a variety of browsers on different platforms. Table 38-1 shows some of the values that your scripts are likely to see. This table does not include, of course, the many values that are not reflected by browsers that do not support JavaScript. The purpose of the table is to show you just a sampling of data that the property can contain from a variety of browsers and operating systems (particularly enlightening if you do not have access to Macintosh or UNIX computers).

**Table 38-1: Typical navigator.userAgent Values**

<i>navigator.userAgent</i>	<i>Description</i>
Mozilla/5.0 (Macintosh; U; PPC Mac OS X X Mach-0; en-US; rv:1.4) Gecko/2003624	Mozilla 1.4 for MacOS X
Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.4 Gecko/2003624 Netscape/7.1 (ax)	Navigator 7.1 for Windows, running under Windows XP Home Edition
Mozilla/4.74 [en] (X11; U; Linux 2.2.154mdktmp i686)	Navigator 4.74, English edition for Linux with U.S. encryption
Mozilla/4.73 (Macintosh; U; PPC)	Navigator 4.73 for PowerPC Macintosh with U.S. encryption
Mozilla/4.02 [en] (Win95; I; Nav)	Navigator-only version of Communicator 4.02, English edition for Windows 95, and export encryption
Mozilla/4.01 [fr] (Win95; I)	Navigator 4.01, French edition for Windows 95, export encryption
Mozilla/3.01Gold (Win95; I)	Navigator 3.01 Gold for Windows 95
Mozilla/3.01 (Macintosh; I; PPC)	Navigator 3.01 for PowerPC Macintosh
Mozilla/3.01 (X11; I; HP-UX A.09.05 9000/720)	Navigator 3.01 for HP-UX on RS-9000
Mozilla/3.01 (X11; I; SunOS 5.4 sun4m)	Navigator 3.01 for SunOS 5.4
Mozilla/3.01Gold [de] (Win16; I)	Navigator 3.01, German edition for Windows 3.0x
Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1; .NET CLR 1.0.3705)	IE 6.0 running under Windows XP Home Edition
Mozilla/4.0 (compatible; MSIE 5.5; Windows NT 5.0)	IE 5.5 running under Windows NT 5.0

**navigator.userAgent**

<i>navigator.userAgent</i>	<i>Description</i>
Mozilla/4.0 (compatible; MSIE 5.0; Windows 98; DigExt)	IE 5.0 for Windows 98 with digital signature
Mozilla/4.0 (compatible; MSIE 5.0; Mac_PowerPC)	IE 5.0 running on a PowerPC-equipped Macintosh
Mozilla/3.0 WebTV/1.2 (compatible; MSIE 2.0)	IE 2 built into a WebTV box, emulating Navigator 3 (its scripting compatibility with Navigator 3 is in question)
Mozilla/2.0 (compatible; MSIE 3.0; 3.0; Windows 3.1)	IE 3 (version for America Online software AOL version 3) for Windows 3.1, emulating Navigator 2
Mozilla/2.0 (compatible; MSIE 3.02; Update a; Windows 95)	IE 3.02, Update a for Windows 95, emulating Navigator 2
Mozilla/2.0 (compatible; MSIE 3.0B; Windows NT)	IE 3 (beta) emulating Navigator 2
Mozilla/5.0 (Macintosh; U; PPC Mac OS X; en-us) AppleWebKit/85 (KHTML, like Gecko) Safari/85	Apple Safari 1.0 (release no. 85) for MacOS X
Opera/7.10 (Windows 98; U) [en]	Opera 7.1 (set to identify as Opera) for Windows 98

Because the `userAgent` property contains a lot of the same information as the `appVersion` property, the same cautions just described apply to the `userAgent` string and the environment data it returns.

Speaking of compatibility and browser versions, the question often arises whether your scripts should distinguish among incremental releases within a browser's generation (for example, 6.0, 6.01, 6.02, and so on). The latest incremental release occasionally contains bug fixes and (rarely) new features on which you may rely. If that is the case, I suggest you look for this information when the page loads and recommend to the user that he or she download the latest browser version. Beyond that, I suggest scripting for the latest version of a given generation and not bothering with branching for incremental releases.

See Chapters 13 and 14 for more information about designing pages for cross-platform deployment.

## Example

Listing 38-1 provides a number of reusable functions that your scripts can employ to determine a variety of information about the currently running browser. This is not intended in any way to be an all-inclusive browser-sniffing routine; instead, I offer samples of how to extract information from the key `navigator` properties to determine various browser conditions.

All functions in Listing 38-1 return a Boolean value inline with the pseudo-question presented in the function's name. For example, the `isWindows()` function returns `true` if the browser is any type of Windows browser; otherwise, it returns `false`. (In Internet Explorer 3, the values are 0 for `false` and -1 for `true`, but those values are perfectly usable in `if` conditional phrases). If this kind of browser detection occurs frequently in your pages, consider moving these functions into an external `.js` source library for inclusion in your pages (see Chapter 13).

When you load this page, it presents fields that display the results of each function depending on the type of browser and client operating system you use.

## Listing 38-1: Functions to Examine Browsers

```
<html>
  <head>
    <title>UserAgent Property Library</title>
    <script type="text/javascript">
      // basic brand determination
      function isNav() {
        return (navigator.appName == "Netscape" && !isOpera() && !isSafari());
      }

      function isIE() {
        return (navigator.appName == "Microsoft Internet Explorer");
      }

      function isOpera() {
        return (navigator.userAgent.indexOf("Opera") != -1);
      }

      function isSafari() {
        return (navigator.userAgent.indexOf("Safari") != -1);
      }

      // operating system platforms
      function isWindows() {
        return (navigator.appVersion.indexOf("Win") != -1);
      }

      function isWin95NT() {
        return (isWindows() && (navigator.appVersion.indexOf("Win16") == -1 &&
navigator.appVersion.indexOf("Windows 3.1") == -1));
      }

      function isMac() {
        return (navigator.appVersion.indexOf("Mac") != -1);
      }

      function isMacPPC() {
        return (isMac() && (navigator.appVersion.indexOf("PPC") != -1 ||
navigator.appVersion.indexOf("PowerPC") != -1));
      }

      function isUnix() {
        return (navigator.appVersion.indexOf("X11") != -1);
      }

      // browser versions
      function isGeneration2() {
        return (parseInt(navigator.appVersion) == 2);
      }

      function isGeneration3() {
        return (parseInt(navigator.appVersion) == 3);
      }

      function isGeneration3Min() {
        return (parseInt(navigator.appVersion.charAt(0)) >= 3);
      }
    </script>
  </head>
</html>
```

**navigator.userAgent**

```

function isNav4_7() {
    return (isNav() && parseFloat(navigator.appVersion) == 4.7);
}

function isMSIE4Min() {
    return (isIE() && navigator.appVersion.indexOf("MSIE") != -1);
}

function isMSIE6_0() {
    return (navigator.appVersion.indexOf("MSIE 6.0") != -1);
}

function isNN6Min() {
    return (isNav() && parseInt(navigator.appVersion) >= 5);
}

// element referencing syntax
function isDocAll() {
    return (document.all) ? true : false;
}

function isDocW3C() {
    return (document.getElementById) ? true : false;
}

// fill in the blanks
function checkBrowser() {
    var form = document.forms[0];
    form.brandNN.value = isNav();
    form.brandIE.value = isIE();
    form.brandSaf.value = isSafari();
    form.brandOp.value = isOpera();
    form.win.value = isWindows();
    form.win32.value = isWin95NT();
    form.mac.value = isMac();
    form.ppc.value = isMacPPC();
    form.unix.value = isUnix();
    form.ver30only.value = isGeneration3();
    form.ver3Up.value = isGeneration3Min();
    form.Nav4_7.value = isNav4_7();
    form.Nav6Up.value = isNN6Min();
    form.MSIE4.value = isMSIE4Min();
    form.MSIE6_0.value = isMSIE6_0();
    form.doc_all.value = isDocAll();
    form.doc_w3c.value = isDocW3C();
}
</script>
</head>
<body onload="checkBrowser()">

</form>
</body>
</html>

```

**Related Items:** appMinorVersion, cpuClass, oscpu, platform properties.

## appMinorVersion

**Value:** One-character string.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

In IE parlance, the *minor version* is indicated by the first digit to the right of the decimal in a full version number. But the “version number” referred to here is the number that the `navigator.appVersion` property reports, not the actual version of the browser. For example, although IE5.5 seems to have a version number of 5 and a minor version number of 5, the `appVersion` reports version 4.0. In this case, the `minorAppVersion` reports 0. Thus, you cannot use the `appMinorVersion` property to detect differences between, say, IE5 and IE5.5. That information is buried deeper within the string returned by `appVersion` and `userAgent`.

## Example

Use The Evaluator (Chapter 13) to examine the two related version properties of your IE browser(s). Type the following two statements into the top text box and observe the results:

```

navigator.appVersion
navigator.minorAppVersion

```

There is a good chance that the values returned are not related to the browser version number shown after MSIE in the `appVersion` value.

**Related Item:** `appVersion` property.

## browserLanguage

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `browserLanguage` property in IE4+ (and the `language` property in NN4+) returns the identifier for a localized language version of the program (it has nothing to do with scripting or programming language). The value of the `browserLanguage` property almost always is the same as the other IE language-related properties, unless the user changes the Windows control panel for regional settings after installing IE. In that case, `browserLanguage` returns the original language of the browser application, while the other properties report the language indicated in the system-level preferences panel.

**Note**

Users of the multilanguage version of Windows 2000/XP can choose alternate languages for menus and dialog boxes. The `browserLanguage` property returns the language you choose for those settings.

These short strings may resemble, but are not identical to, the URL suffixes for countries. Moreover, when a language has multiple dialects, the dialect can also be a part of the identifier. For example, `en` is the identifier for English. However, `en-us` (or `en-US`) represents the American dialect of English, while `en-gb` (or `en-GB`) represents the dialect recognized in Great Britain. NN sometimes includes these values as part of the `userAgent` data as well. Table 38-2 shows a sampling of language identifiers used for all language-related properties of the `navigator` object.

**Table 38-2: Sample navigator.browserLanguage Values**

<i>navigator.language</i>	<i>Language</i>
en	English
de	German
es	Spanish
fr	French
ja	Japanese
da	Danish
it	Italian
ko	Korean
nl	Dutch
pt	Brazilian Portuguese
sv	Swedish

You can assume that a user of a particular language version of the browser or system is also interested in content in the same language. If your site offers multiple language paths, you can use this property setting to automate the navigation to the proper section for the user.

**Related Items:** `navigator.userAgent`, `navigator.language`, `navigator.systemLanguage`, `navigator.userLanguage` properties.

**navigator.cookieEnabled****cookieEnabled****Value:** Boolean.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `cookieEnabled` property allows your scripts to determine easily if the browser has cookie functionality turned on. You can surround cookie-related statements with an `if` construction as follows:

```
if (navigator.cookieEnabled) {
    // do cookie stuff here
}
```

This works reliably only on browsers that implement the property. Because older browsers do not have this `navigator` object property, the `if` condition appears `false` (even though cookies may be turned on).

You can still check for cookie functionality in older browsers, but only clumsily. The technique entails assigning a “dummy” cookie value to the `document.cookie` property and attempting to read back the cookie value. If the value is there, cookies are enabled.

**Example**

Use The Evaluator (Chapter 13) to see the value of the `navigator.cookieEnabled` property on your browsers. Enter the following statement into the top text box:

```
navigator.cookieEnabled
```

Feel free to change the cookie preferences setting temporarily to see the new value of the property. You do not have to relaunch the browser for the new setting to take effect.

**Related Item:** `document.cookie` property.

**cpuClass****Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `cpuClass` property returns one of several fixed strings that identifies the family of central processing units running IE. Possible values and their meanings are as follows:

<i>cpuClass</i>	<i>Description</i>
x86	Intel processor (and some emulators)
PPC	Motorola Power PC processor (for example, Macintosh)
68K	Motorola 68000-family processor (for example, Macintosh)
Alpha	Digital Equipment Alpha processor
Other	Other processors, such as SPARC

The processor is not a good guide to determining the operating system because you can run multiple operating systems on most of the preceding processor families. Moreover, the `cpuClass` value represents the processor that the browser “thinks” it is running on. For example, when a Windows version of IE is hosted by the *Virtual PC* emulator on a PowerPC Macintosh, the `cpuClass` is reported as `x86` even though the actual hardware processor is `PPC`.

## Example

Use The Evaluator (Chapter 13) to see how IE reports the `cpuClass` of your PC. Enter the following statement into the top text box:

```
navigator.cpuClass
```

**Related Item:** `navigator.oscpu` property.

## language

**Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4+, Moz1+, Safari1+

The `NN4+ language` property returns the language code for the browser application. Although the comparable IE property (`navigator.browserLanguage`) has morphed in later versions to focus on the operating system language, NN's property deals exclusively with the language for which the browser application is written.

**Related Item:** `navigator.browserLanguage` property.

## mimeTypes

**Value:** Array of `mimeType` objects.

Read-Only

**Compatibility:** WinIE-, MacIE5, NN4+, Moz1+, Safari1+

A *mime* (*Multipurpose Internet Mail Extension*) type is a file format for information that travels across the Internet. Browsers usually have a limited capability for displaying or playing information beyond HTML text and one or two image standards (`.gif` and `.jpg` are the most common formats). To fill in the gap, browsers maintain an internal list of `mime` types with corresponding instructions on what to do when information of a particular `mime` type arrives at the client. For example, when a CGI program serves up an audio stream in an audio format, the browser locates that `mime` type in its table (the `mime` type is among the first chunk of information to reach the browser from the server) and then launches a helper application or activates a plug-in capable of playing that `mime` type. Your browser is not equipped to display every `mime` type, but it does know how to alert you when you don't have the helper application or plug-in needed to handle an incoming file. For instance, the browser may ask if you want to save the file for later use or switch to a Web page containing more information about the necessary plug-in.

The `mimeTypes` property of the `navigator` object is simply the array of `mime` types about which your browser knows (see the "mimeType Object" section later in this chapter). NN3+ browsers come with dozens of `mime` types already listed in their tables (even if the browser doesn't have the capability to handle all those items automatically). If you have third-party plug-ins in Navigator's plug-ins directory/folder or helper applications registered with Navigator, that array contains these new entries as well.

If your Web pages are media-rich, you want to be sure that each visitor's browser is capable of playing the media your page has to offer. With JavaScript and NN3+, you can cycle through the `mimeTypes` array to find a match for the `mime` type of your media. Then use the properties of the `mimeType` object (detailed later in this chapter) to ensure the optimum plug-in is available. If your media still requires a helper application instead of a plug-in, the array only lists the `mime` type; thus, you can't determine whether a helper application is assigned to this `mime` type from the array list.

**navigator.mimeTypes****Example**

For examples of the `mimeTypes` property and details about using the `mimeType` object, see the discussion of this object later in the chapter. A number of simple examples showing how to use this property to see whether the `navigator` object has a particular MIME type do not go far enough in determining whether a plug-in is installed and enabled to play the incoming data.

**Related Item:** `navigator.plugins` property; `mimeType` object.

**onLine**

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `onLine` property lets scripts determine the state of the offline browsing setting for the browser. Bear in mind that this property does not reveal whether the page is accessed via the Net or a local hard disk. The browser can be in online mode and still access a local page; in this case, the `onLine` property returns `true`.

With the offline browsing capabilities of IE4+, users may prefer to download copies of pages they wish to reference frequently (perhaps on a disconnected laptop computer). In such cases, your pages may want to avoid network-reliant content when accessed offline. For example, if your page includes a link to a live audio feed, you can dynamically generate that link with JavaScript—but do so only if the user is online:

```
if (navigator.onLine) {  
    document.write("<a href='broadcast.rna'>Listen to Audio</a>");  
}
```

**Example**

Use The Evaluator (Chapter 13) to see the online state of your IE browsers. Enter the following statement into the top text box:

```
navigator.onLine
```

Verify your browsing mode by checking the Work Offline choice in the File menu. If it is checked, the `onLine` property should return `false`.

**oscpu**

**Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `oscpu` property of Mozilla-based browsers returns a string that reveals OS- or CPU-related information about the user's environment. The precise string varies widely with the client OS. For instance, a Windows 98 machine reports `Win98`, while a Macintosh running MacOS X reports `PPC Mac OS X Mach-0`. The string formats for Windows NT/XP versions are not standardized, so they offer values such as `WinNT4.0` and `Windows NT 5.0`. Windows XP reports as being `Windows NT` in the `oscpu` property (as it does in the `userAgent` property). UNIX platforms reveal more details, such as the system version and hardware.

**Example**

Use The Evaluator (Chapter 13) with NN6 to see what your client machine reports to you by entering the following statement into the top text box:

```
navigator.oscpu
```

**Related Item:** `navigator.cpuClass` property.

## platform

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `navigator.platform` value reflects the operating system according to the codes established initially by Netscape for its `userAgent` values. Table 38-3 lists typical values of several operating systems.

In the long list of browser detection functions in Listing 38-1, I elected not to use the `navigator.platform` property because it is not backward-compatible. Meanwhile, the other properties in that listing are available to all scriptable browsers.

**Table 38-3: Sample `navigator.platform` Values**

<i>navigator.platform</i>	<i>Operating System</i>
Win32	Windows XP
Win98	Windows 98
WinNT	Windows NT
Win16	Windows 3.x
Mac68k	Mac (680x0 CPU)
MacPPC	Mac (PowerPC CPU)
SunOS	Solaris

Notice that the `navigator.platform` property does not go into versioning of the operating system. Only the raw name is provided.

**Example**

Use The Evaluator (Chapter 13) to see what your computer reports as its operating system. Enter the following statement into the top text box:

```
navigator.platform
```

**Related Item:** `navigator.userAgent` property.

## plugins

**Value:** Array of plug-in objects.

Read-Only

**Compatibility:** WinIE-, MacIE5, NN3+, Moz1+, Safari1+

You rarely find users involved with Web page design who have not heard about *plug-ins* — the technology that enables you to embed new media types and foreign file formats directly into Web documents. For instance, instead of requiring you to view a video clip in a separate window atop the main browser window, a plug-in enables you to make that viewer as much a part of the page design as a static image. The same goes for audio players, 3-D animation, chat sessions — even the display of Microsoft Office documents, such as PowerPoint and Word.

When many browsers launch, they create an internal list of available plug-ins located in a special directory/folder (the name varies with the browser and operating system). The `navigator.plugins` array lists the items registered at launch time. Each plug-in is, itself, an object with several properties.

**navigator.plugins**

The Windows version of IE4+ supports this property only to return an empty array. In other words, the property is defined, but it does not contain `plugin` objects—a nonexistent object in IE for Windows. But on the Macintosh side, IE5 supports the way Netscape Navigator, Mozilla, and Safari allow script inspection of `mime` types and plug-ins. To see ways of determining plug-in support for WinIE, see the section “Plug-in” detection in WinIE’ later in this chapter.

Having your scripts investigate the visitor’s browser for a particular installed plug-in is a valuable capability if you want to guide the user through the process of downloading and installing a plug-in (if the system does not have it currently).

**Example**

For examples of the `plugins` property and for details about using the `plugin` object, see the section “plugin Object” later in this chapter. Also see Chapter 40 on the CD-ROM for information on embedded element objects.

**Related Items:** `navigator.mimeTypes` property; `plugin` object.

`product`

`productSub`

`vendor`

`vendorSub`

**Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari1+

With the Mozilla browser engine being developed in an Open Source environment, any number of vendors might adapt the engine for any number of browser products. Some distributors of the browser, such as ISPs and computer manufacturers, may also tailor the browser slightly for their customers. These four properties can reveal some of the pedigree of the browser currently running scripts on the page.

Two categories of properties—one for the `product`, one for the `vendor`—each have a pair of fields (a primary and secondary field) that can be populated as the vendor sees fit. Some of this information may contain data, such as an identifying number of the *build* (development version) used to generate the product. A script at a computer maker’s Web site page may look for a particular series of values in these properties to welcome the customer or to advise the customer of a later build version that is recommended as an upgrade.

**Example**

Use The Evaluator (Chapter 13) on NN6+/Moz to see the values returned for these four properties (Safari 1.0 doesn’t support `vendorSub`). Enter each of the following statements into the top text box of the page and see the values for each in the Results box:

```
navigator.product  
navigator.productSub  
navigator.vendor  
navigator.vendorSub
```

Also check the value of the `navigator.userAgent` property to see how many of these four property values are revealed in the `userAgent` property.

**Related Item:** `navigator.userAgent` property.

## securityPolicy

**Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4+, Moz1+, Safari-

The Netscape-specific `securityPolicy` property returns a string that indicates which cryptographic scheme is implemented in the current browser. Typical string values include `US` and `CA` domestic policy and `export policy`. Each policy indicates the number of bits used for encryption, usually governed by technology export laws. The corresponding IE property is `document.security`. All Mozilla-based browsers have only one version, and the property's value is an empty string.

**Related Item:** `document.security` property.

## systemLanguage

### userLanguage

**Value:** Language code string.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

These two IE-specific properties report the language code of the written language specified for the operating system. For most operating system versions, these two values are the same. Some Windows versions enable you to set system preferences differently for the base operating system and the language for a given user. Both of these property values can differ from the `navigator.browserLanguage` property if the user downloads and installs the browser with the system set to one language and then changes the system settings to another language.

## Example

Use The Evaluator (Chapter 13) with your IE4+ browser to compare the values of the three language-related properties running on your computer. Enter each of the following statements into the top text box:

```
navigator.browserLanguage
navigator.systemLanguage
navigator.userLanguage
```

Don't be surprised if all three properties return the same value.

**Related Item:** `navigator.browserLanguage` property.

## userAgent

(See `appName`)

## userLanguage

(See `systemLanguage`)

## userProfile

**Value:** `userProfile` object.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `userProfile` property returns a reference to the IE `userProfile` object. This object provides scripted access to a limited range of user profile settings with the user's permission. For details, see the `userProfile` object discussion later in this chapter.

**Related Item:** `userProfile` object.

**navigator.vendor**

vendor

vendorSub

(See product)

**Methods**

javaEnabled()

**Returns:** Boolean.**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

Although most modern browsers ship with Java support turned on, a user can easily turn it off in a preferences dialog box (or even elect not to install it with the browser). Some corporate installations may also turn off Java as the default setting for their users. If your pages specify Java applets, you don't normally have to worry about this property because the applet tag's alternate text fills the page in the places where the applet normally goes. But if you script applets from JavaScript (via LiveConnect, Chapter 44), you don't want your scripts making calls to applets or Java classes if Java support is turned off. In a similar vein, if you create a page with JavaScript, you can fashion two different layouts depending on the availability of Java.

The `navigator.javaEnabled()` method returns a Boolean value reflecting the preferences setting. This value does not reflect Java support in the browser necessarily (and especially not the Java version supported), but rather whether Java is turned on inside the browsers for which this method is supported. A script cannot change the browser's preference setting, but its value does change immediately upon toggling the Preference setting.

**Related Items:** `navigator.preference()` method; LiveConnect (Chapter 44).

preference(*name* [, *val*])**Returns:** Preference value.**Compatibility:** WinIE-, MacIE-, NN4+, Moz-, Safari-

The user normally sets browser preferences. Until NN4 and the advent of signed scripts, almost all settings were completely out of view of scripts — even when it made sense to expose them. But with signed scripts and the `navigator.preference()` method, many NN preferences are now viewable and settable with the user's permission. These preferences were exposed to scripting primarily for the purposes of centralized configuration administration for enterprise installations. I don't recommend altering the browser preferences of a public Web site visitor, even if given permission to do so — the user may not know how much trouble you can cause.

When you want to read a particular preference setting, you pass only the preference name parameter with the method. Reading a preference requires a signed script with the target of `UniversalPreferencesRead` (see Chapter 46 on the CD-ROM). To change a preference, pass both the preference name and the value (with a signed script target of `UniversalPreferencesWrite`).

Table 38-4 shows a handful of scriptable preferences in Mozilla-based browsers (learn more about Mozilla preferences at <http://www.mozilla.org/catalog/end-user/customizing/briefprefs.html>). Most items have corresponding entries in the preferences window in NN4+ (shown in parentheses). Notice that the preference name uses dot syntax. The cookie security level is a single preference value with a matrix of integer values indicating the level.

`navigator.preference()`**Table 38-4: `navigator.preference()` Values Sampler**

<i>navigator.preference</i>	<i>Value</i>	<i>Preference Dialog Listing</i>
<code>security.enable_java</code>	Boolean	(Advanced) Enables Java
<code>javascript.enabled</code>	Boolean	(Advanced) Enables JavaScript
<code>autoupdate.enabled</code>	Boolean	(Advanced) Enables AutoInstall
<code>network.cookie.cookieBehavior</code>	0	(Advanced) Accepts all cookies
<code>network.cookie.cookieBehavior</code>	1	(Advanced) Accepts only cookies that get sent back to the originating server
<code>network.cookie.cookieBehavior</code>	2	(Advanced) Disables cookies
<code>network.cookie.warnAboutCookies</code>	Boolean	(Advanced) Warns you before accepting a cookie

**Tip**

One preference to watch out for is the one that disables JavaScript. If you disable JavaScript, only the user can reenable JavaScript by manually changing the setting in the browser's preferences dialog box.

### Example

The page in Listing 38-2 displays checkboxes or radio buttons for several preference settings plus one text box to show a preference setting value for the size of the browser's disk cache. You will receive a security warning each time the scripts enable the Privilege Manager.

One function reads all the preferences and sets the form control values accordingly. Another function sets a preference when you click its checkbox. Rerunning the `showPreferences()` function also helps verify that you set the preference.

### Listing 38-2: Reading and Writing Browser Preferences

```
<html>
  <head>
    <title>Reading/Writing Browser Preferences</title>
    <script type="text/javascript">
      function setPreference(pref, value) {
        netscape.security.PrivilegeManager.enablePrivilege(
          "UniversalPreferencesWrite");
        navigator.preference(pref, value);
        netscape.security.PrivilegeManager.revertPrivilege(
          "UniversalPreferencesWrite");
        showPreferences();
      }

      function showPreferences() {
        var form = document.forms[0];
        netscape.security.PrivilegeManager.enablePrivilege(
          "UniversalPreferencesRead");
        form.cacheSize.value =
```

*Continued*

**navigator.preference()****Listing 38-2 (continued)**

```

navigator.preference("browser.cache.disk.capacity");
    form.autoIEnable.checked = navigator.preference("autoupdate.enabled");
    var cookieSetting =
navigator.preference("network.cookie.cookieBehavior");
    for (var i = 0; i < 3; i++) {
        document.getElementById("cookie" + i).checked = (i == cookieSetting)
?
        true : false;
    }
    var toolbarSetting =
navigator.preference("browser.chrome.toolbar_style");
    for (var i = 0; i < 3; i++) {
        document.getElementById("toolbar" + i).checked = (i ==
toolbarSetting) ?
        true : false;
    }
    form.cookieWarn.checked = navigator.preference(
        "network.cookie.warnAboutCookies");
    netscape.security.PrivilegeManager.revertPrivilege(
        "UniversalPreferencesRead");
}
</script>
</head>
<body onload="showPreferences()">

/>
    Warn Before Accepting Cookies<br />
    Disk cache is <input type="text" name="cacheSize" size="10" />
    KB<br />
    </form>
</body>
</html>

```

---

**Related Item:** `navigator.javaEnabled()` method.

**taintEnabled()**

**Returns:** Boolean.

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz-, Safari-

Navigator 3 featured a partially implemented security feature called *data tainting*, which was turned off by default. This feature was replaced by signed scripts; but for backward compatibility, the `navigator.taintEnabled()` method is available in more modern browsers that don't employ tainting (in which case, the method always returns `false`). Do not employ this method in your scripts.

## MimeType Object

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
description		
enabledPlugin		
type		
suffixes		

### Syntax

Accessing `MimeType` properties:

```

navigator.mimeTypes[i].property
navigator.mimeTypes["MimeType"].property

```

**Compatibility:** WinIE-, MacIE5, NN3+, Moz1+, Safari1+

### About this object

A `MimeType` object is essentially an entry in the internal array of `mime` types about which the browser knows. NN3+, for example, ships with an internal list of more than five dozen `mime` types. Only a handful of these types are associated with helper applications or plug-ins. But add to that list all of the plug-ins and other helpers you've added, and the number of `mime` types can grow to more than a hundred.

***MimeTypeObject***

The `mime` type for the data is usually among the first bits of information to arrive at a browser from the server. A `mime` type consists of two pieces of information: type and subtype. The traditional way of representing these pieces is as a pair separated by a slash, as in

```
text/html
image/gif
audio/wav
video/quicktime
application/pdf
application/x-zip-compressed
```

If a file does not contain the `mime` type “header” (or a CGI program sending the file does not precede the transmission with the `mime` type string), the browser receives the data as a text/plain `mime` type. When you load the file from a local hard drive, the browser looks to the filename’s extension (the suffix after the period) to figure out the file’s type.

Regardless of the way it determines the `mime` type of the incoming data, the browser then acts according to instructions it maintains internally. You can see these settings by looking at preferences settings usually associated with the name “Applications.”

By having the `MimeType` object available to JavaScript, your page can query a visitor’s NN3+, MacIE5, or Safari browser to discover whether it has a particular `mime` type listed currently and whether the browser has a corresponding plug-in installed and enabled. In such queries, the `MimeType` and `plugin` objects work together to help scripts make these determinations. (For plug-in detection for WinIE, see the section “Plug-in” detection in WinIE’ later in this chapter.)

Because of the close relationship between `MimeType` and `plugin` objects, I save the examples of using these objects and their properties for a section later in this chapter. There you can see how to build functions into your scripts that enable you to examine how well a visitor’s browser is equipped for either a `mime` type or data that requires a specific plug-in. In the meantime, be sure that you understand the properties of both objects.

## Properties

### description

**Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE5, NN3+, Moz1+, Safari1+

While registering with the browser at launch time, plug-ins provide the browser with an extra field of information: a plain-language description of the plug-in. If a particular `mime` type has a plug-in associated with it and enabled for it, the plug-in’s description passes through to become the description of the `MimeType` object. For example, the Adobe Acrobat plug-in (whose `mime` type is `application/pdf`) supplies the following description fields:

```
(NN3/NN4) Acrobat
(NN6+) Acrobat (*.pdf)
```

When a `mime` type does not have a plug-in associated with it (either no plug-in is installed or a helper application is used instead), you often see the `type` property value repeated in the description field.

### enabledPlugin

**Value:** `plugin` object.

Read-Only

**Compatibility:** WinIE-, MacIE5, NN3+, Moz1+, Safari1+

***MimeTypeObject.type***

The descriptions of the `MimeType` and `plugin` objects seem to come full circle when you reach the `MimeType.enabledPlugin` property. The reason is that the property is a vital link between a known `mime` type and the plug-in that the browser engages when data of that type arrives.

Knowing which plug-in is associated with a `mime` type is very important when you have more than one plug-in capable of playing a given `mime` type. For example, the Crescendo `midi` audio plug-in can take the place of the default audio plug-in if you set up your browser that way. Therefore, all `midi` data streams play through the Crescendo plug-in. If you prefer to have your Web page's `midi` sound played only through another plug-in, your script needs to know which plug-in is set to receive your data and perhaps alert the user accordingly. These kinds of conflicts are not common, except where there is strong competition for players of various audio and video media. For other kinds of content, each plug-in developer typically creates a new type of data that has a unique `mime` type. But you have no guarantee of such uniqueness, so I highly recommend a careful check of `mime` type and plug-in if you want your page to look professional.

The `enabledPlugin` property evaluates to a `plugin` object. Therefore, you can dig a bit deeper with this information to fetch the name or filename properties of a plug-in directly from a `MimeType` object. You can use The Evaluator (with NN3+, MacIE5, and Safari) to study the relationship between `MimeType` and `plugin` objects:

1. Enter the following statement into the bottom text box to examine the properties of a `MimeType` object:

```
navigator.mimeTypes[0]
```

Notice that the `mimeTypes` array returns an object.

2. Inspect the `plugin` object from the bottom text box:

```
navigator.mimeTypes[0].enabledPlugin
```

You then see properties and values for a `plugin` object (described later in this chapter).

3. Check the `plugin` object for a different `MimeType` object by using a different index value:

```
navigator.mimeTypes[7].enabledPlugin
```

The `mimeTypes` array index values vary almost with every browser, depending on what the user has installed. Therefore, do not rely on the index position in a script to assume that a particular `MimeType` object is in that position on all browsers.

## Example

See the section “Looking for `mime` Types and Plug-ins” later in this chapter.

**Related Item:** `plugin` object.

## type

**Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE5, NN3+, Moz1+, Safari1+

A `MimeType` object's `type` property is the combination of the type and subtype commonly used to identify the kind of data coming from the server. CGI programs, for example, typically precede a data transmission with a special header string in the following format:

```
Content-type: type/subtype
```

***MimeTypeObject.type***

This string prompts a browser to look up how to treat an incoming data stream of this kind. As you see later in this chapter, knowing whether a particular `mime` type is listed in the `navigator.mimeTypes` array is not enough. A good script must dig deeper to uncover additional information about what is truly available for your data.

The `type` property has a special place in the `MimeType` object in that its string value can act as the index to the `navigator.mimeTypes` array. Therefore, to get straight to the `MimeType` object for, say, the `audio/wav` `mime` type, your script can reference it directly through the `mimeTypes` array:

```
navigator.mimeTypes["audio/wav"]
```

This same reference can then get you straight to the enabled plug-in (if any) for the `mime` type:

```
navigator.mimeTypes["audio/wav"].enabledPlugin
```

**Example**

See the section “Looking for `mime` Types and Plug-ins” later in this chapter.

**Related Item:** `description` property.

**suffixes**

**Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE5, NN3+, Moz1+, Safari1+

Every `mime` type has one or more filename extensions, or suffixes, associated with it. You can read this information for any `MimeType` object via the `suffixes` property. The value of this property is a string. If the `mime` type has more than one suffix associated with it, the string contains a comma-delimited listing as in

```
mpg, mpeg, mpe
```

Multiple versions of a suffix have no distinction among them. Those `mime` types that are best described in four or more characters (derived from a meaningful acronym, such as `mpeg`) have three-character versions to accommodate the “8-dot-3” filename conventions of MS-DOS and its derivatives.

**Example**

See the section “Looking for `mime` Types and Plug-ins” later in this chapter.

**plugin Object**

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
name	refresh()	
filename		
description		
length		

## Syntax

Accessing `plugin` object properties or method:

```
navigator.plugins[i].property | method()  
navigator.plugins["pluginName"].property | method()
```

**Compatibility:** WinIE-, MacIE5, NN3+, Moz1+, Safari1+

## About this object

The `plugin` object offers a view of the plug-in mechanism from the browser's perspective: The software items registered with the browser at launch time stand ready for any matching `mime` type that comes from the Net. One of the main purposes of having these objects scriptable is to let your scripts determine whether a desired plug-in is currently registered with the browser and to help with installing a plug-in.

The close association between the `plugin` and `contentType` objects, demonstrated by the `contentType.enabledPlugin` property, is equally visible coming from the direction of the plug-in. A `plugin` object evaluates to an array of `mime` types that the plug-in interprets. Use The Evaluator (Chapter 13) to experiment with `mime` types from the point of view of a plug-in. Begin by finding the name of the plug-in that your browser uses for a common animation `mime` type:

1. Enter the following statement into the top text box:

```
navigator.contentType["application/x-shockwave-flash"].enabledPlugin.name
```

If you use NN7+, MacIE5, or Safari, the value returned is probably "Shockwave Flash". Copy the name into the clipboard so that you can use it in subsequent statements. The remaining examples show "LiveAudio" where you should paste in your plug-in's name.

2. Enter the following statement into the top text box:

```
navigator.plugins["Shockwave Flash"].length
```

Instead of the typical index value for the array notation, use the actual name of the plug-in. This expression evaluates to a number indicating the total number of different `mime` types that the plug-in recognizes.

3. Look at the first `mime` type specified for the plug-in by entering the following statement into the top text box:

```
navigator.plugins["Shockwave Flash"][0].type
```

The two successive pairs of square brackets is not a typo: Because the entry in the `plugins` array evaluates to an array itself, the second set of square brackets describes the index of the array returned by `plugins["Shockwave Flash"]`—a period does not separate the sets of brackets. In other words, this statement evaluates to the `type` property of the first `contentType` object contained by the Shockwave/Flash plug-in.

I doubt that you will have to use this kind of construction much; if you know the name of the desired plug-in, you know what `mime` types it already supports. In most cases, you come at the search from the `mime` type direction and look for a specific, enabled plug-in. See the section "Looking for `mime` Types and Plug-ins" later in this chapter for details on how to use the `plugin` object in a production setting.

*pluginObject.name()*

## Properties

name

filename

description

length

**Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE5, NN3+, Moz1+, Safari1+

The first three properties of the `plugin` object provide descriptive information about the plug-in file. The plug-in developer supplies the name and description. It's unclear whether future versions of plug-ins will differentiate themselves from earlier ones via either of these fields. Thus, while there is no explicit property that defines a plug-in's version number, that information may be part of the string returned by the `name` or `description` properties.

Be aware that plug-in authors may not assign the same name to every OS platform version of a plug-in. Be prepared for discrepancies across platforms. You should hope that the plug-in that you're interested in has a uniform name across platforms because the value of the `name` property can function as an index to the `navigator.plugins` array to access a particular `plugin` object directly.

Another piece of information available from a script is the plug-in's filename. On some platforms, such as Windows, this data comes in the form of a complete pathname to the plug-in DLL file; on other OS platforms, only the plug-in filename appears.

Finally, the `length` property of a `plugin` object counts the number of `mime` types that the plug-in recognizes (but is not enabled for necessarily). Although you can use this information to loop through all possible `mime` types for a plug-in, a more instructive way is to have your scripts approach the issue via the `mime` type (as discussed later in this chapter).

## Example

See the section “Looking for `mime` Types and Plug-ins” later in this chapter.

**Related Item:** `mimeType.description` property.

## Methods

`refresh()`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE5, NN3+, Moz1+, Safari1+

You may have guessed that many browsers determine their lists of installed plug-ins while they launch. If you drop a new plug-in file into the `plug-ins` directory/folder, you have to quit the browser and relaunch it before the browser sees the new plug-in file. But that isn't a very friendly approach if you take pains to guide a user through downloading and installing a new plug-in file. The minute the user quits the browser, you have a slim chance of getting that person right back. That's where the `refresh()` method comes in.

The `refresh()` method is directed primarily at the browser, but the syntax of the call reminds the browser to refresh just the plug-ins:

```
navigator.plugins.refresh()
```

Interestingly, this command works only for adding a plug-in to the existing collection. If the user removes a plug-in and invokes this method, the removed one stays in the `navigator.plugins` array — although it may not be available for use. Only the act of quitting and relaunching the browser makes a plug-in removal take full effect.

## Looking for mime Types and Plug-Ins

If you go to great lengths to add new media and data types to your Web pages, you certainly want your visitors to reap the benefits of those additions. But you cannot guarantee that they have the requisite plug-ins installed to accommodate that fancy data. Most modern browser versions provide a bit of internal “smarts” by noticing when data requiring an uninstalled plug-in is about to load and trying to help the user install a missing plug-in. You may wish, however, to take more control over the process by examining the user’s browser plug-in functionality prior to loading the external data file.

The best source of information, when available, is the software developer of the plug-in. Macromedia, for example, provides numerous technical notes on its Web site ([www.macromedia.com](http://www.macromedia.com)) about plug-in detection for its various plug-ins and versions. Unfortunately, that kind of assistance is not always easy to find from other vendors.

A lot of the discussion thus far in this chapter addresses the objects that make plug-in and `mime` type support detection possible in some browsers. Netscape for NN3 initially introduced these objects. Since then, they have been adopted by MacIE5 and Safari. Microsoft makes it possible — but not easy — to determine whether a particular plug-in is available for WinIE. The approach for WinIE is entirely different from what I have covered so far; if you wish to perform cross-browser detection, you have to branch your code accordingly. I outline each approach next in its own section, starting with the NN3+/MacIE5/Safari way.

### Overview: Using `mime` Type and plugin objects

The value of performing your own inspection of plug-in support is that you can maintain better control of your site visitors who don’t have the necessary plug-in yet. Rather than merely providing a link to the plug-in’s download site, you can build a more complete interface around the download and installation of the plug-in without losing your visitor. I have some suggestions about such an interface at the end of this discussion.

How you go about inspecting a visitor’s plug-in library depends on what information you have about the data file or stream and how precise you must be in locating a particular plug-in. Some plug-ins may override `mime` type settings that you normally expect to find in a browser. Another issue that complicates matters is that the same plug-in may have a different name (`navigator.plugins[i].name` property), depending on the operating system. Therefore, searching your script for the presence of a plug-in by name is not good enough if the name differs from the Macintosh version to the Windows version. Fortunately, this is less of an issue today than it was in earlier plug-in generations.

One other point that can help you decide the precise approach to take is which information about the plug-in — support for the data `mime` type or the presence of a particular plug-in — is important to your page and scripts. If your scripts rely on the existence of a plug-in that you can script via LiveConnect, be sure that the plug-in is present and enabled for the desired `mime` type (so that the plug-in is ensured of loading when it encounters a reference to the URL of the external data). But if you care only that a plug-in of any kind supports your data’s `mime` type, you can simply make sure that any plug-in is enabled for your MIME type.

To help you jump-start the process in your scripts, I discuss three utility functions you can use in your own scripts. These functions are excerpts from a long listing (Listing 38-3), which is

located in its entirety among the Chapter 38 listing files on this CD-ROM. The pieces not shown here are merely user interface elements that enable you to experiment with these functions.

## Verifying a mime type

Listing 38-3a is a function whose narrow purpose is to determine if the browser currently has plug-in support enabled for a given mime type (in the *type/subtype* format as a string). The first `if` construction verifies that there is a `mime` object for the supplied mime type string. If such an object exists, the next `if` construction determines whether the `enabledPlugin` property of the `mime` object returns a valid object. If so, the function returns `true`—meaning that the mime type has a plug-in (of unknown supplier) available to play the external media.

### Listing 38-3a: Verifying a MIME Type

```
// Pass "<type><subtype>" string to this function to find
// out if the MIME type is registered with this browser
// and that at least some plug-in is enabled for that type.
function mimeIsReady(mime_type) {
    if (navigator.mimeTypes[mime_type]) {
        if (navigator.mimeTypes[mime_type].enabledPlugin) {
            return true;
        }
    }
    return false;
}
```

## Verifying a plug-in

In Listing 38-3b, you let JavaScript see if the browser has a specific plug-in registered in the `navigator.plugins` array. This method approaches the installation question from a different angle. Instead of querying the browser about a known mime type, the function inquires about the presence of a known plug-in. But because more than one registered plug-in can support a given mime type, this function explores one step further to see whether at least one of the plug-in's mime types (of any kind) is enabled in the browser.

### Listing 38-3b: Verifying a Plug-In

```
// Pass the name of a plug-in for this function to see
// if the plug-in is registered with this browser and
// that it is enabled for at least one MIME type of any kind.
function pluginIsReady(plugin) {
    plugin = plugin.toLowerCase();
    for (var i = 0; i < navigator.plugins.length; i++) {
        if (navigator.plugins[i].name.toLowerCase().indexOf(plugin) != -1) {
            for (var j = 0; j < navigator.plugins[i].length; j++) {
                if (navigator.plugins[i][j].enabledPlugin) {
                    return true;
                }
            }
        }
    }
    return false;
}
```

```

    }
    return false;
}

```

The parameter for the `pluginIsReady()` function is a string consisting of the plug-in's name. As discussed earlier, the precise name may vary from OS to OS or from version to version. The function here assumes that you aren't concerned about plug-in versioning. It also assumes (with reasonably good experience behind the assumption) that a brand-name plug-in contains a string with the brand in it. Thus, the `pluginIsReady()` function simply looks for the existence of the passed name within the `plugin` object's `name` property. For example, this function accepts "QuickTime" as a parameter and agrees that there is a match with the plug-in named "QuickTime Plug-in 6.0.2". The script loops through all registered plug-ins for a substring comparison (converting both strings to all lowercase to help overcome discrepancies in capitalization).

Next comes a second repeat loop, which looks through the `mime` types associated with a plug-in (in this case, only a plug-in whose name contains the parameter string). Notice the use of the strange, double-array syntax for the most nested `if` statement: For a given plug-in (denoted by the `i` index), you have to loop through all items in the `mime` types array (`j`) connected to that plug-in. The conditional phrase for the last `if` statement has an implied comparison against `null` (see another way of explicitly showing the `null` comparison in Listing 38-3a). The conditional statement evaluates to either an object or `null`, which JavaScript can accept as `true` or `false`, respectively. The point is that if an enabled plug-in is found for the given `mime` type of the given plug-in, this function returns `true`.

## Verifying both plug-in and mime type

The last utility function (Listing 38-3c) is the safest way of determining whether a visitor's browser is equipped with the "right stuff" to play your media. This function requires both a MIME type and plug-in name as parameters and also makes sure that both items are supported and enabled in the browser before returning `true`.

### Listing 38-3c: Verifying Plug-in and mime Type

```

// Pass "<type>/<subtype>" and plug-in name strings for this
// function to see if both the MIME type and plug-in are
// registered with this browser, and that the plug-in is
// enabled for the desired MIME type.
function mimeAndPluginReady(mime_type,plug_in) {
    if (mimeIsReady(mime_type)) {
        var pluginOfRecord = navigator.mimeTypes[mime_type].enabledPlugin;
        plug_in = plug_in.toLowerCase();
        for (var i = 0; i < navigator.plugins.length; i++) {
            if (navigator.plugins[i].name.toLowerCase().indexOf(plug_in) != -1) {
                if (navigator.plugins[i] == pluginOfRecord) {
                    return true;
                }
            }
        }
    }
}
return false;
}

```

This function starts by calling the `mimeIsReady()` function from Listing 38-3a. After that, the function resembles the one in Listing 38-3b until you reach the most nested statements. Here, instead of looking for any old `mime` type, you insist on the existence of an explicit match between the `mime` type passed as a parameter and an enabled `mime` type associated with the plug-in. To see how these functions work on your NN3+, MacIE5, or Safari browser, open the complete file (`lst38-03.htm`) from this CD-ROM. The actual listing also includes code that branches around IE for Windows and other browsers that don't support this way of inspecting `mime` types and plug-ins.

## Managing manual plug-in installation

If your scripts determine that a visitor does not have the plug-in your data expects, you may want to consider providing an electronic guide to installing the plug-in. One way to do this is to open a new frameset (in the main window). One frame can contain step-by-step instructions with links to the plug-in's download site. The download site's page can appear in the other frame of this temporary window. The steps must take into account all installation requirements for every platform, or, alternatively, you can create a separate installation document for each unique class of platform. For instance, you must decode Macintosh files frequently from `binhex` format and then uncompress them before you move them into the plug-ins folder. Other plug-ins have their own, separate installation program. The final step should include a call to

```
navigator.plugins.refresh()
```

to make sure that the browser updates its internal listings. After that, the script can return to the `document.referrer`, which should be the page that sends the visitor to the installation pages. All in all, the process is cumbersome—it's not like downloading a Java applet. But if you provide some guidance, you stand a better chance of the user returning to play your cool media. Also consider letting the browser's own updating facilities handle the job (albeit not as smoothly in many cases) by simply loading the data into the page, ready or not.

## “Plug-in” detection in WinIE

WinIE4+ provides some built-in facilities that may take the place of plug-in detection in some circumstances. First of all, it's important to recognize that WinIE does not use the term “plug-in” in the same way that Netscape and other browsers use it. Due to the integration between IE and the Windows operating system, WinIE employs system-wide ActiveX controls to handle the job of rendering external content. Some of these controls are designed to be accessed from outside their walls, thus allowing client-side scripts to get and set properties or invoke methods built into the controls. These controls behave a lot like plug-ins, so you frequently see them referenced as “plug-ins,” as they are in this book.

WinIE prefers the `<object>` tag for both loading the plug-in (ActiveX control) and assigning external content to it. One of the attributes of the `object` element is `classid`, which points to a monstrously long string of hexadecimal numbers known as the `guid` (Globally Unique Identifier). When the browser encounters one of these `guids`, it looks into the Windows Registry to get the path to the actual plug-in file. If the plug-in is not installed on the user's machine, the object doesn't load and any other HTML nested inside the `<object>` tag renders instead. Thus, you can display a static image placeholder or HTML message about the lack of the plug-in. But plug-in detection comes in most handy when your scripts need to communicate with the plug-in, such as directing an embedded Windows Media Player plug-in to change sound files or to play. When you build code around a scriptable plug-in, your scripts should make sure that the plug-in object is indeed present so they don't generate errors.

The idea of using the `<object>` tag instead of the `<embed>` tag is that the `<object>` tag loads a specific plug-in, whereas the `mime` type of the data referenced by the `<embed>` tag lets the browser determine which plug-in to use for that `mime` type. It's not uncommon, therefore, to see an `<object>` tag definition surround an `<embed>` tag — both referencing the same external data file. If the optimum plug-in fails to load, the `<embed>` tag is observed, and the browser tries to find any plug-in for the file's `mime` type.

With an `object` element as part of the HTML page, the element itself is a valid object — even if the plug-in fails to load. Therefore, you must do more to validate the existence of the loaded plug-in than simply test for the existence of the `object` element. To that end, you need to know at least one scriptable property of the plug-in. Unfortunately, not all scriptable plug-ins are fully documented, so you occasionally must perform some detective work to determine which scriptable properties are available. While you're on the search for clues, you can also determine the version of the plug-in and make it a minimum version that your `object` element allows to load.

## Tracking down plug-in details

Not everyone has access to the Microsoft programming development environments (for example, Visual Studio) through which you can find out all kinds of information about an installed ActiveX control. If you don't have access, you can still dig deep to get most (if not all) of the information you need. The tools you can use include the Windows Registry Editor (`regedit`), The Evaluator (Chapter 13), and, of course, your text editor and WinIE4+ browser. The following steps take you through finding out everything you need to know about the Windows Media Player control:

1. If you don't know the `guid` for the Media Player (most people get it by copying someone else's code that employs it), you can use the Registry Editor (`regedit.exe`) to find it. Open the Registry Editor (in Win95/98/NT/XP, choose Run from the Start menu and enter `regedit`; if that option is not available in your Windows version, search for the file named `regedit`).
2. Expand the `HKEY_CLASSES_ROOT` folder.
3. Scroll down to the nested folder named `CLSID`, and click that folder.
4. Choose Edit/Find, and enter `Windows Media Player`. If you were searching for a different plug-in, you would enter an identifying name (usually the product name) in this place.
5. Keep pressing F3 (Find Next) until the editor lands upon a folder whose default value (in the right side of the Registry Editor window) shows `Windows Media Player`.
6. The number inside curly braces next to the highlighted folder is the plug-in's `guid`. Right-click the number and choose Copy Key Name. Paste the number into your document somewhere for future reference. Eventually, it will be part of the value assigned to the `classid` attribute of the `object` element.
7. Expand the highlighted folder.
8. Click the folder named `InprocServer32`. The default value should show a pathname to the actual ActiveX control for the Windows Media Player plug-in.
9. Right-click the (Default) name for the path and choose Modify. The full pathname is visible in an editable field.
10. Armed with this pathname information, open My Computer and locate the actual file inside a directory listing.

11. Right-click the file and choose Properties.
12. Click the Version tab (if present).
13. Copy the version number (generally four sets of numbers delimited by commas), and paste it into your document for future reference. Eventually, it will be assigned to the `codebase` attribute of the `object` element.

You are now ready to try loading the plug-in as an object and look for properties you can test for.

14. Add an `object` tag to The Evaluator source code. This can go inside the `head` or just before the `</body>` tag. For example, your tag should look something like the following:

```
<object id="wmp" width="1" height="1"
classid="CLSID:0A4286EA-E355-44FB-8086-AF3DF7645BD9"
codebase="#Version=9,0,0,2980">
</object>
```

Copy and paste the numbers for the `guid` and version. Two points to watch out for: First, be sure that the `guid` value is preceded by `CLSID:` in the value assigned to `classid`; second, be sure the version numbers are preceded by the prefix shown.

15. Load (or reload) the page in WinIE4+.

At this point, the `wmp` object should exist. If the associated plug-in loads successfully, the `wmp` object's properties include properties exposed by the plug-in.

16. Enter `wmp` into the bottom text box to inspect properties of the `wmp` object. Be patient: It may take many seconds for the retrieval of all properties.

In case you can't readily distinguish between the `object` element object properties and properties of the scriptable plug-in, scroll down to the `wmp.innerHTML` property and its values. When an object loads successfully, any parameters that it accepts are reflected in the `innerHTML` for the `object` element. Each `param` element has a name—the name of one of the scriptable properties of the plug-in.

17. Look for one of the properties that has some kind of value by default (in other words, other than an empty string or `false`). In Windows Media Player, this can be `CreationDate`. Use this property as an object detection condition in scripts that need to access the Windows Media Player properties or methods:

```
if (wmp && wmp.CreationDate) {
    // statements that "talk to" plug-in
}
```

## Setting a minimum version number

The four numbers that you grab in step 13 in the previous section represent the version of the plug-in as installed on your computer. Unless you have a way of verifying that your external content runs on earlier versions of the plug-in (if there are earlier versions), you can safely specify *your* version as the minimum.

Specificity rankings for the four numbers of a version decrease as you move from left to right. For example, version 9,0,25,2 is later than 9,0,0,0; version 10,0,0,0 is later than both of them. If you specify 9,0,25,2, and the user has 9,0,24,0 installed, the plug-in does not load and the object isn't available for scripting. On the other hand, a user with 9,0,26,0 has the object present because the `codebase` attribute for the version specifies a minimum allowable version to load.

## When an object requires VBScript

Not all objects that load via the `object` element are scriptable through JavaScript (JScript). Occasionally, an object is designed so that its properties are exposed only to VBScript. This happens, for example, with the Microsoft Windows Media Rights Manager (DRM) object. To find out if the browser (operating system) is equipped with DRM, your page loads the object via the `object` element as usual; however, a separate VBScript section must access the object to test for the existence of one of its properties. Because script segments written in either language can access each other, this isn't a problem provided you know what the property or method is for the object. The following fragment from the Head section of a document demonstrates how JavaScript and VBScript can interact so that JavaScript code can branch based on the availability of DRM:

```
<head>
<object id="drmObj" height="1" width="1"
classid="CLSID:760C4B83-E211-11D2-BF3E-00805FBE84A6"></object>
<script type="text/vbscript">
function hasDRM()
  on error resume next
  drmObj.StoreLicense("")
  if (err.number = 0) then
    hasDRM = true
  else
    hasDRM = false
  end if
end function
</script>
<script type="text/javascript">
var gHasDRM;
if (drmObj && hasDRM()) {
  gHasDRM = true;
} else {
  gHasDRM = false;
}
</script>
</head>
```

The JavaScript segment sets a Boolean global variable to indicate whether the object has loaded correctly. Part of the job is accomplished via the `hasDRM()` function in the VBScript segment. From VBScript, the `drmObj` object responds to the `StoreLicense()` method call, but it throws a VBScript error indicating that no parameter was sent along with the method. Any subsequent scripts in this page can use the `gHasDRM` global variable as a conditional expression before performing any actions requiring the object (which works in tandem with the Windows Media Player).

## screen Object

*Continued*

## screen

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
bufferDepth		
colorDepth		
fontSmoothingEnabled		
height		
pixelDepth		
updateInterval		
width		

## Syntax

Accessing screen object properties:

```
(All)    screen.property
(IE4+)  [window.]navigator.screen.property
```

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

## About this object

Browsers other than from the earliest generations provide a `screen` object that lets your scripts inquire about the size and color settings of the video monitor used to display a page. Properties are carefully designed to reveal not only the raw width and height of the monitor (in pixels), but also what the available width and height are once you take into account the operating system's screen-hogging interface elements (for example, the Windows taskbar and the Mac menu bar).

Internet Explorer 4 provides a `screen` object, although it appears as a property of the `window` object in the IE4+ object model. Only three properties of the IE4+ `screen` object — `height`, `width`, and `colorDepth` — share the same syntax as NN4+'s `screen` object.

## Properties

```
availHeight
availWidth
height
width
```

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

With the availability of window sizing methods in version 4 browsers and later, your scripts may want to know how large the user's monitor is. This is particularly important if you set up an application to run in kiosk mode, which occupies the entire screen. Two pairs of properties let scripts extract the dimensions of the screen. All dimensions are in pixels.

You can extract the gross height and width of the monitor from the `screen.height` and `screen.width` properties. Thus, a monitor rated as a 1024 × 768 monitor returns values of 1024 and 768 for `width` and `height`, respectively.

**screen.availLeft**

But not every pixel of the screen's gross size is available as displayable area for a window. To the rescue come the `screen.availWidth` and `screen.availHeight` properties. For example, 32-bit Windows operating systems display the taskbar. The default location for this bar is at the bottom of the window, but users can reorient it along any edge of the screen. If the default behavior of always showing the taskbar is in force, the bar takes away from the screen real estate available for window display (unless you intentionally size or position a window so that part of the window extends under the bar). When along the top or bottom edge of the screen, the taskbar occupies 28 vertical pixels; when positioned along one of the sides, the bar occupies 60 horizontal pixels. On the Macintosh platform, the 20-pixel-deep menu bar occupies a top strip of the screen. Although you can position and size windows so the menu bar partially covers them, it is not a good idea to open a window in (or move a window into) that location.

You can use the available screen size values as settings for window properties. For example, to arrange a window so that it occupies all available space on the monitor, you must position the window at the top left of the screen and then set the outer window dimensions to the available sizes as follows:

```
function maximize() {
    window.moveTo(0,0);
    window.resizeTo(screen.availWidth, screen.availHeight);
}
```

The preceding function positions the window appropriately on the Macintosh just below the menu bar so that the menu bar does not obscure the window. If, however, the client is running Windows and the user positions the taskbar at the top of the screen, the window is partially hidden under the taskbar (you cannot query the available screen space's coordinates). Also in Windows, the appearance is not exactly the same as a maximized window. See the discussion of the `window.resizeTo()` method in Chapter 16 for more details. Note that MacIE generally returns a value for `screen.availHeight` that is about 24 pixels fewer than the actual available height (even after taking into account the Mac menu bar).

For Navigator 3+ and Mozilla, you can use LiveConnect to access a native Java class that reveals the overall screen size (not the available screen size). If the user runs Navigator 3 and Java is enabled, you can place the following script fragment in the Head portion of your document to set variables with screen width and height:

```
var toolkit = java.awt.Toolkit.getDefaultToolkit();
var screenSize = toolkit.getScreenSize();
```

The `screenSize` variable is an object whose properties (`width` and `height`) contain the pixel measures of the current screen. This LiveConnect technique works only in Netscape and Mozilla browsers (IE does not provide direct access to Java classes). In fact, you can also extract the screen resolution (pixels per inch) in the same manner. The following statement, added after the preceding ones, sets the variable resolution to that value:

```
var resolution = toolkit.getScreenResolution();
```

**Related Items:** `window.innerHeight`, `window.innerWidth`, `window.outerHeight`, `window.outerWidth` properties; `window.moveTo()`, `window.resizeTo()` methods.

**availLeft****availTop**

**FTR:** `screen.availLeft`

**Value:** Integer.

**Compatibility:** WinIE-, MacIE-, NN4+, Moz1+, Safari1+

Read-Only

**screen.availLeft**

The `availLeft` and `availTop` properties return the pixel measure of where the available space of the screen begins. The only time these values are anything other than zero is when a user positions the taskbar along the left or top edges of the screen. For example, if the user positions the taskbar along the top of the screen, you do not want to position a window any higher than the 28 pixels occupied by the taskbar. There are no corresponding properties for IE.

**Example**

If you are a Windows user, you can experiment with these NN4+ properties via The Evaluator (Chapter 13). With the taskbar at the bottom of the screen, enter these two statements into the top text box:

```
screen.availLeft
screen.availTop
```

Next, drag the taskbar to the top of the screen and try both statements again. Now, drag the taskbar to the left edge of the screen and try the statements once more.

**Related Items:** `screen.availWidth`, `screen.availHeight` properties; `window.moveTo()` method.

**bufferDepth**

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

By default, IE does not use any offscreen buffering of page content. But adjusting the `bufferDepth` property enables you to turn on offscreen buffering and control the color depth of the buffer. Using offscreen buffering may improve the smoothness of path-oriented animation through positioning.

The default value (buffering turned off) is 0. By setting the property to -1, you instruct IE to set the color depth of the offscreen buffer to the same color depth as the screen (as set in the control panel). This should be the optimum value, but you can also force the offscreen buffer to have one of the following bit depths: 1, 4, 8, 15, 16, 24, or 32.

**Related Items:** `screen.colorDepth`, `screen.pixelDepth` properties.

**colorDepth****pixelDepth**

**Value:** Integer.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1\_

You can design a page with different color models in mind because your scripts can query the client to find out how many colors the user sets the monitor to display. This is helpful if you have more subtle color schemes that require 16-bit color settings or images tailored to specific palette sizes.

Both the `screen.colorDepth` and `screen.pixelDepth` properties return the number of color bits to which the color client computer's video display control panel is set. The `screen.colorDepth` value may take into account a custom color palette; so for NN4+, you may prefer to rely only on the `screen.pixelDepth` value. (IE4+, however, supports only the `screen.colorDepth` property of this pair.) You can use this value to determine which of two image versions to load, as shown in the following script fragment that runs as the document loads:

```

if (screen.colorDepth > 8 ) {
    document.write("<img src='logoHI.jpg' height='60' width='100' />");
} else {
    document.write("<img src='logoL0.jpg' height=width='100' />");
}

```

In this example, the `logoHI.jpg` image is designed for 16-bit displays or better, while the colors in `logoL0.jpg` are tuned for 8-bit display.

**Related Item:** `screen.bufferDepth` property.

## fontSmoothingEnabled

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

Some versions of the Windows OS have a Display control panel setting for “Smooth Edges” on screen fonts. The `fontSmoothingEnabled` property lets your script see the state of that setting. This setting can affect, for example, which stylesheet you enable because it has font specifications that look good only when smoothing is enabled. A default installation of Windows has this feature turned off.

## updateInterval

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `updateInterval` property is the number of milliseconds between screen updates. The default value of zero lets IE arbitrate among the demands for screen updates in a highly animated setting. If you set this value to a large number, more screen updates are accumulated in a buffer — preventing some animated steps from updating the screen.

# userProfile Object

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
	<code>addReadRequest()</code> <code>clearRequest()</code> <code>doReadRequest()</code> <code>getAttribute()</code>	

## Syntax

Accessing `userProfile` object methods:

```
(IE4+) [window.]navigator.userProfile.method()
```

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

## About this object

The `userProfile` object is an IE-specific (and Windows, at that) property that acts as the gateway to the user profile information that the client computer collects from the user. You can retrieve none of this information via JavaScript without permission from the user. Access to this information is performed in a strict sequence, part of which enables you to define how the request for this private information is worded when the user is presented with the request.

User profile data consists of nearly 30 fields of personal information about the user's contact information. Each of these fields has a name, which by and large conforms to the vCard standard. Your scripts can request one or more specific fields from the list, rather than having to deal with the entire set of fields.

The sequence for accessing this data entails four basic steps:

1. Put the request for each vCard field into a queue that is maintained in the browser's memory (via the `addReadRequest()` method).
2. Execute the batch request, which displays a detailed dialog box to the user (via the `doReadRequest()` method). If a user profile is in effect, the user sees which fields you are requesting plus the data in the vCard. The user then has the chance to deselect one or more of your choices — or disallow access completely.
3. Get each attribute by name (via the `getAttribute()` method). You invoke this method once for each vCard field.
4. Clear the queue of requests (via the `clearRequest()` method).

Returned values are strings. Thus, you can prefill the customer information for an order form or capture the information in hidden fields that are submitted with a visible form.

Listing 38-4 demonstrates the use of the four key methods of the `userProfile` object. After the page loads, it attempts to extract the data from every vCard field and displays both the attribute name and the value as associated with the current user profile in a table. Notice that the names of the attributes are hard-wired because the object does not provide a list of implemented attributes.

### Listing 38-4: Accessing userProfile Data

```
<html>
  <head>
    <title>userProfile Object</title>
    <script type="text/javascript">
      var attrs = ["Business.City","Business.Country","Business.Fax",
        "Business.Phone","Business.State","Business.StreetAddress",
        "Business.URL","Business.Zipcode","Cellular","Company","Department",
        "DisplayName","Email","FirstName","Gender","Home.City","Home.Country",
        "Home.Fax","Home.Phone","Home.State","Home.StreetAddress",
        "Home.Zipcode","Homepage","JobTitle","LastName","MiddleName",
        "Office","Pager"];
      function loadTable() {
        // make sure this executes only in IE4+ for Windows
        if ((navigator.userAgent.indexOf("Win") != -1) &&
          navigator.userProfile) {
          var newRow, newCell, attrValue;
          // queue up requests for every vCard attribute
          for (var i = 0; i < attrs.length; i++) {
            navigator.userProfile.addReadRequest("vCard." + attrs[i]);
```

**userProfile.addReadRequest()**

```

    }
    // dispatch the request to let user accept or deny access
    navigator.userProfile.doReadRequest(1, "JavaScript Bible");
    // append rows to the table with attribute/value pairs
    for (var j = 0; j < attrs.length; j++) {
        newRow = document.all.attrTable.insertRow(-1);
        newRow.bgColor = "#FFFF99";
        newCell = newRow.insertCell(0);
        newCell.innerHTML = "vCard." + attrs[j];
        newCell = newRow.insertCell(1);
        // get the actual value
        attrValue = navigator.userProfile.getAttribute("vCard." +
            attrs[j]);
        newCell.innerHTML = (attrValue) ? attrValue : "&nbsp;";
    }
    // clean up after ourselves
    navigator.userProfile.clearRequest();
} else {
    alert("This example requires IE4+ for Windows.");
}
}
</script>
</head>
<body onload="loadTable()">
<h1>userProfile Object</h1>
<hr />
<table id="attrTable" border="1" cellpadding="5">
<tr bgcolor="#CCFFFF">
<th>vCard Property</th>
<th>Value</th>
</tr>
</table>
</body>
</html>

```

It appears that the newer the version of Windows that the user runs, the more likely that user profile data is available. Even so, there may be little more than name and address data for those users who are careful not to fill out optional fields of Microsoft Web site forms requesting personal information.

Comparable information may be available from NN4+ users on any OS platform via signed scripts that access `ldap` preferences. See the discussion earlier in this chapter about the `navigator.preference()` method.

## Methods

### `addReadRequest("attributeName")`

**Returns:** Boolean.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

Before the user is asked for permission to reveal any personal information, you must queue up requests — even if there is just one field in which you are interested. For each field, use the `addReadRequest()` method and specify as the parameter a string of the attribute name. Acceptable attribute names are as follows:

**userProfile.addReadRequest()**

```

vCard.Business.City
vCard.Business.Country
vCard.Business.Fax
vCard.Business.Phone
vCard.Business.State
vCard.Business.StreetAddress
vCard.Business.URL
vCard.Business.Zipcode
vCard.Cellular
vCard.Company
vCard.Department
vCard.DisplayName
vCard.Email
vCard.FirstName
vCard.Gender
vCard.Home.City
vCard.Home.Country
vCard.Home.Fax
vCard.Home.Phone
vCard.Home.State
vCard.Home.StreetAddress
vCard.Home.Zipcode
vCard.Homepage
vCard.JobTitle
vCard.LastName
vCard.MiddleName
vCard.Office
vCard.Pager

```

All attribute values are case-insensitive.

This method returns a Boolean value of `true` if the addition to the queue succeeds. A returned value of `false` usually means that the attribute value is not valid or that a request for that attribute name is already in the queue. If you fail to clear the queue after compiling one list of attributes, attempts to read the attribute result in a return value of `false`.

**Example**

See Listing 38-4 for an example of the `addReadRequest()` method in action. You can also invoke it from the top text box in The Evaluator. For example, enter the following statement to queue one request:

```
navigator.userProfile.addReadRequest("vCard.LastName")
```

To continue the process, see examples for `doReadRequest()` and `getAttribute()` later in this chapter.

**Related Items:** `clearRequest()`, `doReadRequest()`, and `getAttribute()` methods.

**clearRequest()**

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

After retrieving the attributes whose names are stacked in the request queue, invoke the `clearRequest()` method to empty the queue. It is always good programming practice to clean up after yourself, especially when security concerns are involved.

**Related Items:** `addReadRequest()`, `doReadRequest()`, and `getAttribute()` methods.

**userProfile.doReadRequest()**

```
doReadRequest(reasonCode, identification[,  
domain[, path[, expiration]]])
```

**Returns:** Nothing.

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

Once the names of the desired vCard attributes are stacked in the queue (via the `addReadRequest()` method), invoke the `doReadRequest()` method to prompt the user for the permission that your scripts need to gain access to the data. The user sees a detailed dialog box that lists the vCard fields you are requesting, as well as a description about your reason for wanting the data and who you are.

The first required parameter is an integer representing one of the standard descriptions as defined by the Internet Privacy Working Group. Associated text is displayed in the permission request dialog box that the user sees. The codes and their strings are as follows:

<b>Code</b>	<b>Description String</b>
0	Used for system administration.
1	Used for research and/or product development.
2	Used for completion and support of current transaction.
3	Used to customize the content and design of a site.
4	Used to improve the content of the site, including advertisements.
5	Used for notifying visitors about updates to the site.
6	Used for contacting visitors for marketing of services or products.
7	Used for linking other collected information.
8	Used by site for other purposes.
9	Disclosed to others for customization or improvement of the content and design of the site.
10	Disclosed to others, who may contact you, for marketing of services and/or products.
11	Disclosed to others, who may contact you, for marketing of services and/or products; you have the opportunity to ask a site not to do this.
12	Disclosed to others for any other purpose.

Although these description strings are fixed, you do have an opportunity to include some customized information in the second parameter. The parameter is intended to enable you to identify the Web site or organization requesting the information. Standards recommendations suggest you include a URL to the site, as well. In any case, the second parameter can be any string. But it is not treated like HTML, so do not attempt to include a clickable link here.

Two optional parameters enable you to specify a domain and path within that domain for which the user permissions are to apply. Both of these parameters closely mirror their usage in cookies, but they also depend on the capability to set an expiration date via the fifth parameter. Through IE6, however, the expiration date parameter is ignored. Therefore, permissions expire when the user quits the browser (just like temporary cookies do).

### Example

See Listing 38-4 for an example of the `doReadRequest()` method in action. If you entered the `addReadRequest()` example for The Evaluator earlier in this chapter, you can now bring up the permissions dialog box (if you have a user profile for your version of Windows) by entering the following statement into the top text box:

**userProfile.doReadRequest()**

```
navigator.userProfile.doReadRequest(1, "Just me!")
```

**Related Items:** `addReadRequest()`, `clearRequest()`, and `getAttribute()` methods.

**getAttribute("attributeName")**

**Returns:** String.

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `getAttribute()` method attempts to retrieve the vCard data based on the items queued via the `addReadRequest()` method. A permission dialog box provides the user an opportunity to choose which of the requested items to reveal or to deny all access to the information. Only one attribute name is permitted as a parameter to the `getAttribute()` method, requiring that you invoke the method for each attribute you want to fetch.

**Example**

See Listing 38-4 for an example of the `getAttribute()` method in action. Also, if you followed The Evaluator examples for this object, you can now extract the desired information (provided it is in your user profile). Enter the following statement into the top text box:

```
navigator.userProfile.getAttribute("vCard.LastName")
```

**Related Items:** `addReadRequest()`, `clearRequest()`, and `doReadRequest()` methods.

# Positioned Objects

---

This chapter tackles positioned objects and layers, and investigates the history of Dynamic HTML — the capability to alter content on the fly in response to user interaction — particularly with respect to Netscape Navigator 4, chronologically the first browser to offer these features. The original impetus for this chapter was the NN4 `layer` element and its associated object. What makes this discussion awkward is that the `layer` element and object became dead-end entities that never made it into the W3C standards process. NN6+/Moz instead have adopted the W3C standards for dynamic content, which more closely mimic the way Microsoft implemented its DHTML features starting with IE4. NN6+/Moz explicitly do not provide backward compatibility with scripted `layer` element objects, which also means that you must rewrite legacy Netscape Navigator applications to work in NN6+/Moz, if you haven't been done so already.

That leaves an ungainly task in this chapter to create a bridge between the old `layer` element and the more modern way of working with elements that can be positioned on the page, flown across the page, stacked in front of other elements, or hidden from view. The IE4+ and NN6+/W3C DOM way to accomplish all of this is through Cascading Style Sheets and the scripting thereof.

The NN4 `layer` element is well on its way to becoming a distant memory. But for the sake of historical completeness, the first half of this chapter covers the details of the now defunct `layer` and `ilayer` objects. The second half demonstrates how to apply CSS and modern DOM techniques to manage positioned elements in Mozilla-based browsers, Safari, and others.

## What Is a Layer?

Terminology in the area of positioned elements has become a bit confusing over time. Because NN4 was the earliest browser to be released with positioned elements (the `layer` element), the term *layer* became synonymous with any positioned element. When IE4 came on the scene, it was convenient to call a stylesheet-positioned element (in other words, an element governed by a stylesheet rule with the `position` attribute) a *layer* as a generic term for any positioned element. In fact, NN4 even treated an element that was positioned through stylesheets as if it were a genuine layer object (although with some minor differences).

In the end, the *layer* term made good sense because no matter how it was achieved, a positioned element acted like a layer in front of the body content of a page. Perhaps you have seen how animated cartoons were created before computer animation changed the art.

### In This Chapter

Layer concepts

How to move, hide, and show content

The end of the `layer` element

**document.layerObject**

Layers of clear acetate sheets were assembled atop a static background. Each sheet contained one character or portion of a character. When all the sheets were carefully positioned atop each other, the view (as captured by a still camera) formed a composite frame of the cartoon. To create the next frame of the cartoon, the artist moved one of the layers a fraction of an inch along its intended path and then took another picture.

If you can visualize how that operation works, you have a good starting point for understanding how layers work. Each layer contains some kind of HTML content that exists in its own plane above the main document that loads in a window. You can change or replace the content of an individual layer on the fly without affecting the layout of the other layers; you can also reposition, resize, or hide the entire layer under script control.

One aspect of layers that goes beyond the cartoon analogy is that a layer can contain other layers. When that happens, any change that affects the primary layer—such as moving the layer 10 pixels downward—also affects the layers nested inside. It’s as if the nested layers are passengers of the outer layer. When the outer layer goes somewhere, the passengers do, too. And yet, within the “vehicle,” the passengers may change seats by moving around without regard for what’s going on outside.

With this analogy in mind, many commercial DHTML development tools and content authors refer to positioned elements as layers, which you can move, resize, stack, and hide independently of the body background. Therefore, references throughout this book to layers may mean anything from the NN4 layer object to an element positioned by way of stylesheets.

## NN4 layer Object

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
above	captureEvents()	onblur
background	handleEvent()	onfocus
below	load()	onload
bgcolor	moveAbove()	onmouseout
clip.bottom	moveBelow()	onmouseover
clip.left	moveBy()	
clip.right	moveTo()	
clip.top	moveToAbsolute()	
document	releaseEvents()	
left	resizeBy()	
name	resizeTo()	
pageX	routeEvent()	
pageY		
parentLayer		
siblingAbove		
siblingBelow		
src		
top		
visibility		
zIndex		

## Syntax

Accessing layer object properties or methods:

```
[window.]document.layerName.[document.layerName. ...] property |
method([parameters])
[window.]document.layers[index].[document.layerName. ...]property |
method([parameters])
```

Compatibility: WinIE-, MacIE-, NN4, Moz-, Safari-

## About this object

You can create a layer object in NN4 in one of three ways. The first two ways use NN4-only syntax: the `<layer>` tag in HTML and the new `Layer()` constructor in JavaScript. The tag offers numerous attributes that establish the location, stacking order, and visibility. These attributes, in turn, become scriptable properties. If you create the layer through the constructor, you then use JavaScript to assign values to the object's properties.

The third way to create an NN4 layer object is to assign an absolute-positioned stylesheet rule to a block-level element—most typically a `div` element. This is the way that IE4+ and NN6+ do it, too. In practice, however, a positioned `div` element is not as robust (from rendering and scriptability standpoints) in NN4 as a genuine layer element. Therefore, it is sometimes necessary to branch a page's code to use `document.write()` for a `<layer>` tag in NN4 and a `<div>` tag in IE4+ and NN6+.

## Layer references

The task of assembling JavaScript references to NN4 layers and the objects they contain resembles the same process for framesets (in fact, conceptually, a layer is like a dynamically movable and resizable free-floating frame). Therefore, before you start writing the reference, you must know the relationship between the document *containing* the script and the target of the reference.

To demonstrate how this works, I start with a script in the base document loaded into a window that needs to change the background color (`bgColor` property) of a layer defined in the document. The skeletal HTML is as follows:

```
<html>
  <head>
  </head>
  <body>
    <layer name="Flintstones" src="flintstonesFamily.html"></layer>
  </body>
</html>
```

From a script in the Head section, the statement that changes the layer's `bgColor` property is this:

```
document.Flintstones.bgColor = "yellow";
```

This syntax looks like the way you address any object in a document, such as a link or image. However, things get tricky in that each layer automatically contains a `document` object of its own. That `document` object is what holds the content of the layer. Therefore, if you want to inspect the `lastModified` property of the HTML document loaded into the layer, use this statement:

```
var modDate = document.Flintstones.document.lastModified;
```

**document.layerObject**

The situation gets more complex if the layer has another layer nested inside it (one of those “passengers” that goes along for the ride). If the structure changes to

```
<html>
  <head>
  </head>
  <body>
    <layer name="Flintstones" src="flintstonesFamily.html">
      <layer name="Fred" src="fredFlintstone.html"></layer>
      <layer name="Wilma" src="wilmaFlintstone.html"></layer>
    </layer>
  </body>
</html>
```

references to items in the second level of layers get even longer. For example, to get the `lastModified` property of the `fredFlintstone.html` file loaded into the nested Fred layer, use this reference from the Head script:

```
document.Flintstones.document.Fred.document.lastModified
```

The reason for this is that NN4 does not have a shortcut access to every layer defined in a top-level document. As stated in the description of the `document.layers` property in Chapter 18, the property reflects only the first level of layers defined in a document. You must know the way to San Jose if you want to get its `lastModified` property.

## Layers and forms

Because each layer has its own document, you cannot spread a form across multiple layers. Each layer’s document must define its own `<form>` tags. If you need to submit one form from content located in multiple layers, one of the forms should have an `onsubmit` event handler to harvest all the related form values and place them in hidden input fields in the document containing the submitted form. In this case, you need to know how to devise references from a nested layer outward.

As a demonstration of reverse-direction references, I start with the following skeletal structure that contains multiple nested layers:

```
<html>
  <head>
  </head>
  <body>
    <form name="personal">
      <input type="text" name="emailAddr" />
    </form>
    <layer name="product" src="ultraGizmoLine.html">
      <layer name="color" src="colorChoice.html"></layer>
      <layer name="size" src="sizeChoice.html"></layer>
      <layer name="sendIt" src="submission.html"></layer>
    </layer>
  </body>
</html>
```

Each of the HTML files loaded into the layers also has a `<form>` tag defining some fields or select lists for relevant user choices, such as which specific model of the UltraGizmo line is selected, what color, and in what size. (These last two are defined as separate layers because their positions are animated when they are displayed.) The assumption here is that the Submit button is in the `sendIt` layer. That layer’s document also includes hidden input fields for data to be pulled from the main document’s form and three other layer forms. Two of those layers

are at the same nested level as `sendIt`, one is above it, and the main document's form is at the highest level.

To reach the `value` property of a field named `theColor` in the `color` layer, a script in the `sendIt` layer uses this reference:

```
parentLayer.document.color.document.forms[0].theColor.value
```

Analogous to working with frames, the reference starts with a reference to the next higher level (`parentLayer`) and then starts working its way down through the parent layer's document, the `color` layer, the `color` layer's document, and finally the form therein.

To reach the `value` property of a field named `modelNum` in the `product` layer, the reference starts the same way; but because the form is at the parent layer level, the reference goes immediately to that layer's document and form:

```
parentLayer.document.forms[0].modelNum.value
```

It may seem odd that a reference to an object at a different layer level is shorter than one at the same level (for example, the `color` layer), but the route to the parent layer is shorter than going via the parent layer to a sibling. Finally, to reach the value of the `emailAddr` field in the base document, the reference must ratchet out one more layer as follows:

```
parentLayer.parentLayer.document.forms[0].emailAddr.value
```

The two `parentLayer` entries step the reference out two levels, at which point the scope is in the base layer containing the main document and its form.

## Layers and tables

The document-centered nature of NN4 layers also makes it difficult—if not impossible at times—to incorporate them inside tables. Even defining a layer that is contained by a `td` table cell can cause countless problems.

If you need to have absolute-positioned elements that look as though they are part of a table, I suggest you define the layers as freestanding elements outside of the table. After that, you can position the layers to make them look like they live in the table. You may also need to create empty placeholders in your table to make room for the overlaid layer. You can do this by way of a relative-positioned element inside the table cell whose visibility is hidden. This allows the element to flow as the page loads to accommodate the current browser window dimensions. Scripts can then read the location of the relative-positioned element and use those coordinates to move the absolute-positioned elements that are to overlay the hidden elements.

## Properties

above  
below  
siblingAbove  
siblingBelow

**Value:** Layer object.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

Each layer object is its own physical layer. Given that the variables `x` and `y` traditionally represent width and height, the third dimension—the position of a layer relative to the stack of

**document.layerObject.above**

layers — is called the *z-order*. Layer orders are assigned automatically according to the loading order, with the highest number being the topmost layer. That topmost layer is the one closest to you as you view the page on the monitor.

If two layers are on a page, one layer must always be in front of the other even if they both appear to be transparent and visually overlap each other. Knowing which layer is above the other is important for scripting purposes, especially if your script needs to reorder the layering in response to user action. Layer objects have four properties to help you determine the layers adjacent to a particular layer.

The first pair of properties, *layerObject.above* and *layerObject.below*, takes a global look at all layers defined on the page regardless of the fact that one layer may contain any number of nested layers separate from other batches on the screen. If a layer lies above the one in question, the property contains a reference to that other layer; if no layer exists in that direction, the value is `null`. Attempts to retrieve properties of a nonexistent layer result in runtime scripting errors indicating that the object does not have properties (of course not — an object must exist before it can have properties).

To understand these two properties better, consider a document that contains three layers (in any nesting arrangement you like). The first layer to be defined is on the bottom of the stack. It has a layer above it, but none below it. The second layer in the middle has a layer both above and below it. And the topmost layer has a layer only below it, with no more layers above it (that is, coming toward your eye).

Another pair of properties, *layerObject.siblingAbove* and *layerObject.siblingBelow*, confines itself to the group of layers inside a parent layer container. Just as in real family life, siblings are descended from (teens might say “contained by”) the same parent. An only child layer has no siblings, so both the *layerObject.siblingAbove* and *layerObject.siblingBelow* values are `null`. For two layers from the same parent, the first one to be defined has a sibling layer above it; the other has a sibling layer below it.

It is important to understand the difference between absolute layering and sibling layering to use these properties correctly. A nested layer might be the fifth layer from the bottom among all layers on the page but at the same time be the first layer among siblings within its family group. As you can see, these two sets of properties enable your script to be very specific about the relationships under examination.

Positioned objects in IE4+ and NN6+ have no comparable properties to the four described in this section.

## Example

Listing 39-1 enables you to experiment with just one set of these properties: *layerObject.above* and *layerObject.below*. The page is almost in the form of a laboratory/quiz that enables you to query yourself about the values of these properties for two swappable layers.

### Listing 39-1: A Layer Quiz

```
<html>
  <head>
    <title></title>
    <script type="text/javascript">
      function checkAbove(oneLayer) {
        document.forms[0].errors.value = "";
        document.forms[0].output.value = oneLayer.above.name;
      }
    </script>
  </head>
</html>
```

```

function checkBelow(oneLayer) {
    document.forms[0].errors.value = "";
    document.forms[0].output.value = oneLayer.below.name;
}
function swapLayers() {
    if (document.yeller.above) {
        document.yeller.moveAbove(document.greeny);
    } else {
        document.greeny.moveAbove(document.yeller);
    }
}
function onerror(msg) {
    document.forms[0].output.value = "";
    document.forms[0].errors.value = msg;
    return true;
}
</script>
</head>
<body>
<h1>Layer Ordering</h1>
<hr />
<form>
    Results:<input type="text" name="output" />
    <p><input type="button" value="Who's ABOVE the Yellow layer?"
        onclick="checkAbove(document.yeller)" /><br />
        <input type="button" value="Who's BELOW the Yellow layer?"
        onclick="checkBelow(document.yeller)" /></p>
    <p><input type="button" value="Who's ABOVE the Green layer?"
        onclick="checkAbove(document.greeny)" /><br />
        <input type="button" value="Who's BELOW the Green layer?"
        onclick="checkBelow(document.greeny)" /></p>
    <p><input type="button" value="Swap Layers" onclick="swapLayers()" />
    </p>
    <p>If there are any errors caused by missing<br />
        properties, they will appear below:<br />
        <textarea name="errors" cols="30" rows="3" wrap="virtual">
        </textarea></p>
</form>
<layer name="yeller" bgcolor="yellow" top="110" left="300" width="200"
height="200">
    <b>This is just a yellow layer.</b>
</layer>
<layer name="greeny" bgcolor="lightgreen" top="150" left="340"
width="200" height="200">
    <b>This is just a green layer.</b>
</layer>
</body>
</html>

```

The page contains two layers: one colored yellow and the other light green. Legends on four buttons ask you to guess whether one layer is above or below the other. For example, if you click the button labeled “Who’s ABOVE the Yellow layer?” and the green layer is above it, the name of that green layer appears in the Results field. But if layers are oriented such that the returned value is `null`, the error message (indicating that the nonexistent object doesn’t have a `name` property) appears in the error field at the bottom. Another button enables you to swap the order of the layers so you can try your hand at predicting the results based on your knowledge of layers and the `above` and `below` properties.

**document.layerObject.above**

Positioned objects in IE4+ and NN6 have no comparable properties to the four described in this section.

**Related Items:** `layer.parentLayer` property; `layer.moveAbove()`, `layer.moveBelow()` methods.

**background**

**Value:** Image object.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

You can assign a background image to a layer. The `background` attribute of the `<layer>` tag usually sets the initial image, but you can assign a new image whenever you like via the `layerObject.background` property.

Layer background images are typically like those used for entire Web pages. They tend to be subtle—or at least of such a design and color scheme as not to distract from the primary content of the layer. On the other hand, the background image may in fact be the content. If so, then have a blast with whatever images suit you.

The value of the `layerObject.background` property is an image object (see Chapter 20). To change the image in that property on the fly, you must set the `layerObject.background.src` property to the URL of the desired image (just like changing `document.imageName.src` on the fly). You can remove the background image by setting the `layerObject.background.src` property to `null`. Background images smaller than the rectangle of the layer repeat themselves, just like `document.background` pictures; images larger than the rectangle clip themselves to the rectangle of the layer rather than scaling to fit.

The IE4+ and NN6+ way of handling background images is through the `style.backgroundImage` property.

**Example**

A simple example (see Listing 39-2) defines one layer that features five buttons to change the background image of a second layer. I put the buttons in a layer because I want to make sure the buttons and background layer rectangles align themselves along their top edges on all platforms.

As the second layer loads, I merely assign a gray background color to it and write some reverse (white) text. Most of the images are of the small variety that repeats in the layer. One is a large photograph to demonstrate how images are clipped to the layer's rectangle. Along the way, I hope you also heed the lesson of readability demonstrated by the difficulty of reading text on a wild-looking background. For an example compatible with IE5+ and NN6+, see Listing 39-13.

**Listing 39-2: Setting Layer Backgrounds**

```
<html>
  <head>
    <title>Layer Backgrounds</title>
    <script type="text/javascript">
      function setBg(URL) {
        document.bgExpo.background.src = URL;
      }
    </script>
  </head>
  <body>
```

```

<h1>Layer Backgrounds</h1>
<hr />
<layer name="buttons" top="100">
  <form>
    <input type="button" value="The Usual"
      onclick="setBg('cr_kraft.gif')" /><br />
    <input type="button" value="A Big One"
      onclick="setBg('arch.gif')" /><br />
    <input type="button" value="Not So Usual"
      onclick="setBg('wh86.gif')" /><br />
    <input type="button" value="Decidedly Unusual"
      onclick="setBg('sb23.gif')" /><br />
    <input type="button" value="Quick as..."
      onclick="setBg('lightnin.gif')" /><br />
  </form>
</layer>
<layer name="bgExpo" bgcolor="gray" top="100" left="250" width="300"
  height="260">
  <b><font color="white">Some text, which may or may not read well with
    the various backgrounds.</font></b>
</layer>
</body>
</html>

```

**Related Items:** layer.bgColor property; image object.

## bgColor

**Value:** String.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

A layer's background color fills the entire rectangle with the color set in the `<layer>` tag or from a script at a later time. Color values are the same as for document-related values; they may be in the hexadecimal triplet format or in one of the plain-language color names. You can turn a layer transparent by setting its `bgColor` property to `null`.

You control the corresponding behavior in IE4+ and NN6+ via the `style.backgroundColor` property.

### Example

You can have some fun with Listing 39-3, which uses a number of layer scripting techniques. The page presents a kind of palette of eight colors, each one created as a small layer. Another, larger layer's `bgColor` property changes as you roll the mouse over any color in the palette.

To save HTML lines to create those eight color palette layers, I use a script to establish an array of colors and then `document.write()` the `<layer>` tags with appropriate attribute settings so the layers all line up in a contiguous row. By predefining a number of variable values for the size of the color layers, I can make all of them larger or smaller with the change of only a few script characters.

The document object handles the job of capturing the `mouseover` events. I turn on the document's `captureEvents()` method such that it traps all `mouseover` events and hands them to the `setColor()` function. The `setColor()` function reads the target object's `bgColor` and sets the larger layer's `bgColor` property to the same. If this page had other objects that could receive `mouseover` events for other purposes, I would use `routeEvents()` to let those events pass on to their intended targets. For the purposes of this example, however, the events need to go no further. Listing 39-14 shows the same functionality working in IE5+ and NN6+.

## Listing 39-3: Layer Background Colors

```

<html>
  <head>
    <title>Layer Background Colors</title>
    <script type="text/javascript">
      function setColor(e) {
        document.display.bgColor = e.target.bgColor;
      }
      document.captureEvents(Event.MOUSEOVER);
      document.onmouseover = setColor;
    </script>
  </head>
  <body>
    <h1>Layer Background Colors</h1>
    <hr />
    <script type="text/javascript">
      var oneLayer;
      var colorTop = 100;
      var colorLeft = 20;
      var colorWidth = 40;
      var colorHeight = 40;
      var colorPalette = new Array("aquamarine","coral","forestgreen",
        "goldenrod","red","magenta","navy","teal");
      for (var i = 0; i < colorPalette.length; i++) {
        oneLayer = "<layer name=swatch" + i + " top=" + colorTop;
        oneLayer += " left=" + ((colorWidth * i) + colorLeft);
        oneLayer += " width=" + colorWidth + " height=" + colorHeight;
        oneLayer += " bgcolor=" + colorPalette[i] + ">\</layer>\n";
        document.write(oneLayer);
      }
    </script>
    <layer name="display" bgcolor="gray" top="150" left="80" width="200"
      height="200">
      <center><b><font color="white">Some reversed text to test against
        background colors.</font></b></center>
    </layer>
  </body>
</html>

```

**Related Items:** layer.background property; layer.onmouseover event handler.

## clip

**Value:** String.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

The *layerObject.clip* property is an object (the only one in NN4's document object model that exposes itself as a rectangle object) with six geographical properties defining the position and size of a rectangular area of a layer visible to the user. Those six properties are

- ♦ clip.top
- ♦ clip.left
- ♦ clip.bottom
- ♦ clip.right
- ♦ clip.width
- ♦ clip.height

The unit of measure is pixels, and the values are relative to the top-left corner of the layer object.

A clip region can be the same size as or smaller than the layer object. If the `clip` attribute is not defined in the `<layer>` tag, the clipping region is the same size as the layer. In this case, the `clip.left` and `clip.top` values are automatically zero because the clip region starts at the very top-left corner of the layer's rectangle (measurement is relative to the layer object whose `clip` property you're dealing with). The height and width of the layer object are not available properties in NN4. Therefore, you may have to use other means to get that information into your scripts if you need it. (I do it in Listing 39-4.) Also be aware that even if you set the `height` and `width` attributes of a layer tag, the content rules the initial size of the visible layer unless the tag also includes specific clipping instructions. Images, for example, expand a layer to fit the `height` and `width` attributes of the `<img>` tag; text (either from an external HTML file or inline in the current file) adheres to the `<layer>` tag's `width` attribute but flows down as far as necessary to display every character.

Setting a `clip` property does not move the layer or the content of the layer — only the visible area of the layer. Each adjustment has a unique impact on the apparent motion of the visible region. For example, if you increase the `clip.left` value from its original position of 0 to 20, the entire left edge of the rectangle shifts to the right by 20 pixels. No other edge moves. Changes to the `clip.width` property affect only the right edge; changes to the `clip.height` property affect only the bottom edge. Unfortunately, no shortcuts exist to adjust multiple edges at once. JavaScript is fast enough on most client machines to give the impression that multiple sides are moving if you issue assignment statements to different edges in sequence.

IE4+ and NN6+ have the `style.clip` property to assist in adjusting the clipping rectangle of a layer. But the W3C DOM's `style.clip` object does not offer additional subproperties to access individual edges or dimensions of the clipping rectangle. IE5's read-only `currentStyle` object does provide properties for the four edge dimensions. Listing 39-15 demonstrates how to adjust clipping in IE5+ and NN6+ syntax.

## Example

Because of the edge movement behavior of adjustments to `layerObject.clip` properties, Listing 39-4 enables you to experiment with adjustments to each of the six properties. The document loads one layer that you can adjust by entering alternative values into six text fields — one per property.

As you enter values, all properties are updated to show their current values (via the `showValues()` function). Pay particular attention to the apparent motion of the edge and the effect the change has on at least one other property. For example, a change to the `layerObject.clip.left` value also affects the `layerObject.clip.width` property value.

## Listing 39-4: Adjusting layer.clip Properties

```

<html>
  <head>
    <title>Layer Clip</title>
    <script type="text/javascript">
      var origLayerWidth = 0;
      var origLayerHeight = 0;
      function initializeXY() {
        origLayerWidth = document.display.clip.width;
        origLayerHeight = document.display.clip.height;
        showValues();
      }

      function setClip(field) {
        var clipVal = parseInt(field.value);
        document.display.clip[field.name] = clipVal;
        showValues();
      }
      function showValues() {
        var form = document.layers[0].document.forms[0];
        var propName;
        for (var i = 0; i < form.elements.length; i++) {
          propName = form.elements[i].name;
          if (form.elements[i].type == "text") {
            form.elements[i].value = document.display.clip[propName];
          }
        }
      }
      var intervalID;
      function revealClip() {
        var midWidth = Math.round(origLayerWidth / 2);
        var midHeight = Math.round(origLayerHeight / 2);
        document.display.clip.left = midWidth;
        document.display.clip.top = midHeight;
        document.display.clip.right = midWidth;
        document.display.clip.bottom = midHeight;
        intervalID = setInterval("stepClip()",1);
      }
      function stepClip() {
        var widthDone = false;
        var heightDone = false;
        if (document.display.clip.left > 0) {
          document.display.clip.left += -2;
          document.display.clip.right += 2;
        } else {
          widthDone = true;
        }
        if (document.display.clip.top > 0) {
          document.display.clip.top += -1;
          document.display.clip.bottom += 1;
        } else {
          heightDone = true;
        }
        showValues();
        if (widthDone && heightDone) {
          clearInterval(intervalID);
        }
      }
    </script>
  </head>
  <body>
    <div style="position: absolute; top: 50px; left: 50px; width: 200px; height: 100px; border: 1px solid black; clip: rect(0px 200px 100px 50px);">
      <input type="text" value="0" name="width" style="width: 100%; height: 20px; margin-bottom: 5px;"/>
      <input type="text" value="0" name="height" style="width: 100%; height: 20px; margin-bottom: 5px;"/>
      <input type="button" value="Set Clip" style="width: 100%; height: 20px; margin-bottom: 5px;"/>

      grievances.</p>
  </layer>
</body>
</html>

```

**document.layerObject.clip**

Listing 39-4 has a lot of other scripting in it to demonstrate a couple of other clip area techniques. After the document loads, the `onload` event handler initializes two global variables that represent the starting height and width of the layer as determined by the `clip.height` and `clip.width` properties. Because the `<layer>` tag does not specify any clip attributes, the `layerObject.clip` region is ensured of being the same as the layer's dimensions at load time.

I preserve the initial values for a somewhat advanced set of functions that act in response to the Reveal Original Layer button. The goal of this button is to temporarily shrink the clipping area to nothing and then expand the clip rectangle gradually from the very center of the layer. The effect is analogous to a zoom-out visual effect.

The clip region shrinks to practically nothing by setting all four edges to the same point midway along the height and width of the layer. The script then uses `setInterval()` to control the animation in `setClip()`. To make the zoom even on both axes, I first make sure that the initial size of the layer is an even ratio: twice as wide as it is tall. Each time through the `setClip()` function, the `clip.left` and `clip.right` values are adjusted in their respective directions by 2 pixels and `clip.top` and `clip.bottom` are adjusted by 1 pixel.

To make sure the animation stops when the layer is at its original size, I check whether the `clip.top` and `clip.left` values are their original zero values. If they are, I set a Boolean variable for each side. When both variables indicate that the clip rectangle is its original size, the script cancels the `setInterval()` action.

Listing 39-15 demonstrates how to adjust clipping in IE5+ and NN6+ syntax.

**Related Items:** `layer.pageX`, `layer.pageY` properties; `layer.resizeTo()` method.

**document**

**Value:** document object.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

Your scripts practically never have to retrieve the `document` property of a layer. But it is important to remember that it is always there as the actual container of content in the layer. As described at length in the opening section about the layer object, the `document` object reference plays a large role in assembling addresses to content items and properties in other layers. A document inside a layer has the same powers, properties, and methods of the main document in the browser window or in a frame.

**Related Items:** `document` object.

**left****top**

**Value:** Integer.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

The `layerObject.left` and `layerObject.top` properties correspond to the `left` and `top` attributes of the `<layer>` tag. These integer values determine the horizontal and vertical pixel coordinate point of the top-left corner of the layer relative to the browser window, frame, or parent layer in which it lives. The coordinate system of the layer's most immediate container is the one that these properties reflect.

Adjustments to these properties reposition the layer without adjusting its size. Clipping area values are untouched by changes in these properties. Thus, if you create a draggable layer object that needs to follow a dragged mouse pointer in a straight line along the x or y axis, it is more convenient to adjust one of these properties than to use the `layerObject.moveTo()` method.

IE4+ and NN6+ provide various properties to determine the coordinate location of a positioned element—all through the `style` object.

## Example

To enable you to experiment with manually setting `layerObject.top` and `layerObject.left` properties, Listing 39-5 is a modified version of the `layer.clip` example (Listing 39-4). The current example again has the one modifiable layer, but it has only four text fields in which you can enter values. Two fields are for the `layerObject.left` and `layerObject.top` properties; the other two are for the `layerObject.clip.left` and `layerObject.clip.top` properties. I present both sets of values here to help reinforce the lack of connection between layer and clip location properties in the same layer object.

You can find the corresponding syntax for IE5+ and NN6+ in Listing 39-16.

### Listing 39-5: Comparison of Layer and Clip Location Properties

```

</layer>
</body>
</html>

```

---

**Related Items:** layer.clip, layer.parentLayer properties.

**name****Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

The *layerObject.name* property reflects the name attribute of the `<layer>` tag or name you assign to a positioned `div` or `span` element. This property is read-only. If you don't assign a name to a layer when you create it, Navigator generates a name for the layer in this format:

```
js_layer_nn
```

Here, *nn* is a serial number. That serial number is not the same every time the page loads, so you cannot rely on the automatically generated name to help you script an absolute reference to the layer.

**pageX****pageY****Value:** Integer.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

In Netscape's coordinate terminology, the *page* is the content area of a document. The top-left corner of the page space is point 0,0, and you can position any layer (including a nested layer) on the page relative to this corner. In the `<layer>` tag, the attributes that enable authors to set the position are `pageX` and `pageY`. These values are retrievable and modifiable as the `layerObject.pageX` and `layerObject.pageY` properties, respectively. Note the capitalization of the final letters of these property names.

The `layerObject.pageX` and `layerObject.pageY` values are identical to `layerObject.left` and `layerObject.top` only when the layer in question is at the main document level. That's because the `layerObject.left` and `layerObject.top` values are measured by the next higher container's coordinate system — which, in this case, is the same as the page.

The situation gets more interesting when you're dealing with nested layers. For a nested layer, the `layerObject.pageX` and `layerObject.pageY` values are still measured relative to the page, while `layerObject.left` and `layerObject.top` are measured relative to the next higher layer. If trying to conceive of these differences makes your head hurt, the example in Listing 39-6 should help clear things up for you.

Adjusting the `layerObject.pageX` and `layerObject.pageY` values of any layer has the same effect as using the `layerObject.moveToAbsolute()` method, which measures its coordinate system based on the page. If you create flying layers on your page, you can't go wrong by setting the `layerObject.pageX` and `layerObject.pageY` properties (or using the `moveToAbsolute()` method) in your script. That way, should you add another layer in the hierarchy between the base document and the flying layer, the animation is in the same coordinate system as before the new layer was added.

IE4+ does not provide a pair of properties to determine the location of a positioned element relative to the page, but the `offsetLeft` and `offsetTop` properties provide coordinates within the element's next outermost positioning context. Thus, you may have to "walk" the `offsetParent` trail to accumulate complete coordinate values. In NN6+/W3C, the `offsetLeft` and `offsetTop` properties use the page as the positioning context.

## Example

Listing 39-6 defines one outer layer and one nested inner layer of different colors. The inner layer contains some text content; the outer layer is sized initially to present a colorful border by being below the inner layer and 10 pixels wider and taller.

Two sets of fields display (and enable you to change) the `layerObject.pageX`, `layerObject.pageY`, `layerObject.left`, and `layerObject.top` properties for each of the nested layers. Each set of fields is color-coded to its corresponding layer.

When you change any value, all values are recalculated and displayed in the other fields. For example, the initial `pageX` position for the outer layer is 200 pixels; for the inner layer, the `pageX` value is 205 pixels (accounting for the 5-pixel "border" around the inner layer). If you change the outer layer's `pageX` value to 220, the outer layer moves to the right by 20 pixels, taking the inner layer along for the ride. The `layer.pageX` value for the inner layer after the move is 225 pixels.

The outer layer values for the pairs of values are always the same no matter what. But for the inner layer, the page values are significantly different from the `layer.left` and `layer.top` values because these latter values are measured relative to their containing layer — the outer layer. If you move the outer layer, the inner layer values for `layerObject.left` and `layerObject.top` don't change one iota. Listing 39-17 shows the comparable syntax for IE5+ and NN6+/W3C.

## Listing 39-6: Testing Nested Layer Coordinate Systems

```

<html>
  <head>
    <title>Nested Layer PageX/PageY</title>
    <script type="text/javascript">
      function setOuterPage(field) {
        var layerVal = parseInt(field.value);
        document.outerDisplay[field.name] = layerVal;
        showValues();
      }
      function setOuterLayer(field) {
        var layerVal = parseInt(field.value);
        document.outerDisplay[field.name] = layerVal;
        showValues();
      }
      function setInnerPage(field) {
        var layerVal = parseInt(field.value);
        document.outerDisplay.document.innerDisplay[field.name] = layerVal;
        showValues();
      }
      function setInnerLayer(field) {
        var layerVal = parseInt(field.value);
        document.outerDisplay.document.innerDisplay[field.name] = layerVal;
        showValues();
      }
      function showValues() {
        var form = document.layers[0].document.forms[0];
        form.elements[0].value = document.outerDisplay.pageX;
        form.elements[1].value = document.outerDisplay.pageY;
        form.elements[2].value = document.outerDisplay.left;
        form.elements[3].value = document.outerDisplay.top;
        form.elements[4].value =
          document.outerDisplay.document.innerDisplay.pageX;
        form.elements[5].value =
          document.outerDisplay.document.innerDisplay.pageY;
        form.elements[6].value =
          document.outerDisplay.document.innerDisplay.left;
        form.elements[7].value =
          document.outerDisplay.document.innerDisplay.top;
      }
    </script>

```

**document.layerObject.pageX**

**Related Items:** `layer.left`, `layer.top`, `window.innerHeight`, `window.innerWidth` properties; `layer.moveToAbsolute()` method.

**parentLayer**

**Value:** Object.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

Every layer has a parent that contains that layer. In the case of a layer defined at the main document level, its parent layer is the window or frame containing that document (the “page”). For this kind of layer, the `layerObject.parentLayer` property object is a window object. But for any nested layer contained by a layer, the `parentLayer` property is a layer object.

Be aware of the important distinction between `layerObject.parentLayer` and `layerObject` below. As a parent layer can contain multiple layers in the next containment level, each of those layers’ `parentLayer` properties evaluate to that same parent layer. But because each layer object is its own physical layer among the stack of layers on a page, the `layer.below` property in each layer points to a different object—the layer next lower in z-order.

Keeping the direction of things straight can get confusing. On the one hand, you have a layer’s parent, which, by connotation, is higher up the hierarchical chain of layers. On the other hand, the order of physical layers is such that a parent more than likely has a lower z-order than its children because it is defined earlier in the document.

Use the `layerObject.parentLayer` property to assemble references to other nested layers. See the discussion about layer references at the beginning of this chapter for several syntax examples.

IE4+ offers an `offsetParent` property, which comes close to the functionality of the `layerObject.parentLayer` property.

**Related Items:** `layer.above`, `layer.below` properties.

**siblingAbove****siblingBelow**

(See `layer.above` and `layer.below` properties earlier in this chapter)

**src**

**Value:** String.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

Content for a layer may come from within the document that defines the layer or from an external source, such as an HTML or image file. If defined by a `<layer>` tag, an external file is specified by the `src` attribute. This attribute is reflected by the `layerObject.src` property.

The value of this property is a string of the URL of the external file. If you do not specify an `src` attribute in the `<layer>` tag, the value returns `null`. Do not set this property to an empty string in an effort to clear the layer of content: `document.write()` or load an empty page instead. Otherwise, the empty string is treated like a URL, and it loads the current client directory.

You can, however, change the content of a layer by loading a new source file into the layer. Simply assign a new URL to the `layerObject.src` property. Again, if a layer has nested layers inside it, those nested layers are blown away by the content that loads into the layer whose `src` property you change. The new file, of course, can be an HTML file that defines its own nested layers, which then become part of the page’s object model.

Netscape also provides the `layerObject.load()` method to insert new content into a layer. One advantage of this method is that an optional second parameter enables you to redefine the width of the layer at the same time you specify a new document. But if you are simply replacing the content in the same width layer, you can use either way of loading new content.

Be aware that the height and width of a replacement layer are governed as much by their hard-coded content size as by the initial loading of any layer. For example, if your layer is initially sized at a width of 200 pixels and your replacement layer document includes an image whose width is set to 500 pixels, the layer expands its width to accommodate the larger content — unless you also restrict the view of the layer via the `layerObject.clip` properties. Similarly, longer text content flows beyond the bottom of the previously sized layer unless restricted by clipping properties.

Positioned elements in IE4+ and NN6+/W3C do not provide a direct way to load external content into them. That's what the W3C sees as the purpose of the `iframe` element. Even so, as Listing 39-18 shows, you can script your way around this limitation if it's absolutely necessary.

## Example

Setting the `layerObject.src` property of a layer that is a member of a layer family (that is, a family with at least one parent and one child) can be tricky business if you're not careful. Listing 39-7 presents a workspace for you to see how changing the `src` property of outer and inner layers affects the scenery.

When you first load the document, one outer layer contains one inner layer (each with a different background color). Control buttons on the page enable you to set the `layerObject.src` property of each layer independently. Changes to the inner layer content affect only that layer. Long content forces the inner layer to expand its depth, but the inner layer's view is automatically clipped by its parent layer.

Changing the outer layer content, however, removes the inner layer completely. Code in the following listing shows one way to examine for the presence of a particular layer before attempting to load new content in it. If the inner layer doesn't exist, the script creates a new layer on the fly to replace the original inner layer.

### Listing 39-7: Setting Nested Layer Source Content

```
<html>
  <head>
    <title>Layer Source</title>
    <script type="text/javascript">
      function loadOuter(doc) {
        document.outerDisplay.src = doc;
      }
      function loadInner(doc) {
        var nested = document.outerDisplay.document.layers;
        if (nested.length > 0) {
          // inner layer exists, so load content or restore
          if (doc) {
            nested[0].src = doc;
          } else {
            restoreInner(nested[0]);
          }
        } else {
          // prompt user about restoring inner layer
```

Continued

## Listing 39-7 (continued)

```

        if (confirm("The inner layer has been removed by loading an outer
            document. Restore the original layers?")) {
            restoreLayers(doc);
        }
    }
}
function restoreLayers(doc) {
    // reset appearance of outer layer
    document.outerDisplay.bgColor = "coral";
    document.outerDisplay.resizeTo(370,190); // sets clip
    document.outerDisplay.document.write("");
    document.outerDisplay.document.close();
    // generate new inner layer
    var newInner = new Layer(360, document.layers["outerDisplay"]);
    newInner.bgColor = "aquamarine";
    newInner.moveTo(5,5);
    if (doc) {
        // user clicked an inner content button
        newInner.src = doc;
    } else {
        // return to pristine look
        restoreInner(newInner);
    }
    newInner.visibility = "show";
}
function restoreInner(inner) {
    inner.document.write("<html><body><p><b>Placeholder text for raw inner
        layer.</b></p></body></html>");
    inner.document.close();
    inner.resizeTo(360,180); // sets clip
}
</script>
</head>
<body>
<b>Setting the <tt>layer.src</tt> Property of Nested Layers</b>
<hr />
Click the buttons to see what happens when you load new source documents
into the <font color="coral">outer layer</font> and <font
color="aquamarine">inner layer</font> objects.
<layer top="100" bgcolor="coral">
    <form>
        Load into outer layer:<br />
        <input type="button" value="Article I"

        <input type="button" value="Entire Bill of Rights"
            onclick="loadOuter('bofright.htm')" /><br />
    </form>
</layer>
<layer top="220" bgcolor="aquamarine">
    <form>
        Load into inner layer:<br />
        <input type="button" value="Article I"
            onclick="loadInner('article1.htm')" /><br />
        <input type="button" value="Entire Bill of Rights"

```

```

        onclick="loadInner('bofright.htm')" /><br />
        <input type="button" value="Restore Original"
        onclick="loadInner()" /><br />
    </form>
</layer>
<layer name="outerDisplay" bgcolor="coral" top="100" left="200"
width="370" height="190">
    <layer name="innerDisplay" bgcolor="aquamarine" top="5" left="5"
width="360" height="180">
        <p><b>Placeholder text for raw inner layer.</b></p>
    </layer>
</layer>
</body>
</html>

```

Restoring the original layers via script (as opposed to reloading the document) does not perform a perfect restoration. The key difference is that the scripts use the `layerObject.resizeTo()` method to set the layers to the height and width established by the `<layer>` tags that create the layers in the first place. This method, however, sets the clipping rectangle of the layer—not the layer’s size. Therefore, if you use the script to restore the layers, loading the longer text file into either layer does not force the layer to expand to display all the content; the clipping region governs the view.

**Related Items:** `layer.load()`, `layer.resizeTo()` methods.

## visibility

**Value:** String.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

A layer’s `visibility` property can use one of three settings: `show`, `hide`, or `inherit`—the same values you can assign to the `visibility` attribute of the `<layer>` tag. But NN4 also enables you to set the property to `hidden` and `visible`, which are the values for the `style.visibility` property used in IE4+ and NN6+/W3C.

Unlike many other layer properties, you can set the `visibility` property such that a layer can either follow the behavior of its parent or strike out on its own. By default, a layer’s `visibility` property is set to `inherit`, which means the layer’s visibility is governed solely by that of its parent (and of *its* parent, if the nesting includes many layers). When the governing parent’s property is, say, `hide`, the child’s property remains `inherit`. Thus, you cannot tell whether an inheriting layer is presently visible or not without checking up the hierarchy (with the help of the `layerObject.parentLayer` property). However, you can override the parent’s behavior by setting the current layer’s property explicitly to `show` or `hide`. This action does not alter in any way other parent-child relationships between layers.

## Example

Use the page in Listing 39-8 to see how the `layerObject.visibility` property settings affect a pair of nested layers. When the page first loads, the default `inherit` setting is in effect. Changes you make to the outer layer by clicking the outer layer buttons affect the inner layer, but setting the inner layer’s properties to `hide` or `show` severs the visibility relationship between parent and child. Listing 39-19 shows this example with IE5+ and NN6+/W3C DOM syntax.

## Listing 39-8: Nested Layer Visibility Relationships

```

<html>
  <head>
    <title>Layer Source</title>
    <script type="text/javascript">
      function setOuterVis(type) {
        document.outerDisplay.visibility = type;
      }
      function setInnerVis(type) {
        document.outerDisplay.document.innerDisplay.visibility = type;
      }
    </script>
  </head>
  <body>

    width="370" height="190">
      <layer name="innerDisplay" bgcolor="aquamarine" top="5" left="5"
      width="360" height="180">
        <p><b>Placeholder text for raw inner layer.</b></p>
      </layer>
    </layer>
  </body>
</html>

```

## zIndex

**Value:** Integer.

Read/Write

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

Close relationships exist among the `layerObject.above`, `layerObject.below`, and `layerObject.zIndex` properties. When you define a layer in a document with the `<layer>` tag, you can supply only one of the three attributes (`above`, `below`, and `z-index`). After the layer is generated with any one of those attributes, the document object model automatically assigns values to at least two of those properties (`layerObject.above` and `layerObject.below`) unless you specify the `z-index` attribute; in this case, all three properties are assigned to the layer. If you don't specify any of these properties, the physical stacking order of the layers is the same as in the HTML document. The `layerObject.above` and `layerObject.below` properties are set as described in their discussion earlier in this chapter. But the `layerObject.zIndex` properties for all layers are zero.

### Note

The CSS attribute is spelled with a hyphen after the "z." Because a JavaScript property name cannot contain a hyphen, the character was removed for the property name. The capital "I" is important because JavaScript properties are case-sensitive.

Changes to `layerObject.zIndex` values affect the stacking order only of sibling layers. You can assign the same value to two layers, but the last layer to have its `layerObject.zIndex` property set lies physically above the other one. Therefore, if you want to ensure a stacking order, set the `zIndex` values for all layers within a container. Each value should be a unique number.

Stacking order is determined simply by the value of the integer assigned to the property. If you want to stack three sibling layers, the order is the same if you assign them the values of 1, 2, 3 or 10, 13, 50. As you modify a `layerObject.zIndex` value, the `layerObject.above` and `layerObject.below` properties for all affected layers change as a result.

Avoid setting `zIndex` property values to negative numbers in NN4. Negative values are treated as their absolute (positive) values for ordering.

For IE4+ and NN6+/W3C, the `style.zIndex` property controls z-order.

## Example

The relationships among the three stacking property values can be difficult to visualize. Listing 39-9 offers a way to see the results of changing the `layerObject.zIndex` properties of three overlapping sibling layers.

The sequence of the `<layer>` tags in the document governs the original stacking order. Because the attribute is not set in the HTML, the initial values appear as zero for all three layers. But, as the page reveals, the `layerObject.above` and `layerObject.below` properties are automatically established. When a layer has no other layer object above it, the page shows (none). Also, if the layer below the bottom of the stack is the main window, a strange inner layer name is assigned (something like `_js_layer_21`).

To experiment with this page, first make sure you understand the `layerObject.above` and `layerObject.below` readings for the default order of the layers. Then, assign different orders to the layers with value sequences such as 3-2-1, 1-3-2, 2-2-2, and so on. Each time you enter one new value, check the actual layers to see if their stacking order changed and how that affected the other properties of all layers.

Listing 39-20 shows how to achieve the same action with IE5+ and NN6+/W3C syntax.

## Listing 39-9: Relationships Among zIndex, above, and below

```

<html>
  <head>
    <title>Layer zIndex</title>
    <script type="text/javascript">
      function setZ(field) {
        switch (field.name) {
          case "top" :
            document.top.zIndex = parseInt(field.value);
            break;
          case "mid" :
            document.middle.zIndex = parseInt(field.value);
            break;
          case "bot" :
            document.bottom.zIndex = parseInt(field.value);
        }
        showValues();
      }
      function showValues() {
        document.layers[0].document.forms[0].bot.value =
          document.bottom.zIndex;

```

**Related Items:** `layer.above`, `layer.below` properties; `layer.moveAbove()`, `layer.moveBelow()` methods.

## Methods

### load("URL", newLayerWidth)

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

One way to change the content of an NN4 layer after it loads is to use the `layerObject.load()` method. This method has an advantage over setting the `layerObject.src` property because the second parameter is a new layer width for the content if one is desired. If you don't specify the second parameter, a small default value is substituted for you (unless the new document hard-wires widths to its elements that must expand the current width). If you are concerned about a new document being too long for the existing height of the layer, use the `layerObject.resizeTo()` method or set the individual `layerObject.clip` properties before loading the new document. This keeps the viewable area of the layer at a fixed size.

IE4+ and NN6+/W3C object models don't have a method like this, but you can work around the situation (as shown in Listing 39-18) and then adjust the `style.width` property of the positioned element.

### Example

Buttons in Listing 39-10 enable you to load short and long documents into a layer. The first two buttons don't change the width (in fact, the second parameter to `layerObject.load()` is the `layerObject.clip.left` value). For the second two buttons, a narrower width than the original is specified. Click the Restore button frequently to return to a known state.

## Listing 39-10: Loading Documents into Layers

```

<html>
  <head>
    <title>Layer Loading</title>
    <script type="text/javascript">
      function loadDoc(URL,width) {
        if (!width) {
          width = document.myLayer.clip.width;
        }
      }
    </script>
  </head>
</html>

```

**document.LayerObject.moveAbove()**

```

        document.myLayer.load(URL, width);
    }
</script>
</head>

            <input type="button" value="Large Doc/Existing Width"
                onclick="loadDoc('bofright.htm')" />
            <p><input type="button" value="Small Doc/Narrower Width"
                onclick="loadDoc('article1.htm',200)" /><br />
                <input type="button" value="Large Doc/Narrower Width"
                onclick="loadDoc('bofright.htm',200)" /></p>
            <p><input type="button" value="Restore"
                onclick="location.reload()" /></p>
        </form>
    </layer>
    <layer name="myLayer" bgcolor="yellow" top="90" left="300" width="300"
        height="190">
        <p><b>Text loaded in original document.</b></p>
    </layer>
</body>
</html>

```

**Related Item:** layer.src property.

**moveAbove(layerObject)**

**moveBelow(layerObject)**

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

With the exception of the *layerObject.zIndex* property, the layer object does not let you adjust properties that affect the global stacking order of layers. The *layerObject.moveAbove()* and *layerObject.moveBelow()* methods enable you to adjust a layer in relation to another layer object. Both layers in the transaction must be siblings — they must be in the same container, whether it be the base document window or some other layer. You cannot move existing layers from one container to another; you must delete the layer from the source and create a new layer in the destination. Neither of these methods affects the viewable size or coordinate system location of the layer.

The syntax for these methods is a little strange at first because the statement that makes these work has two layer object references in it. Named first in the statement (to the left of the method name, separated by a period) is the layer object you want to move. The sole parameter for each method is a reference to the layer object that is the physical reference point for the trip. For example, in this statement,

```
document.fred.moveAbove(document.ginger);
```

the instruction moves the fred layer above the ginger layer. The fred layer can be in any stacking relation to ginger; but, again, both layers must be in the same container.

**document.layerObject.moveAbove()**

Obviously, after one of these moves, the `layerObject.above` and `layerObject.below` properties of some or all layers in the container feel the ripple effects of the shift in order. If you have several layers that are out of order because of user interaction with your scripts, you can reorder them using these methods — or, more practically, by setting their `layerObject.zIndex` properties. In the latter case, it is easier to visualize through your code how the ordering is handled with increasing `zIndex` values for each layer.

There is no comparable method for IE4+ or NN6+/W3C.

**Example**

You can see the `layerObject.moveAbove()` method at work in Listing 39-1.

**Related Items:** `layer.above`, `layer.below`, `layer.zIndex` properties.

`moveBy(deltaX, deltaY)`

`moveTo(x, y)`

`moveToAbsolute(x, y)`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

Much of what CSS-Positioning is all about is being able to precisely plant an element on a Web page. The unit of measure is the pixel, with the coordinate space starting at an upper-left corner at location 0,0. That coordinate space for a layer is typically the container (parent layer) for that layer. The `layerObject.moveTo()` and `layerObject.moveBy()` methods let scripts adjust the location of a layer inside that coordinate space — very much the way `window.moveTo()` and `window.moveBy()` work for window objects.

Moving a layer entails moving it (and its nested layers) without adjusting its size or stacking order. You can accomplish animation of a layer by issuing a series of `layerObject.moveTo()` methods if you know the precise points along the path. Or you can nudge the layer by increments in one or both axes with the `layerObject.moveBy()` method.

In case you need to position a layer with respect to the page's coordinate system (for example, you are moving items from multiple containers to a common point), the `layerObject.moveToAbsolute()` method bypasses the layer's immediate container. The 0,0 point for this method is the top-left corner of the document. Be aware, however, that you can move a layer to a position such that some or all of it lies out of range of the container's clip rectangle.

Moving positioned layers in IE4+ and NN6+/W3C requires adjusting the `style.left` and `style.top` properties (or the `style.pixelLeft`, `style.pixelTop`, `style.posLeft`, and `style.posTop` properties in IE4+).

**Example**

Listing 39-11 shows a demonstration of the `layerObject.moveTo()` method. It is a simple script that enables you to click and drag a layer around the screen. The script employs the coordinate values of the `mousemove` event; after compensating for the offset within the layer at which the click occurs, the script moves the layer to track the mouse action.

I want to present this example for an additional reason: to explain an important user interface difference between Windows and Macintosh versions of NN4. In Windows versions, you can click and hold the mouse button down on an object and let the object receive all the `mousemove` events as you drag the cursor around the screen. On the Macintosh, however, NN4 tries to

`document.layerObject.moveBy()`

compensate for the lack of a second mouse button by popping up a context-sensitive menu at the cursor position when the user holds the mouse button down for more than just a click. To prevent the pop-up menu from appearing, the `engage()` method invoked by the `onmousedown` event handler ends with `return false`.

Notice in the following listing how the layer captures a number of mouse events. Each one plays an important role in creating a mode that is essentially like a `mouseStillDown` event (which doesn't exist in NN4's event model). The `mousedown` event sets a Boolean flag (`engaged`) indicating that the user clicked down in the layer. At the same time, the script records how far away from the layer's top-left corner the `mousedown` event occurred. This offset information is needed so that any setting of the layer's location takes this offset into account (otherwise, the top-left corner of the layer would jump to the cursor position and be dragged from there).

During the drag (`mousedown` events firing with each mouse movement), the `dragIt()` function checks whether the drag mode is engaged. If so, the layer is moved to the page location calculated by subtracting the original downstroke offset from the `mousemove` event location on the page. When the user releases the mouse button, the `mouseup` event turns off the drag mode Boolean value.

Listing 39-21 shows a version of this example for IE5+ and NN6+/W3C.

### Listing 39-11: Dragging a Layer

```
<html>
  <head>
    <title>Layer Dragging</title>
    <script type="text/javascript">
      var engaged = false;
      var offsetX = 0;
      var offsetY = 0;
      function dragIt(e) {
        if (engaged) {
          document.myLayer.moveTo(e.pageX - offsetX, e.pageY - offsetY);
        }
      }
      function engage(e) {
        engaged = true;
        offsetX = e.pageX - document.myLayer.left;
        offsetY = e.pageY - document.myLayer.top;
        return false;
      }
      function release() {
        engaged = false;
      }
    </script>
  </head>
  <body>
    <b>Dragging a Layer</b>
    <hr />
    <layer name="myLayer" bgcolor="lightgreen" top="90" left="100"
      width="300" height="190">
      <p><b>Drag me around the window.</b></p>
    </layer>
    <script type="text/javascript">
```

*Continued*

**document.layerObject.moveBy()****Listing 39-11 (continued)**

```

    document.myLayer.captureEvents(Event.MOUSEDOWN | Event.MOUSEUP |
        Event.MOUSEMOVE);
    document.myLayer.onmousedown = engage;
    document.myLayer.onmouseup = release;
    document.myLayer.onmousemove = dragIt;
</script>
</body>
</html>

```

**Related Items:** `layer.resizeBy()`, `layer.resizeTo()`, `window.moveBy()`, `window.moveTo()` methods.

**resizeBy(deltaX, deltaY)**

**resizeTo(width, height)**

**FTR:** `document.layerObject.resizeBy()`

**Returns:** Nothing.

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

The basic functionality and parameter requirements of the `layerObject.resizeBy()` and `layerObject.resizeTo()` methods are similar to the identically named methods of the `window` object. You should, however, be cognizant of some considerations unique to layers.

Unlike resizing a window, which causes all content to reflow to fit the new size, the layer sizing methods don't adjust the size of the layer. Instead, these methods control the size of the clipping region of the layer. Therefore, the content of the layer does not reflow automatically when you use these methods any more than it does when you change individual `layerObject.clip` values.

Another impact of this clipping region relationship deals with content that extends beyond the bounds of the layer. For example, if you provide `height` and `width` attributes to a `<layer>` tag, content that requires more space to display itself than those attribute settings afford automatically expands the viewable area of the layer. To rein in such runaway content, you can set the `clip` attribute. But because the layer resize methods adjust the clipping rectangle, oversized content doesn't overflow the `<layer>` tag's height and width settings. This may or may not be beneficial for you, depending on your design intentions. Adjusting the size of a layer with either method affects only the position of the right and bottom edges of the layer. The top-left location of the layer does not move.

Neither IE4+ nor NN6+/W3C provides a similar method, but you can accomplish the same effects by adjusting the `style` properties of a positioned element.

## Example

It is important to understand the ramifications of content flow when these two methods resize a layer. Listing 39-12a (and the companion document Listing 39-12b) shows you how to set the lower-right corner of a layer to be dragged by a user for resizing the layer (much like grabbing the resize corner of a document window). Three radio buttons enable you to choose whether and when the content should be redrawn to the layer — never, after resizing, or during resizing.

`document.layerObject.resizeBy()`

Event capture is very much like that in Listing 39-11 for layer dragging. The primary difference is that drag mode is engaged only when the mouse event takes place in the region of the lower-right corner. A different kind of offset value is saved here because, for resizing, the script needs to know the mouse event offset from the right and bottom edges of the layer.

Condition statements in the `resizeIt()` and `release()` functions verify whether a specific radio button is checked to determine when (or if) the content should be redrawn. I designed this page with the knowledge that its content might be redrawn. Therefore, I built the content of the layer as a separate HTML document that loads in the `<layer>` tag.

Redrawing the content requires reloading the document into the layer. I use the `layerObject.load()` method because I want to send the current `layerObject.clip.width` as a parameter for the width of the clip region to accommodate the content as it loads.

An important point to know about reloading content into a layer is that all property settings for the layer's event capture are erased when the document loads. Overcoming this behavior requires setting the layer's `onload` event handler to set the layer's event capture mechanism. If the layer event capturing is specified as part of the statements at the end of the document, the layer ignores some important events needed for the dynamic resizing after the document reloads the first time.

As you experiment with the different ways to resize and redraw, you see that redrawing during resizing is a slow process because of the repetitive loading (from cache) needed each time. On slower client machines, it is easy for the cursor to outrun the layer region, causing the layer to not get `mouseover` events at all. It may not be the best-looking solution, but I prefer to redraw after resizing the layer.

Listing 39-22 shows a version designed for the IE5+ and NN6+/W3C object models. Because content automatically reflows in those browsers, you do not have to load the content of the positioned element from an external document.

### Listing 39-12a: Resizing a Layer

```
<html>
  <head>
    <title>Layer Resizing</title>
    <script type="text/javascript">
      var engaged = false;
      var offsetX = 0;
      var offsetY = 0;
      function resizeIt(e) {
        if (engaged) {
          document.myLayer.resizeTo(e.pageX + offsetX, e.pageY + offsetY);
          if (document.forms[0].redraw[2].checked) {
            document.myLayer.load("1st39-12b.htm",
              document.myLayer.clip.width);
          }
        }
      }
      function engage(e) {
        if (e.pageX > (document.myLayer.clip.right - 10) &&
          e.pageY > (document.myLayer.clip.bottom - 10)) {
          engaged = true;
          offsetX = document.myLayer.clip.right - e.pageX;
          offsetY = document.myLayer.clip.bottom - e.pageY;
        }
      }
    </script>
  </head>
</html>
```

*Continued*

## Listing 39-12a (continued)

```

    }
  }
  function release() {
    if (engaged && document.forms[0].redraw[1].checked) {
      document.myLayer.load("1st39-12b.htm",
        document.myLayer.clip.width);
    }
    engaged = false;
  }
  function grabEvents() {
    document.myLayer.captureEvents(Event.MOUSEDOWN | Event.MOUSEUP |
      Event.MOUSEMOVE);
  }
</script>
</head>
<body>
  <b>Resizing a Layer</b>
  <hr />
  <form>
    Redraw layer content:<br />
    <input type="radio" name="redraw" checked="checked" />Never <input
    type="radio" name="redraw" />After resize <input type="radio"
    name="redraw" />During resize
  </form>
  <layer name="myLayer" src="1st39-12b.htm" bgcolor="lightblue" top="120"
  left="100" width="300" height="190" onload="grabEvents()">
  </layer>
  <script type="text/javascript">
    document.myLayer.onmousedown = engage;
    document.myLayer.onmouseup = release;
    document.myLayer.onmousemove = resizeIt;
  </script>
</body>
</html>

```

## Listing 39-12b: Content for the Resizable Layer

```

<html>
  <head>
    <title></title>
  </head>
  <body>
    <p><b>Resize me by dragging the lower right corner.</b></p>
    <script type="text/javascript">
      if (navigator.userAgent.indexOf("Mac") != -1) {
        document.write("(Mac users: Ctrl-Click me first; then Click to stop
        dragging.)");
      }
    </script>
  </body>
</html>

```

**Related Items:** layer.moveBy(), layer.moveTo(), window.resizeBy(), window.resizeTo() methods.

## Event handlers

### onblur onfocus

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

A user gets no visual cue when a layer receives focus. But a click on the clipping region of a layer triggers a `focus` event that can be handled with an `onFocus` event handler. Clicking anywhere on the page outside of that layer area fires a `blur` event. Changing the stacking order of sibling layers does not fire either event unless mouse activity occurs in one of the layers.

If your layer contains elements that have their own `focus` and `blur` events (such as text fields), those objects' event handlers still fire even if you also have the same event handlers defined for the layer. The layer's events fire after the text field's events.

Unlike comparable event handlers in windows, layer events for `blur` and `focus` do not have companion methods to bring a layer into focus or to blur it. However, if you use the `focus()` and/or `blur()` methods on applicable form elements in a layer, the layer's corresponding event handlers are triggered as a result.

**Related Items:** `textbox.blur()`, `textbox.focus()` methods.

### onload

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

Scripting layers can sometimes lead to instances of unfortunate sequences of loading. For example, if you want to set some layer object properties via a script (that is, not in the `<layer>` tag), you can do so only after the layer object exists in the document object model. One way to make sure the object exists is to place the scripting in `<script>` tags at the end of the document. Another way is to specify an `onload` event handler in the tag, as shown in Listing 39-12a.

Each time you load a document into the layer — either via the `src` attribute in the `<layer>` tag or by invoking the `layerObject.load()` method — the `onload` event handler runs. But also be aware that an interaction occurs between a layer's `onload` event handler and an `onload` event handler in the `<body>` tag of a document loaded into a layer. If the document body has an `onload` event handler, the layer's `onload` event handler does not fire. You get one or the other, but not both.

**Related Item:** `window.onload` event handler.

### onmouseout onmouseover

**Compatibility:** WinIE-, MacIE-, NN4, Moz-, Safari-

A layer knows when the cursor rolls into and out of its clipping region. Like several other objects in the document object model, the layer object has `onmouseover` and `onmouseout` event handlers that enable you to perform any number of actions in response to those user activities. Typically, a layer's `onmouseover` event handler changes colors, hides, or shows pseudo-borders devised of colored layers behind the primary layer; sometimes, it even changes the text or image content. The status bar is also available to plant plain-language legends about the purpose of the layer or offer other relevant help.

Both events occur only once per entrance to, and egress from, a layer's region by the cursor. If you want to script actions dependent upon the location of the cursor in the layer, you can use `layerObject.captureEvents()` to grab `mousemove` and all types of mouse button events. This kind of event capture generates an event object (see Chapter 25) that includes information about the coordinate position of the cursor at the time of the event.

**Related Items:** `link.onmouseout`, `link.onmouseover`, `area.onmouseout`, `area.onmouseover` event handlers.

## Positioned Elements in the Modern DOM

With the dwindling NN4 installed base, you can focus on applying “layer” techniques in browsers whose object models expose every element of an object and whose rendering engines automatically reflow content in response to changes. This section follows the sequence of examples in the discussion about NN4's layer object but shows you how to accomplish the same operations and learn the behavior of positioned elements in IE4+, NN6+, and W3C-compatible browsers.

An important facet that these newer browsers have in common is the `style` property of every renderable element object. Most adjustments to the location, layering, size, and visibility of positioned elements use the `style` object associated with each element. Cross-browser complications ensue, however, with some aspects of nested layers. Plus, there is the ever-present difference between the IE- and NN-class browsers with respect to the event objects — how to reference the event object and the names of its properties. Some of the examples that follow have more code in them than their corresponding NN4 layer version shown earlier in this chapter. Most of the additional code concerns itself with accommodating the different event object models.

One more point about the following examples: The syntax adopted for references to element objects uses the W3C DOM `document.getElementById()` method, which is supported in IE5+, NN6+/Mozilla, and Safari. If you intend to apply any of the techniques in these examples to applications that run exclusively in an IE environment (and must be compatible with IE4), you can substitute the `document.all` referencing syntax.

## Changing element backgrounds

Listing 39-13 demonstrates the syntax and behavior of setting background images via the `style.backgroundImage` property. Note the CSS-style syntax for the URL value assigned to the `style.backgroundImage` property. It's a good lesson to learn that most `style` properties are strings, and their values are in the same format as the values normally assigned in a stylesheet definition.

Removing a background image requires setting the URL to `null`. Also, a background image overlays whatever color (if any) you assign to the element. If the background image has transparent regions, the background color shows through.

### Listing 39-13: Setting Layer Backgrounds (W3C)

```
<html>
  <head>
    <title>Layer Backgrounds (W3C)</title>
    <script type="text/javascript">
      function setBg(URL) {
        document.getElementById("bgExpo").style.backgroundImage =
```

```

        "url(" + URL + ")";
    }
</script>
</head>
<body>
  <h1>Layer Backgrounds (W3C)</h1>
  <hr />
  <div id="buttons" style="position:absolute; top:100">
    <form>
      <input type="button" value="The Usual"
        onclick="setBg('cr_kraft.gif')" /><br />
      <input type="button" value="A Big One"
        onclick="setBg('arch.gif')" /><br />
      <input type="button" value="Not So Usual"
        onclick="setBg('wh86.gif')" /><br />
      <input type="button" value="Decidedly Unusual"
        onclick="setBg('sb23.gif')" /><br />
      <input type="button" value="Quick as..."
        onclick="setBg('lightnin.gif')" />
      <p><input type="button" value="Remove Image"
        onclick="setBg(null)" /><br /></p>
    </form>
  </div>
  <div id="bgExpo"
    style="position:absolute; top:100; left:250; width:300; height:260;
    background-color:gray">
    <span style="font-weight:bold; color:white">Some text, which may or
    may not read well with the various backgrounds.</span>
  </div>
</body>
</html>

```

Listing 39-14 focuses on background color. A color palette is laid out as a series of rectangles. As the user rolls atop a color in the palette, the color is assigned to the background of the layer. Because of the regularity of the `div` elements generated for the palette, this example uses scripts to write them dynamically to the page as the page loads. This lets the `for` loop handle all the positioning math based on initial values set as global variables.

Perhaps of more interest here than the background color setting is the event handling. First of all, because the target browsers all employ event bubbling, the page lets a single event handler at the document level wait for `mouseover` events to bubble up to the document level. But because the `mouseover` event of every element on the page bubbles there, the event handler must filter the events and process only those on the palette elements.

The `setColor()` method begins by equalizing the IE4+ and NN6+/W3C DOM event object models. If an object is assigned to the `evt` parameter variable, that means the W3C DOM browser is processing the event; otherwise, it's IE4+ — meaning that the `window.event` object contains the event information. Whichever browser performs the processing, the event object is assigned to the `evt` variable. After verifying that a valid event triggered the function, the next step is to equalize the different, event-model-specific property names for the event's target element. For W3C DOM browsers, the property is `target`, while IE4+ uses `srcElement`. The final validation is to check the `className` property of the event's target element. Because all elements acting as palette colors share the same `class` attribute, the `className` property is examined. If the value is `palette`, the `mouseover` event has occurred on one of the colors. Now it's time to extract the target element's `style.backgroundColor` property and assign that color to the same property of the main positioned element.

## Listing 39-14: Layer Background Colors (W3C)

```

<html>
  <head>
    <title>Layer Background Colors (W3C)</title>
    <script type="text/javascript">
      function setColor(evt) {
        evt = (evt) ? evt : (window.event) ? window.event : "";
        if (evt) {
          var elem = (evt.target) ? evt.target : evt.srcElement;
          if (elem.className == "palette") {
            document.getElementById("display").style.backgroundColor =
              elem.style.backgroundColor;
          }
        }
      }
      document.onmouseover = setColor;
    </script>
  </head>
  <body>
    <h1>Layer Background Colors (W3C)</h1>
    <hr />
    <script type="text/javascript">
      var oneLayer;
      var colorTop = 100;
      var colorLeft = 20;
      var colorWidth = 40;
      var colorHeight = 40;
      var colorPalette = new Array("aquamarine","coral","forestgreen",
        "goldenrod","red","magenta","navy","teal");
      for (var i = 0; i < colorPalette.length; i++) {
        oneLayer = "<div id='swatch" + i + "' class='palette'";
        oneLayer += "style='position:absolute; top:" + colorTop + "';";
        oneLayer += "left:" + ((colorWidth * i) + colorLeft) + "';";
        oneLayer += "width:" + colorWidth + "'; height:" + colorHeight + "';";
        oneLayer += "background-color:" + colorPalette[i] + "'></div>\n";
        document.write(oneLayer);
      }
    </script>
    <div id="display"
      style="position:absolute; top:150; left:80; width:200; height:200;
        background-color:gray">
      <span style="font-weight:bold; color:white; text-align:center">Some
        reversed text to test against background colors.</span>
    </div>
  </body>
</html>

```

## Layer clipping

Working with clipping rectangles is a bit cumbersome using CSS syntax because the object model standard does not provide separate readouts or controls over individual edges of a clipping rectangle. IE5+ enables you to read individual edge dimensions via the `currentStyle` object (for example, `currentStyle.clipTop`), but these properties are read-only.

Based on these limitations, Listing 39-15 is implemented in a way that, for the sake of convenience, preserves the current clipping rectangle edge values as global variables. Any adjustments to individual edge values are first recorded in those variables (in the `setClip()` function), and then the `style.clip` property is assigned the long string of values in the required format (in the `adjustClip()` function). The `showValues()` function reads the variable values and displays updated values after making the necessary calculations for the width and height of the clipping rectangle.

As a demonstration of a “reveal” visual effect (which you can carry out more simply in WinIE4+ via a transition filter), the `revealClip()` function establishes beginning clip values at the mid-points of the width and height of the layer. Then the `setInterval()` method loops through `stepClip()` until the clipping rectangle dimensions match those of the layer.

### Listing 39-15: Adjusting Layer clip Properties (W3C)

```
<html>
<head>
  <title>Layer Clip</title>
  <script type="text/javascript">
    var origLayerWidth = 0
    var origLayerHeight = 0
    var currTop, currRight, currBottom, currLeft
    function init() {
      origLayerWidth =
        parseInt(document.getElementById("display").style.width);
      origLayerHeight =
        parseInt(document.getElementById("display").style.height);
      currTop = 0;
      currRight = origLayerWidth;
      currBottom = origLayerHeight;
      currLeft = 0;
      showValues();
    }

    function setClip(field) {
      var val = parseInt(field.value);
      switch (field.name) {
        case "top" :
          currTop = val;

Listing 39-16 enables you to compare the results of adjusting a clipping rectangle versus the size of a positioned element. This example goes a bit further than the corresponding NN4 layer version (Listing 39-5) in that it enables you to adjust the dimensions of the entire layer (via the `style.left` and `style.right` properties) as well as the right and bottom edges of the clipping rectangle associated with the layer. As a bonus, the code includes a function that converts the `style.clip` string into an object representing the rectangle of the clipping rectangle (in other words, with four properties, one for each edge). Values from that `rectangle` object populate two of the fields on the page, providing dynamic readouts of the clipping rectangle's right and bottom edges.

Global variables still temporarily store the clipping rectangle values so that the `adjustClip()` function can operate just as it does in Listing 39-15. Note that the clipping rectangle is explicitly defined in the stylesheet rule for the positioned element. This is necessary for the element's `style.clip` property to have some values with which to start.

### Listing 39-16: Comparison of Layer and Clip Location Properties (W3C)

```

## Scripting nested layers

Working with nested layer locations, especially in a cross-browser manner, presents numerous browser-specific syntax problems that need equalization to behave the same to all users. Some discrepancies even appear between Windows and Macintosh versions of IE.

The scenario for Listing 39-17 consists of one positioned layer (greenish) nested inside another (reddish). The inner layer is initially sized and positioned so that the outer layer extends 5 pixels in each direction. Text boxes enable you to adjust the coordinates for either layer relative to the entire page as well as the layer's positioning context. If you make a change to any one value, all the others are recalculated and displayed to show you the effect the change has on other coordinate values.

As you see when you load the page, the outer element's positioning context is the page, so the "page" and "container" coordinates are the same (although the calculations to achieve this equality are not so simple across all browsers). The inner layer's initial page coordinates are to the right and down 5 pixels in each direction, and the coordinates within the container show those 5 pixels.

Because of browser idiosyncrasies, calculating the coordinates within the page takes the most work. The `getGrossOffsetLeft()` and `getGrossOffsetTop()` functions perform those calculations in the page. Passed a reference to the positioned element to be measured, the first number to grab is whatever the browser returns as the `offsetLeft` or `offsetTop` value of the element (see Chapter 15). These values are independent of the `style` property, and they can report different values for different browsers. IE, for example, measures the offset with respect to whatever it determines as the next outermost positioning context. NN6+, on the other hand, treats the page as the positioning context regardless of nesting. So, as long as there is an `offsetParent` element, a `while` loop starts accumulating the `offsetLeft` measures of each succeeding offset parent element going outward from the element. But even before that happens, a correction for MacIE must be accounted for. If there is a difference between the `style.left` and `offsetLeft` property values of an element, that difference is added to the offset. In MacIE5, for example, failure to correct this results in the "page" and "container" values of the outer layer being 10 pixels different in each direction. Values returned from these two gross measures are inserted in the readouts for the "page" measures of both inner and outer elements.

Reading the coordinates relative to each element's "container" is easy: The `style.left` and `style.top` properties have the correct values for all browsers. Moving a layer with respect to its positioning context (the "container" values) is equally easy: assign the entered values to the same `style.left` and `style.top` properties.

Moving the layers with respect to the page coordinate planes (via the `setOuterPage()` and `setInnerPage()` functions) involves going the long way to assign values that take each browser's positioning idiosyncrasies into account. The way you move a positioned element (cross-browser, anyway) is to assign a value to the `style.left` and `style.top` properties. These values are relative to their positioning context, but NN6+ doesn't offer any shortcuts to reveal what element is the positioning context for a nested element. Calls to the `getNetOffsetLeft()` and `getNetOffsetTop()` functions do the inverse of the `getGrossOffsetLeft()` and `getGrossOffsetTop()` functions. Because the values received from the text box are relative to the entire page, the values must have any intervening positioning contexts subtracted from that value in order to achieve the net positioning values that can be applied to the `style.left` and `style.top` properties. To get there, however, a call to the `getParentLayer()` function cuts through the browser-specific implementations of container references to locate the positioning context so that its coordinate values can be subtracted properly. The same kind of

correction for MacIE is required here as in the gross offset calculations; but here, the correction is subtracted from the value that eventually is returned as the value for either the `style.left` or `style.top` of the layer.

Let me add one quick word about the condition statements of the `while` constructions in the `getNetOffsetLeft()` and `getNetOffsetTop()` functions. You see here a construction not used frequently in this book, but one that is perfectly legal. When the conditional expression evaluates, the `getParentLayer()` method is invoked, and its returned value is assigned to the `elem` variable. That expression evaluates to the value returned by the function. As you can see from the `getParentLayer()` function definition, a value is returned as either an element reference or `null`. The `while` condition treats a value of `null` as `false`; any reference to an object is treated as `true`. Thus, the conditional expression does not use a comparison operator but rather executes some code and branches based on the value returned by that code. NN6+ reports JavaScript warnings (not errors) for this construction because it tries to alert you to a common scripting bug that occurs when you use the `=` operator when you really mean the `==` operator. But an NN warning is not the same as a script error, so don't be concerned when you see these messages in the JavaScript Console window during your debugging.

### Listing 39-17: Testing Nested Layer Coordinate Systems (W3C)

```
<html>
  <head>
    <title>Nested Layer Coordinates (W3C)</title>
    <script type="text/javascript">
      // offsets within page
      function getGrossOffsetLeft(elem) {
        var offset = 0;
        while (elem.offsetParent) {
          // correct for MacIE discrepancy between offset and style
          // coordinates, but not if the parent is HTML element (NN6+)
          offset += (elem.offsetParent.tagName != "HTML") ?
            parseInt(elem.style.left) - parseInt(elem.offsetLeft) : 0;
          elem = elem.offsetParent;
          offset += elem.offsetLeft;
        }
        return offset;
      }
      function getGrossOffsetTop(elem) {
        var offset = 0;
        while (elem.offsetParent) {
          // correct for MacIE discrepancy between offset and style
          // coordinates, but not if the parent is HTML element (NN6+)
          offset += (elem.offsetParent.tagName != "HTML") ?
            parseInt(elem.style.top) - parseInt(elem.offsetTop) : 0;
          elem = elem.offsetParent;
          offset += elem.offsetTop;
        }
        return offset;
      }
    </script>
  </head>
  // offsets within element's positioning context
```

```

---

Try entering a variety of values in all text boxes to see what happens. Here is one possible sequence of tests and explanations:

1. Increase the red Page X value to 250. This moves the outer layer to the right by 50 pixels. Because the green layer is nested inside, it moves along with it. The green's Page X value also increases by 50, but its Container X value remains the same because the inner layer maintains the same relationship with the outer layer as before.
2. Increase the green Page X value to 300. This action shifts the position of the green inner layer by 45 pixels, making it a total of 50 pixels inset within its positioning context. Because the outer layer does not have its clipping rectangle set, the inner layer's content bleeds beyond the width of the red layer.
3. Set the Container Y value to -50. This action moves the green inner layer upward so that its top is 50 pixels above the top of its red container. As a result, the Page Y value of the inner layer is 80, while the Page Y value of the red outer layer remains at 130 (thus, the 50-pixel difference).

As you experiment with moving the layers around, you may encounter some screen refresh problems where traces of the inner layer remain when moved beyond the outer layer's rectangle. Take these bugs into account when you design the actions of your script-controlled positioning.

## Loading external HTML into a layer

The NN4 `layer` object had an unfair advantage when it came to loading external content into it: the element was designed to do just that, acting in some ways like the W3C-endorsed `iframe` element.

Because the IE4+ and W3C DOM object models embrace the `iframe` element, using that element may be the easy way for you to designate a space within a page for external content. In fact, you can even assign a stylesheet rule that absolute-positions the `iframe` precisely on the page where you want it. Be sure to set the `frameborder` attribute to 0 unless you want the border to be visible to the user (and then watch out for content that may overrun the rectangle and cause scrollbars to appear). In this case, you must then leave all the formatting and stylesheet control of that content to the HTML loaded into the `iframe`, just as if it were in a separate window or frame. To load different content into the element, assign a different URL to the `src` property of the `iframe` element object.

As one more example that more closely simulates the loading of external content into a layer, Listing 39-18 demonstrates a somewhat ugly workaround that lets a layer's background color or image show through some kinds of HTML content. The technique works only in IE5.5+ and NN6+/W3C because these browser generations are the first to offer scripted access to the HTML you need to load into an intermediate (and hidden) `iframe` before stuffing the content into the layer.

A hidden `iframe` element is the initial recipient of the external HTML file, as loaded by the `loadOuter()` method. When that file loads, the `transferHTML()` method is invoked to copy the `innerHTML` of just the body element of the content window of the `iframe` (note the different syntax for NN6+ — the `contentDocument` property — and IE5.5+ — the `contentWindow` property). By eliminating the `body` element and any tags in the head, you prevent the tags in the layer from conflicting with the tags for the main document. As a result, however, notice how the background color set for the layer shows through the HTML plugged into the layer.

HTML element objects (other than `iframe`) were not designed to get their content from external files. But, as Listing 39-18 shows, where there is a will there is a way — even if the workaround isn't pretty.

### Listing 39-18: Setting Layer Source Content (W3C)

```
<html>
  <head>
    <title>Loading External Content into a Layer (W3C)</title>
    <script type="text/javascript">
      function loadOuter(doc) {
        document.getElementById("hiddenContent").src = doc;
        // workaround for missing onload event in iframe for NN6+
        if (!document.getElementById("hiddenContent").onload) {
          setTimeout("transferHTML()", 1000);
        }
      }
      function transferHTML() {
        var srcFrame = document.getElementById("hiddenContent");
        var srcContent = (srcFrame.contentDocument) ?
          srcFrame.contentDocument.getElementsByTagName("BODY")[0].innerHTML
          : (srcFrame.contentWindow) ?
          srcFrame.contentWindow.document.body.innerHTML : "";
        document.getElementById("outerDisplay").innerHTML = srcContent;
      }
    </script>
  </head>
  <body>
    <h1>Loading External Content into a Layer (W3C)</h1>
    <hr />
    <p>Click the buttons to see what happens when you load new source
    documents into the <font color="coral">layer</font> object.</p>
    <div
    style="position:absolute; top:150; width:200; background-color:coral">
      <form>
        Load into outer layer:<br />
        <input type="button" value="Article I"
        onclick="loadOuter('article1.htm')" /><br />
        <input type="button" value="Entire Bill of Rights"
        onclick="loadOuter('bofright.htm')" /><br />
      </form>
    </div>
```

```

<div id="outerDisplay"
  style="position:absolute; top:150; left:250; width:370; height:190;
    background-color:coral">
  <p><b>Placeholder text for layer.</b></p>
</div>
<iframe id="hiddenContent" style="visibility:hidden"
  onload="transferHTML()"></iframe>
</body>
</html>

```

## Positioned element visibility behavior

There is very little code in Listing 39-19 because it simply adjusts the `style.visibility` property of an outer layer and a nested, inner layer. You can see that when the page loads, the green inner layer's visibility is automatically set to inherit the visibility of its containing outer layer. When you click the outer layer buttons, the inner layer blindly follows the settings.

Things change, however, once you start adjusting the properties of the inner layer independently of the outer layer. With the outer layer hidden, you can show the inner layer (except in Safari 1.0). Only by setting the `visibility` property of the inner layer to `inherit` can you make it rejoin the outer layer in its behavior.

### Listing 39-19: Nested Layer Visibility Relationships (W3C)

```

<html>
  <head>
    <title>layer.style.visibility (W3C)</title>
    <script type="text/javascript">
      function setOuterVis(type) {
        document.getElementById("outerDisplay").style.visibility = type;
      }
      function setInnerVis(type) {
        document.getElementById("innerDisplay").style.visibility = type;
      }
    </script>
  </head>
  <body>

style="position:absolute; top:5; left:5; width:360; height:180;
background-color:aquamarine">
    <p><b>Placeholder text for raw inner layer.</b></p>
  </div>
</div>
</body>
</html>

```

## Scripting layer stacking order

Listing 39-20 is simpler than its NN4 layer-specific version (Listing 39-9) because the W3C DOM, as implemented in IE4+ and NN6+/Mozilla/Safari, does not have properties that reveal the equivalent of the `layerObject.above` or `layerObject.below` properties. Therefore, Listing 39-20 confines itself to enabling you to adjust the `style.zIndex` property values of three overlapping layers. All three layers (none of which are nested inside another) initially set their `zIndex` values to 0, meaning that the source code order rules the stacking order.

Listing 39-20: Relationships Among `zIndex` Values (W3C)

```

<html>
  <head>
    <title>layer.style.zIndex</title>
    <script type="text/javascript">
      function setZ(field) {
        switch (field.name) {
          case "top" :
            document.getElementById("topLayer").style.zIndex =
              parseInt(field.value);
            break;
          case "mid" :
            document.getElementById("middleLayer").style.zIndex =
              parseInt(field.value);

```

```

        break;
    case "bot" :
        document.getElementById("bottomLayer").style.zIndex =
            parseInt(field.value);
    }
    showValues();
}
function showValues() {
    var botLayer = document.getElementById("bottomLayer");
    var midLayer = document.getElementById("middleLayer");
    var topLayer = document.getElementById("topLayer");

    document.forms[0].bot.value = botLayer.style.zIndex;
    document.forms[1].mid.value = midLayer.style.zIndex;
    document.forms[2].top.value = topLayer.style.zIndex;
}
</script>
</head>
<body onload="showValues()">
<h1><tt>layer.style.zIndex</tt> Property of Sibling Layers</h1>
<hr />
Enter new zIndex values to see the effect on three layers.

</div>
</body>
</html>

```

## Dragging and resizing a layer

Listing 39-21 is an IE4+- and W3C-compatible version of the layer dragging example shown earlier in Listing 39-11. The basic structure is the same, with event handler functions for engaging the drag mode, handling the mouse movement while in drag mode, and releasing the element at the end of the journey.

There is a lot more code in this version for several reasons. The main reason is to accommodate the two event object models in IE and NN6+/W3C browsers. First of all, event bubbling is used so that all mouse events are handled at the document level. Thus, all of the event handlers need to equalize the event object and event target element, as well as filter events so that the action occurs only when a draggable element (as identified by its `className` property) is the target of the event action.

The toughest job involves the `engage()` function because it must use the two different event and element object models to establish the offset of the `mousedown` event within the draggable element. For WinIE, this also means taking the scrolling of the body into account. To get the element to reposition itself with mouse motion, the `dragIt()` function applies browser-specific coordinate values to the `style.left` and `style.top` properties of the draggable element. This function is invoked very frequently in response to the `mousemove` event.

Nothing in this example, however, treats the `zIndex` stacking order, which must be addressed if the page contains multiple, draggable items. See the map puzzle game in Chapter 56 on the CD-ROM for an example of processing multiple, draggable items.

## Listing 39-21: Dragging a Layer (W3C)

```

<html>
  <head>
    <title>Layer Dragging</title>
    <style type="text/css">
      .draggable {cursor:hand}
    </style>
    <script type="text/javascript">
      var draggedElem;
      var offsetX = 0;
      var offsetY = 0;
      function dragIt(evt) {
        evt = (evt) ? evt : (window.event) ? window.event : "";
        var targElem = (evt.target) ? evt.target : evt.srcElement;
        if (draggedElem) {
          targElem = draggedElem;
          if (targElem.className == "draggable") {
            while (targElem.id != "myLayer" && targElem.parentNode) {
              targElem = targElem.parentNode;
            }
            if (evt.pageX) {
              targElem.style.left = evt.pageX - offsetX + "px";
              targElem.style.top = evt.pageY - offsetY + "px";
            } else {
              targElem.style.left = evt.clientX - offsetX + "px";
              targElem.style.top = evt.clientY - offsetY + "px";
            }
            return false;
          }
        }
      }
      function engage(evt) {
        evt = (evt) ? evt : (window.event) ? window.event : "";
        var targElem = (evt.target) ? evt.target : evt.srcElement;
        if (targElem.className == "draggable") {
          while (targElem.id != "myLayer" && targElem.parentNode) {
            targElem = targElem.parentNode;
          }
          if (targElem.id == "myLayer") {
            draggedElem = targElem;
            if (evt.pageX) {
              offsetX = evt.pageX - targElem.offsetLeft;
              offsetY = evt.pageY - targElem.offsetTop;
            } else {
              offsetX = evt.offsetX - document.body.scrollLeft;
              offsetY = evt.offsetY - document.body.scrollTop;
              if (navigator.userAgent.indexOf("Win") == -1) {
                offsetX += document.body.scrollLeft;
                offsetY += document.body.scrollTop;
              }
            }
          }
        }
        return false;
      }
    </script>
  </head>
  <body>
    <div id="myLayer" class="draggable" style="border: 1px solid black; width: 100px; height: 100px; position: absolute; top: 50px; left: 50px; text-align: center; line-height: 100px; font-size: 10px;">
      Layer Dragging
    </div>
  </body>
</html>

```

*Continued*

## Listing 39-21 (continued)

```

    }
  }
}
function release(evt) {
  evt = (evt) ? evt : (window.event) ? window.event : "";
  var targElem = (evt.target) ? evt.target : evt.srcElement;
  if (targElem.className == "draggable") {
    while (targElem.id != "myLayer" && targElem.parentNode) {
      targElem = targElem.parentNode;
    }
    if (draggedElem && targElem.id == "myLayer") {
      draggedElem = null;
    }
  }
}
</script>
</head>
<body>
  <h1>Dragging a Layer</h1>
  <hr />
  <div id="myLayer" class="draggable"
  style="position:absolute; top:90; left:100; width:300; height:190;
  background-color:lightgreen">
    <span class="draggable"><b>Drag me around the window.</b></span>
    <script type="text/javascript">
      document.onmousedown = engage;
      document.onmouseup = release;
      document.onmousemove = dragIt;
    </script>
  </div>
</body>
</html>

```

The final listing in this section, Listing 39-22, applies many example components used thus far to let scripts control the resizing of a positionable element by dragging the lower-right, 20-pixel region. A lot of the hairy code in the `engage()` function is for determining if the `onmousedown` event occurs in the invisible 20-pixel square.

The `resizeIt()` function resembles the `dragIt()` function of Listing 39-21, but the adjustments are made to the width and height of the positionable element. A fair amount of math determines the width of the element in response to the cursor's instantaneous location and sets the `style.width` and `style.height` properties accordingly.

## Listing 39-22: Resizing a Layer (W3C)

```

<html>
  <head>
    <title>Layer Resizing</title>
    <script type="text/javascript">
      var draggedElem;
      var offsetX = 0;
      var offsetY = 0;

```

```

function resizeIt(evt) {
    evt = (evt) ? evt : (window.event) ? window.event : "";
    var targElem = (evt.target) ? evt.target : evt.srcElement;
    if (draggedElem) {
        if (evt.pageX) {
            targElem.style.width = (evt.pageX - targElem.offsetLeft -
                offsetX) + "px";
            targElem.style.height = (evt.pageY - targElem.offsetTop -
                offsetY) + "px";
        } else {
            var elemWidth = evt.clientX - targElem.offsetLeft - offsetX -
                parseInt(targElem.style.left) -
                parseInt(targElem.offsetLeft));
            var elemHeight = evt.clientY - targElem.offsetTop - offsetY -
                (parseInt(targElem.style.top) -
                parseInt(targElem.offsetTop));
            targElem.style.width = elemWidth + "px";
            targElem.style.height = elemHeight + "px";
        }
    }
}

function engage(evt) {
    evt = (evt) ? evt : (window.event) ? window.event : "";
    var targElem = (evt.target) ? evt.target : evt.srcElement;
    if (targElem.className == "draggable") {
        while (targElem.id != "myLayer" && targElem.parentNode) {

## Listing 39-22 (continued)

```

        if (targElem.className == "draggable") {
            while (targElem.id != "myLayer" && targElem.parentNode) {
                targElem = targElem.parentNode;
            }
            if (draggedElem && targElem.id == "myLayer") {
                draggedElem = null;
            }
        }
    }
</script>
</head>
<body>
  <h1>Resizing a Layer (W3C)</h1>
  <hr />
  <div id="myLayer" class="draggable"
  style="position:absolute; top:170; left:100; width:300; height:190;
  background-color:lightblue">
    <span>Here is some content inside the layer. See what happens to it as
    you resize the layer via the bottom-right 20-pixel handle.</span>
  </div>
  <script type="text/javascript">
    document.onmousedown = engage;
    document.onmouseup = release;
    document.onmousemove = resizeIt;
  </script>
</body>
</html>

```

This chapter only scratches the surface in the kinds of positioned element actions you can control via scripts. You may have seen examples of positioned element scripting at sites around the Web. For example, some pages have subject headers fly into place—even “bounce” around until they settle into position. Or elements can go in circles or spirals to get your attention (or distract you, as the case may be). The authors of those tricks apply formulas from other disciplines (such as games programming) to the `style` object properties of a positioned element.

Sometimes the effects are there just for the sake of looking cool (at first, anyway) or because the page author knows how to script those effects. Your chief guide in implementing such features, however, should be whether the scripting genuinely adds value to the content offering. If you don't improve the content by adding a flying doo-dad or pulsating images, then leave them out. A greater challenge is finding meaningful ways to apply positioning techniques. Done the right way and for the right reason, they can significantly enhance the visitor's enjoyment of your application.

# Embedded Objects

---

In addition to the typical content that you see in Web pages — primarily text and images — you can embed other kinds of content into the page. Such embedded content usually requires the powers of additional software, such as plug-in players or other external code processors, to load and display the content. All of this external content is added to a page by one of three HTML elements: `applet`, `embed`, or `object`. In the HTML 4.0 standard, the `applet` element, which was intended originally for loading Java applets, is deprecated in favor of the newer `object` element. An `object` element is intended to be more extensible, meaning that it has enough attributes and power to summon the Java virtual machine if the incoming code is a Java applet, or run an ActiveX program (in IE for Windows, that is). The `embed` element is commonly used to display a plug-in control panel directly in the document, rather than having the panel appear in a separate window, but it, too, is gradually giving way to the `object` element.

In all cases, when a visual element is embedded via any of these elements, the control panel or applet occupies a segregated rectangular space on the page and generally confines its activities to that rectangle. But in some browsers and plug-in player types, JavaScript can also interact with the content or the player, allowing your scripts to extend themselves with powers for actions, such as controlling audio playback or the operation of a Java applet. Don't expect universal browser support for controlling plug-ins.

This chapter's primary focus is not on the content and players that you can control as it is on the HTML element objects that load the content or players into the page in the first place. Most of the properties represent nothing more than scriptable access to the element HTML attributes. The property descriptions in this chapter are therefore not extensive. Online HTML references (including the W3C HTML 4.0 specification and the Microsoft Developer Network documentation) should fill in the attribute value information quite well. In practice, scripts have very little interaction with these element objects, but if you ever need to know what's scriptable, you'll find that information here. As for controlling applets and plug-ins, you can find information about that in Chapter 44.

## applet Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

### In This Chapter

Using `embed` element objects

Exploring the `object` element object

Understanding the unusual `param` element

## applet

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
align	(Applet methods)	oncellchange
alt		ondataavailable
altHTML		ondatasetchanged
archive		ondatasetcomplete
code		onload
codeBase		onrowenter
height		onrowexit
hspace		onrowsdelete
name		onrowsinserted
object		onscroll
vspace		
width		
(Applet variables)		

## Syntax

Accessing applet element object properties or methods:

```
(NN3+/IE4+)    [window.]document.appletName.property | method([parameters])
(NN3+/IE4+)    [window.]document.applets[index].property | method([parameters])
(IE4+)         [window.]document.all.appletID.property | method([parameters])
(IE5+/W3C)     [window.]document.getElementById("appletID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari1+

## About this object

The fact that the applet, itself, can expose public instance variables and public methods as properties and methods of the applet object means that the scriptable characteristics of an applet object are highly dependent upon the way the applet was written. You can learn more about how to compose an applet that exposes its innards to JavaScript in Chapter 44.

Perhaps the most important point to remember about accessing applets is that you must have them loaded and running before you can address them as objects. Although you cannot query an applet to find out whether it's loaded (as you can with an image), you can rely on the `onload` event handler of a window to fire only when all applets in the window are loaded and running (with the occasional version- or platform-specific bug in frames, as described in the `window.onload` event handler discussion in Chapter 16). IE4+ also features an `onload` event handler for the applet element directly, but applets tend to be the last things to load on a page. Therefore, you won't be able to use an applet embedded in a document to help you create the HTML content of that page as it loads, but an applet can provide content for new documents or for modifiable elements of a page. With the highly dynamic object models of IE4+ and W3C, this can lead to all kinds of possibilities.

Java applets have also been used to maintain contact with a server after the page has loaded by way of a servlet running on the server. A servlet allows the applet to query or be refreshed with instantaneously updated information without having to reload the page. Of course, getting a sophisticated applet to run in a wide range of browsers and operating systems is a challenge unto itself.

A large set of event handlers for this element (all but `onload` and `onscroll`) is related to the application of WinIE data binding for `param` elements nested inside an `applet` element. These events fire when a variety of actions occur to the data source or recordset associated with the applet. For more about applying data binding to an `applet` element, see <http://msdn.microsoft.com/workshop/author/databind/dataconsumer.asp>.

## Properties

### align

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `align` property controls either the horizontal or vertical alignment of the element with regard to surrounding content. String values of `left` or `right` cause the applet rectangle to cling to the left or right edges of its next outermost positioning context. String values of `abs-bottom`, `absmiddle`, `baseline`, `bottom`, `middle`, `texttop`, or `top` influence the vertical alignment with respect to adjacent text, with the same kind of results as corresponding values of the `style.verticalAlign` property.

**Related Items:** `style.verticalAlign` property.

### alt

**Value:** String.

Read/Write

**Compatibility:** WinIE6+, MacIE6+, NN6+, Moz1+, Safari1+

The `alt` property represents the `alt` attribute, which should contain text that displays in the browser in the event that the applet does not load or the user has Java turned off in the browser preferences. This information should be set as the `applet` element's attribute, because assigning text to the property after the applet attempts to load does not insert the text into the page.

**Related Items:** `altHTML` property.

### altHTML

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `altHTML` property is supposed to provide an `applet` element with HTML content to render if the applet doesn't load. In practice, assigning an HTML string to this property has no effect on an `applet` element.

**Related Items:** `alt` property.

**applet.archive**

## archive

**Value:** String.

Read/Write

**Compatibility:** WinIE6+, MacIE-, NN6+, Moz1+, Safari+

The `archive` property represents the `archive` attribute, which points to the URL of a compressed (.zip) file containing Java class files needed for the applet. The archive must include the class file that is assigned to the `code` attribute to get the applet loaded and started.

**Related Items:** `code` property.

## code

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `code` property is the URL string of the Java class file that is to begin loading the applet (or the property may be the entire applet if it consists of a single class file). You cannot change the code assigned to an applet after the element has loaded (even if the applet code did not load successfully).

**Related Items:** `codeBase` property.

## codeBase

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `codeBase` property is the string of the path on the server to the Java class file that is to begin loading the applet (or the property may be the entire applet if it consists of a single class file). The actual Java class filename is not part of the `codeBase` property.

**Related Items:** `code` property.

## height

## width

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `height` and `width` properties represent the `height` and `width` attributes of the applet element. Although these values should be set via attributes in the tag, these properties can adjust the size of the applet after the fact in IE5+.

**Related Items:** `hspace`, `vspace` properties.

## hspace

## vspace

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `hspace` and `vspace` properties represent the `hspace` and `vspace` attributes of the applet element, which control the number of pixels of transparent padding around the applet element on the page. Although these values should be set via attributes in the tag, these properties can adjust the size of the applet padding after the fact in IE5+.

**Related Items:** `height`, `width` properties.

**name****Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `name` property represents the `name` attribute, a holdover from the early implementations of the `applet` element before `id` attributes were used to identify elements. The value assigned to the `name` attribute is the name you can use to reference applets in all browsers that support accessing applets: `document.appletName`.

**object****Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `object` property represents the `object` attribute, which, according to the W3C HTML standard, points to the URL of a serialized (that is, “saved”) version of the applet’s current state.

**Related Items:** `code` property.**vspace**(See `hspace`)**width**(See `height`)

## object Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

## Syntax

Accessing `object` element object properties or methods:

```
(IE4+)           [window.]document.all.objectID.property | method([parameters])
(IE5+/W3C)      [window.]document.getElementById("objectID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

## About this object

The `object` element is intended to be the primary way to add external content (that is, content that the browser itself does not render) to a page. For example, WinIE uses it to load ActiveX controls (whether from the server or locally). The `object` element is also destined to replace usage of the `applet` and `embed` elements.

As with the `applet` element, `object`, scripts can frequently control the programs and plug-ins that get loaded into the browser through the `object` tag. Chapter 44 shows you how to do that for common objects. The property listings here are merely for the properties of the element, most of which mimic the attributes available for the `object` element. Even though the properties are exposed, they are very rarely scripted, except perhaps to adjust the size of the space occupied by a media controller. Most properties are read-only after their values are set by attributes in the element's tag. But if your scripts are creating the `object` element anew, scripts can set the property values the first time to initialize the object.

In the list of properties that begins this object's coverage, several are marked with an asterisk (\*). These properties are defined in the W3C DOM Level 2 specification, and placeholders are included in version 6 browsers (and NN7/Mozilla1.4). But as of this writing, there is no indication that these properties are "connected."

A large set of event handlers for this element (all but `onload` and `onscroll`) is related to the application of WinIE data binding for `param` elements nested inside an `object` element. These events fire when a variety of actions occur to the data source or recordset associated with the program associated with the element. For more about applying data binding to an `object` element, see <http://msdn.microsoft.com/workshop/author/databind/dataconsumer.asp>.

## Properties

### align

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari1+

The `align` property controls either the horizontal or vertical alignment of the element with regard to surrounding content. String values of `left` or `right` cause the object rectangle to cling to the left or right edges of its next outermost positioning context. String values of `abs-bottom`, `absmiddle`, `baseline`, `bottom`, `middle`, `texttop`, or `top` influence the vertical alignment with respect to adjacent text, with the same kind of results as corresponding values of the `style.verticalAlign` property.

**Related Items:** `style.verticalAlign` property.

### alt

**Value:** String.

Read/Write

**Compatibility:** WinIE6+, MacIE-, NN-, Moz-, Safari-

The `alt` property represents the `alt` attribute, which should contain text that displays in the browser in the event that the object or its data do not load. This information should be set as the `object` element's attribute, because assigning text to the property after the object attempts to load does not insert the text into the page.

**Related Items:** `altHTML` property.

### altHTML

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `altHTML` property is supposed to provide an `object` element with HTML content to render if the object doesn't load. In practice, assigning an HTML string to this property has no effect on an `object` element.

**Related Items:** `alt` property.

### BaseHref

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `BaseHref` property returns the full URL path to the current document.

**Related Items:** `baseURI` property.

### baseURI

**Value:** String.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN7+, Moz1+, Safari-

The `baseURI` property returns the full URL (URI) path to the current document.

**Related Items:** `BaseHref` property.

**object.border****border****Value:** Number as string.

Read/Write

**Compatibility:** WinIE6+, MacIE-, NN6+, Moz1+, Safari1+

The `border` property controls the thickness of the border around the object, in pixels. You must specify the border thickness as a string, as in "6" for 6 pixels.

**classid****Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `classid` property represents the `classid` attribute of the `object` element. IE for Windows uses this attribute to assign the Globally Unique ID (GUID) of an ActiveX control. For example, to load a (nearly) invisible Windows Media Player object into a page, the HTML is as follows:

```
<object id="medPlayer" width="1" height="1"
  classid="CLSID:22d6f312-b0f6-11d0-94ab-0080c74c7e95"
  codebase="#Version=1,0,0,0">
```

If your script then accesses the `classid` property of the `medPlayer` object, the value returned is the complete string as assigned to the attribute:

```
CLSID:22d6f312-b0f6-11d0-94ab-0080c74c7e95
```

Note that the `CLSID:` prefix is also part of the string value. Even if the object does not load (for example, because the object is missing or an error is in the long `classid` string), the property value reports the value as assigned to the attribute.

The HTML 4.0 specification indicates that the `classid` attribute be used for any kind of external class files, including Java applets. But in practice, IE wants applet URLs supplied to the `code` attribute (a non-HTML 4.0 attribute).

**Related Items:** `code` property.**code****Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `code` property is the URL string of a Java class file that is to begin loading the applet (or the property may be the entire applet if it consists of a single class file). You cannot change the code assigned to an applet after the element has loaded (even if the applet code did not load successfully).

**Related Items:** `codeBase` property.**codeBase****Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `codeBase` property is the string of the path on the server to the source of the applet or ActiveX control referenced by the `classid` or `code` attributes. IE4+ also uses the `codebase` attribute to specify a minimum version of control that is to load, if the attribute is available. This facet is discussed in Chapter 38's coverage of plug-in detection for WinIE.

**Related Items:** `code` property.

**object.hspace****codeType****Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `codeType` property is a string of the `mime` type of whatever object is pointed to by the `code` attribute value.

**Related Items:** `type` property.**contentDocument****Value:** Document node reference.

Read-Only

**Compatibility:** WinIE-, MacIE-, NN6+, Moz1+, Safari-

The `contentDocument` property returns the document node created by the object, if it exists.

**data****Value:** URL as string.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `data` property provides access to the URL of a file containing data for the object, as opposed to the object itself.

**form****Value:** Object reference.

Read-Only

**Compatibility:** WinIE4+, MacIE5, NN6+, Moz1+, Safari1+

The `form` property returns a reference to the `form` element that contains the object, if there is one. This property only applies if the object is acting as a control within a form.

**height****width****Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `height` and `width` properties represent the `height` and `width` attributes of the object element. Although these values should be set via attributes in the tag, these properties can adjust the size of the embedded element after the fact in IE5+.

**Related Items:** `hspace`, `vspace` properties.**hspace****vspace****Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `hspace` and `vspace` properties represent the `hspace` and `vspace` attributes of the object element, which control the number of pixels of transparent padding around the object element on the page. Although these values should be set via attributes in the tag, these properties can adjust the size of the padding around the element after the fact in IE5+.

**Related Items:** `height`, `width` properties.

**object.name**

## name

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `name` property represents the `name` attribute of the `object` element. The better form is to assign an `id` to the `object` element and use accepted reference syntax for element IDs.

## object

**Value:** External object.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN-, Moz-, Safari-

The `object` property returns a reference to the object contained by the `object` element. This property is essential if the program running inside the `object` element has the same property or method names as the `object` element itself. For example, consider a Java applet loaded into the `object` element as follows:

```
<object code="coolApplet" id="myAPPLET" ... >
```

If the applet code contained a public variable called `height`, an attempt to read or write that property through the `object` element will cause the element's properties to be read, and not the applet's properties. Therefore, if you insert the `object` property in the reference, the script reaches into the applet object for the property:

```
document.getElementById("myAPPLET").object.height = 40;
```

If there is no ambiguity between element and object property and method names, the browser looks first at the element and then the object to find a match.

## type

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari1+

The `type` property represents the `type` attribute of the `object` element, which is intended to warn the browser about the `mime` type of data that is to be loaded into the object's process.

**Related Items:** `codeType` property.

## useMap

**Value:** String.

Read/Write

**Compatibility:** WinIE6+, MacIE-, NN6+, Moz1+, Safari1+

The `useMap` property identifies the URL of an image map; the image map is described by the `map` element in the same document. The value of the `useMap` property includes a hash mark followed by the name of the image map, as specified in the `usemap` attribute of the `object` element.

## vspace

(See `hspace`)

## width

(See `height`)

## embed Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
align	(Object methods)	onload
height		onscroll
hidden		
name		
pluginspage		
src		
units		
width		
(Object variables)		

### Syntax

Accessing embed element object properties or methods:

```
(IE4+)           [window.]document.all.objectID.property | method([parameters])
(IE5+/W3C)      [window.]document.getElementById("objectID").property |
method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN3+, Moz1+, Safari-

### About this object

An `embed` element is a carryover from the early browser days. Although never adopted by the W3C HTML standard, the `embed` element has been used in NN and IE as a way to embed non-native content (for example, sounds, video clips, and custom `mime` types for plug-ins, such as Shockwave) into a page. What gets embedded into the page is the controller or viewer for whatever kind of data the `embed` element points to (via the `src` attribute).

The `embed` element is far less sophisticated than the `object` element, but current browsers continue to support it. If you have been using the `embed` element in previous applications, it may be a good idea to start gravitating toward the `object` element. For backward-compatibility purposes, nesting an `embed` element inside an `object` element is not uncommon, both of which attempt to load the same content and plug-in. Browsers that know about the `object` element will load the content that way; older browsers will use the `embed` element and its attributes and parameters.

Because an `embed` element loads a plug-in (including ActiveX control types of plug-ins in WinIE), you can reference the plug-in's properties and methods through the `embed` object's reference.

**embed.align**

## Properties

### align

**Value:** String.

Read/Write

**Compatibility:** WinIE-, MacIE5+, NN6+, Moz1+, Safari-

The `align` property controls either the horizontal or vertical alignment of the element with regard to surrounding content. String values of `left` or `right` cause the object rectangle to cling to the left or right edges of its next outermost positioning context. String values of `absbottom`, `absmiddle`, `baseline`, `bottom`, `middle`, `texttop`, or `top` influence the vertical alignment with respect to adjacent text, with the same kind of results as corresponding values of the `style.verticalAlign` property.

**Related Items:** `style.verticalAlign` property.

### height

### width

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari-

The `height` and `width` properties represent the `height` and `width` attributes of the `embed` element. Although these values should be set via attributes in the tag, these properties can adjust the size of the element after the fact in IE5+.

### hidden

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `hidden` property represents the `hidden` attribute of the `embed` element. When an `embed` element is hidden, neither controller nor the content is shown. Application of this element in modern browsers should use stylesheets to hide and show the element.

**Related Items:** `style.visibility` property.

### name

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN6+, Moz1+, Safari-

The `name` property represents the `name` attribute of the `embed` element. The better form is to assign an `id` to the `embed` element and use accepted reference syntax for element IDs.

### pluginspage

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `pluginspage` property represents the `pluginspage` attribute of the `embed` element. This attribute is a URL that gets applied to a link in the browser if the plug-in associated with the external file's `mime` type cannot be found on the client.

**src****Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `src` property represents the `src` attribute of the `embed` element. This attribute points to the external file that is to be loaded into the browser via the associated plug-in. Scripts can assign a new URL string to this property to load a different file into the current plug-in.

**units****Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE-, NN-, Moz-, Safari-

The `units` property returns the unit of measure assigned with the `length` value of the `height` and `width` properties, in pixels.

**Related Items:** `height`, `width` properties.

## The Odd Case of the param Element

HTML pages pass parameters to Java applets, plug-ins, and ActiveX controls by way of `param` elements that are nested inside `applet`, `embed`, and `object` elements. Although a `param` element object is defined by the W3C DOM Level 2 specification, it does not show up on some browsers' radar when you try to reference the `param` element by itself. Even assigning an `id` to a `param` element or using `document.getElementsByTagName("param")` fail to allow references to access an individual `param` element object. At most, you can retrieve the `innerHTML` property of the surrounding element. But even here, the values returned may not necessarily be precisely the HTML you specify in the document.

In practice, this limitation is not particularly important. For one thing, even if you could access the `param` elements of an embedded object or program, attempts to modify the values would be wasted: Those values are read at load time only. Secondly, a well-designed plug-in, applet, or ActiveX control will provide its own properties or methods to retrieve the current settings of whatever properties are initialized via the `param` elements.

# XML Objects

---

**X**ML (eXtensible Markup Language) is an undeniably hot topic in the Internet world, and has been for the past few years. Not only has the W3C organization formed multiple working groups and recommendations for XML and its offshoots, but the W3C DOM recommendation also has XML in mind when it comes to defining how elements, attributes, and data of any kind — not just the HTML vocabulary — are exposed to browsers as an object model. Most of the arcana of the W3C DOM Core specification — especially the structure based on the node — are in direct response to the XML possibilities of documents that are beginning to travel the Internet.

During its early explorations into XML and browsers, Microsoft devised a custom HTML element — the `<xml>` tag — that allowed authors to embed XML data into an HTML document. These tags created what were called XML *data islands*. A more practical solution came slightly later with the creation of an ActiveX control that could retrieve XML data (from either a static `.xml` file or a Web service that returns XML-structured data) into a Web page without disturbing the HTML portion. Scripts could then use W3C DOM methods and properties to read the node tree as needed. Mozilla browsers emulate the behavior of this `XMLHttpRequest` control so that both WinIE and Mozilla-based browsers (all OSes) can load external XML data into a page for script inspection and manipulation.

This chapter covers both WinIE XML data islands and the more flexible `XMLHttpRequest` object. Out of necessity, this book assumes that you are already familiar with XML such that your server-based applications serve up XML data exclusively, embed XML islands into HTML documents, or convert database data into XML. The focus of this chapter, and application examples of Chapters 52 and 57, is how to access XML data and apply that data to rendered HTML content.

## Elements and Nodes

Once you leave the specialized DOM vocabulary of HTML elements, the world can appear rather primitive — a highly granular world of node hierarchies, elements, element attributes, and node data. This granularity is a necessity in an environment in which the elements are far from generic and the structure of data in a document does not have to follow a format handed down from above. One Web application can describe an individual's contact information with one set of elements, while another application uses a completely different approach to element names, element nesting, and their sequence.

### In This Chapter

Treating XML elements as objects

Creating IE XML data islands

Accessing XML element attributes

Using the `XMLHttpRequest` object

Fortunately, most, if not all, scripting you do on XML data is on data served up by your own applications. Therefore, you know what the structure of the data is — or you know enough of it to let your scripts access the data.

The discussion of the W3C DOM in Chapter 14 should serve as a good introduction to the way you need to think about elements and their content. All relevant properties and methods are listed among the items shared by all elements in Chapter 15.

XML data, whether delivered “raw” or embedded in a WinIE HTML document as a *data island* is a hierarchy of nodes. Typically, the outermost nodes are elements. Some elements have attributes, each of which is a typical name/value pair. Some elements have data that goes between the start and end tags of the element (such data is a text node nested inside the element node). And some elements can have both attributes and data. When an XML data collection contains the equivalent of multiple database records, an element container whose tag name is the same as each of the other records surrounds each record. Thus, the `getElementsByTagName()` method frequently accesses a collection of like-named elements.

Once you have a reference to an element node, you can reference that element’s attributes as properties; however, a more formal access route is via the `getAttribute()` method of the element. If the element has text data between its start and end tags, you can access that data from the element’s reference by calling the `firstChild.data` property (although you may want to verify that the element has a child node of the text type before committing to retrieving the data).

Of course, your specific approach to `xml` elements and their data varies with what you intend to script with the data. For example, you may wish to do nothing more with scripting than enable a different stylesheet for the data based on a user choice. The XSL (eXtensible Stylesheet Language) standard is a kind of (non-JavaScript) scripting language for transforming raw `xml` data into a variety of presentations. But you can still use JavaScript to connect user-interface elements that control which of several stylesheets renders the data. Or, as demonstrated in Chapters 52 and 57, you may wish to use JavaScript for more explicit control over the data and its rendering, taking advantage of JavaScript sorting and data manipulation facilities along the way.

Table 41-1 is a summary of W3C DOM Core objects, properties, and methods that you are most likely to use in extracting data from `xml` elements. You can find details of all of these items in Chapter 15.

---

**Table 41-1: Properties and Methods for XML Element Reading**

---

<i>Property or Method</i>	<i>Description</i>
<code>Node.nodeValue</code>	Data of a text node
<code>Node.nodeType</code>	Which node type
<code>Node.parentNode</code>	Reference to parent node
<code>Node.childNodes</code>	Array of child nodes
<code>Node.firstChild</code>	First of all child nodes
<code>Node.lastChild</code>	Last of all child nodes
<code>Node.previousSibling</code>	Previous node at same level
<code>Node.nextSibling</code>	Next node at same level
<code>Element.parentNode</code>	Reference to parent node
<code>Element.childNodes</code>	Array of child nodes

<i>Property or Method</i>	<i>Description</i>
<code>Element.firstChild</code>	First of all child nodes
<code>Element.lastChild</code>	Last of all child nodes
<code>Element.previousSibling</code>	Previous node at same level
<code>Element.nextSibling</code>	Next node at same level
<code>Element.tagName</code>	Tag name
<code>Element.getAttribute(<i>name</i>)</code>	Retrieves attribute (Attr) object
<code>Element.getElementsByTagName(<i>name</i>)</code>	Array of nested, named elements
<code>Attr.name</code>	Name part of attribute object's name/value pair
<code>Attr.value</code>	Value part of attribute object's name/value pair

## xml Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>src</code> <code>XMLDocument</code>		

## Syntax

Accessing xml element object properties or methods:

```
(IE5+) [window.]document.all.elementID.property | method([parameters])
```

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

## About this object

The `xml` element object is the primary container of an `xml` data island within an HTML page. If your scripts intend to traverse the node hierarchy within the element, or simply access properties of nested elements, you should assign an identifier to the `id` attribute of the XML element. For example, if the XML data contains results from a database query for music recordings that match some user-entered criteria, each returned record might be denoted as a recording element as follows:

```
<xml id="results">
  <searchresults>
    <recording>
      ...elements with details...
    </recording>
    <recording>
      ...elements with details...
    </recording>
```

**xml**

```

    <recording>
      ...elements with details...
    </recording>
  </searchresults>
</xml>

```

Your script can now obtain an array of references to recording elements as follows:

```

var recs =
  document.getElementById("results").getElementsByTagName("recording");

```

Although it is also true that there is no known HTML element with the tag name recording (which enables you to use `document.getElementsByTagName("recording")`), the unpredictability of xml data element names is reason enough to limit the scope of the `getElementsByTagName()` method to the xml data island.

The W3C DOM Level 2 does not define an xml element object within the HTML section. You cannot simply embed an XML document inside an HTML document: The standards clearly indicate that a document can be one or the other, but not both. Although the NN6/7 DOM can recognize custom elements, the browser understandably gets confused when custom elements have tag names that already belong to the HTML DTD. Therefore, I do not recommend attempting to embed custom elements into an HTML document for NN6/7 unless it someday implements a mechanism similar to IE's XML data islands.

## Properties

### src

**Value:** String.

Read/Write

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `src` property represents the `src` attribute of the `xml` element. The attribute points to the URL of an external xml document whose data is embedded within the current HTML document.

### XMLDocument

**Value:** Object reference.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN-, Moz-, Safari-

The `XMLDocument` property returns a reference to Microsoft's proprietary XML document object and the object model associated with it (the so-called XML DOM). A lot of this object model is patterned after the W3C DOM model, but access to these properties is via a rather roundabout way. For more details, visit

<http://msdn.microsoft.com/xml/reference/xml/dom/start.asp>

## XMLHttpRequest Object

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
readyState	abort()	
responseText	getAllResponseHeaders()	

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
responseXML	getResponseHeader()	
status	open()	
statusText	send()	

## Syntax

Accessing XMLHttpRequest object properties or methods:

```
(IE5+/Moz) XMLHttpRequestObjectRef.property | method([parameters])
```

**Compatibility:** WinIE5+, MacIE-, NN7+, Moz1+, Safari-

## About this object

The XMLHttpRequest object is an abstract object that lets your scripts retrieve XML data from, or send XML data to, any URL designed for that purpose. All of the action occurs invisibly to the user, and it is the responsibility of your scripts to make the connection with the server and process the XML data either after retrieval or prior to submission. This object was originally designed by Microsoft as part of its XML Core Services (MSXML), as first released as part of Internet Explorer 5 for Windows. Mozilla engineers have implemented much of the same functionality in Mozilla browsers, with almost identical syntax.

Where the IE and Mozilla variations differ is how you create the object to begin. Because the IE version is an ActiveX control, you create the object using the `ActiveXObject` constructor function. For Mozilla, the XMLHttpRequest object has its own constructor. Therefore, to equalize the creation of the two versions in a single document, you need to branch your code accordingly. Use object detection to handle the branching most effectively:

```
var req;
if (window.XMLHttpRequest) {
    req = new XMLHttpRequest();
} else if (window.ActiveXObject) {
    req = new ActiveXObject("Microsoft.XMLHTTP");
}
```

After the object is created, the basic syntax for opening a connection, sending the request, and retrieving the response data is the same for both WinIE and Mozilla. To retrieve an XML document (node tree) from a URL source, the basic sequence is as follows:

```
req.open("GET", "sourceURL", false);
req.send(null);
var xmlDocument = req.responseXML;
```

At this point, scripts can inspect the contents of the `xmlDocument` value by way of W3C DOM node properties and methods.

### Note

The XMLHttpRequest object in Mozilla-based browsers must reference pages served from a Web server, and not a local file. You can experiment successfully from a “personal Web server” running on your PC, but not with files accessed through the `file:` protocol.

Listing 41-1 shows a utility script that retrieves XML content from a URL (passed as a parameter to the `loadXML()` function) in a cross-browser manner. Additional error checking verifies

**xmlHttpRequest**

that the retrieval is successful, or reports the error to the user. If the browser running the script does not support the XML reading feature, the user is alerted of that, as well. The XML document object is preserved in a global variable called `xDoc`.

**Listing 41-1: Utility XML Data Reading Script**

```
// XML document
var xDoc;

// retrieve XML document as document object
function loadXMLDoc(url) {
    var req;
    if (window.XMLHttpRequest) {
        req = new XMLHttpRequest();
        req.open("GET", url, false);
        req.send(null);
    } else if (window.ActiveXObject) {
        req = new ActiveXObject("Microsoft.XMLHTTP");
        if (req) {
            req.open("GET", url, false);
            req.send();
        }
    }
    if (req) {
        if (req.status == 200) {
            xDoc = req.responseXML;
            if (xDoc && typeof xDoc.childNodes != "undefined" &&
                xDoc.childNodes.length == 0) {
                xDoc = null;
            }
        } else {
            alert("There was a problem retrieving the XML data:\n" +
                req.statusText);
        }
    } else {
        alert("Sorry, this browser isn't equipped to read XML data.");
    }
}
}
```

Properties and methods described in this chapter are those that the object has in common for both WinIE and Mozilla browsers. The WinIE object has some additional features, which you can study at Microsoft's MSXML 4.0 developer pages at [http://msdn.microsoft.com/library/en-us/xmlsdk/htm/dom\\_reference\\_2kdh.asp](http://msdn.microsoft.com/library/en-us/xmlsdk/htm/dom_reference_2kdh.asp). You can see examples of this object within the applications of Chapters 52 and 57.

## Properties

### readyState

**Value:** Integer.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN7+, Moz1+, Safari-

Your scripts can read the value of the `readyState` property to determine the state of the `XMLHttpRequest` object, particularly while it is operating during its initialization or data

transfer. Values are the same as for other objects that offer this property. See Table 15-6 for integer values and their meanings. If you are scripting exclusively for WinIE, you can assign an `onreadystatechange` event handler to the `XMLHttpRequest` object; the event function can then inspect the `readyState` property for further processing.

**Related Items:** `status` property.

## responseText

**Value:** String.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN7+, Moz1+, Safari-

After the `send()` method executes, and if the server returns any data (as it will with a GET operation), you can access a string version of the returned data via the `responseText` property. If the returned data is an XML document, this property provides a string-only version of the entire content.

**Related Items:** `responseXML` property.

## responseXML

**Value:** XML document object.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN7+, Moz1+, Safari-

After the `send()` method executes, and if the server returns any data (as it will with a GET operation), you can access the returned W3C DOM-compliant document object via the `responseXML` property. The object to which this property points is a genuine document node (`nodeType` of 9), which gives your scripts the power to walk the node tree, and retrieve tags, attributes, and text nodes inside elements, as you would with any DOM document.

As the examples in Chapters 52 and 57 demonstrate, you can use the data from the XML document to build HTML that displays the XML content in the format of your choice (using JavaScript as a more flexible alternative to XSL). If your page is interactive to the extent that users can modify the content, you may then modify the document tree stored in your script variable and send the revised XML back to the server by opening a new `XMLHttpRequest` connection pointing to the URL that accepts the posted data.

**Related Items:** `responseText` property; `open()` method.

## status

**Value:** Integer.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN7+, Moz1+, Safari-

After the `send()` method executes, you can read the status of the transaction via the `status` property. The value is an integer corresponding to the response issued by the server at the end of the transaction. A successful transaction value is 200 (corresponding to the OK `statusText` property value). Perhaps the other most common status value is 404, which occurs if the URL you supply to the `open()` method points to a file or source not found on the server. As shown in Listing 41-1, you can use the 200 value as the key to determining if the transaction is a success, and then simply report any other value to the user (although inexperienced users may not understand the meaning of the status text). A complete list of status values can be found at [http://msdn.microsoft.com/library/en-us/xmlsdk/html/xml\\_pro\\_sz\\_0h4k.asp](http://msdn.microsoft.com/library/en-us/xmlsdk/html/xml_pro_sz_0h4k.asp).

**Related Items:** `statusText` property.

**xmlHttpRequest.statusText****statusText****Value:** String.

Read-Only

**Compatibility:** WinIE5+, MacIE-, NN7+, Moz1+, Safari-

After the `send()` method executes, you can read the plain-language status of the transaction via the `statusText` property. The value is a string corresponding to the response integer by the server at the end of the transaction. A successful transaction value is OK (corresponding to the 200 `status` property value). Use the `status` property for testing the results in your script, and the `statusText` property to report errors to users. See Listing 41-1.

**Related Items:** `status` property.

## Methods

**abort()****Returns:** Nothing.**Compatibility:** WinIE5+, MacIE-, NN7+, Moz1+, Safari-

The `abort()` method stops any transaction currently in progress. This method is the scripted equivalent of clicking a browser's Stop button while it retrieves contents of a Web page.

**Related Items:** `readyState` property; `send()` method.**getAllResponseHeaders()****getResponseHeader("headerName")****Returns:** String.**Compatibility:** WinIE5+, MacIE-, NN7+, Moz1+, Safari-

For each transaction, the server transmits a series of name/value pairs as a header to the actual data. The `getAllResponseHeaders()` method returns the complete set as received by the `XMLHttpRequest` object. Such a header set may look like the following:

```
Date: Mon, 06 Oct 2003 03:12:59 GMT
Server: Apache/1.3.27 (Darwin)
Last-Modified: Sun, 05 Oct 2003 22:13:04 GMT
Etag: "12babe-3a2-3f809770"
Accept-Ranges: bytes
Content-Length: 930
Keep-Alive: timeout=15, max=100
Connection: Keep-Alive
Content-Type: text/xml
```

If you want to retrieve the value of just one of the headers, use the `getResponseHeader()` method and pass as a parameter a string with only the name portion of one of the headers. For example:

```
var size = req.getResponseHeader("Content-Length");
```

The parameter is not case-sensitive, but the spelling (along with any hyphen in the name) is critical.

**Related Items:** `readyState` property; `send()` method.

```
open("method", "URL"[, asyncFlag[,
"userName"[, "password"]]])
```

**Returns:** Nothing.

**Compatibility:** WinIE5+, MacIE-, NN7+, Moz1+, Safari-

Use the `open()` method to specify the transaction type and URL of the destination of the request. The *method* parameter may be either GET (for retrieving data from a server) or POST (for sending XML to a server). The *URL* may be either relative to the current page, or a complete `http: URL`.

Three additional parameters are optional. The first is a Boolean value for whether the request should be asynchronous. If `true` (the default), the `XMLHttpRequest` object does not wait for a response (after the `send()` method) before continuing with script processing. By setting this parameter to `false`, you ensure that processing continues only after the transaction has completed or timed out. If you'd rather not wait for the transaction to complete, but instead have some action occur when the returned data has arrived, you can assign an `onload` event handler to the `XMLHttpRequest` object, and let that event handler process the incoming data:

```
var req;
if (window.XMLHttpRequest) {
    req = new XMLHttpRequest();
} else if (window.ActiveXObject) {
    req = new ActiveXObject("Microsoft.XMLHTTP");
}
req.onload = processXML; // event handler function reference
req.open("GET", "sourceURL", false);
req.send(null);
```

The other optional parameters are strings for a username and password if one is needed to access the URL.

Note that the `open()` method merely fills various properties of the request, and that the request does not occur until the `send()` method is invoked.

**Related Items:** `open()` method.

## send(*content*)

**Returns:** Nothing.

**Compatibility:** WinIE5+, MacIE-, NN7+, Moz1+, Safari-

After setting the characteristics of the request via the `open()` method and its parameters, invoke the `send()` method to trigger the actual request over the network. For a GET operation, specify `null` as the parameter. But for a POST operation, the parameter should be a reference to a DOM document that has been assembled in script. You may also specify a string as the value being posted to the request's URL.

**Related Items:** `open()` method.

# The Regular Expression and RegExp Objects

---

**W**eb programmers who have worked in Perl (and other Web application programming languages) know the power of regular expressions for processing incoming data and formatting data for readability in an HTML page or for accurate storage in a server database. Any task that requires extensive search and replacement of text can greatly benefit from the flexibility and conciseness of regular expressions. Version 4 browsers brought that power to JavaScript, although it is more fully fleshed out in IE5.5+.

Most of the benefit of JavaScript regular expressions accrues to those who script their CGI programs on servers that support a JavaScript version that contains regular expressions. But that's not to exclude the client-side from application of this "language within a language." If your scripts perform client-side data validations or any other extensive text entry parsing, consider using regular expressions rather than cobbling together comparatively complex JavaScript functions to perform the same tasks.

## Regular Expressions and Patterns

In several chapters earlier in this book, I describe expressions as any sequence of identifiers, keywords, and/or operators that evaluate to some value. A regular expression follows that description, but has much more power behind it. In essence, a regular expression uses a sequence of characters and symbols to define a pattern of text. Such a pattern is used to locate a chunk of text in a string by matching up the pattern against the characters in the string.

An experienced JavaScript writer may point out the availability of the `string.indexOf()` and `string.lastIndexOf()` methods that can instantly reveal whether a string contains a substring and even where in the string that substring begins. These methods work perfectly well when the match is exact, character for character. But if you want to do more sophisticated matching (for example, does the string contain a five-digit ZIP code?), you'd have to cast aside those handy string methods and write some parsing functions. That's the beauty of a regular expression: It lets you define a matching substring that has some intelligence about it and can follow guidelines you set as to what should or should not match.

### In This Chapter

What regular expressions are

How to use regular expressions for text search-and-replace

How to apply regular expressions to string object methods

The simplest kind of regular expression pattern is the same kind you use in the `string.indexOf()` method. Such a pattern is nothing more than the text that you want to match. In JavaScript, one way to create a regular expression is to surround the expression by forward slashes. For example, consider the string

```
Oh, hello, do you want to play Othello in the school play?
```

This string and others may be examined by a script whose job it is to turn formal terms into informal ones. Therefore, one of its tasks is to replace the word “hello” with “hi.” A typical brute force search-and-replace function starts with a simple pattern of the search string. In JavaScript, you define a pattern (a regular expression) by surrounding it with forward slashes. For convenience and readability, I usually assign the regular expression to a variable, as in the following example:

```
var myRegularExpression = /hello/;
```

In concert with some regular expression or string object methods, this pattern matches the string “hello” wherever that series of letters appears. The problem is that this simple pattern causes problems during the loop that searches and replaces the strings in the example string: It finds not only the standalone word “hello,” but also the “hello” in “Othello.”

Trying to write another brute force routine for this search-and-replace operation that looks only for standalone words would be a nightmare. You can’t merely extend the simple pattern to include spaces on either or both sides of “hello,” because there could be punctuation — a comma, a dash, a colon, or whatever — before or after the letters. Fortunately, regular expressions provide a shortcut way to specify general characteristics, including a feature known as a word boundary. The symbol for a word boundary is `\b` (backslash, lowercase b). If you redefine the pattern to include these specifications on both ends of the text to match, the regular expression creation statement looks like this:

```
var myRegularExpression = /\bhello\b/;
```

When JavaScript uses this regular expression as a parameter in a special string object method that performs search-and-replace operations, it changes only the standalone word “hello” to “hi,” and passes over “Othello” entirely.

If you are still learning JavaScript and don’t have experience with regular expressions in other languages, you have a price to pay for this power: Learning the regular expression lingo filled with so many symbols means that expressions sometimes look like cartoon substitutions for swear words. The goal of this chapter is to introduce you to regular expression syntax as implemented in JavaScript rather than engage in lengthy tutorials for this language. Of more importance in the long run is understanding how JavaScript treats regular expressions as objects and distinctions between instances of regular expression objects and the `RegExp` static object. I hope the examples in the following sections begin to reveal the powers of regular expressions.

## Language Basics

To cover the depth of the regular expression syntax, I divide the subject into three sections. The first covers simple expressions (some of which you’ve already seen). Then I get into the wide range of special characters used to define specifications for search strings. Last comes an introduction to the usage of parentheses in the language, and how they not only help in grouping expressions for influencing calculation precedence (as they do for regular math expressions), but also how they temporarily store intermediate results of more complex expressions for use in reconstructing strings after their dissection by the regular expression.

## Simple patterns

A simple regular expression uses no special characters for defining the string to be used in a search. Therefore, if you want to replace every space in a string with an underscore character, the simple pattern to match the space character is

```
var re = / /;
```

A space appears between the regular expression start-end forward slashes. The problem with this expression, however, is that it knows only how to find a single instance of a space in a long string. Regular expressions can be instructed to apply the matching string on a global basis by appending the `g` modifier:

```
var re = / /g;
```

When this `re` value is supplied as a parameter to the `replace()` method that uses regular expressions (described later in this chapter), the replacement is performed throughout the entire string, rather than just once on the first match found. Notice that the modifier appears after the final forward slash of the regular expression creation statement.

Regular expression matching—like a lot of other aspects of JavaScript—is case-sensitive. But you can override this behavior by using one other modifier that lets you specify a case-insensitive match. Therefore, the following expression

```
var re = /web/i;
```

finds a match for “web,” “Web,” or any combination of uppercase and lowercase letters in the word. You can combine the two modifiers together at the end of a regular expression. For example, the following expression is both case-insensitive and global in scope:

```
var re = /web/gi;
```

In compliance with the ECMA-262 Edition 3 standard, IE5.5+, NN6+/Moz, and Safari also allow a flag to force the regular expression to treat carriage-return-delimited lines of a multiline string as separate substrings with their own start and end boundaries. That modifier is the letter `m`.

## Special characters

The regular expression in JavaScript borrows most of its vocabulary from the Perl regular expression. In a few instances, JavaScript offers alternatives to simplify the syntax, but also accepts the Perl version for those with experience in that arena.

Significant programming power comes from the way regular expressions allow you to include terse specifications about such facets as types of characters to accept in a match, how the characters are surrounded within a string, and how often a type of character can appear in the matching string. A series of escaped one-character commands (that is, letters preceded by the backslash) handle most of the character issues; punctuation and grouping symbols help define issues of frequency and range.

You saw an example earlier how `\b` specified a word boundary on one side of a search string. Table 42-1 lists the escaped character specifiers in JavaScript regular expressions. The vocabulary forms part of what are known as metacharacters—characters in expressions that are not matchable characters themselves, but act more as commands or guidelines of the regular expression language.

**Table 42-1: JavaScript Regular Expression Matching Metacharacters**

<i>Character</i>	<i>Matches</i>	<i>Example</i>
<code>\b</code>	Word boundary	<code>/\bor/</code> matches “origami” and “or” but not “normal” <code>/or\b/</code> matches “traitor” and “or” but not “perform” <code>/\bor\b/</code> matches full word “or” and nothing else
<code>\B</code>	Word non-boundary	<code>/\Bor/</code> matches “normal” but not “origami” <code>/or\B/</code> matches “normal” and “origami” but not “traitor” <code>/\Bor\B/</code> matches “normal” but not “origami” or “traitor”
<code>\d</code>	Numeral 0 through 9	<code>/\d\d\d/</code> matches “212” and “415” but not “B17”
<code>\D</code>	Non-numeral	<code>/\D\D\D/</code> matches “ABC” but not “212” or “B17”
<code>\s</code>	Single white space	<code>/over\sbite/</code> matches “over bite” but not “overbite” or “over bite”
<code>\S</code>	Single non-white space	<code>/over\Sbite/</code> matches “over-bite” but not “overbite” or “over bite”
<code>\w</code>	Letter, numeral, or underscore	<code>/A\w/</code> matches “A1” and “AA” but not “A+”
<code>\W</code>	Not letter, numeral, or underscore	<code>/A\W/</code> matches “A+” but not “A1” and “AA”
<code>.</code>	Any character except newline	<code>/.../</code> matches “ABC”, “1+3”, “A 3”, or any three
<code>[...]</code>	Character set	<code>/[AN]BC/</code> matches “ABC” and “NBC” but not “BBC”
<code>[^...]</code>	Negated character set	<code>/[^AN]BC/</code> matches “BBC” and “CBC” but not “ABC” or “NBC”

Not to be confused with the metacharacters listed in Table 42-1 are the escaped string characters for tab (`\t`), newline (`\n`), carriage return (`\r`), formfeed (`\f`), and vertical tab (`\v`).

Let me further clarify about the `[...]` and `[^...]` metacharacters. You can specify either individual characters between the brackets (as shown in Table 42-1) or a contiguous range of characters or both. For example, the `\d` metacharacter can also be defined by `[0-9]`, meaning any numeral from zero through nine. If you only want to accept a value of 2 and a range from 6 through 8, the specification would be `[26-8]`. Similarly, the accommodating `\w` metacharacter is defined as `[A-Za-z0-9_]`, reminding you of the case-sensitivity of regular expression matches not otherwise modified.

All but the bracketed character set items listed in Table 42-1 apply to a single character in the regular expression. In most cases, however, you cannot predict how incoming data will be formatted — the length of a word or the number of digits in a number. A batch of extra metacharacters lets you set the frequency of the occurrence of either a specific character or a type of character (specified like the ones in Table 42-1). If you have experience in command-line operating systems, you can see some of the same ideas that apply to wildcards also apply to regular expressions. Table 42-2 lists the counting metacharacters in JavaScript regular expressions.

**Table 42-2: JavaScript Regular Expression Counting Metacharacters**

<i>Character</i>	<i>Matches Last Character</i>	<i>Example</i>
*	Zero or more times	<code>/Ja*vaScript/</code> matches "JavaScript", "JavaScript", and "JaaavaScript" but not "JovaScript"
?	Zero or one time	<code>/Ja?vaScript/</code> matches "JavaScript" or "JavaScript" but not "JaaavaScript"
+	One or more times	<code>/Ja+vaScript/</code> matches "JavaScript" or "JaaavaScript" but not "JavaScript"
{ <i>n</i> }	Exactly <i>n</i> times	<code>/Ja{2}vaScript/</code> matches "JaaavaScript" but not "JavaScript" or "JavaScript"
{ <i>n</i> , }	<i>n</i> or more times	<code>/Ja{2,}vaScript/</code> matches "JaaavaScript" or "JaaavaScript" but not "JavaScript"
{ <i>n</i> , <i>m</i> }	At least <i>n</i> , at most <i>m</i> times	<code>/Ja{2,3}vaScript/</code> matches "JaaavaScript" or "JaaavaScript" but not "JavaScript"

Every metacharacter in Table 42-2 applies to the character immediately preceding it in the regular expression. Preceding characters may also be matching metacharacters from Table 42-1. For example, a match occurs for the following expression if the string contains two digits separated by one or more vowels:

```
/\d[aeiouy]+\d/
```

The last major contribution of metacharacters is helping the regular expression search a particular position in a string. By position, I don't mean something such as an offset—the matching functionality of regular expressions can tell me that. But, rather, whether the string to look for should be at the beginning or end of a larger string or (if the `m` modifier is added to the regular expression assignment) a line of that larger string. Table 42-3 shows the positional metacharacters for JavaScript's regular expressions.

**Table 42-3: JavaScript Regular Expression Positional Metacharacters**

<i>Character</i>	<i>Matches Located</i>	<i>Example</i>
^	At beginning of a string or line	<code>/^Fred/</code> matches "Fred is OK" but not "I'm with Fred" or "Is Fred here?"
\$	At end of a string or line	<code>/Fred\$/</code> matches "I'm with Fred" but not "Fred is OK" or "Is Fred here?"

For example, you may want to make sure that a match for a Roman numeral is found only when it is at the start of a string, rather than when it is used inline somewhere else. If the document contains Roman numerals in an outline, you can match all the top-level items that are flush left with the document with a regular expression, such as the following:

```
 /^[IVXMDCL]+\./m
```

This expression matches any combination of Roman numeral characters at the start of a line followed by a period (the period is a special character in regular expressions, as shown in Table 42-1, so that you have to escape the period to offer it as a character), provided the Roman numeral is at the beginning of a line and has no tabs or spaces before it. There would also not be a match in a line that contains, for example, the phrase “see Part IV” because the Roman numeral is not at the beginning of a line.

Speaking of lines, a line of text is a contiguous string of characters delimited by a newline and/or carriage return (depending on the operating system platform). Word wrapping in `textarea` elements does not affect the starts and ends of true lines of text.

## Grouping and backreferencing

Regular expressions obey most of the JavaScript operator precedence laws with regard to grouping by parentheses and the logical Or operator. One difference is that the regular expression Or operator is a single pipe character (`|`) rather than JavaScript’s double pipe.

Parentheses have additional powers that go beyond influencing the precedence of calculation. Any set of parentheses (that is, a matched pair of left and right) stores the results of a found match of the expression within those parentheses. Parentheses can be nested inside one another. Storage is accomplished automatically, with the data stored in an indexed array accessible to your scripts and to your regular expressions (although through different syntax). Access to these storage bins is known as *backreferencing*, because a regular expression can point backward to the result of an expression component earlier in the overall expression. These stored subcomponents come in handy for replace operations, as demonstrated later in this chapter.

## Object Relationships

JavaScript has a lot going on behind the scenes when you create a regular expression and perform the simplest operation with it. As important as the regular expression language described earlier in this chapter is to applying regular expressions in your scripts, the JavaScript object interrelationships are perhaps even more important if you want to exploit regular expressions to the fullest.

The first concept to master is that two entities are involved: a regular expression instance object and the `RegExp` static object. Both objects are core objects of JavaScript and are not part of the document object model. Both objects work together, but have entirely different sets of properties that may be useful to your application.

When you create a regular expression (even via the `/.../` syntax), JavaScript invokes the new `RegExp()` constructor, much the way a new `Date()` constructor creates a date object around one specific date. The regular expression instance object returned by the constructor is endowed with several properties containing details of its data. At the same time, the single, static `RegExp` object maintains its own properties that monitor regular expression activity in the current window (or frame).

To help you see the typically unseen operations, I step you through the creation and application of a regular expression. In the process, I show you what happens to all of the related object properties when you use one of the regular expression methods to search for a match.

### Note

Several properties of both the regular expression instance object and the static `RegExp` object shown in the following “walk-through” are not available in IE until version 5.5. All are available in NN4+. See the individual property listings later in this chapter for compatibility ratings.

The starting text that I use to search through is the beginning of Hamlet’s soliloquy (assigned to an arbitrary variable named `mainString`):

```
var mainString = "To be, or not to be: That is the question:";
```

If my ultimate goal is to locate each instance of the word “be,” I must first create a regular expression that matches the word “be.” I set the regular expression up to perform a global search when eventually called upon to replace itself (assigning the expression to an arbitrary variable named `re`):

```
var re = /\bbe\b/g;
```

To guarantee that only complete words “be” are matched, I surround the letters with the word boundary metacharacters. The final “g” is the global modifier. The variable to which the expression is assigned, `re`, represents a regular expression object whose properties and values are as follows:

<i>Object.PropertyName</i>	<i>Value</i>
<code>re.source</code>	<code>"\bbe\b/g"</code>
<code>re.global</code>	<code>true</code>
<code>re.ignoreCase</code>	<code>false</code>
<code>re.lastIndex</code>	<code>0</code>

A regular expression’s `source` property is the string consisting of the regular expression syntax (less the literal forward slashes). Each of the two possible modifiers, `g` and `i`, have their own properties, `global` and `ignoreCase`, whose values are Booleans indicating whether the modifiers are part of the source expression. The final property, `lastIndex`, indicates the index value within the main string at which the next search for a match should start. The default value for this property in a newly hatched regular expression is zero so that the search starts with the first character of the string. This property is read/write, so your scripts may want to adjust the value if they must have special control over the search process. As you see in a moment, JavaScript modifies this value over time if a global search is indicated for the object.

The `RegExp` constructor does more than just create regular expression objects. Like the `Math` object, the `RegExp` object is always “around” — one `RegExp` per window or frame — and tracks regular expression activity in a script. Its properties reveal what, if any, regular expression pattern matching has just taken place in the window. At this stage of the regular expression creation process, the `RegExp` object has only one of its properties set:

<i>Object.PropertyName</i>	<i>Value</i>
<code>RegExp.input</code>	
<code>RegExp.multiline</code>	<code>false</code>
<code>RegExp.lastMatch</code>	
<code>RegExp.lastParen</code>	
<code>RegExp.leftContext</code>	
<code>RegExp.rightContext</code>	
<code>RegExp.\$1</code>	
...	
<code>RegExp.\$9</code>	

The last group of properties (`$1` through `$9`) is for storage of backreferences. But because the regular expression I define above doesn't have any parentheses in it, these properties are empty for the duration of this examination and omitted from future listings in this "walk-through" section.

With the regular expression object ready to go, I invoke the `exec()` regular expression method, which looks through a string for a match defined by the regular expression. If the method is successful in finding a match, it returns a third object whose properties reveal a great deal about the item it found (I arbitrarily assign the variable `foundArray` to this returned object):

```
var foundArray = re.exec(mainString);
```

JavaScript includes a shortcut for the `exec()` method if you turn the regular expression object into a method:

```
var foundArray = re(mainString);
```

Normally, a script would check whether `foundArray` is `null` (meaning that there was no match) before proceeding to inspect the rest of the related objects. Because this is a controlled experiment, I know at least one match exists, so I first look into some other results. Running this simple method has not only generated the `foundArray` data, but also altered several properties of the `RegExp` and regular expression objects. The following shows you the current stage of the regular expression object:

<i>Object.PropertyName</i>	<i>Value</i>
<code>re.source</code>	<code>"\bbe\b"</code>
<code>re.global</code>	<code>true</code>
<code>re.ignoreCase</code>	<code>false</code>
<code>re.lastIndex</code>	<code>5</code>

The only change is an important one: The `lastIndex` value has bumped up to 5. In other words, this one invocation of the `exec()` method must have found a match whose offset plus length of matching string shifts the starting point of any successive searches with this regular expression to character index 5. That's exactly where the comma after the first "be" word is in the main string. If the global (`g`) modifier had not been appended to the regular expression, the `lastIndex` value would have remained at zero, because no subsequent search would be anticipated.

As the result of the `exec()` method, the `RegExp` object has had a number of its properties filled with results of the search:

<i>Object.PropertyName</i>	<i>Value</i>
<code>RegExp.input</code>	
<code>RegExp.multiline</code>	<code>false</code>
<code>RegExp.lastMatch</code>	<code>"be"</code>
<code>RegExp.lastParen</code>	
<code>RegExp.leftContext</code>	<code>"To "</code>
<code>RegExp.rightContext</code>	<code>", or not to be: That is the question:"</code>

From this object you can extract the string segment that was found to match the regular expression definition. The main string segments before and after the matching text are also available individually (in this example, the `leftContext` property has a space after “To”). Finally, looking into the array returned from the `exec()` method, some additional data is readily accessible:

<i>Object.PropertyName</i>	<i>Value</i>
<code>foundArray[0]</code>	"be"
<code>foundArray.index</code>	3
<code>foundArray.input</code>	"To be, or not to be: That is the question:"

The first element in the array, indexed as the zeroth element, is the string segment found to match the regular expression, which is the same as the `RegExp.lastMatch` value. The complete main string value is available as the input property. A potentially valuable piece of information to a script is the index for the start of the matched string found in the main string. From this last bit of data, you can extract from the found data array the same values as `RegExp.leftContext` (with `foundArray.input.substring(0, foundArray.index)`) and `RegExp.rightContext` (with `foundArray.input.substring(foundArray.index, foundArray[0].length)`).

Because the regular expression suggested a multiple execution sequence to fulfill the global flag, I can run the `exec()` method again without any change. While the JavaScript statement may not be any different, the search starts from the new `re.lastIndex` value. The effects of this second time through ripple through the resulting values of all three objects associated with this method:

```
var foundArray = re.exec(mainString);
```

Results of this execution are as follows (changes are in boldface).

<i>Object.PropertyName</i>	<i>Value</i>
<code>re.source</code>	"\bbe\bg"
<code>re.global</code>	true
<code>re.ignoreCase</code>	false
<code>re.lastIndex</code>	19
<code>RegExp.input</code>	
<code>RegExp.multiline</code>	false
<code>RegExp.lastMatch</code>	"be"
<code>RegExp.lastParen</code>	
<code>RegExp.leftContext</code>	" , or not to "
<code>RegExp.rightContext</code>	": That is the question:"
<code>foundArray[0]</code>	"be"
<code>foundArray.index</code>	17
<code>foundArray.input</code>	"To be, or not to be: That is the question:"

Because there was a second match, `foundArray` comes back again with data. Its `index` property now points to the location of the second instance of the string matching the regular expression definition. The regular expression object's `lastIndex` value points to where the next search would begin (after the second “be”). And the `RegExp` properties that store the left and right contexts have adjusted accordingly.

If the regular expression were looking for something less stringent than a hard-coded word, some other properties may also be different. For example, if the regular expression defined a format for a ZIP code, the `RegExp.lastMatch` and `foundArray[0]` values would contain the actual found ZIP codes, which would likely be different from one match to the next.

Running the same `exec()` method once more does not find a third match in my original `mainString` value, but the impact of that lack of a match is worth noting. First of all, the `foundArray` value is `null` — a signal to our script that no more matches are available. The regular expression object's `lastIndex` property reverts to zero, ready to start its search from the beginning of another string. Most importantly, however, the `RegExp` object's properties maintain the same values from the last successful match. Therefore, if you put the `exec()` method invocations in a repeat loop that exits after no more matches are found, the `RegExp` object still has the data from the last successful match, ready for further processing by your scripts.

## Using Regular Expressions

Despite the seemingly complex hidden workings of regular expressions, JavaScript provides a series of methods that make common tasks involving regular expressions quite simple to use (assuming you figure out the regular expression syntax to create good specifications). In this section, I present examples of syntax for specific kinds of tasks for which regular expressions can be beneficial in your pages.

### Is there a match?

I said earlier that you can use `string.indexOf()` or `string.lastIndexOf()` to look for the presence of simple substrings within larger strings. But if you need the matching power of regular expression, you have two other methods to choose from:

```
regexObject.test(string)
string.search(regexObject)
```

The first is a regular expression object method, the second a string object method. Both perform the same task and influence the same related objects, but they return different values: a Boolean value for `test()` and a character offset value for `search()` (or `-1` if no match is found). Which method you choose depends on whether you need only a true/false verdict on a match or the location within the main string of the start of the substring.

Listing 42-1 demonstrates the `search()` method on a page that lets you get the Boolean and offset values for a match. Some default text and regular expression is provided (it looks for a five-digit number). You can experiment with other strings and regular expressions. Because this script creates a regular expression object with the new `RegExp()` constructor method, you do not include the literal forward slashes around the regular expression.

**Listing 42-1: Looking for a Match**

```

<html>
  <head>
    <title>Got a Match?</title>
    <script type="text/javascript">
      function findIt(form) {
        var re = new RegExp(form.regexp.value);
        var input = form.main.value;
        if (input.search(re) != -1) {
          form.output[0].checked = true;
        } else {
          form.output[1].checked = true;
        }
      }
      function locateIt(form) {
        var re = new RegExp(form.regexp.value);
        var input = form.main.value;
        form.offset.value = input.search(re);
      }
    </script>
  </head>
  <body>
    <b>Use a regular expression to test for the existence of a string.</b>
    <hr />
    <form>
      Enter some text to be searched:<br />
      <textarea name="main" cols="40" rows="4" wrap="virtual">
        The most famous ZIP code on Earth may be 90210.</textarea><br />
      Enter a regular expression to search:<br />
      <input type="text" name="regexp" size="30" value="\b\d\d\d\d\b" />
      <p><input type="button" value="Is There a Match?"
        onclick="findIt(this.form)" /> <input type="radio"
        name="output" />Yes <input type="radio" name="output" />No</p>
      <p><input type="button" value="Where is it?"
        onclick="locateIt(this.form)" /> <input type="text" name="offset"
        size="4" /></p>
      <p><input type="reset" /></p>
    </form>
  </body>
</html>

```

## Getting information about a match

For the next application example, the task is not only to verify that a one-field date entry is in the desired format, but also to extract match components of the entry and use those values to perform further calculations in determining the day of the week. The regular expression in the example that follows is a fairly complex one, because it performs some rudimentary range checking to make sure the user doesn't enter a month over 12 or a date over 31. What it does

not take into account is the variety of lengths of each month. But the regular expression and method invoked with it extract each date object component in such a way that you can perform additional validation on the range to make sure the user doesn't try to give September 31 days. Also be aware that this is not the only way to perform date validations in forms. Chapter 43 offers additional thoughts on the matter that work without regular expressions for backward compatibility.

Listing 42-2 contains a page that has a field for date entry, a button to process the date, and an output field for display of a long version of the date, including the day of the week. At the start of the function that does all the work, I create two arrays to hold the plain language names of the months and days. These arrays are used only if the user enters a valid date.

Next comes the regular expression to be matched against the user entry. If you can decipher all the symbols, you see that three components are separated by potential hyphen or forward slash entries (`[\\-\\/]`). These symbols must be escaped in the regular expression. Importantly, each of the three component definitions is surrounded by parentheses, which are essential for the various objects created with the regular expression to remember their values for extraction later.

Here is a brief rundown of what the regular expression is looking for:

- ♦ A string beginning after a word break
- ♦ A string value for the month that contains a 1 plus a 0 through 2; or an optional 0 plus a 1 through 9
- ♦ A hyphen or forward slash
- ♦ A string value for the date that starts with a 0 plus a 1 through 9; or starts with a 1 or 2 and ends with a 0 through 9; or starts with a 3 and ends with 0 or 1
- ♦ Another hyphen or forward slash
- ♦ A string value for the year that begins with 19 or 20, followed by two digits

An extra pair of parentheses must surround the `19|20` segment to make sure that either one of the matching values is attached to the two succeeding digits. Without the parentheses, the logic of the expression attaches the digits only to `20`.

For invoking the regular expression action, I select the `exec()` method, assigning the returned object to the variable `matchArray`. I can also use the `string.match()` method here. Only if the match is successful (that is, all conditions of the regular expression specification are met) does the major processing continue in the script.

The parentheses around the segments of the regular expression instruct JavaScript to assign each found value to a slot in the `matchArray` object. The month segment is assigned to `matchArray[1]`, the date to `matchArray[2]`, and the year to `matchArray[3]` (`matchArray[0]` contains the entire matched string). Therefore, the script can extract each component to build a plain-language date string with the help of the arrays defined at the start of the function. I even use the values to create a new date object that calculates the day of the week for me. After I have all pieces, I concatenate them and assign the result to the value of the output field. If the regular expression `exec()` method doesn't match the typed entry with the expression, the script provides an error message in the field.

## Listing 42-2: Extracting Data from a Match

```

<html>
  <head>
    <title>Got a Match?</title>
    <script type="text/javascript">
      function extractIt(form) {
        var months = ["January", "February", "March", "April", "May", "June",
          "July", "August", "September", "October", "November", "December"];
        var days = ["Sunday", "Monday", "Tuesday", "Wednesday", "Thursday",
          "Friday", "Saturday"];
        var re = /\b(1[0-2]|0?[1-9])[\-\/](0?[1-9]|[12][0-9]|3[01])[\-
          \/]((19|20)\d{2})/;
        var input = form.entry.value;
        var matchArray = re.exec(input);
        if (matchArray) {
          var theMonth = months[matchArray[1] - 1] + " ";
          var theDate = matchArray[2] + ", ";
          var theYear = matchArray[3];
          var dateObj = new Date(matchArray[3],
            matchArray[1]-1, matchArray[2]);
          var theDay = days[dateObj.getDay()] + " ";
          form.output.value = theDay + theMonth + theDate + theYear;
        } else {
          form.output.value = "An invalid date.";
        }
      }
    </script>
  </head>
  <body>
    <b>Use a regular expression to extract data from a string:</b>
    <hr />
    <form>
      Enter a date in the format mm/dd/yyyy or mm-dd-yyyy:<br />
      <input type="text" name="entry" size="12" />
      <p><input type="button" value="Extract Date Components"
        onclick="extractIt(this.form)" /></p>
      <p>The date you entered was:<br />
        <input type="text" name="output" size="40" /></p>
      <p><input type="reset" /></p>
    </form>
  </body>
</html>

```

## String replacement

To demonstrate using regular expressions for performing search-and-replace operations, I choose an application that may be of value to many page authors who have to display and format large numbers. Databases typically store large integers without commas. After five or six digits, however, such numbers are difficult for users to read. Conversely, if the user needs to enter a large number, commas help ensure accuracy.

Helping the procedure in JavaScript regular expressions is the `string.replace()` method (see Chapter 27). The method requires two parameters, a regular expression to search the string and a string to replace any match found in the string. The replacement string can be properties of the `RegExp` object as it stands after the most recent `exec()` method.

Listing 42-3 demonstrates how only a handful of script lines can do a lot of work when regular expressions handle the dirty work. The page contains three fields. Enter any number you want in the first one. A click of the Insert Commas button invokes the `commafy()` function in the page. The result is displayed in the second field. You can also enter a comma-filled number in the second field and click the Remove Commas button to see the inverse operation executed through the `decommafy()` function.

Specifications for the regular expression accept any positive or negative string of numbers. The keys to the action of this script are the parentheses around two segments of the regular expression. One set encompasses all characters not included in the second group: a required set of three digits. In other words, the regular expression is essentially working from the rear of the string, chomping off three-character segments and inserting a comma each time a set is found.

A `while` repeat loop cycles through the string and modifies the string (in truth, the string object is not being modified, but, rather, a new string is generated and assigned to the old variable name). I use the `test()` method because I don't need the returned value of the `exec()` method. The `test()` method impacts the regular expression and `RegExp` object properties the same way as the `exec()` method, but more efficiently. The first time the `test()` method runs, the part of the string that meets the first segment is assigned to the `RegExp.$1` property; the second segment, if any, is assigned to the `RegExp.$2` property. Notice that I'm not assigning the results of the `exec()` method to any variable, because for this application I don't need the array object generated by that method.

Next comes the tricky part. I invoke the `string.replace()` method, using the current value of the string (`num`) as the starting string. The pattern to search for is the regular expression defined at the head of the function. But the replacement string may look strange to you. The replacement string is replacing whatever the regular expression matches with the value of `RegExp.$1`, a comma, and the value of `RegExp.$2`. The `RegExp` object should not be part of the references used in the `replace()` method parameter. Because the regular expression matches the entire `num` string, the `replace()` method is essentially rebuilding the string from its components, plus adding a comma before the second component (the last freestanding three-digit section). Each `replace()` method invocation sets the value of `num` for the next time through the `while` loop and the `test()` method.

Looping continues until no matches occur — meaning that no more freestanding sets of three digits appear in the string. Then the results are written to the second field on the page.

### Listing 42-3: Replacing Strings via Regular Expressions

```
<html>
  <head>
    <title>Got a Match?</title>
    <script type="text/javascript">
      function commafy(form) {
        var re = /(-?\d+)(\d{3})/;
        var num = form.entry.value;
        while (re.test(num)) {
          num = num.replace(re, "$1,$2");
        }
        form.commaOutput.value = num;
      }
    </script>
  </head>
</html>
```

```

    }
    function decommafy(form) {
        var re = /,/g;
        form.plainOutput.value = form.commaOutput.value.replace(re,"");
    }
</script>
</head>
<body>
  <b>Use a regular expression to add/delete commas from numbers:</b>
  <hr />
  <form>
    Enter a large number without any commas:<br />
    <input type="text" name="entry" size="15" />
    <p><input type="button" value="Insert commas"
      onclick="commafy(this.form)" /></p>
    <p>The comma version is:<br />
      <input type="text" name="commaOutput" size="20" /></p>
    <p><input type="button" value="Remove commas"
      onclick="decommafy(this.form)" /></p>
    <p>The un-comma version is:<br />
      <input type="text" name="plainOutput" size="15" /></p>
    <p><input type="reset" /></p>
  </form>
</body>
</html>

```

Removing the commas is an even easier process. The regular expression is a comma with the global flag set. The `replace()` method reacts to the global flag by repeating the process until all matches are replaced. In this case, the replacement string is an empty string. For further examples of using regular expressions with string objects, see the discussions of the `string.match()`, `string.replace()`, and `string.split()` methods in Chapter 27.

## Regular Expression Object

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
constructor	compile()	
global	exec()	
ignoreCase	test()	
lastIndex		
multiline		
source		

### Syntax

Accessing regular expression properties or methods:

```
regularExpressionObject.property | method([parameters])
```

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

## About this object

The regular expression object is created on the fly by your scripts. Each regular expression object contains its own pattern and other properties. Deciding which object creation style to use depends on the way the regular expression will be used in your scripts.

When you create a regular expression with the literal notation (that is, with the two forward slashes), the expression is automatically compiled for efficient processing as the assignment statement executes. The same is true when you use the new `RegExp()` constructor and specify a pattern (and optional modifier flags) as a parameter. Whenever the regular expression is fixed in the script, use the literal notation; when some or all of the regular expression is derived from an external source (for example, user input from a text field), assemble the expression as a parameter to the new `RegExp()` constructor. A compiled regular expression should be used at whatever stage the expression is ready to be applied and reused within the script. Compiled regular expressions are not saved to disk or given any more permanence beyond the life of a document's script (that is, it dies when the page unloads).

However, there may be times in which the specification for the regular expression changes with each iteration through a loop construction. For example, if statements in a `while` loop modify the content of a regular expression, compile the expression inside the `while` loop, as shown in the following skeletal script fragment:

```
var srchText = form.search.value;
var re = new RegExp(); // empty constructor
while (someCondition) {
    re.compile("\\s+" + srchText + "\\s+", "gi");
    statements that change srchText
}
```

Each time through the loop, the regular expression object is both given a new expression (concatenated with metacharacters for one or more white spaces on both sides of some search text whose content changes constantly) and compiled into an efficient object for use with any associated methods.

## Properties

### constructor

(See `string.constructor` in Chapter 27)

### global

### ignoreCase

**Value:** Booleans.

Read-Only

**Compatibility:** WinIE5.5+, MacIE5+, NN4+, Moz1+, Safari1+

These two properties reflect the regular expression `g` and `i` modifier flags, if any, associated with a regular expression. Settings are read-only and are determined as the object is created. Each property is independent of the other.

*regularExpressionObject.compile()*

## lastIndex

**Value:** Integer.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `lastIndex` property indicates the index counter of the main string to be searched against the current regular expression object. When a regular expression object is created, this value is zero, meaning that there have been no searches with this object, and the default behavior of the first search is to start at the beginning of the string.

If the regular expression has the global modifier specified, the `lastIndex` property value advances to some higher value after the object is used in a method to match within a main string. The value is the position in the main string immediately after the previous matched string (and not including any character of the matched string). After locating the final match in a string, the method resets the `lastIndex` property to zero for the next time. You can also influence the behavior of matches by setting this value on the fly. For example, if you want the expression to begin its search at the fourth character of a target string, you change the setting immediately after creating the object, as follows:

```
var re = /somePattern/;
re.lastIndex = 3; // fourth character in zero-based index system
```

**Related Items:** Match result object index property.

## multiline

**Value:** Boolean.

Read-Only

**Compatibility:** WinIE5.5+, MacIE5, NN6+, Moz1+, Safari1+

The `multiline` property reveals whether searches extend across multiple lines of a target string, as directed by the optional `m` modifier flag for a regular expression. NN4+ also includes the same-named property for the `RegExp` object (see the following section).

**Related Items:** `RegExp.multiline` property.

## source

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `source` property is simply the string representation of the regular expression used to define the object. This property is read-only.

## Methods

`compile("pattern", ["g" | "i" | "m"])`**Returns:** Regular expression object.**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari-

Use the `compile()` method to compile on the fly a regular expression whose content changes continually during the execution of a script. See the discussion earlier about this object for an example. Other regular expression creation statements (the literal notation and the new `RegExp()` constructor that passes a regular expression) automatically compile their expressions. The `m` pattern modifier is available in IE5.5+ and NN6+/W3C.

**regularExpressionObject.exec()****exec("string")****Returns:** Match array object or null.**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The `exec()` method examines the string passed as its parameter for at least one match of the specification defined for the regular expression object. The behavior of this method is similar to that of the `string.match()` method (although the `match()` method is more powerful in completing global matches). Typically, a call to the `exec()` method is made immediately after the creation of a regular expression object, as in the following example:

```
var re = /somePattern/;
var matchArray = re.exec("someString");
```

Much happens as a result of the `exec()` method. Properties of both the regular expression object and window's `RegExp` object are updated based on the success of the match. The method also returns an object that conveys additional data about the operation. Table 42-4 shows the properties of this returned object.

**Table 42-4: Match Found Array Object Properties**

<i>Property</i>	<i>Description</i>
<code>index</code>	Zero-based index counter of the start of the match inside the string
<code>input</code>	Entire text of original string
<code>[0]</code>	String of most recent matched characters
<code>[1], . . . [n]</code>	Parenthesized component matches

Some of the properties in this returned object echo properties in the `RegExp` object. The value of having them in the regular expression object is that their contents are safely stowed in the object while the `RegExp` object and its properties may be modified soon by another call to a regular expression method. Items the two objects have in common are the `[0]` property (mapped to the `RegExp.lastMatch` property) and the `[1], . . . [n]` properties (the first nine of which map to `RegExp.$1` . . . `RegExp.$9`). Although the `RegExp` object stores only nine parenthesized subcomponents, the returned array object stores as many as are needed to accommodate parenthesis pairs in the regular expression.

If no match turns up between the regular expression specification and the string, the returned value is `null`. See Listing 42-2 for an example of how this method can be applied. An alternate shortcut syntax may be used for the `exec()` method. Turn the regular expression into a function, as in

```
var re = /somePattern/;
var matchArray = re("someString");
```

**Related Items:** `string.match()` method.**test("string")****Returns:** Boolean.**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari1+

The most efficient way to find out if a regular expression has a match in a string is to use the `test()` method. Returned values are `true` if a match exists and `false` if not. In case you need more information, a companion method, `string.search()`, returns the starting index value of the matching string. See Listing 42-1 for an example of this method in action.

**Related Items:** `string.search()` method.

## RegExp Object

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<input/> lastMatch lastParen leftContext multiline prototype rightContext \$1, ... \$9	(None)	(None)

### Syntax

Accessing RegExp properties:

`RegExp.property`

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari-

### About this object

Beginning with version 4 browsers, the browser maintains a single instance of a `RegExp` object for each window or frame. The object oversees the action of all methods that involve regular expressions (including the few related string object methods). Properties of this object are exposed not only to JavaScript in the traditional manner, but also to a parameter of the method `string.replace()` for some shortcut access (see Listing 42-3).

With one `RegExp` object serving all regular expression-related methods in your document's scripts, you must exercise care in accessing or modifying this object's properties. You must make sure that the `RegExp` object has not been affected by another method. Most properties are subject to change as the result of any method involving a regular expression. This may be reason enough to use the properties of the array object returned by most regular expression methods instead of the `RegExp` properties. The former stick with a specific regular expression object even after other regular expression objects are used in the same script. The `RegExp` properties reflect the most recent activity, irrespective of the regular expression object involved.

In the following listings, I supply the long, JavaScript-like property names. But each property also has an abbreviated, Perl-like manner to refer to the same properties. You can use these shortcut property names in the `string.replace()` method if you need the values.

*RegExp*.input

## Properties

### input

**Value:** String.

Read/Write

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz-, Safari-

The `RegExp.input` property is the main string against which a regular expression is compared in search of a match. In all of the example listings earlier in this chapter, the property was `null`. Such is the case when the main string is supplied as a parameter to the regular expression-related method.

But many text-related document objects have an unseen relationship with the `RegExp` object. If a `text`, `textarea`, `select`, or `link` object contains an event handler that invokes a function containing a regular expression, the `RegExp.input` property is set to the relevant textual data from the object. You don't have to specify any parameters for the event handler call or in the function called by the event handler. For `text` and `textarea` objects, the `input` property value becomes the content of the object; for the `select` object, it is the text (not the value) of the selected option; and for a `link`, it is the text highlighted in the browser associated with the link (and reflected in the link's `text` property).

Having JavaScript set the `RegExp.input` property for you may simplify your script. You can invoke either of the regular expression methods without having to specify the main string parameter. When that parameter is empty, JavaScript applies the `RegExp.input` property to the task. You can also set this property on the fly if you want. The short version of this property is `$_` (dollar sign underscore).

**Related Items:** Matching array object `input` property.

### multiline

**Value:** Boolean.

Read/Write

**Compatibility:** WinIE5.5+, MacIE5+, NN4+, Moz1+, Safari-

The `RegExp.multiline` property determines whether searches extend across multiple lines of a target string. This property is automatically set to `true` as an event handler of a `textarea` triggers a function containing a regular expression. You can also set this property on the fly if you want. The short version of this property is `$`. This version of the property (as distinct from the `multiline` property of an instance of a regular expression) is not defined in the ECMA-262 specification and is based on an early, incorrect implementation.

**Related Items:** Regular expression instance object `multiline` property.

### lastMatch

**Value:** String.

Read-Only

**Compatibility:** WinIE5.5+, MacIE5+, NN4+, Moz1+, Safari-

After execution of a regular expression-related method, any text in the main string that matches the regular expression specification is automatically assigned to the `RegExp.lastMatch` property. This value is also assigned to the `[0]` property of the object array returned after the `exec()` and `string.match()` methods find a match. The short version of this property is `$&`.

**Related Items:** Matching array object `[0]` property.

## lastParen

**Value:** String.

Read-Only

**Compatibility:** WinIE5.5+, MacIE5+, NN4+, Moz1+, Safari-

When a regular expression contains many parenthesized subcomponents, the `RegExp` object maintains a list of the resulting strings in the `$1`, `...`, `$9` properties. You can also extract the value of the last matching parenthesized subcomponent with the `RegExp.lastParen` property, which is a read-only property. The short version of this property is `$+`.

**Related Items:** `RegExp.$1`, `...`, `$9` properties.

## leftContext

## rightContext

**Value:** String.

Read-Only

**Compatibility:** WinIE5.5+, MacIE5+, NN4+, Moz1+, Safari-

After a match is found in the course of one of the regular expression methods, the `RegExp` object is informed of some key contextual information about the match. The `leftContext` property contains the part of the main string to the left of (up to but not including) the matched string. Be aware that the `leftContext` starts its string from the point at which the most recent search began. Therefore, for second or subsequent times through the same string with the same regular expression, the `leftContext` substring varies widely from the first time through.

The `rightContext` consists of a string starting immediately after the current match and extending to the end of the main string. As subsequent method calls work on the same string and regular expression, this value obviously shrinks in length until no more matches are found. At this point, both properties revert to `null`. The short versions of these properties are `$`` and `$'` for `leftContext` and `rightContext`, respectively.

## prototype

(See `String.prototype` in Chapter 27)

## \$1...\$9

**Value:** String.

Read-Only

**Compatibility:** WinIE4+, MacIE4+, NN4+, Moz1+, Safari-

As a regular expression method executes, any parenthesized result is stored in `RegExp`'s nine properties reserved for just that purpose (called backreferences). The same values (and any beyond the nine that `RegExp` has space for) are stored in the array object returned with the `exec()` and `string.match()` methods. Values are stored in the order in which the left parenthesis of a pair appears in the regular expression, regardless of nesting of other components.

You can use these backreferences directly in the second parameter of the `string.replace()` method, without using the `RegExp` part of their address. The ideal situation is to encapsulate components that need to be rearranged or recombined with replacement characters. For example, the following script function turns a name that is last name first into first name last:

```
function swapEm() {
  var re = /(\w+),\s*(\w+)/;
  var input = "Lincoln, Abraham";
  return input.replace(re,"$2 $1");
}
```

## ***RegExp.\$1***

In the `replace()` method, the second parenthesized component (just the first name) is placed first, followed by a space and the first component. The original comma is discarded. You are free to combine these shortcut references as you like, including multiple times per replacement, if it makes sense to your application.

**Related Items:** Matching array object `[1]`. . . `[n]` properties.

# Data-Entry Validation

---

**G**ive users a field in which to enter data and you can be sure that some users will enter the wrong kind of data. Often the “mistake” is accidental—a slip of the pinkie on the keyboard; other times, users intentionally type the incorrect entry to test the robustness of your application. Whether you solicit a user’s entry for client-side scripting purposes or for input into a server-based CGI or database, you should use JavaScript on the client to handle validation of the user’s entry. Even for a form connected to a CGI script, it’s far more efficient (from the perspective of bandwidth, server load, and execution speed) to let client-side JavaScript get the data straight before your server program deals with it.

## Real-Time versus Batch Validation

You have two opportunities to perform data-entry validation in a form: as the user enters data into a form and just before the form is submitted. I recommend you take advantage of both of these opportunities.

### Real-time validation triggers

The most convenient time to catch an error is immediately after the user makes it—especially for a long form that requests a wide variety of information. You can make the user’s experience less frustrating if you catch an entry mistake just after the user enters the information: his or her attention is already focused on the nature of the content (or some paper source material may already be in front of the user). It is much easier for the user to address the same information entry right away.

A valid question for the page author is how to trigger the real-time validation. Backward-compatible text boxes have two potential event handlers for this purpose: `onchange` and `onblur`. I personally avoid `onblur` event handlers, especially ones that can display an alert dialog box (as a data-entry validation is likely to do). Because a good validation routine brings focus to the errant text box, you can get some odd behavior with the interaction of the `focus()` method and the `onblur` event handler. Users who wish to continue past an invalid field are locked in a seemingly endless loop.

### In This Chapter

Validating data as it is being entered

Validating data immediately prior to submission

Organizing complex data-validation tasks

The problem with using `onchange` as the validation trigger is that a user can defeat the validation. A change event occurs only when the text of a field indeed changes when the user tabs or clicks out of the field. If the user is alerted about some bad entry in a field and doesn't fix the error, the change event doesn't fire again. In some respects, this is good because a user may have a legitimate reason for passing by a particular form field initially with the intention of returning to the entry later. Because a user can defeat the `onchange` event handler trigger, I recommend you also perform batch validation prior to submission.

In NN4+, IE4+, and W3C browsers, you also have the luxury of letting keyboard events trigger validations. This is most helpful when you want to prevent some character(s) from being entered into a field. For example, if a field is supposed to contain only a positive integer value, you can use the `onkeypress` event handler of the text box to verify that the character just typed is a number. If the character is not a number, the event is trapped and no character reaches the text box. You should also alert the user in some way about what's going on. Listing 43-1 demonstrates a simplified version of this kind of keyboard trapping, compatible with NN4+/IE4+/W3C event models (but not fully functional in Safari 1.0). The message to the user is displayed in the status bar. Displaying the message there has the advantage of being less intrusive than an alert dialog box (and keeps the text insertion cursor in the text box), but it also means that users might not see the message. The `onsubmit` event handler in the listing prevents a press of the Enter key in this one-field form from reloading this sample page.

### Listing 43-1: Allowing Only Numbers into a Text Box

```
<html>
  <head>
    <title>Letting Only Numbers Pass to a Form Field</title>
    <script type="text/javascript">
      function checkIt(evt) {
        evt = (evt) ? evt : window.event;
        var charCode = (evt.charCode) ? evt.charCode :
          ((evt.which) ? evt.which : evt.keyCode);
        if (charCode > 31 && (charCode < 48 || charCode > 57)) {
          status = "This field accepts numbers only.";
          return false;
        }
        status = "";
        return true;
      }
    </script>
  </head>
  <body>
    <h1>Letting Only Numbers Pass to a Form Field</h1>
    <hr />
    <form onsubmit="return false">
      Enter any positive integer: <input type="text" name="numeric"
        onkeypress="return checkIt(event)" />
    </form>
  </body>
</html>
```

Keyboard event monitoring isn't practical for most validation actions, however. For example, if the user is supposed to enter an e-mail address, you need to validate the complete entry for the presence of an @ symbol (via the `onchange` event handler). On the other hand, you can be granular about your validations and use both the `onchange` and `onkeypress` event handlers; you employ the latter for blocking invalid characters in e-mail addresses (such as spaces).

## Batch mode validation

In all scriptable browsers, a form's `onsubmit` event handler cancels the submission if the handler evaluates to `return false`. Additional submission event cancelers include setting the IE4+ `event.returnValue` property to `false` and invoking the `evt.preventDefault()` method in NN6+/W3C (see Chapter 25 on event objects for details). You can see an example of the basic `return false` behavior in Listing 23-4 of Chapter 23. That example uses the results of a `window.confirm()` dialog box to determine the return value of the event handler. But you can also use a return value from a series of individual text box validation functions. If any one of the validations fails, the user is alerted and the submission is canceled.

Before you worry about two versions of validation routines loading down the scripts in your page, you'll be happy to know that you can reuse the same validation routines in both the real-time and batch validations. Later in this chapter, I demonstrate what I call "industrial-strength" data-entry validation adapted from a real intranet application. But before you get there, you should learn about general validation techniques that you can apply to both types of validations.

## Designing Filters

The job of writing data-validation routines essentially involves designing filters that weed out characters or entries that don't fit your programming scheme. Whenever your filter detects an incorrect entry, it should alert the user about the nature of the problem and enable the user to correct the entry.

Before you put a `text` or `textarea` object into your document that invites users to enter data, you must decide if any possible entry can disturb the execution of the rest of your scripts. For example, if your script must have a number from that field to perform calculations, you must filter out any entry that contains letters or punctuation—except for periods if the program can accept floating-point numbers. Your task is to anticipate every possible entry users can make and allow only those entries your scripts can use.

Not every entry field needs a data-validation filter. For example, you may prompt a user for information that is eventually stored as a `document.cookie` or in a string database field on the server for future retrieval. If no further processing takes place on that information, you may not have to worry about the specific contents of that field.

One other design consideration is whether a text field is even the proper user interface element for the data required of the user. If the range of choices for a user entry is small (a dozen or fewer), a more sensible method is to avoid the data-entry problem altogether by turning that field into a `select` element. Your HTML attributes for the object ensure that you control the kind of entry made to that object. As long as your script knows how to deal with each of the options defined for that object, you're in the clear.

## Building a Library of Filter Functions

A number of basic data-validation processes function repeatedly in form-intensive HTML pages. Filters for integers only, numbers only, empty entries, alphabet letters only, and the like are put to use every day. If you maintain a library of generalizable functions for each of your data-validation tasks, you can drop these functions into your scripts at a moment's notice and be assured that they will work. For NN3+ and IE4+, you can also create the library of validation functions as a separate `.js` library file and link the scripts into any HTML file that needs them.

Making validation functions generalizable requires careful choice of wording and logic so that they return Boolean values that make syntactical sense when called from elsewhere in your scripts. As you see later in this chapter, when you build a larger framework around smaller functions, each function is usually called as part of an `if...else` conditional statement. Therefore, assign a name that fits logically as part of an `if` clause in plain language. For example, you can name a function that checks whether an entry is empty `isEmpty()`. The calling statement for this function is

```
if (isEmpty(value)) { ... }
```

From a plain-language perspective, the expectation is that the function returns `true` if the passed value is empty. With this design, the statements nested in the `if` construction handle empty entry fields. I revisit this design later in this chapter when I start stacking multiple-function calls together in a larger validation routine.

To get you started with your library of validation functions, this chapter provides some building blocks that you can learn from and use as starting points for more specific filters of your own design. You can choose between fully backward-compatible (a) and regular expression (b) versions for many of them. Some of these functions are put to use in the JavaScript application in Chapter 50.

### isEmpty()

This first function, shown in Listing 43-2a, checks to see if the incoming value is either empty or `null`. Adding a check for `null` means that you can use this function for purposes other than just text-object validation. For example, if another function defines three parameter variables, but the calling function passes only two, the third variable is set to `null`. If the script then performs a data-validation check on all parameters, the `isEmpty()` function responds that the `null` value is devoid of data.

#### Listing 43-2a: Is an Entry Empty or Null?

```
// general purpose function to see if an input value has been
// entered at all
function isEmpty(inputStr) {
    if (inputStr == null || inputStr == "") {
        return true;
    }
    return false;
}
```

This function uses a Boolean `or` operator (`||`) to test for the existence of a `null` value or an empty string in the value passed to the function. Because the name of the function implies a true response if the entry is empty, that value is the one that returns to the calling statement if either condition is true. Because a `return` statement halts further processing of a function, the `return false` statement lies outside of the `if` construction. If processing reaches this statement, the `inputStr` value has failed the test.

If this seems like convoluted logic—`return true` when the value is empty—you can also define a function that returns the inverse values. You can name it `isNotEmpty()`. As it turns out, however, typical processing of an empty entry is better served when the test returns a `true` than when the value is empty—aiding the `if` construction that calls the function in the first place.

The regular expression version, shown in Listing 43-2b, examines whether the input string has one or more characters of any kind in it.

#### Listing 43-2b: Is an Entry Empty or Null? (regex version)

```
// regular expression function to see if an input value has been
// entered at all
function isEmpty(inputStr) {
    var re = /.+/;
    if (!inputStr.match(re)) {
        return true;
    }
    return false;
}
```

## isPosInteger()

This next function examines each character of the value to make sure that only numbers from 0 through 9 with no punctuation or other symbols exist. The goal of the function in Listing 43-3a is to weed out any value that is not a positive integer.

#### Listing 43-3a: Test for Positive Integers

```
// general purpose function to see if a suspected numeric input
// is a positive integer
function isPosInteger(inputVal) {
    inputStr = inputVal.toString();
    for (var i = 0; i < inputStr.length; i++) {
        var oneChar = inputStr.charAt(i);
        if (oneChar < "0" || oneChar > "9") {
            return false;
        }
    }
    return true;
}
```

Notice that this function makes no assumption about the data type of the value that is passed as a parameter. If the value had come directly from a text object, it would already be a string and the line that forced data conversion to a string would be unnecessary. But to generalize the function, the conversion is included to accommodate the possibility that it may be called from another statement that has a numeric value to check.

The function requires you to convert the input value to a string because it performs a character-by-character analysis of the data. A `for` loop picks apart the value one character at a time. Rather than force the script to invoke the `string.charAt()` method twice for each time through the loop (inside the `if` condition), one statement assigns the results of the method to a variable, which is then used twice in the `if` condition. Placing the results of the `charAt()` method into a variable makes the `if` condition shorter and easier to read and also is microscopically more efficient.

In the `if` condition, the ASCII value of each character is compared against the range of 0 through 9. This method is safer than comparing numeric values of the single characters because one of the characters can be nonnumeric. (You can encounter all kinds of other problems trying to convert that character to a number for numeric comparison.) The ASCII value, on the other hand, is neutral about the meaning of a character: If the ASCII value is less than 0 or greater than 9, the character is not valid for a genuine positive integer. The function bounces the call with a false reply. On the other hand, if the `for` loop completes its traversal of all characters in the value without a hitch, the function returns `true`.

You may wonder why this validation function doesn't use the `parseInt()` global function (see Chapter 34). That function returns `NaN` only if the first character of the input string is not a number. But because `parseInt()` and `parseFloat()` peel off any initial numeric values from a string, neither returns `NaN` if the input string is, for example, `35a`.

The regular expression version (Listing 43-3b) allows a string consisting entirely of any number of numerals.

#### Listing 43-3b: Test for Positive Integers (regex version)

```
// regular expression function to see if a suspected numeric input
// is a positive integer
function isPosInteger(inputStr) {
    var re = /^\\d*$/;
    inputStr = inputStr.toString();
    if (!inputStr.match(re)) {
        return false;
    }
    return true;
}
```

## isInteger()

The next possibility includes the entry of a negative integer value. Listing 43-4a shows that you must add an extra check for a leading negation sign.

**Listing 43-4a: Checking for Leading Minus Sign**

```

// general purpose function to see if a suspected numeric input
// is a positive or negative integer
function isInteger(inputVal) {
    inputStr = inputVal.toString();
    for (var i = 0; i < inputStr.length; i++) {
        var oneChar = inputStr.charAt(i);
        if (i == 0 && oneChar == "-") {
            continue;
        }
        if (oneChar < "0" || oneChar > "9") {
            return false;
        }
    }
    return true;
}

```

When a script can accept a negative integer, the filter must enable the leading minus sign to pass unscathed. You cannot just add the minus sign to the `if` condition of Listing 43-4a because you can accept that symbol only when it appears in the first position of the value—anywhere else makes the value an invalid number. To handle the possibility of a leading minus sign, you add another `if` statement whose condition looks for a special combination: the first character of the string (as indexed by the loop-counting variable) and the minus character. If both of these conditions are met, execution immediately loops back around to the update expression of the `for` loop (because of the `continue` statement) rather than carrying out the second `if` statement, which would obviously fail. By putting the `i == 0` comparison operation at the front of the condition, you ensure the entire condition short circuits to `false` for all subsequent iterations through the loop.

The regular expression version (Listing 43-4b) is identical to the one for `isPosInteger()` except that the regular expression allows for one leading hyphen.

**Listing 43-4b: Checking for Leading Minus Sign (regex version)**

```

// regular expression function to see if a suspected numeric input
// is a positive or negative integer
function isInteger(inputStr) {
    var re = /^[^-]?\d*$/;
    inputStr = inputStr.toString();
    if (!inputStr.match(re)) {
        return false;
    }
    return true;
}

```

## isNumber()

The final numeric filter function in this series enables any integer or floating-point number to pass while filtering out all others (Listing 43-5a). All that distinguishes an integer from a floating-point number for data-validation purposes is the decimal point.

### Listing 43-5a: Testing for a Decimal Point

```
// general purpose function to see if a suspected numeric input
// is a positive or negative number
function isNumber(inputVal) {
    oneDecimal = false;
    inputStr = inputVal.toString();
    for (var i = 0; i < inputStr.length; i++) {
        var oneChar = inputStr.charAt(i);
        if (i == 0 && oneChar == "-") {
            continue;
        }
        if (oneChar == "." && !oneDecimal) {
            oneDecimal = true;
            continue;
        }
        if (oneChar < "0" || oneChar > "9") {
            return false;
        }
    }
    return true;
}
```

Anticipating the worst, however, the function cannot simply treat a decimal point at any position within the string as a valid character. Such an act assumes that no one would ever enter more than one decimal point into a numeric text field. Only one decimal point is allowed for this function (as well as for JavaScript math). Therefore, you add a Boolean flag variable (`oneDecimal`) to the function and a separate `if` condition that sets that flag to `true` when the function encounters the first decimal point. Should another decimal point appear in the string, the final `if` statement gets a crack at the character. Because the character falls outside the ASCII range of 0 through 9, it fails the entire function.

If you want to accept only positive floating-point numbers, you can make a new version of this function by removing the statement that lets the leading minus sign through. Be aware that this function works only for values that are not represented in exponential notation.

A slight modification to the regular expression from Listing 43-4b—allowing a single decimal point between any number of numerals—turns the validation function into one that tests for any positive or negative number, with or without numbers to the right of the decimal, as shown in Listing 43-5b.

**Listing 43-5b: Testing for a Decimal Point (regexp version)**

```
// regular expression function to see if a suspected numeric input
// is a positive or negative number
function isNumber(inputStr) {
    var re = /^[^-]?\d*\.\d*$/;
    inputStr = inputStr.toString();
    if (!inputStr.match(re)) {
        return false;
    }
    return true;
}
```

## Custom validation functions

The listings shown so far in this chapter should give you plenty of source material to use in writing customized validation functions for your applications. Listing 43-6 shows an example of such an application-specific variation (extracted from the application in Chapter 50).

**Listing 43-6: A Custom Validation Function**

```
// function to determine if value is in acceptable range
// for this application
function inRange(inputStr) {
    num = parseInt(inputStr);
    if (num < 1 || num > 586 && num < 596 || num > 599 && num < 700 ||
        num > 728) {
        return false;
    }
    return true;
}
```

For this application, you need to see if an entry falls within multiple ranges of acceptable numbers. The first statement of the `inRange()` function converts the incoming value to a number (via the `parseInt()` function) so that the value can be compared numerically against maximum and minimum values of several ranges within the database. Following the logic of the previous validation functions, the `if` condition looks for values outside the acceptable range, so it can alert the user and return a `false` value.

The `if` condition is quite a long sequence of operators. As you noticed in the list of operator precedence (see Chapter 32), the Boolean `and` operator (`&&`) has precedence over the Boolean `or` operator (`||`). Therefore, the `and` expressions evaluate first, followed by the `or` expressions. Parentheses may help you better visualize what's going on in that monster condition:

```
if (num < 1 || (num > 586 && num < 596) || (num > 599 && num < 700) ||
    num > 728)
```

In other words, you exclude four possible ranges from consideration:

- ♦ Values less than 1
- ♦ Values between 586 and 596
- ♦ Values between 599 and 700
- ♦ Values greater than 728

Any value for which any one of these tests is true yields a Boolean `false` from this function. Combining all these tests into a single condition statement eliminates the need to construct an otherwise complex series of nested `if` constructions.

## Combining Validation Functions

When you design a page that requests a particular kind of text input from a user, you often need to call more than one data-validation function to handle the entire job. For example, if you merely want to test for a positive integer entry, your validation should test for the presence of any entry as well as the validation as an integer.

After you know the kind of permissible data that your script will use after validation, you're ready to plot the sequence of data validation. Because each page's validation task is different, I supply some guidelines to follow in this planning rather than prescribe a fixed route for all to take.

My preferred sequence is to start with examinations that require less work and increase the intensity of validation detective work with succeeding functions. I borrow this tactic from real life: When a lamp fails to turn on, I look for a pulled plug or a burned-out lightbulb before tearing the lamp's wiring apart to look for a short.

Using the data-validation sequence from the data-entry field (which must be a three-digit number within a specified range) in Chapter 50, I start with the test that requires the least amount of work: Is there an entry at all? After my script is ensured an entry of some kind exists, it next checks whether that entry is "all numbers as requested of the user." If so, the script compares the number against the ranges of numbers in the database.

To make this sequence work together efficiently, I create a master validation function consisting of nested `if...else` statements. Each `if` condition calls one of the generalized data-validation functions. Listing 43-7 shows the master validation function.

### Listing 43-7: Master Validation Function

```
// Master value validator routine
function isValid(inputStr) {
    if (isEmpty(inputStr)) {
        alert("Please enter a number into the field before clicking the
            button.");
        return false;
    } else {
        if (!isNumber(inputStr)) {
            alert("Please make sure entries are numbers only.");
            return false;
        } else {
            if (!inRange(inputStr)) {
```

```

        var msg = "Sorry, the number you entered is not part of our
            database.";
        msg += "Try another three-digit number.";
        alert(msg);
        return false;
    }
}
}
return true;
}

```

---

This function, in turn, is called by the function that controls most of the work in this application. All that the main function wants to know is whether the entered number is valid. The details of validation are handed off to the `isValid()` function and its special-purpose validation testers.

I construct the logic in Listing 43-7 so that if the input value fails to be valid, the `isValid()` function alerts the user of the problem and returns `false`. That means I have to watch my `true`s and `false`s very carefully.

In the first validation test, an empty value is a bad thing; thus, when the `isEmpty()` function returns `true`, the `isValid()` function returns `false` because an empty string is not a valid entry. In the second test, a number value is good so the logic has to flip 180 degrees. The `isValid()` function returns `false` only if the `isNumber()` function returns `false`. But because `isNumber()` returns `true` when the value is a number, I switch the condition to test for the opposite results of the `isNumber()` function by negating the function name (preceding the function with the Boolean `not (!)` operator). This operator works only with a value that evaluates to a Boolean expression — which the `isNumber()` function always does. The final test for being within the desired range works on the same basis as `isNumber()`, using the Boolean `not` operator to turn the results of the `inRange()` function into the method that works best for this sequence.

Finally, if all validation tests fail to find bad or missing data, the entire `isValid()` function returns `true`. The statement that calls this function can now proceed with processing, ensured that the value entered by the user will work.

The Boolean logic of the backward-compatible and regular expression versions of the core validation functions is the same. Therefore, you can use either version with the master validation function.

There is one additional point worth reinforcing, especially for newcomers. Although all these functions seem to be passing around the same input string as a parameter, notice that any changes made to the value (such as converting it to a string or number) are kept private to each function. These subfunctions never touch the original value in the calling function — they work only with copies of the original value. Therefore, even after the data validation takes place, the original value is in its original form and ready to go.

## Date and Time Validation

You can scarcely open a bigger can of cultural worms than when trying to program around the various date and time formats in use around the world. If you have ever looked through the possible settings in your computer's operating system, you can begin to understand the difficulty of this issue.

Trying to write JavaScript that accommodates all of the world's date and time formats for validation is an enormous, if not wasteful, challenge. It's one thing to validate that a text box contains data in the form `xx/xx/xxxx`, but there are also valid value concerns that can get very messy on an international basis. For example, while North America typically uses the `mm/dd/yyyy` format, a large portion of the rest of the world uses `dd/mm/yyyy` (with different delimiter characters, as well). Therefore, how should your validation routine treat the entry `20/03/2002`? Is it incorrect because there are not 20 months in a year; or is it correct as March 20th? To query a user for this kind of information, I suggest you divide the components into individually validated fields (separate text objects for hours and minutes) or make `select` element entries whose individual values can be assembled at submit time into a hidden date field for processing by the database that needs the date information. (Alternately, you can let your server CGI handle the conversion.)

Despite my encouragement to “divide and conquer” date entries, there may be situations in which you feel it's safe to provide a single text box for date entry (perhaps for a form that is used on a corporate intranet strictly by users in one country). You see some more sophisticated code later in this chapter, but a “quick-and-dirty” solution runs along these lines:

1. Use the entered data (for example, in `mm/dd/yyyy` format) as a value passed to the new `Date()` constructor function.
2. From the newly created date object, extract each of the three components (month, day, and year) into separate numeric values (with the help of `parseInt()`).
3. Compare each of the extracted values against the corresponding date, month, and year values returned by the date object's `getDate()`, `getMonth()`, and `getFullYear()` methods (adjusting for zero-based values of `getMonth()`).
4. If all three pairs of values match, the entry is apparently valid.

Listing 43-8a puts this action sequence to work in a backward-compatible way. The `validateDate()` function receives a reference to the field being checked. A copy of the field's value is made into a date object, and its components are read. If any part of the date conversion or component extraction fails (because of improperly formatted data or unexpected characters), one or more of the variable values becomes `NaN`. This code assumes that the user enters a date in the `mm/dd/yyyy` format, which is the sequence that the `Date` object constructor expects its data. If the user enters `dd/mm/yyyy`, the validation fails for any day beyond the twelfth.

### Listing 43-8a: Simple Date Validation

```
<html>
  <head>
    <title>Simple Date Validation</title>
    <script type="text/javascript">
      function validateDate(fld) {
        var testMo, testDay, testYr, inpMo, inpDay, inpYr, msg;
        var inp = fld.value;
        status = "";
        // attempt to create date object from input data
        var testDate = new Date(inp);
        // extract pieces from date object
        testMo = testDate.getMonth() + 1;
        testDay = testDate.getDate();
        testYr = testDate.getFullYear();
```

```

// extract components of input data
inpMo = parseInt(inp.substring(0, inp.indexOf("/")), 10);
inpDay = parseInt(inp.substring((inp.indexOf("/") + 1),
    inp.lastIndexOf("/")), 10);
inpYr = parseInt(inp.substring((inp.lastIndexOf("/") + 1),
    inp.length), 10);
// make sure parseInt() succeeded on input components
if (isNaN(inpMo) || isNaN(inpDay) || isNaN(inpYr)) {
    msg = "There is some problem with your date entry.";
}
// make sure conversion to date object succeeded
if (isNaN(testMo) || isNaN(testDay) || isNaN(testYr)) {
    msg = "Couldn't convert your entry to a valid date. Try again.";
}
// make sure values match
if (testMo != inpMo || testDay != inpDay || testYr != inpYr) {
    msg = "Check the range of your date value.";
}
if (msg) {
    // there's a message, so something failed
    alert(msg);
    // work around IE timing problem with alert by
    // invoking a focus/select function through setTimeout();
    // must pass along reference of fld (as string)
    setTimeout("doSelection(document.forms['" +
        fld.form.name + "'].elements['" + fld.name + "'])", 0);
    return false;
} else {
    // everything's OK; if browser supports new date method,
    // show just date string in status bar
    status = (testDate.toLocaleDateString) ?
        testDate.toLocaleDateString() : "Date OK";
    return true;
}
}

// separate function to accommodate IE timing problem
function doSelection(fld) {
    fld.focus();
    fld.select();
}
</script>
</head>
<body>
<h1>Simple Date Validation</h1>
<hr />
<form name="entryForm" onsubmit="return false">
    Enter any date (mm/dd/yyyy): <input type="text" name="startDate"
    onchange="validDate(this)" />
</form>
</body>
</html>

```

You can also use regular expressions for date validation. A version of the above listing using regular expressions at the core is found in Listing 43-8b.

## Listing 43-8b: Simple Date Validation

```

<html>
  <head>
    <title>Simple Date Validation (regex)</title>
    <script type="text/javascript">
      function validDate(fld) {
        var testMo, testDay, testYr, inpMo, inpDay, inpYr, msg;
        var inp = fld.value;
        status = "";
        var re = /\b\d{1,2}[/-]\d{1,2}[/-]\d{4}\b/;
        if (re.test(inp)) {
          var delimChar = (inp.indexOf("/") != -1) ? "/" : "-";
          var delim1 = inp.indexOf(delimChar);
          var delim2 = inp.lastIndexOf(delimChar);
          mo = parseInt(inp.substring(0, delim1), 10);
          day = parseInt(inp.substring(delim1+1, delim2), 10);
          yr = parseInt(inp.substring(delim2+1), 10);
          var testDate = new Date(yr, mo-1, day);
          if (testDate.getDate() == day) {
            if (testDate.getMonth() + 1 == mo) {
              if (testDate.getFullYear() == yr) {
                msg = "";
              } else {
                msg = "There is a problem with the year entry.";
              }
            } else {
              msg = "There is a problem with the month entry.";
            }
          } else {
            msg = "There is a problem with the date entry.";
          }
        } else {
          msg = "Incorrect date format. Enter as mm/dd/yyyy.";
        }
        if (msg) {
          // there's a message, so something failed
          alert(msg);
          // work around IE timing problem with alert by
          // invoking a focus/select function through setTimeout();
          // must pass along reference of fld (as string)
          setTimeout("doSelection(document.forms['" +
            fld.form.name + "'].elements['" + fld.name + "'])", 0);
          return false;
        } else {
          // everything's OK; if browser supports new date method,
          // show just date string in status bar
          window.status = (testDate.toLocaleDateString) ?
            testDate.toLocaleDateString() : "Date OK";
          return true;
        }
      }
    }
  }
}

```

```

// separate function to accommodate IE timing problem
function doSelection(fld) {
    fld.focus();
    fld.select();
}
</script>
</head>
<body>
<h1>Simple Date Validation</h1>
<hr />
<form name="entryForm" onsubmit="return false">
    Enter any date (mm/dd/yyyy): <input type="text" name="startDate"
    onchange="validDate(this)" />
</form>
</body>
</html>

```

## Selecting Text Fields for Reentry

During both real-time and batch validations, it is especially helpful to the user if your code—upon discovering an invalid entry—not only brings focus to the subject text field, but also selects the content for the user. By preselecting the entire field, you make it easy for the user to just retype the data into the field for another attempt (or to begin using the left and right arrow keys to move the insertion cursor for editing). The reverse type on the field text also helps bring attention to the field. (Not all operating systems display a special rectangle around a focused text field.)

Form fields have both `focus()` and `select()` methods, which you should invoke for the subject field in that order. IE for Windows, however, exhibits undesirable behavior when trying to focus and select a field immediately after you close an alert dialog box. In most cases, the field does not keep its focus or selection. This is a timing problem, but one that you can cure by processing the focus and select actions through a `setTimeout()` method. The bottom of the script code of Listing 43-9 demonstrates how to do this.

Method calls to the form field reside in a separate function (called `doSelection()` in this example). Obviously, the methods need a reference to the desired field, so the `doSelection()` function requires access to that reference. You can use a global variable to accomplish this (set the value in the validation function; read it in the `doSelection()` function), but globals are not elegant solutions to passing transient data. Even though the validation function receives a reference to the field, that is an object reference, and the `setTimeout()` function's first parameter cannot be anything but a string value. Therefore, the reference to the text field provides access to names of both the form and field. The names fill in as index values for arrays so that the assembled string (upon being invoked) evaluates to a valid object reference:

```
"doSelection(document.forms['" + fld.form.name + "'].elements['" + fld.name +
"'])"
```

Notice the generous use of built-in `forms` and `elements` object arrays, which allow the form and field names to assemble the reference without resorting to the onerous `eval()` function.

For timing problems such as this one, no additional time is truly needed to let IE recover from whatever ails it. Thus, the time parameter is set to 0 milliseconds. Using the `setTimeout()` portal is enough to make everything work. There is no penalty for using this construction with NN or MacIE, even though they don't need it.

## An “Industrial-Strength” Validation Solution

I had the privilege of working on a substantial intranet project that included dozens of forms, often with two or three different kinds of forms displayed simultaneously within a frameset. Data-entry accuracy was essential to the validity of the entire application. My task was to devise a data-entry validation strategy that not only ensured accurate entry of data types for the underlying (SQL) database, but also intelligently prompted users who made mistakes in their data entry.

### Structure

From the start, the validation routines were to be in a client-side library linked in from an external `.js` file. That would allow all forms to share the validation functions. Because there were multiple forms displayed in a frameset, it would prove too costly in download time and memory requirements to include the `validations.js` file in every frame's document. Therefore, the library was moved to load in with the frameset. The `<script src="validations.js">``</script>` tag set went in the Head portion of the framesetting document.

This logical placement presented a small challenge for the workings of the validations because there had to be two-way conversations between a validation function (in the frameset) and a form element (nested in a frame). The mechanism required that a reference to the frame containing the form element be passed as part of the validation routine so that the validation script could make corrections, automatic formatting, and erroneous field selections from the frameset document's script. (In other words, the frameset script needed a path back to the form element making the validation call.)

### Dispatch mechanism

From the specification drawn up for the application, it is clear that there are more than two dozen specific types of validations across all the forms. Moreover, multiple programmers work on different forms. It is helpful to standardize the way validations are called, regardless of the validation type (number, string, date, phone number, and so on).

My idea was to create one `validate()` function that contained parameters for the current frame, the current form element, and the type of validation to perform. This would make it clear to anyone reading the code later that an event handler calling `validate()` performed validation, and the details of the code were in the `validations.js` library file.

In `validations.js`, I converted a string name of a validation type into the name of the function that performs the validation in order to make this idea work. As a bridge between the two, I created what I called a *dispatch lookup table* for all the primary validation routines that would be called from the forms. Each entry of the lookup table had a label consisting of the name of the validation and a method that invoked the function. Listing 43-9 shows an excerpt of the entire lookup table creation mechanism.

**Listing 43-9: Creating the Dispatch Lookup Table**

```

/*
  Begin validation dispatching mechanism
*/
function dispatcher(validationFunc) {
    this.doValidate = validationFunc;
}
var dispatchLookup = new Array();
dispatchLookup["isNotEmpty"] = new dispatcher(isNotEmpty);
dispatchLookup["isPositiveInteger"] = new dispatcher(isPositiveInteger);
dispatchLookup["isDollarsOnly8"] = new dispatcher(isDollarsOnly8);
dispatchLookup["isUSState"] = new dispatcher(isUSState);
dispatchLookup["isZip"] = new dispatcher(isZip);
dispatchLookup["isExpandedZip"] = new dispatcher(isExpandedZip);
dispatchLookup["isPhone"] = new dispatcher(isPhone);
dispatchLookup["isConfirmed"] = new dispatcher(isConfirmed);
dispatchLookup["isNY"] = new dispatcher(isNY);
dispatchLookup["isNum16"] = new dispatcher(isNum16);
dispatchLookup["isM90_M20Date"] = new dispatcher(isM90_M20Date);
dispatchLookup["isM70_0Date"] = new dispatcher(isM70_0Date);
dispatchLookup["isM5_P10Date"] = new dispatcher(isM5_P10Date);
dispatchLookup["isDateFormat"] = new dispatcher(isDateFormat);

```

Each entry of the array is assigned a dispatcher object, whose custom object constructor assigns a function reference to the object's `doValidate()` method. For these assignment statements to work, their corresponding functions must be defined earlier in the document. You can see some of these functions later in this section.

The link between the form elements and the dispatch lookup table is the `validate()` function, shown in Listing 43-10. A call to `validate()` requires a minimum of three parameters, as shown in the following example:

```

<input type="text" name="phone" size="10"
onchange="parent.validate(window, this, 'isPhone')" />

```

The first is a reference to the frame containing the document that is calling the function (passed as a reference to the current window). The second parameter is a reference to the form control element itself (using the `this` operator). After that, you see one or more individual validation function names as strings. This last design allows more than one type of validation to take place with each call to `validate()` (for example, in case a field must check for a data type and check that the field is not empty).

**Listing 43-10: Main Validation Function**

```

// main validation function called by form event handlers
function validate(frame, field, method) {
    gFrame = frame;
    gField = window.frames[frame.name].document.forms[0].elements[field.name];
    var args = validate.arguments;

```

*Continued*

**Listing 43-10** (*continued*)

```

for (i = 2; i < args.length; i++) {
    if (!dispatchLookup[args[i]].doValidate()) {
        return false;
    }
}
return true;
}

```

In the `validate()` function, the frame reference is assigned to a global variable that is declared at the top of the `validations.js` file. Validation functions in this library need this information to build a reference back to a companion field required of some validations (explained later in this section). A second global variable contains a reference to the calling form element. Because the form element reference by itself does not contain information about the frame in which it lives, the script must build a reference out of the information passed as parameters. The reference must work from the framesetting document down to the frame, its form, and form element name. Therefore, I use the `frame` and `field` object references to get their respective names (within the `frames` and `elements` arrays) to assemble the text field's object reference; the resulting value is assigned to the `gField` global variable. I choose to use global variables in this case because passing these two values to numerous nested validation functions could be difficult to track reliably. Instead, the only parameter passed to specific validation functions is the value under test.

Next, the script creates an array of all arguments passed to the `validate()` function. A for loop starts with an index value of 2, the third parameter containing the first validation function name. For each one, the named item's `doValidate()` method is called. If the validation fails, this function returns `false`; but if all validations succeed, this function returns `true`. Later you see that this function's returned value is the one that allows or disallows a form submission.

## Sample validations

Above the dispatching mechanism in the `validations.js` are the validation functions themselves. Many of the named validation functions have supporting utility functions that other named validation functions often use. Because of the eventual large size of this library file (the production version was about 40KB), I organized the functions into two groups: the named functions first, and the utility functions below them (but still before the dispatching mechanism at the bottom of the document).

To demonstrate how some of the more common data types are validated for this application, I show several validation functions and, where necessary, their supporting utility functions. Figure 43-1 shows a sample form that takes advantage of these validations. (You have a chance to try it later in this chapter.) When you are dealing with critical corporate data, you must go to extreme lengths to ensure valid data. And to help users see their mistakes quickly, you need to build some intelligence into validations where possible.

### U.S. state name

The design specification for forms that require entry of a U.S. state calls for entry of the state's two-character abbreviation. A companion field to the right displays the entire state name as user feedback verification. The `onchange` event handler not only calls the validation, but it also feeds the focus to the field following the expanded state field so users are less likely to type into it.

The screenshot shows a web browser window titled "GiantCo Contractor Database - Microsoft Internet Explorer". The browser's address bar is empty, and the menu bar includes "File", "Edit", "View", "Favorites", "Tools", and "Help". The toolbar contains standard navigation icons. The main content area displays a form titled "Contractor Information".

The form fields are as follows:

- First Name: CHARLES
- Last Name: ALKAN
- Company: FINGER TWISTERS, INC
- Address 1: 40 AESOP WAY
- Address 2: (empty)
- City: SALTARELLE
- State: LA LOUISIANA
- ZIP: (empty)
- Phone: (empty)
- SSN: (empty)
- Licensed (Y/N/U): (empty)
- No. of Employees: (empty)
- Liability Cov Amt: (empty)
- Coverage Exp. Date: (empty)
- Confirm: (empty)

At the bottom of the form, there are two buttons: "Save" and "Reset". The browser's status bar at the bottom shows "Done" and "My Computer".

**Figure 43-1:** Sample form for industrial-strength validations.

Before the validation can even get to the expansion part, it must first validate that the entry is a valid, two-letter abbreviation. Because I need both the abbreviation and the full state name for this validation, I create an array of all the states using each state abbreviation as the index label for each entry. Listing 43-11 shows that array creation.

#### Listing 43-11: Creating a U.S. States Array

```
// States array
var USStates = new Array(51);
USStates["AL"] = "ALABAMA";
USStates["AK"] = "ALASKA";
USStates["AZ"] = "ARIZONA";
USStates["AR"] = "ARKANSAS";
USStates["CA"] = "CALIFORNIA";
USStates["CO"] = "COLORADO";
USStates["CT"] = "CONNECTICUT";
USStates["DE"] = "DELAWARE";
USStates["DC"] = "DISTRICT OF COLUMBIA";

The existence of this array comes in handy in determining if the user enters a valid, two-state abbreviation. Listing 43-12 shows the actual `isUSState()` validation function that puts this array to work.

The function's first task is to assign an uppercase version of the entered value to a local variable (`inputStr`), which is the value being analyzed throughout the rest of the function. If the user enters something in the field (`length > 0`) but no entry in the `USStates` array exists for that value, the entry is not a valid state abbreviation. Time to go to work to help out the user.

## Listing 43-12: Validation Function for U.S. States

```

// input value is a U.S. state abbreviation; set entered value to all uppercase
// also set companion field (NAME="<xxx>_expand") to full state name
function isUSState() {
    var inputStr = gField.value.toUpperCase();
    if (inputStr.length > 0 && USStates[inputStr] == null) {
        var msg = "";
        var firstChar = inputStr.charAt(0);
        if (firstChar == "A") {
            msg += "\n(Alabama = AL; Alaska = AK; Arizona = AZ; Arkansas = AR)";
        }
        if (firstChar == "D") {
            msg += "\n(Delaware = DE; District of Columbia = DC)";
        }
        if (firstChar == "I") {
            msg += "\n(Idaho = ID; Illinois = IL; Indiana = IN; Iowa = IA)";
        }
        if (firstChar == "M") {
            msg += "\n(Maine = ME; Maryland = MD; Massachusetts = MA; " +
                "Michigan = MI; Minnesota = MN; Mississippi = MS; " +
                "Missouri = MO; Montana = MT)";
        }
        if (firstChar == "N") {
            msg += "\n(Nebraska = NE; Nevada = NV)";
        }
        alert("Check the spelling of the state abbreviation." + msg);
        gField.focus();
        gField.select();
        return false;
    }
    gField.value = inputStr;
    var expandField =
        window.frames[gFrame.name].document.forms[0].elements[gField.name +
            "_expand"];
    expandField.value = USStates[inputStr];
    return true;
}

```

The function assumes that the user tried to enter a valid state abbreviation but either had incorrect source material or momentarily forgot a particular state's abbreviation. Therefore, the function examines the first letter of the entry. If that first letter is any one of the five identified as causing the most difficulty, a legend for all states beginning with that letter is assigned to the `msg` variable (for running on newer browsers only, a `switch` construction is preferred). An alert message displays the generic alert, plus any special legend if one is assigned to the `msg` variable. When the user closes the alert, the field has focus and its text is selected. (This application runs solely on Navigator, so the IE `setTimeout()` workaround isn't needed — but you can add it very easily, especially thanks to the global variable reference for the field.) The function returns `false` at this point.

If, on the other hand, the abbreviation entry is a valid one, the field is handed the uppercase version of the entry. The script then uses the two global variables set in `validate()` to create a reference to the expanded display field (whose name must be the same as the entry field plus `"_expand"`). That expanded display field is then supplied the `USStates` array entry value corresponding to the abbreviation label. All is well with this validation, so it returns `true`.

You can see here that the so-called validation routine is doing far more than simply checking validity of the data. By communicating with the field, converting its contents to uppercase, and talking to another field in the form, a simple call to the validation function yields a lot of mileage.

## Date validation

Many of the forms in this application have date fields. In fact, dates are an important part of the data maintained in the database behind the forms. All users of this application are familiar with standard date formats in use in the United States, so I don't have to worry about the possibility of cultural variations in date formats. Even so, I want the date entry to accommodate the common date formats, such as `mmddyyyy`, `mm/dd/yyyy`, and `mm-dd-yyyy` (as well as accommodate two-digit year entries spanning 1930 to 2029).

The plan also calls for going further in helping users enter dates within certain ranges. For example, a field used for a birth date (the listings are for medical professionals) should recommend dates starting no more than 90 years, and no less than 20 years, from the current date. And to keep this application running well into the future, the ranges should be on a sliding scale from the current year, no matter when it might be. Whatever the case, the date range validation is only a recommendation and not a transaction stopper.

Rather than create separate validation functions for each date field, I create a system of reusable validation functions for each date range (several fields on different forms require the same date ranges). Each one of these individual functions calls a single, generic date-validation function that handles the date-range checking. Listing 43-13 shows a few examples of these individual range-checking functions.

### Listing 43-13: Date Range Validations

```
// Date Minus 90/Minus 20
function isM90_M20Date() {
    if (gField.value.length == 0)
        return true;
    var thisYear = getTheYear();
    return isDate((thisYear - 90),(thisYear - 20));
}

// Date Minus 70/Minus 0
function isM70_0Date() {
    if (gField.value.length == 0)
        return true;
    var thisYear = getTheYear();
    return isDate((thisYear - 70),(thisYear));
}

// Date Minus 5/Plus 10
```

```
function isM5_P10Date() {
    if (gField.value.length == 0)
        return true;
    var thisYear = getTheYear();
    return isDate((thisYear - 5),(thisYear + 10));
}
```

The naming convention I create for the functions includes the two range components relative to the current date. A letter “M” means the range boundary is minus a number of years from the current date; “P” means the range is plus a number of years. If the boundary should be the current year, a zero is used. Therefore, the `isM5_P10Date()` function performs range checking for boundaries between 5 years before and 10 years after the current year.

Before performing any range checking, each function makes sure there is some value to validate. If the field entry is empty, the function returns `true`. This is fine here because dates are not required when the data is unknown.

Next, the functions get the current four-digit year. The code here had to work originally with browsers that did not have the `getFullYear()` method available yet. Therefore, the Y2K fix described in Chapter 29 was built into the application:

```
function getTheYear() {
    var thisYear = (new Date()).getFullYear();
    thisYear = (thisYear < 100) ? thisYear + 1900 : thisYear;
    return thisYear;
}
```

The final call from the range validations is to a common `isDate()` function, which handles not only the date range validation but also the validation for valid dates (for example, making sure that September has only 30 days). Listing 43-14 shows this monster-sized function. Because of the length of this function, I interlace commentary within the code listing.

#### Listing 43-14: Primary Date Validation Function

```
// date field validation (called by other validation functions that specify
// minYear/maxYear)
function isDate(minYear,maxYear,minDays,maxDays) {
    var inputStr = gField.value;
```

To make it easier to work with dates supplied with delimiters, I first convert hyphen delimiters to slash delimiters. The pre-regular expression `replaceString()` function is the same one described in Chapter 27; it is located in the utility functions part of the `validations.js` file.

```
    // convert hyphen delimiters to slashes
    while (inputStr.indexOf("-") != -1) {
        inputStr = replaceString(inputStr,"-","/");
    }
```

For validating whether the gross format is OK, I check whether zero or two delimiters appear. If the value contains only one delimiter, the overall formatting is not acceptable. The error alert shows models for acceptable date-entry formats.

```

    var delim1 = inputStr.indexOf("/");
    var delim2 = inputStr.lastIndexOf("/");
    if (delim1 != -1 && delim1 == delim2) {
        // there is only one delimiter in the string
        alert("The date entry is not in an acceptable format.\n\nYou can enter
dates in the following formats: mmddyyyy, mm/dd/yyyy, or mm-dd-yyyy. (If the
month or date data is not available, enter \'01\' in the appropriate
location.)");
        gField.focus();
        gField.select();
        return false;
    }

```

If there are two delimiters, I tear apart the string into components for month, day, and year. Because two-digit entries can begin with zeros, I make sure the `parseInt()` functions specify base-10 conversions.

```

    if (delim1 != -1) {
        // there are delimiters; extract component values
        var mm = parseInt(inputStr.substring(0,delim1),10);
        var dd = parseInt(inputStr.substring(delim1 + 1,delim2),10);
        var yyyy = parseInt(inputStr.substring(delim2 + 1, inputStr.length),10);

```

For no delimiters, I tear apart the string and assume two-digit entries for the month and day and two or four digits for the year.

```

    } else {
        // there are no delimiters; extract component values
        var mm = parseInt(inputStr.substring(0,2),10);
        var dd = parseInt(inputStr.substring(2,4),10);
        var yyyy = parseInt(inputStr.substring(4,inputStr.length),10);
    }

```

The `parseInt()` functions reveal whether any entry is not a number by returning `NaN`, so I check whether any of the three values is not a number. If so, an alert signals the formatting problem and supplies acceptable models.

```

    if (isNaN(mm) || isNaN(dd) || isNaN(yyyy)) {
        // there is a non-numeric character in one of the component values
        alert("The date entry is not in an acceptable format.\n\nYou can enter
dates in the following formats: mmddyyyy, mm/dd/yyyy, or
mm-dd-yyyy.");
        gField.focus();
        gField.select();
        return false;
    }

```

Next, I perform some gross range validation on the month and date to make sure that months are entered from 1 to 12 and dates from 1 to 31. I take care of aligning exact month lengths later.

```

    if (mm < 1 || mm > 12) {
        // month value is not 1 thru 12
        alert("Months must be entered between the range of 01 (January) and 12
(December).");
        gField.focus();
        gField.select();
        return false;
    }

```

```

if (dd < 1 || dd > 31) {
    // date value is not 1 thru 31
    alert("Days must be entered between the range of 01 and a maximum of 31
        (depending on the month and year).");
    gField.focus();
    gField.select();
    return false;
}

```

Before getting too deep into the year validation, I convert any two-digit year within the specified range to its four-digit equivalent.

```

// validate year, allowing for checks between year ranges
// passed as parameters from other validation functions
if (yyyy < 100) {
    // entered value is two digits, which we allow for 1930-2029
    if (yyyy >= 30) {
        yyyy += 1900;
    } else {
        yyyy += 2000;
    }
}

var today = new Date();

```

I designed this function to work with a pair of year ranges or date ranges (so many days before and/or after today). If the function is passed date ranges, the first two parameters must be passed as null. This first batch of code works with the date ranges (because the minYear parameter is null).

```

if (!minYear) {
    // function called with specific day range parameters
    var dateStr = new String(monthDayFormat(mm) + "/" + monthDayFormat(dd) +
        "/" + yyyy);
    var testDate = new Date(dateStr);
    if (testDate.getTime() < (today.getTime() + (minDays * 24 * 60 * 60 *
        1000))) {
        alert("The most likely range for this entry begins " + minDays +
            " days from today.");
    }
    if (testDate.getTime() > today.getTime() + (maxDays * 24 * 60 * 60 *
        1000)) {
        alert("The most likely range for this entry ends " + maxDays +
            " days from today.");
    }
}

```

You can also pass hard-wired, four-digit years as parameters. The following branch compares the entered year against the range specified by those passed year values.

```

} else if (minYear && maxYear) {
    // function called with specific year range parameters
    if (yyyy < minYear || yyyy > maxYear) {
        // entered year is outside of range passed from calling function
        alert("The most likely range for this entry is between the years " +
            minYear + " and " + maxYear + ". If your source data indicates a
            date outside this range, then enter that date.");
    }
} else {

```

For year parameters passed as positive or negative year differences, I begin processing by getting the four-digit year for today's date. Then I compare the entered year against the passed range values. If the entry is outside the desired range, an alert reveals the preferred year range within which the entry should fall. But the function does not return any value here because an out-of-range value is not critical for this application.

```

    // default year range (now set to (this year - 100) and (this year + 25))
    var thisYear = today.getYear();
    if (thisYear < 100) {
        thisYear += 1900;
    }
    if (yyyy < minYear || yyyy > maxYear) {
        alert("It is unusual for a date entry to be before " + minYear + " or
            after " + maxYear + ". Please verify this entry.");
    }
}

```

One more important validation is to make sure that the entered date is valid for the month and year. Therefore, the various date components are passed to functions to check against month lengths, including the special calculations for the varying length of February. Listing 43-15 shows these functions. The alert messages they display are smart enough to inform the user what the maximum date is for the entered month and year.

```

if (!checkMonthLength(mm,dd)) {
    gField.focus();
    gField.select();
    return false;
}
if (mm == 2) {
    if (!checkLeapMonth(mm,dd,yyyy)) {
        gField.focus();
        gField.select();
        return false;
    }
}

```

The final task is to reassemble the date components into a format that the database wants for its date storage and stuff it into the form field. If the user enters an all-number or hyphen-delimited date, it is automatically reformatted and displayed as a slash-delimited, four-digit-year date.

```

// put the Informix-friendly format back into the field
gField.value = monthDayFormat(mm) + "/" + monthDayFormat(dd) + "/" + yyyy;
return true;
}

```

A utility function invoked multiple times in the previous function converts a single-digit month or day number to a string that might have a leading zero:

```

// convert month or day number to string,
// padding with leading zero if needed
function monthDayFormat(val) {
    if (isNaN(val) || val == 0) {
        return "01";
    } else if (val < 10) {
        return "0" + val;
    }
    return "" + val;
}

```

**Listing 43-15: Functions to Check Month Lengths**

```

// check the entered month for too high a value
function checkMonthLength(mm,dd) {
  var months = new Array("", "January", "February", "March", "April", "May",
    "June", "July", "August", "September", "October", "November", "December");
  if ((mm == 4 || mm == 6 || mm == 9 || mm == 11) && dd > 30) {
    alert(months[mm] + " has only 30 days.");
    return false;
  } else if (dd > 31) {
    alert(months[mm] + " has only 31 days.");
    return false;
  }
  return true;
}

// check the entered February date for too high a value
function checkLeapMonth(mm,dd,yyyy) {
  if (yyyy % 4 > 0 && dd > 28) {
    alert("February of " + yyyy + " has only 28 days.");
    return false;
  } else if (dd > 29) {
    alert("February of " + yyyy + " has only 29 days.");
    return false;
  }
  return true;
}

```

This is a rather extensive date-validation routine, but it demonstrates how thorough you must be when a database relies on accurate entries. The more prompting and assistance you can give to users to ferret out problems with invalid entries, the happier those users will be.

**Cross-confirmation fields**

The final validation type that I cover here is probably not a common request, but it demonstrates how the dispatch mechanism created at the outset expands so easily to accommodate this enhanced client request. The situation is that some fields (mostly dates in this application) are deemed critical pieces of data because this data triggers other processes from the database. As a further check to ensure entry of accurate data, a number of values are set up for entry twice in separate fields — and the fields have to match exactly. In many ways, this mirrors the two passes you are often requested to make when you set a password: enter two copies and let the computer compare them to make sure you typed what you intended to type.

I established a system that places only one burden on the many programmers working on the forms: although you can name the primary field anything you want (to help alignment with database column names, for example), you must name the secondary field the same plus `“_xcm”` — which stands for *cross-confirm*. Then, pass the `isConfirmed` validation name to the `validate()` function after the date range validation name, as follows:

```
onchange="parent.validate(window, this, 'isM5_P10Date', 'isConfirmed')"
```

In other words, after the entered value is initially checked against a required date range, the `isConfirmed()` validation function compares the fully vetted, properly formatted date in the current field against its parallel entry.

Listing 43-16 shows the one function in `validations.js` that handles the confirmation in both directions. After assigning a copy of the entry field value to the `inputStr` variable, the function next sets a Boolean flag (`primary`) that lets the rest of the script know if the entry field is the primary or secondary field. If the string `"_xcfm"` is missing from the field name, the entry field is the primary field.

For the primary field branch, the script assembles the name of the secondary field and compares the content of the secondary field's value against the `inputStr` value. If they are not the same, the user is entering a new value into the primary field, and the script empties the secondary field to force reentry to verify that the user enters the proper data.

For the secondary field entry branch, the script assembles a reference to the primary field by stripping away the final five characters of the secondary field's name. I can use the `lastIndexOf()` string method instead of the longer way involving the string's length; but after experiencing so many platform-specific problems with `lastIndexOf()` in Navigator, I decided to play it safe. Finally, the two values are compared, with an appropriate alert displayed if they don't match.

#### Listing 43-16: Cross-Confirmation Validation

```
// checks an entry against a parallel, duplicate entry to
// confirm that correct data has been entered
// Parallel field name must be the main field name plus "_xcfm"
function isConfirmed() {
    var inputStr = gField.value;
    // flag for whether field under test is primary (true) or confirmation field
    var primary = (gField.name.indexOf("_xcfm") == -1);
    if (primary) {
        // clear the confirmation field if primary field is changed
        var xcfmField =
window.frames[gFrame.name].document.forms[0].elements[gField.name + "_ xcfm"];
        var xcfmValue = xcfmField.value;
        if (inputStr != xcfmValue) {
            xcfmField.value = "";
            return true;
        }
    } else {
        var xcfmField =
window.frames[gFrame.name].document.forms[0].elements[gField.name.substring(0,(g
Field.name.length-5))];
        var xcfmValue = xcfmField.value;
        if (inputStr != xcfmValue) {
            alert("The main and confirmation entry field contents do not match.
            Both fields must have EXACTLY the same content to be accepted by
            the database.");
            gField.focus();
            gField.select();
            return false;
        }
    }
    return true;
}
```

## Last-minute check

Every validation event handler is designed to return `true` if the validation succeeds. This comes in handy for the batch validation that performs one final check of the entries triggered by the form's `onsubmit` event handler. This event handler calls a `checkForm()` function and passes the form control object as a parameter. That parameter helps create a reference to the form element that is passed to each validation function.

Because successful validations return `true`, you can nest consecutive validation tests so that the most nested statement of the construction is `return true` because all validations have succeeded. The form's `onsubmit` event handler is as follows:

```
onsubmit="return checkForm(this)"
```

And the following code fragment is an example of a `checkForm()` function. A separate `isDateFormat()` validation function called here checks whether the field contains an entry in the proper format — meaning that it has likely survived the range checking and format shifting of the real-time validation check.

```
function checkForm(form) {
    if (parent.validate(window, form.birthdate, "isDateFormat")) {
        if (parent.validate(window, form.phone, "isPhone")) {
            if (parent.validate(window, form.name, "isNotEmpty")) {
                return true;
            }
        }
    }
    return false;
}
```

If any one validation fails, the field is given focus and its content is selected (controlled by the individual validation function). In addition, the `checkForm()` function returns `false`. This, in turn, cancels the form submission.

## Try it out

Listing 43-17 is a definition for a frameset that not only loads the validation routines described in this section, but also loads a page with a form that exercises the validations in real-time and batch mode just prior to submission. The form appears earlier in this chapter in Figure 43-1.

### Listing 43-17: Frameset for Trying validation.js

```
<html>
  <head>
    <title>GiantCo Contractor Database</title>
    <script type="text/javascript" src="validation.js">
    </script>
    <script type="text/javascript">
      function blank() {
        return "<html><body bgcolor='lightsteelblue'>&#92;/body>&#92;/html>";
      }
    </script>
  </head>
</html>
```

*Continued*

## Listing 43-17 (continued)

```
    </script>
</head>
<frameset frameborder="" cols="20%,80%">
  <frame name="toc" src="javascript:parent.blank()" />
  <frame name="entries" src="lst43-18.htm" />
</frameset>
</html>
```

---

The application scenario for the form is the entry of data into a company's contractor database. Some fields are required, and the date field must be cross-confirmed with a second entry of the same data. If the form passes its final validation prior to submission, the form reloads and you see a readout of the form data that would have been submitted from the previous form had the `action` been set to a server CGI program URI.

## Plan for Data Validation

I devoted this entire chapter to the subject of data validation because it represents the one area of error checking that almost all JavaScript authors should be concerned with. If your scripts (client-side or server-side) perform processing on user entries, you want to prevent script errors at all costs.

# Scripting Java Applets and Plug-Ins

---

**N**etscape was the first to implement the facility enabling JavaScript scripts, Java applets, and plug-ins to communicate with each other under one technology umbrella, called LiveConnect (first implemented in NN3). Microsoft met the challenge and implemented a large part of that technology for WinIE4, but of course without using the Netscape-trademarked name for the technology. The name is a convenient way to refer to the capability, so you find it used throughout this chapter applying to any browser that supports such facilities. This chapter focuses on the scripting side of LiveConnect: approaching applets and plug-ins from scripts and accessing scripts from Java applets.

Except for the part about talking to scripts from inside a Java applet, I don't assume you have any knowledge of Java programming. The primary goal here is to help you understand how to control applets and plug-ins (including ActiveX controls in WinIE) from your scripts. If you're in a position to develop specifications for applets, you also learn what to ask of your Java programmers. But if you are also a Java applet programmer, you learn the necessary skills to get your applets in touch with HTML pages and scripts.

## LiveConnect Overview

Before you delve too deeply into the subject, you should be aware that LiveConnect features are not available in all modern browsers, much to the chagrin of many. The following browsers do not support this technology:

- ◆ MacIE
- ◆ NN4.6 (due to an oversight when the version was released)
- ◆ NN6.0 (although it is supported in NN7+)
- ◆ Safari 1.0

Such a broad swath of browsers not supporting the feature makes it difficult to design a public Web application that relies on LiveConnect features. Design your pages accordingly.

### In This Chapter

Communicating with Java applets from scripts

Accessing scripts and objects from Java applets

Controlling scriptable plug-ins

The internal mechanisms that allow scripts to communicate with applets and plug-ins are quite different for NN and IE. NN3 and NN4 relied exclusively on the Java virtual machine (JVM) that shipped with most OS platform versions of the browsers. In NN4+, the JVM doesn't load until it is needed, sometimes causing a brief delay in initial execution. For the most part, though, the underlying Java engine is invisible to the scripter (you) and certainly to the visitors of your sites. At most, visitors see status bar messages about applets loading and running.

WinIE, on the other hand, has its own internal architecture for communicating between processes. To Windows, most processes are treated as components that have properties and methods accessible to other components.

Whether you use the technology to communicate with a Java applet or an ActiveX control, the advantage to you as an author is that LiveConnect extends the document object model to include objects and data types that are not a part of the HTML world. HTML, for instance, does not have a form control element that displays real-time stock ticker data; nor does HTML have the capability to treat a sound file like anything more than a URL to be handed off to a helper application. With LiveConnect, however, your scripts can treat the applet that displays the stock ticker as an object whose properties and methods can be modified after the applet loads; scripts can also tell the sound when to play or pause by controlling the plug-in that manages the incoming sound file.

## Why Control Java Applets?

A question I often hear from experienced Java programmers is, “Why bother controlling an applet via a script when you can build all the interactivity you want into the applet itself?” This question is valid if you come from the Java world, but it takes a viewpoint from the HTML and scripting world to fully answer it.

Java applets exist in their own private rectangles, remaining largely oblivious to the HTML surroundings on the page. Applet designers who don't have extensive Web page experience tend to regard their applets as the center of the universe rather than as components of HTML pages.

As a scripter, on the other hand, you may want to use those applets as powerful components to spiff up the overall presentation. Using applets as prewritten objects enables you to make simple changes to the HTML pages — including the geographic layout of elements and images — at the last minute, without having to rewrite and recompile Java program code. If you want to update the look with an entirely new graphical navigation or control bar, you can do it directly via HTML and scripting.

When it comes to designing or selecting applets for inclusion into my scripted page, I prefer using applet interfaces that confine themselves to data display, putting any control of the data into the hands of the script, rather than using onscreen buttons in the applet rectangle. I believe this setup enables much greater last-minute flexibility in the page design — not to mention consistency with HTML form element interfaces — than putting everything inside the applet rectangle.

## A Little Java

If you plan to look at a Java applet's scripted capabilities, you can't escape having to know a little about Java applets and some terminology. The discussion goes more deeply into object orientation than you have seen with JavaScript, but I'll try to be gentle.

### Java building blocks classes

One part of Java that closely resembles JavaScript is that Java programming deals with objects, much the way JavaScript deals with a page's objects. Java objects, however, are not the familiar HTML objects but rather more basic building blocks, such as tools that draw to the screen and data streams. But both languages also have some non-HTML kinds of objects in common: strings, arrays, numbers, and so on.

Every Java object is known as a *class*—a term from the object-orientation world. When you use a Java compiler to generate an applet, that applet is also a class, which happens to incorporate many Java classes, such as strings, image areas, font objects, and the like. The applet file you see on the disk is called a class file and its file extension is `.class`. This file is the one you specify for the `code` attribute of an `<applet>` tag, or the newer `<object>` tag (the `<applet>` tag is deprecated in HTML 4.0).

### Java methods

Most JavaScript objects have methods attached to them that define what actions the objects are capable of performing. A string object, for instance, has the `toUpperCase()` method that converts the string to all uppercase letters. Java classes also have methods. Many methods are predefined in the base Java classes embedded inside the virtual machine. But inside a Java applet, the author can write methods that either override the base method or deal exclusively with a new class created in the program. These methods are, in a way, like the functions you write in JavaScript for a page.

Not all methods, however, are created the same. Java lets authors determine how visible a method is to outsiders. The types of methods that you, as a scripter, are interested in are the ones declared as public methods. You can access such methods from JavaScript via a syntax that falls very much in line with what you already know. For example, a common public method in applets stops an applet's main process. Such a Java method may look like this:

```
public void stop() {
    if(thread != null) {
        thread = null;
    }
}
```

The `void` keyword simply means that this method does not return any values (compilers need to know this stuff). Assuming that you have one applet loaded in your page, the JavaScript call to this applet method is

```
document.applets[0].stop();
```

Listing 44-1a shows how all this works with the `<applet>` tag for a scriptable digital clock applet example. The script includes calls to two of the applet's methods: to stop and to start the clock.

### Listing 44-1a: Stopping and Starting an Applet

```
<html>
  <head>
    <title>A Script That Could Stop a Clock</title>
    <script type="text/javascript">
      function pauseClock() {
        document.clock1.stop();
      }
      function restartClock() {
        document.clock1.start();
      }
    </script>
  </head>
  <body>
    <h1>Simple control over an applet</h1>
    <hr />
    <applet code="ScriptableClock.class" name="clock1" width="500"
      height="45">
      <param name="bgColor" value="Green" />
      <param name="fgColor" value="Blue" />
    </applet>
    <form name="widgets1">
      <input type="button" value="Pause Clock" onclick="pauseClock()" />
      <input type="button" value="Restart Clock" onclick="restartClock()" />
    </form>
  </body>
</html>
```

The syntax for accessing the method (in the two functions) is just like JavaScript in that the references to the applet's methods include the applet object (`clock1` in the example), which is contained by the document object.

## XHTML-friendly applets

Because the XHTML standard does not recognize the `<applet>` tag, you need to work a little markup magic to use modern `<object>` tags that operate in both IE and Mozilla-based browsers. The difficulty arises in the way the two browsers specify some attribute or parameter values for Java applets. To demonstrate how you can embed an applet into a document exclusively with the `<object>` tag and work simultaneously in IE and Mozilla-based browsers, Listing 44-1b shows a modified version of Listing 44-1a.

An important feature of the listing is a Microsoft proprietary markup feature called *conditional comments* ([msdn.microsoft.com/workshop/author/dhtml/overview/ccomment\\_ovw.asp](http://msdn.microsoft.com/workshop/author/dhtml/overview/ccomment_ovw.asp)). These HTML comment tags, with their special comment text, allow IE to skip over HTML markup. In Listing 44-1b, only the first `<object>` tag is rendered in WinIE; Mozilla, on

the other hand, loads both, but does not load the applet in the first tag because the attribute and parameter values are not in the format that Mozilla requires for loading a Java applet. In addition to the tag markup differences, note that the functions controlling the applet create references to the applet object differently. Mozilla has two `object` elements with the same name deal with, meaning that there is an array of objects with that name; thus the script pulls a reference to the second one when two are detected.

### Listing 44-1b: Stopping and Starting an Applet (XHTML)

```

<html>
  <head>
    <title>A Script That Could Stop a Clock</title>
    <script type="text/javascript">
      function pauseClock() {
        // get ref to second object for non-WinIE
        var applet = (document.clock1.length) ? document.clock1[1] :
document.clock1;
        applet.stop();
      }
      function restartClock() {
        var applet = (document.clock1.length) ? document.clock1[1] :
document.clock1;
        applet.start();
      }
    </script>
  </head>
  <body>
    <h1>Simple control over an applet</h1>
    <hr />
    <object name="clock1" classid="clsid:8AD9C840-044E-11D1-B3E9-00805F499D93"
      width="500" height="45">
      <param name="code" value="ScriptableClock.class" />
      <param name="codebase" value="." />
      <param name="bgColor" value="Green" />
      <param name="fgColor" value="Blue" />
      <!--[if !IE] Non-WinIE Browsers -->
      <object name="clock1" classid="java:ScriptableClock.class"
codebase="."
      width="500" height="45">
      <param name="bgColor" value="Green" />
      <param name="fgColor" value="Blue" />
      </object>
      <!-- <![endif]-->
    </object>

    <form name="widgets1">
      <input type="button" value="Pause Clock" onclick="pauseClock()" />
      <input type="button" value="Restart Clock" onclick="restartClock()" />
    </form>
  </body>
</html>

```

## Java applet “properties”

The Java equivalents of JavaScript object properties are called public instance variables. These variables are akin to JavaScript global variables. If you have access to some Java source code, you can recognize a public instance variable by its `public` keyword:

```
public String fontName;
```

Java authors must specify a variable’s data type when declaring any variable. That’s why the `String` data type appears in the preceding example.

Your scripts can access these variables with the same kind of syntax that you use to access JavaScript object properties. If the `fontName` variable in `ScriptableClock.class` had been defined as a public variable (it is not), you could access or set its value directly, as shown in the following example:

```
var theFont = document.applets[0].fontName;  
document.applets[0].fontName = "Courier";
```

## Accessing Java fields

In a bit of confusing lingo, public variables and methods are often referred to as *fields*. These elements are not the kind of text entry fields that you see on the screen; rather, they’re like slots (another term used in Java) where you can slip in your requests and data. Remember these terms, because they may appear from time to time in error messages as you begin scripting applets.

## Scripting Applets in Real Life

Because the purpose of scripting an applet is to gain access to the inner sanctum of a compiled program, the program should be designed to handle such rummaging around by scripters. If you can’t acquire a copy of the source code or don’t have any other documentation about the scriptable parts of the applet, you may have a difficult time knowing what to script and how to do it.

## Getting to scriptable methods

If you write your own applets or are fortunate enough to have the source code for an existing applet, the safest way to modify the applet variable settings or the running processes is through applet methods. Although setting a public variable value may enable you to make a desired change, you don’t know how that change may impact other parts of the applet. An applet designed for scriptability should have a number of methods defined that enable you to make scripted changes to variable values.

To view a sample of an applet designed for scriptability, open the Java source code file for Listing 44-2 from the CD-ROM. A portion of that program listing is shown in the following example.

**Listing 44-2: Partial Listing for ScriptableClock.java /\***

```

        Begin public methods for getting
        and setting data via LiveConnect
    */
    public void setTimeZone(String zone) {
        stop();
        timeZone = (zone.startsWith("GMT")) ? true : false;
        start();
    }

    public void setFont(String newFont, String newStyle, String newSize) {
        stop();
        if (newFont != null && newFont != "")
            fontName = newFont;
        if (newStyle != null && newStyle != "")
            setFontStyle(newStyle);
        if (newSize != null && newSize != "")
            setFontSize(newSize);
        displayFont = new Font(fontName, fontStyle, fontSize);
        start();
    }

    public void setColor(String newbgColor, String newfgColor) {
        stop();
        bgColor = parseColor(newbgColor);
        fgColor = parseColor(newfgColor);
        start();
    }

    public String getInfo() {
        String result = "Info about ScriptableClock.class\r\n";
        result += "Version/Date: 1.0d1/2 May 1996\r\n";
        result += "Author: Danny Goodman (dannyg@dannyg.com)\r\n";
        result += "Public Variables:\r\n";
        result += "    (None)\r\n\r\n";
        result += "Public Methods:\r\n";
        result += "    setTimeZone(\"GMT\" | \"Locale\")\r\n";
        result += "    setFont(\"fontName\", \"Plain\" | \"Bold\" | \"Italic\",
        \"fontSize\")\r\n";
        result += "    setColor(\"bgColorName\", \"fgColorName\")\r\n";
        result += "        colors: Black, White, Red, Green, Blue, Yellow\r\n";
        return result;
    }
    /*
    End public methods for scripted access.
    */

```

---

The methods shown in Listing 44-2 are defined specifically for scripted access. In this case, they safely stop the applet thread before changing any values. The last method is one I recommend to applet authors. The method returns a small bit of documentation containing information about the kind of methods that the applet likes to have scripted and what you can have as the passed parameter values.

Now that you see the amount of scriptable information in this applet, look at Listing 44-3, which takes advantage of that scriptability by providing several HTML form elements as user controls for the clock. The results are shown in Figure 44-1.

### Listing 44-3: A More Fully Scripted Clock

```
<html>
  <head>
    <title>Clock with Lots o' Widgets</title>
    <script type="text/javascript">
      function setTimeZone(popup) {
        var choice = popup.options[popup.selectedIndex].value;
        document.clock2.setTimeZone(choice);
      }

      function setColor(form) {
        var bg = form.backgroundColor.options[
          form.backgroundColor.selectedIndex].value;
        var fg = form.foregroundColor.options[
          form.foregroundColor.selectedIndex].value;
        document.clock2.setColor(bg, fg);
      }

      function setFont(form) {
        var fontName = form.theFont.options[form.theFont.selectedIndex].value;
        var fontStyle = form.theStyle.options[
          form.theStyle.selectedIndex].value;
        var fontSize = form.theSize.options[form.theSize.selectedIndex].value;
        document.clock2.setFont(fontName, fontStyle, fontSize);
      }
      function getAppletInfo(form) {
        form.details.value = document.clock2.getInfo();
      }

      function showSource() {
        var newWindow = window.open("ScriptableClock.java","",
          "width=450,height=300,resizable,scrollbars");
      }
    </script>
  </head>
  <body>
    <applet code="ScriptableClock.class" name="clock2" width="500"
      height="45">
      <param name="bgColor" value="Black" />
      <param name="fgColor" value="Red" />
    </applet>
    <form name="widgets2">
```

```

<p><textarea name="details" rows="11" cols="70">
  </textarea></p>
</form>
<hr />
</body>
</html>

```

**Figure 44-1:** Scripting more of the ScriptableClock applet.

Very little of the code here controls the applet—only the handful of functions near the top. The rest of the code makes up the HTML user interface for the form element controls. After you open this document from the CD-ROM, be sure to click the Applet Info button to see the methods that you can script and the way that the parameter values from the JavaScript side match up with the parameters on the Java method side.

## Applet limitations

Because of concerns about security breaches via LiveConnect, Netscape clamps down on some powers that would be nice to have via a scripted applet. The most noticeable barrier is the one that prevents applets from accessing the network under scripted control. Therefore, even though a Java applet has no difficulty reading or writing text files from the server, such capabilities—even if built into an applet of your own design—won't be carried out if triggered by a JavaScript call to the applet.

Some clever hacks used to be posted on the Web, but they were rather cumbersome to implement and may no longer work on more modern browsers. You can also program the Java applet to fetch a text file after it starts up and then script the access of that value from JavaScript (as described in the following section). Signed scripts (see Chapter 46) and applets can break through these security barriers after the user has given explicit permission to do so.

## Faceless applets

Until LiveConnect came along, Java applets were generally written to show off data and graphics — to play a big role in the presentation on the page. But if you prefer to let an applet do the heavy algorithmic lifting for your pages while the HTML form elements and images (or Dynamic HTML facilities of newer browsers) do the user interface, you essentially need what I call a *faceless applet*.

The method for embedding a faceless applet into your page is the same as embedding any applet: Use the `<applet>` and/or `<object>` tag; the `<object>` tag is the recommended approach for modern browsers, but the `<applet>` tag is better supported in early Java-powered browsers. For a faceless applet, specify only 1 pixel for both the `height` and `width` attributes (0 has strange side effects). This setting creates a dot on the screen, which, depending on your page's background color, may be completely invisible to page visitors. Place it at the bottom of the page, if you like.

To show how nicely this method can work, Listing 44-4 provides the Java source code for a simple applet that retrieves a specific text file and stores the results in a Java variable available for fetching by the JavaScript shown in Listing 44-5. The HTML even automates the loading process by triggering the retrieval of the Java applet's data from an `onload` event handler.

### Listing 44-4: Java Applet Source Code

```
import java.net.*;
import java.io.*;

public class FileReader extends java.applet.Applet implements Runnable {

    Thread thread;
    URL url;
    String output;
    String fileName = "Bill of rights.txt";

    public void getFile(String fileName) throws IOException {
        String result, line;
        InputStream connection;
        DataInputStream dataStream;
        StringBuffer buffer = new StringBuffer();

        try {
            url = new URL(getDocumentBase(), fileName);
        }
        catch (MalformedURLException e) {
            output = "AppletError " + e;
        }

        try {
            connection = url.openStream();
            dataStream = new DataInputStream(new BufferedInputStream(connection));
```

*Continued*

## Listing 44-4 (continued)

```

        while ((line = dataStream.readLine()) != null) {
            buffer.append(line + "\n");
        }
        result = buffer.toString();
    }
    catch (IOException e) {
        result = "AppletError: " + e;
    }
    output = result;
}
public String fetchText() {
    return output;
}

public void init() {
}

public void start() {
    if (thread == null) {
        thread = new Thread(this);
        thread.start();
    }
}
public void stop() {
    if (thread != null) {
        thread = null;
    }
}

public void run(){
    try {
        getFile(fileName);
    }
    catch (IOException e) {
        output = "AppletError: " + e;
    }
}
}

```

All the work of actually retrieving the file is performed in the `getFile()` method (which runs immediately after the applet loads). Notice that the name of the file to be retrieved, `Bill of Rights.txt`, is stored as a variable near the top of the code, making it easy to change for a recompilation, if necessary. You can also modify the applet to accept the filename as an applet parameter, specified in the HTML code. Meanwhile, the only hook that JavaScript needs is the one public method called `fetchText()`, which merely returns the value of the output variable, which in turn holds the file's contents.

This Java source code must be compiled into a Java class file (already compiled and included on the CD-ROM as `FileReader.class`) and placed in the same directory as the HTML file that loads this applet. Also, no explicit pathname for the text file is supplied in the source code, so the text file is assumed to be in the same directory as the applet.

## Listing 44-5: HTML Asking Applet to Read Text File

```

<html>
  <head>
    <title>Letting an Applet Do The Work</title>
    <script type="text/javascript">
      function getFile(form) {
        var output = document.readerApplet.fetchText();
        form.fileOutput.value = output;
      }
      function autoFetch() {
        var output = document.readerApplet.fetchText();
        if (output != null) {
          document.forms[0].fileOutput.value = output;
          return;
        }
        var t = setTimeout("autoFetch()",1000);
      }
    </script>
  </head>
  <body onload="autoFetch()">
    <h1>Text from a text file...</h1>
    <form name="reader">
      <input type="button" value="Get File" onclick="getFile(this.form)" />
      <p><textarea name="fileOutput" rows="10" cols="60" wrap="hard">
        </textarea></p>
      <p><input type="Reset" value="Clear" /></p>
    </form>
    <applet code="FileReader.class" name="readerApplet" width="1" height="1">
    </applet>
  </body>
</html>

```

Because an applet is usually the last detail to finish loading in a document, you can't use an applet to generate the page immediately. At best, an HTML document can display a pleasant welcome screen while the applet finishes loading itself and running whatever it does to prepare data for the page's form elements. In IE4+ and NN6+/MoZ, the page can then be dynamically constructed out of the retrieved data; for NN4, you can create a new layer object, and use `document.write()` to install content into that layer. Notice in Listing 44-5 that the `onload` event handler calls a function that checks whether the applet has supplied the requested data. If not, the same function is called repeatedly in a timer loop until the data is ready and the `textarea` can be set. The `<applet>` tag is located at the bottom of the Body, set to 1 pixel square—invisible to the user. No user interface exists for this applet, so you have no need to clutter up the page with any placeholder or bumper sticker.

Figure 44-2 shows the page generated by the HTML and applet working together. The Get File button is merely a manual demonstration of calling the same applet method that the `onload` event handler calls.

A faceless applet may be one way for Web authors to hide what may otherwise be JavaScript code that is open to any visitor's view. For example, if you want to deliver a small data collection lookup with a document, but don't want the array of data to be visible in the JavaScript code, you can create the array and lookup functionality inside a faceless applet. Then use

form controls and JavaScript to act as query entry and output display devices (or dynamically generate a table in IE4+ and W3C DOM browsers). Because the parameter values passed between JavaScript and Java applets must be string, numeric, or Boolean values, you won't be able to pass arrays without performing some amount of conversion either within the applet or the JavaScript code (JavaScript's `string.split()` and `array.join()` methods help a great deal here).

## Data type conversions

The example in this chapter does not pass any parameters to the applet's methods, but you are free to do so. You need to pay attention to the way in which values are converted to Java data types. JavaScript strings and Boolean values are converted to Java String and Boolean objects. All JavaScript numbers, regardless of their subtype (that is, integer or floating-point number), are converted to `Float` objects. Therefore, if a method must accept a numeric parameter from a script, the parameter variable in the Java method must be defined as a `Float` type.

The distinction between JavaScript string values and string objects can impact data being passed to an applet. If an applet method requires a string object as a parameter, you may have to explicitly convert a JavaScript string value (for example, a string from a text field) to a string object via the `new String()` constructor (see Chapter 27).

You can also pass references to objects, such as form control elements. Such objects get wrapped with a `JSObject` type (see discussion about this class later in the chapter). Therefore, parameter variables must be established as type `JSObject` (and the `netscape.javascript.JSObject` class must be imported into the applet).

**Figure 44-2:** The page with text retrieved from a server file.

## Applet-to-Script Communication

The flip side of scripted applet control is having an applet control script and HTML content in the page. Before you undertake this avenue in page design, you must bear in mind that any calls made from the applet to the page are hard-wired for the specific scripts and HTML elements in the page. If this level of tight integration and dependence suits the application, the link up will be successful.

**Note**

The discussion of applet-to-script communication assumes you have experience writing Java applets. I use Java jargon quite freely in this discussion.

### What your applet needs

NN3 and later (including Mozilla) come with a zipped set of special class files tailored for use in LiveConnect. In NN3, the file is named `java_30` or `java_301`, the latter one being the latest version; in NN4, the file is named `java40.jar`. For NN6+/Moz, the class files are located in an archive called `jaws.jar` (Windows) or `MRJPlugin.jar` (Mac). Use the file search facility of the OS to locate the relevant file on your system. Microsoft versions of these class files are also included in IE4+, buried in one of the large `.zip` files in the `Windows\Java\Packages` directory (the files you need are in one of the multi-megabyte `.zip` files, whose gibberish names change from version to version—open each with an unzip utility and look for the two packages mentioned next). The browser must see these class files (and have both Java and JavaScript enabled in the preferences screens) for LiveConnect to work.

The easiest way to access the ZIP file for LiveConnect classes is to install the Java SDK, which includes the `jaws.jar` file in its runtime `lib` directory. You then need to add the file to the Java `classpath` environment variable. Following is an example of how this is accomplished at the command line:

```
set classpath=c:\j2sdk1.4.1_02\jre\lib\jaws.jar
```

Of course, your specific Java SDK installation may be different in terms of version numbering, but the command should be very similar. With the `jaws.jar` file available in the `classpath`, you're ready to use LiveConnect objects in Java code and build an applet.

Following are the two vital classes in the `netscape` package (yes, even in IE), which is the Java package made available in the LiveConnect ZIP file (`jaws.jar`):

```
netscape.javascript.JSObject
netscape.javascript.JSException
```

Both classes must be imported to your applet via the Java `import` compiler directive:

```
import netscape.javascript.*;
```

When the applet runs, the LiveConnect-aware browser knows how to find the two classes, so that the user doesn't have to do anything special as long as the supporting files are in their default locations.

### What your HTML needs

As a security precaution, an `<applet>` tag requires one extra attribute to give the applet permission to access the HTML and scripting inside the document. That attribute is the single word `mayscript`, and it can go anywhere inside the `<applet>` tag, as follows:

```
<applet code="myApplet.class" height="200" width="300" mayscript="mayscript" />
```

If you are using the `<object>` tag, add the `mayscript` feature as a parameter:

```
<param name="mayscript" value="true" />
```

Permission is not required for JavaScript to access an applet's methods or properties, but if the applet initiates contact with the page, this attribute is required.

## About JSObject class

The portal between the applet and the HTML page that contains it is the `netscape.javascript.JSObject` class. This object's methods let the applet contact document objects and invoke JavaScript statements. Table 44-1 shows the object's methods and one static method.

**Table 44-1: JSObject Class Methods**

<i>Method</i>	<i>Description</i>
<code>call(String functionName, Object args[])</code>	Invokes JavaScript function, argument(s) passed as an array
<code>eval(String expression)</code>	Invokes a JavaScript statement
<code>getMember(String elementName)</code>	Retrieves a named object belonging to a container
<code>getSlot(Int index)</code>	Retrieves indexed object belonging to a container
<code>getWindow(Applet applet)</code>	Static method retrieves applet's containing window
<code>removeMember(String elementName)</code>	Removes a named object belonging to a container
<code>setMember(String elementName, Object value)</code>	Sets value of a named object belonging to a container
<code>setSlot(int index, Object value)</code>	Sets value of an indexed object belonging to a container
<code>toString()</code>	Returns string version of JSObject

Just as the `window` object is the top of the document object hierarchy for JavaScript references, the `window` object is the gateway between the applet code and the scripts and document objects. To open that gateway, use the `JSObject.getWindow()` method to retrieve a reference to the document window. Assign that object to a variable that you can use throughout your applet code. The following code fragment shows the start of an applet that assigns the window reference to a variable named `mainwin`:

```
import netscape.javascript.*;

public class myClass extends java.applet.Applet {
    private JSObject mainwin;

    public void init() {
        mainwin = JSObject.getWindow(this);
    }
}
```

If your applet will be making frequent trips to a particular object, you may want to create a variable holding a reference to that object. To accomplish this, the applet needs to make progressively deeper calls into the document object hierarchy with the `getMember()` method. For example, the following sequence assumes `mainwin` is a reference to the applet's document window. Eventually the statements set a form's field object to a variable for use elsewhere in the applet:

```
JSObject doc = (JSObject) mainwin.getMember("document");
JSObject form = (JSObject) doc.getMember("entryForm");
JSObject phonefld = (JSObject) form.getMember("phone");
```

Another option is to use the Java `eval()` method to execute an expression from the point of view of any object. For example, the following statement gets the same field object from the preceding fragment:

```
JSObject phonefld = mainwin.eval("document.entryForm.phone");
```

As soon as you have a reference to an object, you can access its properties via the `getMember()` method, as shown in the following example, which reads the `value` property of the text box, and casts the value into a Java `String` object:

```
String phoneNum = (String) phonefld.getMember("value");
```

Two `JSObject` class methods let your applet execute arbitrary JavaScript expressions and invoke object methods: the `eval()` and `call()` methods. Use these methods with any `JSObject`. If a value is to be returned from the executed statement, you must cast the result into the desired object type. The parameter for the `eval()` method is a string of the expression to be evaluated by JavaScript. Scope of the expression depends on the object attached to the `eval()` method. If you use the `window` object, the expression would exist as if it were a statement in the document script (not defined inside a function).

Using the `call()` method is convenient for invoking JavaScript functions in the document, although it requires a little more preparation. The first parameter is a string of the function name. The second parameter is an array of arguments for the function. Parameters can be of mixed data types, in which case the array would be of type `Object`. If you don't need to pass a parameter to the function call, you can define an array of a single empty string value (for example, `String arg[] = {""}`) and pass that array as the second parameter.

## Data type conversions

The strongly typed Java language is a mismatch for loosely typed JavaScript. As a result, with the exception of Boolean and string objects (which are converted to their respective JavaScript objects), you should be aware of the way LiveConnect adapts data types to JavaScript.

Any Java object that contains numeric data is converted to a JavaScript number value. Because JavaScript numbers are IEEE doubles, they can accommodate just about everything Java can throw its way.

If the applet extracts an object from the document and then passes that `JSObject` type back to JavaScript, that passed object is converted to its original JavaScript object type. But objects of other classes are passed as their native objects wrapped in JavaScript "clothing." JavaScript can access the applet object's methods and properties as if the object were a JavaScript object. Finally, Java arrays are converted to the same kind of JavaScript array created via the `new Array()` constructor. Elements can be accessed by integer index values (not named index values). All other JavaScript array properties and methods apply to this object as well.

## Example applet-to-script application

To demonstrate several techniques for communicating from an applet to both JavaScript scripts and document objects, I present an applet that displays two simple buttons (see Figure 44-3). One button generates a new window, spawned from the main window, filling the window with dynamically generated content from the applet. The second button communicates from the applet to that second window by invoking a JavaScript function in the document. One last part of the demonstration shows the applet changing the value of a text box when the applet starts up.

Listing 44-6 shows the source code for the Java applet.

Because the applet generates two buttons, the code begins by importing the AWT interface builder classes. I also import the `netscape.javascript` package to get the `JSObject` class. The name of this sample class is `JtoJSDemo`. I declare four global variables: two for the windows, two for the applet button objects.

### Listing 44-6: Java Applet Source Code

```
import java.awt.*;
import java.awt.event.*;
import netscape.javascript.*;

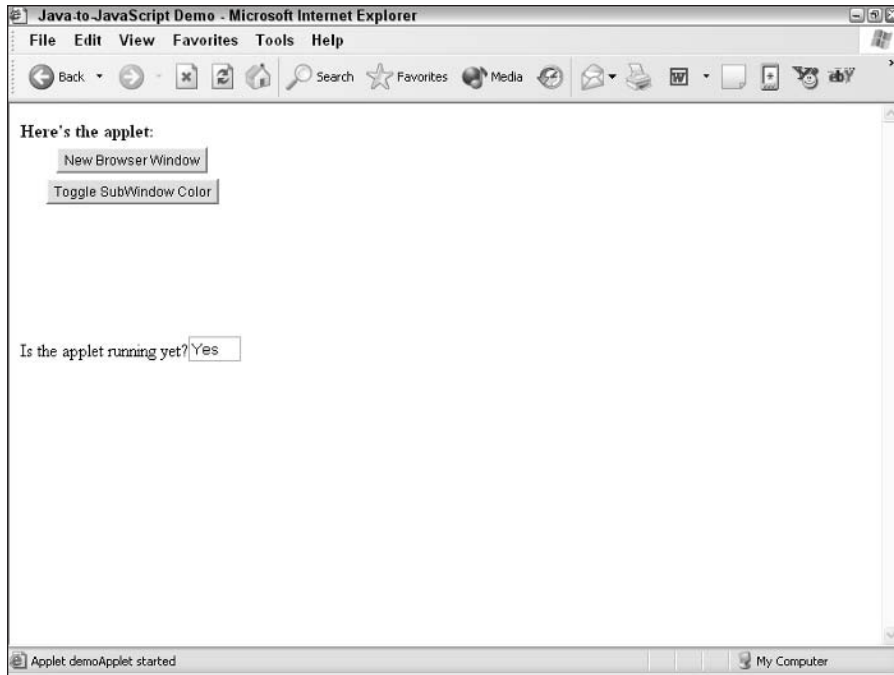

public class JtoJSDemo extends java.applet.Applet implements ActionListener {
    private JSObject mainwin, subwin;
    private Button newWinButton, toggleButton;
```

The applet's `init()` method establishes the user interface elements for this simple applet. A white background is matched in the HTML with a white document background color, making the applet appear to blend in with the page. I use this opportunity to set the `mainwin` variable to the browser window that contains the applet.

```
    public void init() {
        setBackground(Color.white);
        newWinButton = new Button("New Browser Window");
        toggleButton = new Button("Toggle SubWindow Color");
        this.add(newWinButton);
        this.add(toggleButton);
        newWinButton.addActionListener(this);
        toggleButton.addActionListener(this);
        mainwin = JSObject.getWindow(this);
    }
```

As soon as the applet starts, it changes the `value` property of a text box in the HTML form. Because this is a one-time access to the field, I elected to use the `eval()` method from the point of view of the main window, rather than build successive object references through the object hierarchy with the `getMember()` method.

```
    public void start() {
        mainwin.eval("document.indicator.running.value = 'Yes'");
    }
```

**Figure 44-3:** The applet displays two buttons seamlessly on the page.

Event handling is quite simple in this application. A click of the first button invokes `doNewWindow()`; a click of the second invokes `toggleColor()`. Both methods are defined later in the applet.

```
public void actionPerformed(ActionEvent evt) {
    Button source = (Button)evt.getSource();
    if (source == newWinButton) {
        doNewWindow();
    } else if (source == toggleButton) {
        toggleColor();
    }
}
```

One of the applet's buttons calls the `doNewWindow()` method defined here. I use the `eval()` method to invoke the JavaScript `window.open()` method. The string parameter of the `eval()` method is exactly like the statement that appears in the page's JavaScript to open a new window. The `window.open()` method returns a reference to that subwindow, so that the statement here captures the returned value, casting it as a `JSObject` type for the `subwin` variable. That `subwin` variable can then be used as a reference for another `eval()` method that writes to that second window. Notice that the object to the left of the `eval()` method governs the recipient of the `eval()` method's expression. The same is true for closing the writing stream to the subwindow.

**Note**

Unfortunately, the IE4+ implementation of `JSObject` does not provide a suitable reference to the external window after it is created. Therefore, the window does not receive its content or respond to color changes in this example. Due to other anomalies with subwindows, I advise against using LiveConnect powers with multiple windows in IE4+.

**Listing 44-6 (continued): Java Applet Source Code**

```
void doNewWindow() {
    subwin = (JSObject) mainwin.eval(
        "window.open('', 'fromApplet', 'height=200,width=200')");
    subwin.eval("document.write('<html><body bgcolor=white>Howdy from the
        applet!</body></html>')");
    subwin.eval("document.close()");
}
```

The second button in the applet calls the `toggleColor()` method. In the HTML document, a JavaScript function named `toggleSubWindowColor()` takes a window object reference as an argument. Therefore, I first assemble a one-element array of type `JSObject` consisting of the subwin object. That array is the second parameter of the `call()` method, following a string version of the JavaScript function name being called.

```
void toggleColor() {
    if (subwin != null) {
        JSObject arg[] = {subwin};
        mainwin.call("toggleSubWindowColor", arg);
    }
}
```

Now onto the HTML that loads the preceding applet class and is the recipient of its calls. The document is shown in Listing 44-7. One function is called by the applet. A text box in the form is initially set to “No” but gets changed to “Yes” by the applet after it has finished its initialization. The only other item of note is that the `<applet>` tag includes a `mayscript` attribute to allow the applet to communicate with the page.

**Listing 44-7: HTML Document Called by Applet**

```
<html>
  <head>
    <title>Java-to-JavaScript Demo</title>
    <script type="text/javascript">
      function toggleSubWindowColor(wind) {
        if (wind.closed) {
          alert("The subwindow is closed. Can't change it's color.");
        } else {
          wind.document.bgColor = (wind.document.bgColor == "#ffffff") ?
            "red" : "white";
        }
      }
    </script>
  </head>
```

```

<body bgcolor="#FFFFFF">
  <b>Here's the applet:</b><br />
  <applet code="JtoJSDemo.class" name="demoApplet" height="150" width="200"
  mayscript="mayscript">
  </applet>
  <form name="indicator">
    Is the applet running yet?<input type="text" name="running" size="4"
    value="No" />
  </form>
</body>
</html>

```

---

## Scripting Plug-Ins

Controlling a plug-in (or Windows ActiveX control in IE) from JavaScript is much like controlling a Java applet. But you have more browser-specific concerns to worry about, even at the HTML level. Not all plug-ins are scriptable, of course, nor do all browsers permit such scripting, as described at the start of this chapter. Yet even when you have found the right combination of browser version(s) and plug-in(s), you must also learn what the properties and/or methods of the plug-in are so that your scripts can control them. For common plug-in duties, such as playing audio, the likelihood that all users will have the same audio playback plug-in installed in a particular browser brand and operating system is perhaps too small to entrust your programming to a single plug-in. If, on the other hand, you are using a plug-in that works only with a special data type, your page need check only that the plug-in is installed (and that it is the desired minimum version).

In this section of the chapter, you'll begin to understand the HTML issues and then examine two separate audio playback examples. One example lets users change tunes being played back; the other arrives with five sounds, each of which is controlled by a different onscreen interface element. Both of these audio playback examples employ a library that has been designed to provide basic audio playback interfaces to the most popular scriptable audio playback plug-in, Windows Media Player.

The main goal of the library is to act as an API (Application Programming Interface) between your scripts and the player. The API presents a simple vocabulary to let your scripts control the Windows Media Player. If you wish to control only a more modern version of the player (version 9 or later), you can modify the details for that player's more complex syntax in the API, while leaving your other interface code untouched.

### The HTML side

Depending on the browser, operating system, and plug-in technology that you're using, one of two tags can be used to put a plug-in's powers into the page. With the plug-in embedded within the page (even if you don't see it), the plug-in becomes part of the document's object model, which means that your scripts can address it.

### Using embed

The old way of embedding non-document content into a page was to use the `<embed>` tag. Even though the W3C HTML standard has never recognized the `embed` element, it has been a part of browser implementations since the first embeddable media. The element is also a bit of a chameleon, because beyond a common set of recognized attributes, such as the `src` attribute

that points to the content file to be loaded into the plug-in, its attributes are extensible to include items that apply only to a given plug-in. Uncovering the precise lists of attributes and values for a plug-in is not always easy, and frequently requires digging deeply into the developer documentation of the plug-in's producer. It is not unusual for a page author to anticipate that multiple plug-ins could play a particular kind of data (as is the case in the audio examples later in this chapter). Therefore, a single `embed` element may include attributes that apply to more than one plug-in. You have to hope that the plug-ins' developers chose unique names for their attributes or that like-named attributes mean the same thing in multiple plug-ins. Any attributes that a plug-in doesn't recognize are ignored.

Typical behavior for a plug-in is to display some kind of controller or other panel in a rectangle associated with the media. You definitely need to specify the `height` and `width` attribute values of such an `embed` element if it is to display visual media (some video plug-ins let you hide the controls, while still showing the viewing area). For audio, however, you can specify a 1-pixel value for both dimensions, and leave the controls to your HTML content. Browsers that recognize stylesheets can also set `embed` elements to be invisible.

As an example of what an `embed` element may look like, the following code could be used in Netscape 4 to load a QuickTime or LiveAudio player into a page (with the goal of using scripts to control the player):

```
<embed name="jukebox"
  height="1"
  width="1"
  src="Beethoven.aif"
  hidden="true"
  autostart="false"
  autoplay="false"
  enablejavascript="true"
  mastersound="mastersound">
</embed>
```

After the page loads and encounters this tag, the browser reaches out to the server and loads the sound file into the plug-in, where it sits quietly until the plug-in is instructed to play it.

## WinIE/W3C object

The more modern and now preferred way to get external media into the document is to load the plug-in as an object via the `<object>` tag. The `object` element is endorsed by the W3C HTML standard, and has been supported in IE since IE4. In many ways the `<object>` tag works like the `<applet>` tag in that aside from specifying attributes that load the plug-in, additional nested `param` elements let you make numerous settings to the plug-in while it loads, including the name of the file to pre-load. As with a plug-in's attributes, an object's parameters are unique to the object and are documented (somewhere) for every object intended to be put into an HTML page.

The Windows operating system has a special (that is, far from intuitive) way it refers to the plug-in program (ActiveX control): through its class `id` (also known as a `guid`). You must know this long string of numbers and letters in order to embed the object into your page.

The following example is an `object` element that loads the Windows Media Player 9.x plug-in (ActiveX control) into a page:

```
<object id="jukebox" width="1" height="1"
  classid="CLSID:6BF52A52-394A-11d3-B153-00C04F79FAA6"
  <param name="FileName" value="Beethoven.aif" />
  <param name="AutoStart" value="false" />
</object>
```

When you compare the `embed` and `object` approaches, you can see many similar properties and values, which are just expressed differently (for example, attributes versus `param` elements).

## Using `embed` and `object` together

Because a public Web page must usually appeal to a broad range of browsers, you should design such a page to work with as many browsers as possible. For the convenience of your scripting, referring to a plug-in object by the same identifier is helpful, whether it is loaded via an `embed` or `object` element.

To the rescue comes a handy behavior of the `object` element. It is designed in such a way that you can nest the associated `embed` element inside the `object` element's tag set. If the browser doesn't know about the `object` element, that element is ignored, but the `embed` element is picked up. Similarly, if the browser that knows about the `object` element fails to load the plug-in identified in its attributes, the nested `embed` elements also get picked up. Therefore, you can combine the `object` and `embed` elements as shown in the following example, which demonstrates loading a movie file into a QuickTime plug-in:

```
<object classid="clsid:02BF25D5-8C17-4B23-BC80-D3488ABDDC6B"
        codebase="http://www.apple.com/qtactivex/qtplugin.cab"
        width="180" height="160" id="clip1" >
  <param name="src" value="videoClip.mov" />
  <embed width="180" height="160" src="videoClip.mov"
        name="clip1" enablejavascript="true">
  </embed>
</object>
```

Notice that the identifier assigned to the `id` of the `object` element and to the `name` of the `embed` element are the same. In NN3 and NN4 only one of these two elements will be valid in the document, but because Mozilla browsers recognize both types of elements, you'll have to reference only one of the identically named elements (as described with Listing 44-1b earlier in this chapter).

## The API approach

In this section, you see one version of an API that is tailor-made for the Windows Media Player. The API has its own initialization routine, which alerts users of ill-equipped browsers with a relevant message about why their browser can't get the most out of the page.

This API is far from the be-all, end-all library, although you will see that it does quite a bit as-is. The code is offered as a starting point for your further development. Such development may take the shape of adding more operations to the API or adding capabilities for additional scriptable plug-ins. For example, although the API as shown supports the older Windows Media Player 6, Microsoft continues to upgrade the Player to new versions (with new `guids` for your `object` tags) that have new command vocabularies. There is no reason that the API cannot be extended for new generations of Windows Media Player, while maintaining backward compatibility for the Version 6 generation.

You can find the complete API code on the CD-ROM within the folder of example listings for this chapter. The API file is named `MPAudioAPI.js`. Check out the following high points of this library.

### Loading the library

Adding the library to your page is no different from any external `.js` library file. Include the following tag in the head of your page:

```
<script type="text/javascript" src="MPAudioAPI.js"></script>
```

Except for two global variable initializations, no immediate code runs from the library. All of its activity is invoked from event handlers or other script statements in the main page.

## Initializing the library

The first job for the library is to validate that the player has loaded successfully. Before the library can do this, all loading of the `object` or `embed` elements must be concluded so that the objects exist for the initialization routine to examine. Therefore, use the `onload` event handler in the body to invoke the `initAudioAPI()` function. Parameters to be passed to this function are IDs of the `object` elements that represent individual players (in case there are more than one).

The following is an excerpt from Listing 44-9, which shows how the `jukebox` player object is initialized (all sound files for examples in this chapter have the `.aif` filename extension):

```
onload="initAudioAPI('jukebox')"
```

As you see later in Listing 44-10, the `initAudioAPI()` function lets you initialize multiple player objects. Each object has its own ID. For example, the following initializes the library for two different embedded plug-in objects:

```
onload="initAudioAPI('cNatural','cSharp')"
```

When the function receives multiple arguments, it loops through them, performing the initializations in sequence. The `initAudioAPI()` function follows:

```
function initAudioAPI() {
    var args = initAudioAPI.arguments;
    var id;
    for (var i = 0; i < args.length; i++) {
        // don't init any more if browser lacks scriptable sound
        if (OKToTest) {
            id = args[i];
            players[id] = new API(id);
            validateSupport(id);
        }
    }
}
```

Notice that parameter variables are not explicitly declared for the function, but are, instead, retrieved via the `arguments` property of the function. The global `OKToTest` flag, initialized to `true` when the library loads, is set to `false` if the validation of a plug-in fails. The conditional construction here prevents multiple alerts from appearing when multiple plug-in parameters are passed to the initialization function.

## Sound player API objects

One of the jobs of the initialization routine is to create a player object for each plug-in identifier. The object's constructor is as follows:

```
// AudioAPI object constructor
function API(id) {
    this.id = id;
    this.play = API_play;
    this.stop = API_stop;
    this.pause = API_pause;
    this.rewind = API_rewind;
    this.load = API_load;
    this.getVolume = API_getVolume;
    this.setVolume = API_setVolume;
}
```

The object becomes a convenient place to preserve properties for each sound controller. But the bulk of the object is reserved for assigning methods—the methods that your main page's scripts invoke to play and stop the player, adjust its volume, and so on. The method names to the left of the assignment statements in the object constructor are the names your scripts use; the functions in the library (for example, `API_play()`) are the ones that send the right command to the right plug-in.

Each of these objects (even if there is only one for the page) is maintained in a hash table-like array (named `players[]`) in the library. The plug-in object's identifier is the string index for the array entry. This provides the gateway to your page's scripts. For example, if you initialize the library with a single identifier, `jukebox`, you access the methods of the library's jukebox-related player object through the array and the identifier:

```
players["jukebox"].rewind();
```

### Invoking methods

Many of the player's method names are simple enough as-is (e.g., `play()`), but developing an API allows you to devise your own vocabulary for more complex operations. For example, Windows Media Player has no explicit method for rewinding the current tune, but you can assemble the equivalent operations into your own `rewind()` method, as shown in Listing 44-8. When your script invokes `players["jukebox"].rewind()`, the combined operations of the `API_rewind()` method do their jobs.

#### Listing 44-8: The API's Primary Functions

```
function API_play(n) {
    if (document.all(this.id).HasError) {
        alert("MediaPlayer Alert: " + document.all(this.id).ErrorDescription);
    } else {
        document.all(this.id).PlayCount = n;
        document.all(this.id).Play();
    }
}

function API_stop() {
    document.all(this.id).Stop();
}

function API_pause() {
    // Pause() method broken for IE5+
    document.all(this.id).Stop();
}

function API_rewind() {
    document.all(this.id).Stop();
    document.all(this.id).CurrentPosition = 0;
}

function API_load(URL) {
    document.all(this.id).Open(URL);
}
```

## Building a jukebox

The first example that utilizes the `MPAudioAPI.js` library is a jukebox that provides an interface (admittedly not pretty—that's for you to whip up) for selecting and controlling multiple sound files with a single plug-in tag set. The assumption for this application is that only one sound at a time need be handy for immediate playing.

Listing 44-9 shows the code for the jukebox. All sound files specified in the example are in the same folder as the listing on the companion CD-ROM (the AIFF-format files sound better in some plug-ins than others, so don't worry about the audio quality of these demo sounds).

### Listing 44-9: A Scripted Jukebox

```
<html>
  <head>
    <title>Oldies but Goody's</title>
    <script type="text/javascript" src="MPAudioAPI.js"></script>
    <script type="text/javascript">
      // make sure currently selected tune is preloaded
      function loadFirst(id) {
        var choice = document.forms[0].musicChoice;
        var sndFile = choice.options[choice.selectedIndex].value;
        players[id].load(sndFile);
      }
      // swap tunes
      function changeTune(id, choice) {
        players[id].load(choice.options[choice.selectedIndex].value);
      }
      // control and display volume setting
      function raiseVol(id) {
        var currLevel = players[id].getVolume();
        currLevel += Math.ceil(Math.abs(currLevel)/10);
        players[id].setVolume(currLevel);
        displayVol(id);
      }
      function lowerVol(id) {
        var currLevel = players[id].getVolume();
        currLevel -= Math.floor(Math.abs(currLevel)/10);
        players[id].setVolume(currLevel);
        displayVol(id);
      }
      function displayVol(id) {
        document.forms[0].volume.value = players[id].getVolume();
      }
    </script>
  </head>
  <body onload="initAudioAPI(['jukebox']); loadFirst('jukebox');
    displayVol('jukebox')">
    <form>

        width="2" height="2" id="jukebox" >
    <param name="autstart" value="false" />
</object>
</body>
</html>

```

You can see the user interface in Figure 44-4. One `select` element contains a list of three possible choices. Most of the interface, however, consists of buttons that ultimately invoke methods of the current plug-in.

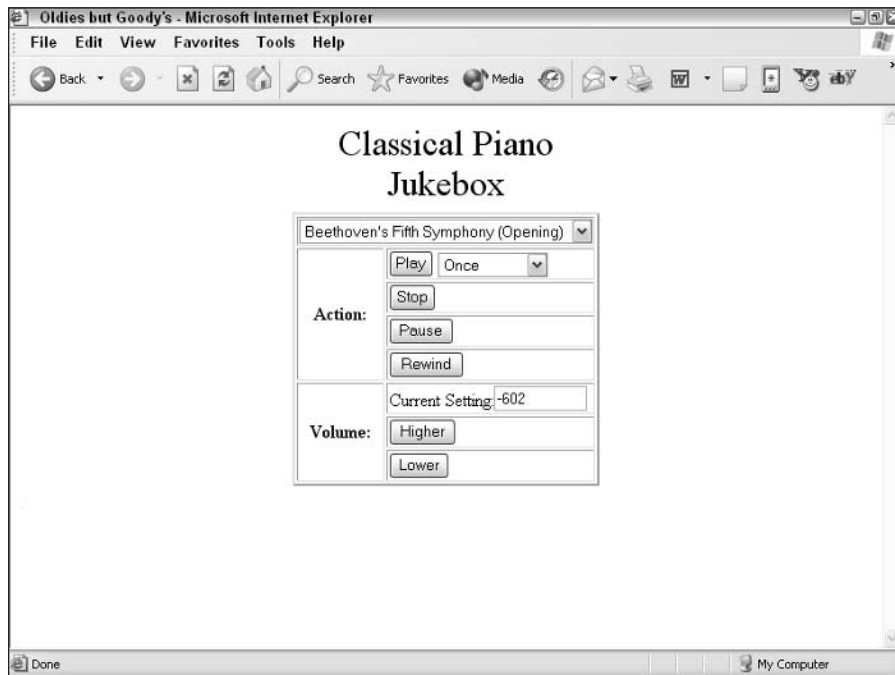

Figure 44-4: The jukebox page.

All functions defined for this page are designed to be as generalizable as possible. Thus, the identifier of the plug-in is passed as a parameter to each. If another plug-in were added to this page, the same functions could be used without modification, provided calls to the functions passed the identifier of the other plug-in.

All of the button controls are pretty straightforward except the Play button's `onclick` event handler. It invokes the `players[id].play()` method, but that method requires a parameter of how many times the sound should be played. In this user interface, a `select` element controls that information. Getting the value of the selected item creates a lengthy reference, but that's what is taking up so much space in the parameter slot of the `play()` method call.

## Embedding multiple sounds

The final example of embedded media serves as a base on which you can build a page that needs to play multiple sounds without the user explicitly loading them. For example, you may have buttons generate different sounds after users click them (I'm not recommending this interface, but that won't necessarily stop you). Figure 44-5 shows you the simple five-key piano keyboard. The page loads five different sounds into the page, one for each note (actual piano sounds in this case). Each sound was recorded for about four seconds, so that you can get the action of attack and delay, just like a real piano. If you mouse-down on a key, the sound plays for up to four seconds (getting softer all the time) or until you mouse up on the key (the attack time on the sample sounds on the CD-ROM is not instantaneous, so you may have to hold a key down for a fraction of a second to start the sound). The colors of the keys also change slightly to provide further user feedback to the action.

Figure 44-5: Controller for five sounds.

Thanks to the `MPAudioAPI.js` library, very little code in this page is associated with the sounds. Far more is involved with the image swaps and the loading of the five plug-ins. Listing 44-10 shows the code for the page.

### Listing 44-10: Scripting Multiple Sounds

</body>
</html>

```

Perhaps the trickiest part of this entire demonstration lies in the way the keyboard art and user interface are created. Because the white keys are not rectangular, the black key art is dropped atop the white keys by way of positioned elements.

When you use the page, you may notice a slight delay in getting the sound to be heard after pressing down on a key. On older, slower machines, this delay is even more noticeable. Take this behavior into account when designing interactive sound.

## Scripting Java Classes Directly

LiveConnect, as implemented in Netscape and Mozilla browsers, allows scripts to access Java classes as if they were part of the JavaScript environment. Because you need to know your way around Java before programming Java classes directly from JavaScript, I won't get into too much detail in this book. Fortunately, the designers of JavaScript have done a good job of creating JavaScript equivalents for the most common Java language functionality, so there is not a strong need to access Java classes on a daily basis.

To script Java classes, it helps to have a good reference guide to the classes built into Java. Though intended for experienced Java programmers, *Java in a Nutshell* (O'Reilly & Associates, Inc.) offers a condensed view of the classes, their constructors, and their methods.

Java's built-in classes are divided into major groups (called *packages*) to help programmers find the right class and method for any need. Each package focuses on one particular aspect of programming, such as classes for user interface design in application and applet windows, network access, and basic language constructs, such as strings, arrays, and numbers. References to each class (object) defined in Java are "dot" references, just as in JavaScript. Each item following a dot helps zero-in on the desired item. As an example, consider one class that is part of the base language class. The base language class is referred to as

```
java.lang
```

One of the objects defined in `java.lang` is the `String` object, whose full reference is

```
java.lang.String
```

To access one of its methods, you use an invocation syntax with which you are already familiar:

```
java.lang.String.methodName([parameters])
```

To demonstrate accessing Java from JavaScript, I call upon one of Java's `String` object methods, `java.lang.String.equalsIgnoreCase()`, to compare two strings. Equivalent ways are available for accomplishing the same task in JavaScript (for example, comparing both strings in their `toUpperCase()` or `toLowerCase()` versions), so don't look to this Java demonstration for some great new powers along these lines.

Before you can work with data in Java, you have to construct a new object. Of the many ways to construct a new `String` object in Java, you use the one that accepts the actual string as the parameter to the constructor:

```
var mainString = new java.lang.String("TV Guide");
```

At this point, your JavaScript variable, `mainString`, contains a reference to the Java object. From here, you can call this object's Java methods directly:

```
var result = mainString.equalsIgnoreCase("tv Guide");
```

Even from JavaScript, you can use Java classes to create objects that are Java arrays and access them via the same kind of array references (with square brackets) as JavaScript arrays. In a few cases, you can use Java classes to obtain additional information about the user environment, such as the user's IP address (but not e-mail address). The process involves a couple of Java class calls, as follows:

```
var localhost = java.net.InetAddress.getLocalHost();  
var IP = localhost.getHostAddress();
```

The more you work with these two languages, the more you see how much Java and JavaScript have in common.

# Debugging Scripts

---

One of the first questions that an experienced programmer asks about a programming environment is what support is there for debugging code. Even the best coders in the world make mistakes when they draft programs. Sometimes, the mistakes are a mere slip of a finger on the keyboard; other times, they result from not being careful with expression evaluation or object references. The cause of the mistake is not the issue: finding the mistake and getting help to fix it is.

Some debugging tools are available for the latest browsers. For the most part, they have come from the browser makers themselves, or they are tied very closely to a particular authoring environment. Some of these tools are very quirky; others require significant investments in authoring environments. Discussion about debugging tools in this chapter, however, focuses on simple tools you can download online. By understanding the true meaning of error messages and working out the problem with the tools provided here, you should be able to overcome your bugs.

## Syntax versus Runtime Errors

As a page loads into a JavaScript-enabled browser, the browser attempts to create an object model out of the HTML and JavaScript code in the document. Some types of errors crop up at this point. These are mostly syntax errors, such as failing to include a closing brace after a function's statements. Such errors are structural in nature, rather than about values or object references.

Runtime errors involve failed connections between function calls and their functions, mismatched data types, and undeclared variables located on the wrong side of assignment operators. Such runtime errors can occur as the page loads if the script lines run immediately as the page loads. Runtime errors located in functions won't crop up until the functions are called — either as the page loads or in response to user action.

Because of the interpreted nature of JavaScript, the distinction between syntax and runtime errors blurs. But as you work through whatever problem halts a page from loading or a script from running, you have to be aware of differences between true errors in language and your errors in logic or evaluation.

### In This Chapter

Identifying the type of error plaguing a script

Interpreting error messages

Preventing problems before they occur

## Error Message Notification

As the browsers have evolved through several generations, the ways in which script errors are reported to the user (and to you as the author) have also changed. The biggest changes came in WinIE4 and NN4.5. Prior to those versions, script errors always displayed some kind of alert dialog box with information about the error. Because these alerts could confuse non-technical users, the newer browsers are much more subtle about the presence of errors. In fact the notification mechanism is so subtle, that it is easy to miss the fact that a script error has occurred. Even if you do notice, you must then exercise your mouse a bit more to view the details.

When a script error occurs in WinIE4+, the status bar displays a yellow alert icon plus a brief text message indicating that an error has occurred. A syntax error that occurs while the page loads usually signifies that the page has loaded, but with errors. A runtime error's message simply indicates that an error occurred. To view details about the error, you must double-click the yellow icon in the status bar. The default appearance of the error message alert dialog box window includes a button named Show Details. Clicking this button expands the window to reveal whatever details the browser is reporting about the error. If you leave the window expanded, the next time it opens, it will also be expanded. It is a good idea for scripters to also check the box that forces the browser to show the error dialog box whenever an error occurs. This is simply a shortcut to manually double-clicking the status bar error icon.

### Netscape/Mozilla console windows

For NN4 browsers starting with NN4.5, a user receives error notification through a message in the status bar. The instructions there indicate how to view the error details: If you type

```
javascript:
```

into the toolbar's Location box or into the dialog box that lets you open a new page, an entirely new, non-modal window appears. This window is called the Communicator Console. In contrast to the one message per window approach of IE, the Communicator Console window continues to record all script errors in sequence (in a scrolling frame), even when the Console window is closed. You can keep this window open all the time, and simply bring it to the front whenever you need to view errors. If you are developing on a large video monitor, you can let the Console window stick out to the right of the browser window. If an error occurs, not only does the message appear in the browser status bar, but you'll also see the scrollbar of the Console window's top frame appear — an even more explicit indication that an error occurred (assuming you click the Clear Console button every time you are ready to try another test run).

Netscape changed the name of the window for NN6+, now calling it the JavaScript Console. Opening this window is less cryptic than before: Choose Tasks/Tools/JavaScript Console from the menu bar. NN6+/Mozilla does not provide notification of errors in the status bar, so it is up to you to be vigilant for something running amok. This is all the more reason to keep the JavaScript Console window open while you are writing and debugging your scripts. Even if things appear to be OK, periodically check the Console window to be sure.

### Safari errors

As delivered to users, Safari 1.0 completely conceals script errors. To be able to see script errors at all, you must enter a command into the MacOS X Terminal program window. The first step is to enable an otherwise hidden Debug menu in the Safari application. With Safari closed, launch Terminal and enter the following command exactly as shown:

```
defaults write com.apple.Safari IncludeDebugMenu 1
```

Launch Safari and another MacOS X utility application called Console. In the Safari Debug menu, choose “Log JavaScript Exceptions” so that the menu item is checked. Hereafter in the current session, all script errors appear in the Console window (along with other system-generated messages). Each time you launch Safari, you must enable the logging feature in the Debug menu.

## Multiple error messages

The modality of IE error message alert dialog boxes tends to force just one message to appear. In other words, when the first error occurs, the browser stops recording further errors. In NN/Moz, however, it is not uncommon for multiple errors to be listed (or, in older versions, multiple error windows to show up). But you need to understand how to treat these multiple errors to get to the root of the problem.

The usual reaction is to look at the last message to appear in the sequence. That, however, is usually the error message least likely to lead you to the true problem. Error messages are dumped to the NN/Moz Console window in the order in which they occur. This means that the first error in the list is the most important error message of them all. More than likely, the first error points to a problem that throws off the rest of the script, thus triggering all of the other error messages. For example, if a statement that initializes a variable has a syntax error in it, all other statements that rely on that variable will fail, because the variable appears to be undefined.

When you encounter multiple errors, don’t start any serious debugging until you locate the first error message. You must tackle this one before any others. The solution to the first one may cause the other errors to go away. This is all the more reason, when authoring in NN4.5+, to keep the Console window open, and clear it before loading any page or executing any scripts.

## Error Message Details

Error reporting comes in three flavors depending on the browser: NN/Moz, WinIE, or MacIE. One of these groups may be better (that is, more accurate and explicit) at reporting some kinds of errors than the other groups. By and large, however, you can count on error details to include three basic clues to help you track down the error: the file in which the error occurred, the location of the error within the source code, and a textual description of the error. Browsers outside of NN/Moz and IE typically utilize an approach similar to one of the three mentioned here, but Safari 1.0’s error reporting supplies precious little detail about any error. The Mozilla-based browsers tend to furnish the most accurate and helpful error messages.

### Error filename

Although MacIE error messages do not explicitly reveal the name of the file whose source code contains the error, in practice, only the NN/Moz browsers do the best job of telling the truth. Of course, when the script and HTML are all on one page, it doesn’t require a brain surgeon to know that the error occurs from that page’s source code. But if you link in external `.js` libraries, the NN/Moz browsers provide the URL to the `.js` file. WinIE, on the other hand, indicates the HTML page that loads the external library, making it difficult to know precisely where the error is.

## Error location

All browsers (except Safari 1.0) provide a source code line number and character position where the error supposedly occurs. For self-contained pages with no dynamically created content, the reporting tends to be accurate (also see the IE “Object expected” error message details described later in this chapter), but the accuracy is much closer in NN browsers than IE. And if your page links in an external library, the line number provided by WinIE and MacIE is practically useless. The sense you get is that the lines of the `.js` file become embedded within the main page’s script, but how that is supposed to help an author find the precise problem line is a mystery—even the most feature-laden text editor knows only how to display line numbers for a single document.

NN/Moz browsers, however, not only point to the correct `.js` file, but to the line number within that file. You are much more likely to get to the root of a problem, especially in an external `.js` file, through NN/Moz error messages.

Line number reporting has improved with each browser generation, but anomalies still exist. Perhaps the most egregious is the tendency for IE to report a problem at a line number whose source code is HTML with an event handler. The problem, it turns out, will be somewhere in the function being invoked by the event handler. Another possibility in all browsers is that the line number being reported is below the line that contains the problem. Consider the following simple source code listing (with line numbers from the source code editor) that intentionally contains a syntax error (a missing brace after the first function):

```

1:   <html>
2:     <head>
3:       <script type="text/javascript">
4:         function tarzan() {
5:           var x = 1;
6:
7:           function jane() {
8:             var y = 3;
9:           }
10:        </script>
11:     </head>
12:     <body>
13:       Hello.
14:     </body>
15:   </html>

```

When you load this page into browsers, all of them report a problem with a missing right brace (NN is a bit more explicit with its message, indicating that a right brace is missing after a function body). But where do the browsers point to the error? By looking at the code as a human, you can see that the missing brace belongs in Line 6. But now examine the code from the point of view of a script interpreter engine: It sees the opening brace on Line 4, and then a new function declaration starting on Line 7. To the interpreter, this means that the `jane()` function is probably nested inside the `tarzan()` function, and it is the `tarzan()` function that is lacking the right brace following the `jane()` function. Therefore, the error line number comes in at Line 10 (although MacIE5 reports Line 9). Your scripts won’t likely be this simple, so the distance between the reported error line number and the location of the actual problem can be substantial and difficult to spot without using some of the tips and tools described later in this chapter.

IE sometimes has a nasty habit of identifying the location of the problem at Line 1, Character 1. All this means is that you need to put your detective skills to work that much harder. Common causes for this behavior are references to HTML objects that don't exist (or there is a mismatch between the identifier of the element and your script reference to it) and errors that affect global functions or window methods. To find the genuine problem line, you can use tracing techniques described later in this chapter.

## Error message text

Because so many permutations exist of the potential errors you can make in scripts and the ways the JavaScript interpreters in different browsers regard these errors, presenting hard-and-fast solutions to every JavaScript error message is impossible. What I can do, however, is list the most common and head-scratch-inducing error messages and relate the kinds of non-obvious problems that can trigger such messages.

### “Object expected”

This error message is often one of the least helpful that you see in IE. The line number associated with the message typically points to a line in the source code that invokes a function. If you define event handlers as attributes of element tags, the line number being reported may correspond to the line containing that HTML tag.

The most obvious problem is that the function being invoked is not regarded as a valid function in the page (the “object” referred to here is the function object). This problem can be the result of an HTML or script error earlier in the document. The problem can also be the result of some error in the function itself that failed to let the interpreter treat the function as a genuine function object. Most typically, these kinds of problems are detected as syntax errors while the page loads (for example, an imbalanced set of parentheses or braces), but not always.

As a first-strike tactic, you need to determine if the function is being invoked at all. By placing an alert in the first line of the function and triggering the function, you can see if script execution is reaching that point. If that works okay, move the alert downward through the function to find out where the error is actually being triggered. The line before the alert that fails is the likely culprit.

### “Expected <something>”

This message usually points straight at the problem line. Most of the “things” that the statement expects are self-explanatory. If a right parenthesis is missing from a pair, that is the “thing” shown to be expected. Detecting in the message the difference between a brace and parenthesis isn't always easy, so look at the message carefully. Not quite as intuitive is when the message says “Expected identifier”. This error refers to an expression that typically is trying to use a reserved word as a variable name. Look into Appendix B for a list of reserved words, none of which you may use as names of things or variables.

### “<Something> is undefined”

This message is fairly easy to understand, yet at times difficult to diagnose. For variable names, the message usually means that you have an uninitialized variable name sitting in the position of a right-hand operand or a unary operand. This variable name has not been declared or assigned with any value prior to this erroneous statement. Perhaps you're attempting to use a variable name that has been initialized only as a local variable in another function. You may

also have intended the right-hand value to be a string, but you forgot to enclose it in quotes, forcing JavaScript to look upon it as a reference to something. Another possibility is that you misspelled the name of a previously declared variable. JavaScript rightly regards this item as a new, undeclared variable. Misspellings, you will recall, include errors in upper- and lower-case in the very case-sensitive JavaScript world.

If the item is a function name, you may have to perform a bit of detective work. Though the function may be defined properly, a problem in the script above the function (for example, imbalanced braces) makes JavaScript fail to see the function. In other cases, you may be trying to invoke a function in another window or frame but forgot to include the reference to that distant spot in the call to the function.

A less likely case, but a confusing one to diagnose, is when you are assembling string versions of function calls or array references out of literal strings and variable values. The following simplified example is assembling a string that is a function call to be triggered by `setTimeout()`:

```
function doA() {
    var x = "joe";
    setTimeout("doB(" + x + ")", 5000);
}
```

Even though the value of `x` is a string when it is concatenated to the call to the `doB()` function, the value gets evaluated as if it were a variable name. An error crops up saying that “joe is undefined”. Because you want to pass the value of `x` as a parameter, you must nest its value inside a pair of quotes, as follows:

```
function doA() {
    var x = "joe";
    setTimeout("doB('" + x + "')", 5000);
}
```

The difference in the code is extremely subtle, but absolutely necessary.

### “<Something> is not a function”

As with the preceding one, this error message can be one of the most frustrating, because when you look at the script, it appears as though you have clearly defined a function by that name, and you’re simply having an event handler or other running statement call that function. The first problems to look for are mismatched case of letters in the calling statement and function and the reuse of a variable or HTML object name by the function name.

This latter item is a no-no—it confuses JavaScript into thinking that the function doesn’t exist, even though the object name doesn’t have parentheses appended to it and the function does. I’ve also seen this error appear when other problems existed in the script above the function named in the error message, and the named function was the last one in a script.

In NN, this message appears when you attempt to invoke a function that is not implemented for a particular object. For example, if you attempt to use a W3C DOM method in NN4, the error reports that the method you tried to invoke “is not a function.”

### “Object doesn’t support this property or method”

This IE message reports that a valid object does not provide support for a method you just attempted to invoke. In practice, this message rarely appears as the result of referencing an object’s nonexistent property, because the language allows for extending an object’s list of properties by assignment. If you do a lot of development in IE5+ for Windows, you may see a lot of this message when testing the page in IE5 for the Macintosh, whose complement of implemented object methods is somewhat smaller.

## “Unterminated string literal”

### “Unterminated string constant”

NN is far more helpful with this type of message, because along with the error message, it displays the code fragment that tripped the error. You will see the beginning (or all) of the string that is the culprit. If you simply forgot to close a string quote pair, the error most frequently appears when you try to concatenate strings or nest quoted strings. Despite the claim that you can nest alternating double and single quotes, I often have difficulties using this nesting method beyond the second nested level (single quotes inside a double-quoted string). At different times, I’ve gotten away with using a pair of `\` inline quote symbols for a third layer. If that syntax fails, I break up the string so that nesting goes no deeper than two layers. If necessary, I even back out the most nested string and assign it to a variable in the preceding line — concatenating it into the more complex string in the next line.

In all versions of Navigator through NN4, avoid statements in scripts that extend for more than 255 characters. If you use a text editor that counts the column number as you type, use this measure as a guide for long statements. Break up long statements into shorter strings, but make sure to close the string at the end of the line. If you place a carriage return in the middle of a string in your source code, the first line’s string is unterminated. If you want to break long lines into shorter ones, close the string at the end of each line and use the `+` operator:

```
var myString = "Lorem ipsum dolor sit amet, consectetur " +
  "adipiscing elit, sed do eiusmod tempor incididunt " +
  "ut labore et dolore magna aliqua."
```

## “Missing } after function body”

### “Expected }”

This error usually is easy to recognize in a simple function definition because the closing brace is missing at the end of the function. But when the function includes additional nested items, such as `if...else` or `for` loop constructions, you begin dealing with multiple pairs of braces within the function. The JavaScript interpreter doesn’t always determine exactly where the missing brace belongs, and thus it simply defaults to the end of the function. This location is a natural choice, I guess, because from a global perspective of the function, one or more of the right braces that ripple down to the end of the function usually are missing.

In any case, this error message means that a brace is missing somewhere in a function above the referenced line number. Do an inventory count for left and right braces and see whether a discrepancy occurs in the counts. One of those nested constructions is probably missing a closing brace. Some programmer-oriented text editors also include tools for finding balanced pairs of braces and parentheses.

## “<Something> is not a number”

The variable name singled out in this error message is most likely a string or null value. The line of JavaScript that trips it up has an operator that demands a number. When in doubt about the data type of a variable destined for a math operation, use the `parseInt()` or `parseFloat()` functions to convert strings to numbers.

I have also encountered this error when it provides no clue about what isn’t a number — the error message simply says, “is not a number.” The root of the problem ended up having nothing to do with numbers. A structural imbalance in the script triggered this bogus error message.

**“<Something> has no property named . . .”****“<Something> has no properties”**

When a statement trips this error message, an object reference has usually gone awry in an assignment or comparison expression. You probably attempted to reference a property of an object, but something is wrong with the object reference, or you’re trying to retrieve a property that doesn’t exist for that object. If the reference is an extended one, you may have to dig to find the precise problem with the reference. Consider the following two statements that attempt to access the `value` property of a button named `calcme`:

```
document.forms.calcme.value
document.forms[0].calcme.value
```

The NN errors for these two statements would read “document.forms.calcme has no properties” and “document.forms[0].calcme has no properties”. Causes for the two errors are quite different. The obvious problem with them both may seem to be that the button’s name is incorrectly referenced as `calcme` instead of `calcMe`. That, indeed, is the error for the second statement. But a more fundamental problem also plagues the first statement: the `document.forms` reference (a valid object, returning an array of forms) needs an array index in this instance, because it needs to look into a particular form for one of its objects. Unfortunately, both error messages look alike at first glance, and you cannot tell from them which statement has two errors and which has one.

But what you can do when this kind of error appears is use the reference that is returned with the error message to check your work. Start verifying the accuracy of your references from left to right. Later in this chapter, you see how to use the embeddable Evaluator tool to verify the existence of object references.

**“<Something> is null or not an object”**

This message is the IE version of the previous NN error message. A big difference is that the reference returned as part of the error message includes the complete reference. Therefore, a reference to a nonexistent `calcme` button in a form yields the error message “‘document.forms[0].calcme.value’ is null or not an object”. Your first instinct is to be suspicious of the `value` property part of the reference. The detective work to find the problem is the same as in the NN version: verify the reference piece by piece, working from left to right. Again, the embeddable Evaluator described later in this chapter can assist in this task.

**“<Something> has no property indexed by [i]”**

Look carefully at the object reference in this error message. The last item has an array index in the script, but the item is not an array value type. Users commonly make this mistake within the complex references necessary for radio buttons and `select` options. Make sure that you know which items in those lengthy references are arrays and which are simply object names that don’t require array values.

**“<Something> can’t be set by assignment”**

This error message tells you either that the property shown is read-only or that the reference points to an object, which must be created via a constructor function rather than by simple assignment.

## “Test for equality (==) mistyped as assignment (=)?

### Assuming equality test.”

The first time I received this error, I was amazed by JavaScript’s intelligence. I had, indeed, meant to use the equality comparison function (==) but had entered only a single equal sign. JavaScript is good at picking out these situations where Boolean values are required. In NN6+, this message is demoted to just a warning rather than an error.

## “Function does not always return a value”

Often while designing deeply nested `if...else` constructions, your mind follows a single logic path to make sure that a particular series of conditions is met, and that the function returns the desired values under those conditions. What is easy to overlook is that there may be cases in which the decision process may “fall through” all the way to the bottom without returning any value, at which point the function must indicate a value that it returns, even if it is a 0 or empty (but most likely a Boolean value). JavaScript checks the organization of functions to make sure that each condition has a value returned to the calling statement. The error message doesn’t tell you where you’re missing the return statement, so you have to do a bit of logic digging yourself.

## “Access disallowed from scripts at <URL> to documents at <URL>”

### “Access is denied”

These messages (NN and IE versions, respectively) indicate that a script in one frame or window is trying to access information in another frame or window that has been deemed a potential security threat. Such threats include any `location` object property or other information about the content of the other frame when the other frame’s document comes from a protocol, server, or host that is different from the one serving up the document doing the fetching.

Even the best of intentions can be thwarted by these security restrictions. For example, you may be developing an application that blends data in cooperation with another site. Security restrictions, of course, don’t know that you have a cooperative agreement with the other Web site, and you have no workaround for accessing a completely different domain unless you use signed scripts for NN (see Chapter 46) or an IE user has browser security levels set dangerously loose.

Another possible trigger for these errors is that you are using two different servers in the same domain or different protocols (for example, using `https:` for the secure part of your commerce site, while all catalog info uses the `http:` protocol). If the two sites have the same domain (for example, `giantco.com`) but different server names or protocols, you can set the `document.domain` properties of documents so that they recognize each other as equals. See Chapter 46 for details on these issues and the restrictions placed on scripts that mean well, but that can be used for evil purposes.

IE, especially Windows versions, frequently clamps down too severely on inter-window and inter-frame communication. Don’t be surprised to encounter security problems trying to communicate between a main window and another window whose content is dynamically generated by scripts in the main window. This error can be incredibly frustrating. Sometimes, serving the main page from a server (instead of reading it from a local hard disk) can solve the problem, but not always. You are safest if the content of both windows or frames are documents served from the same server and domain.

### “Unspecified error”

This completely unhelpful IE error message is not a good sign because it means that whatever error is occurring is not part of the well-traveled decision tree that the browser uses to report errors. All is not lost, however. That the browser has not crashed means that you can still attempt to get at the root of the problem through various tracing tactics described later in this chapter.

### “Uncaught exception”

You may encounter these messages in NN6+/Moz, although usually not as a result of your scripts unless you are using some of the browser’s facilities to dive into inner workings of the browser. These messages are triggered by the browser’s own programming code, and indicate a processing error that was not properly wrapped inside error trapping mechanisms. The details associated with such an error point to the Mozilla browser’s own source code modules and internal routines. If you can repeat the error and can do so in a small test case page, you are encouraged to submit a report to <http://bugzilla.mozilla.org>, the bug tracking site for the Mozilla browser.

### “Too many JavaScript errors”

You may see this message in NN if it detects a runaway train generating errors uncontrollably. This message was far more important in the days of separate error windows, because a buggy repeat loop could cause NN to generate more error windows than it could do safely.

## Warnings in Mozilla’s Console

The Mozilla browser’s JavaScript Console window reports both outright errors and another class of notices called *warnings*. Whereas an error may cause script execution to stop, a warning is generally less catastrophic. A warning typically alerts the content author of looming problems, such as deprecated DOM terms that are still supported merely for backward compatibility—but that should be avoided going forward.

Another common warning advises that the server delivered some external content without correct headers. This happens frequently when a server supplies `.css` filters for link elements without the correct content-type header (`text/css` or similar). These are server configuration issues that should be fixed if they’re under your control. You may turn off warnings in the JavaScript Console window by clicking the Errors button.

## Sniffing Out Problems

It doesn’t take many error-tracking sessions to get you in the save-switch-reload mode quickly. Assuming that you know this routine (described in Chapter 3), the following are some techniques I use to find errors in my scripts when the error messages aren’t being helpful in directing me right to the problem.

### Check the HTML tags

Before I look into the JavaScript code, I review the document carefully to make sure that I’ve written all my HTML tags properly. That includes making sure that all tags have closing angle brackets and that all tag pairs have balanced opening and closing tags. Digging deeper, especially in tags near the beginning of scripts, I make sure that all tag attributes that must be

enclosed in quotes have the quote pairs in place. Running your document through an HTML validator can help you spot markup mistakes in complex documents. The W3C's Markup Validation Service is a good place to start ([validator.w3c.org](http://validator.w3c.org)).

A browser may be forgiving about sloppy HTML as far as layout goes, but the JavaScript interpreter isn't as accommodating. Finally, I ensure that the `<script>` tag pairs are in place (they may be in multiple locations throughout my document) and that the `type="text/javascript"` attribute value has both of its quotes.

## View the source

Your success in locating bugs by viewing the source in the browser varies widely with the kind of content on the page and the browser you use. Very frequently, authors place perhaps too much importance in what they see in the source window.

For a straight, no-frame HTML page, viewing the source provides a modicum of comfort by letting you know that the entire page has arrived from the server. Some versions of NN might flash a questionable HTML construction, but don't expect miracles.

**Note**

NN4 exhibits a notorious bug in the source view if your HTML tags include style attributes for element-specific stylesheets. You may "see double" in these lines, whereby the style attribute appears to be repeated (although usually beginning with "tyle...") in what looks to be gibberish. This problem is a bug in the source viewer and does not accurately represent what the browser-rendering engine is using as source code.

Examining the source code for framesetting documents or individual frames, you must first give focus to the desired element. For an individual frame, click in the frame, and then right-click (or Ctrl-click on the Mac) on the frame's background to get the contextual menu. One of the items should indicate a source view of the frame. To view the framesetter's source, press the Tab key until the Address/Location field of the browser is selected. Then choose to view the source from the Edit menu.

Where the source view would be most helpful, but often fails, is to display dynamically generated HTML. Your best chance will be for pages whose entire content is generated by script. This is about the only place you can appreciate the difference between `document.write()` and `document.writeln()`, because the latter puts carriage returns after the end of each string passed as a parameter to the method. The result is a more readable source view. Most recent browsers, with the exception of NN6+/Moz, display the HTML as written by your script. NN4 does this in a window whose URL indicates the `wysiwyg:` protocol—an internal indication of dynamically generated content.

But when only part of the page is generated by script, few browsers combine the hard-wired and dynamic code in the source view. Instead, you see only the hard-wired HTML and scripts. To work around this for IE4+ and NN6+, you can use the embeddable Evaluator (later in this chapter) and read the `innerHTML` property of any elements you want.

## Timing problems

One problem category that is very difficult to diagnose is the so-called timing problem. There are no hard-and-fast rules that govern when you are going to experience such a problem. Very experienced scripters develop an instinct about when timing is causing a problem that has no other explanation.

A timing problem usually means that one or more script statements are executing before the complete action of an earlier statement has finished its task. JavaScript runs within a single thread inside the browser, meaning that only one statement can run at a time. But there are times when a statement invokes some browser service that operates in its own thread and therefore doesn't necessarily finish before the next JavaScript statement runs. If the next JavaScript statement relies on the previous statement's entire task having been completed, the script statement appears to fail, even though it actually runs as it should.

These problems crop up especially when scripts work with another browser window, and especially in IE for Windows (ironic in a way). In discussions in this book about form field validation, for example, I recommend that after an instructive alert dialog box notifies the user of the problem with the form, the affected text field should be given focus and its content selected. In WinIE, however, after the user closes the alert dialog box, the script statements that focus and select operate before the operating system has finished putting the alert away and refreshing the screen. The result is that the focused and selected text box loses its focus by the time the alert has finally disappeared.

The solution is to artificially slow down the statements that perform the focus and select operations. By placing these statements in a separate function, and invoking this function via the `window.setTimeout()` method, the browser catches its breath before executing the separate function—even when the delay parameter is set to zero. A similar delay is utilized when opening and writing to a new window, as shown in the example for `window.open()` in Chapter 16.

## Reopen the file

If I make changes to the document that I truly believe should fix a problem, but the same problem persists after a reload, I reopen the file via the File menu. Sometimes, when you run an error-filled script more than once, the browser's internals get a bit confused. Reloading does not clear the bad stuff, although sometimes an unconditional reload (clicking Reload while holding Shift) does the job. Reopening the file, however, clears the old file entirely from the browser's memory and loads the most recently fixed version of the source file. I find this situation to be especially true with documents involving multiple frames and tables and those that load external `.js` script library files. In severe cases, you may even have to restart the browser to clear its cobwebs, but this is less necessary in recent browsers. You should also consider turning off the cache in your development browser(s).

## Find out what works

When an error message supplies little or no clue about the true location of a runtime problem, or when you're faced with crashes at an unknown point (even during document loading), you need to figure out which part of the script execution works properly.

If you have added a lot of scripting to the page without doing much testing, I suggest removing (or commenting out) all scripts except the one(s) that may get called by the document's `onload` event handler. This is primarily to make sure that the HTML is not way out of whack. Browsers tend to be quite lenient with bad HTML, so that this tactic won't necessarily tell the whole story. Next, add back the scripts in batches. Eventually, you want to find where the problem really is, regardless of the line number indicated by the error message alert.

To narrow down the problem spot, insert one or more alert dialog boxes into the script with a unique, brief message that you will recognize as reaching various stages (such as `alert("HERE-1")`). Start placing alert dialog boxes at the beginning of any groups of statements that execute and try the script again. Keep moving these dialog boxes deeper into the script (perhaps into other functions called by outer statements) until the error or crash occurs. You now know where to look for problems. See also an advanced tracing mechanism described later in this chapter.

## Comment out statements

If the errors appear to be syntactical (as opposed to errors of evaluation), the error message may point to a code fragment several lines away from the problem. More often than not, the problem exists in a line somewhere above the one quoted in the error message. To find the offending line, begin commenting out lines one at a time (between reloading tests), starting with the line indicated in the error message. Keep doing this until the error message clears the area you're working on and points to some other problem below the original line (with the lines commented out, some value is likely to fail below). The most recent line you commented out is the one that has the beginning of your problem. Start looking there.

## Check runtime expression evaluation

I've said many times throughout this book that one of the two most common problems scripters face is an expression that evaluates to something you don't expect (the other common problem is an incorrect object reference). In lieu of a debugger that would let you step through scripts one statement at a time while watching the values of variables and expressions, you have a few alternatives to displaying expression values while a script runs.

The simplest approaches to implement are an alert box and the status bar. Both the alert dialog box and status bar show you almost any kind of value, even if it is not a string or number. An alert dialog box can even display multiple-line values.

Because most expression evaluation problems come within function definitions, start such explorations from the top of the function. Every time you assign an object property to a variable or invoke a string, math, or date method, insert a line below that line with an `alert()` method or `window.status` assignment statement (`window.status = someValue`) that shows the contents of the new variable value. Do this one statement at a time, save, switch, and reload. Study the value that appears in the output device of choice to see if it's what you expect. If not, something is amiss in the previous line involving the expression(s) you used to achieve that value.

This process is excruciatingly tedious for debugging a long function, but it's absolutely essential for tracking down where a bum object reference or expression evaluation is tripping up your script. When a value comes back as being undefined or null, more than likely the problem is an object reference that is incomplete (for example, trying to access a frame without the `parent.frames[i]` reference), using the wrong name for an existing object (check case), or accessing a property or method that doesn't exist for that object.

When you need to check the value of an expression through a long sequence of script statements or over the lifetime of a repeat loop's execution, you are better off with a listing of values along the way. In the section "A Simple Trace Utility" later in this chapter, I show you how to capture trails of values through a script.

## Debugging Tools

For a truly interactive debugger to work effectively with client-side JavaScript, the debugger must be highly integrated into the browser. This appears to have been a primary stumbling block in the availability of JavaScript debuggers. At best, we have some browser-specific debuggers, but this leaves other browsers completely out in the cold. The only browsers that have debuggers available for them are Internet Explorer for Windows, Netscape 4, and Mozilla.

### WinIE Script Debugger

You can download the Microsoft Script Debugger and documentation from <http://msdn.microsoft.com/downloads/list/webdev.asp>. The debugger that is being used with IE6 is essentially the same debugger that has been around since IE4.

After you install the Script Debugger, you must tell your copy of IE to enable it. Go to the Tools ⇨ Internet Options menu, click on the Advanced tab, and look for the “Disable script debugging” item in the Browsing category. Make sure that this box is unchecked. For good measure, quit and relaunch the browser. If script errors appear as usual, without an option letting you go into the debugger, help it along by choosing View ⇨ Script Debugger ⇨ Open.

When a runtime error occurs, you will be brought to the Debugger window, which will highlight the affected line. Script execution is paused, allowing you to inspect the value of variables and such. Open the Command window, and type any variable name (local or global) that should be active at the paused line. Press Enter, and the next line of the Command window shows the value of that variable.

You can also explicitly set breakpoints in the code, and single-step through the code. At each step, you can enter another variable name or property reference to see its current value.

Be prepared, however, for a less than satisfactory experience with this debugger. If your scripts are loaded from external `.js` files, the debugger does not track that code or line numbers reliably. In fact, it's not uncommon for the debugger to open with the completely wrong line of code highlighted, making single stepping impossible. Simply said, don't bring high expectations to the Script Debugger.

Perhaps Microsoft would rather you use the more sophisticated debugging facilities of their Visual Studio development software. It is a rather expensive solution if all you need is script debugging.

### Mozilla's Venkman Debugger

When you install the Mozilla browser, you automatically receive its debugger, codenamed Venkman. This is a new component designed for the new Mozilla browser generation. You may also install it into Netscape 7 and other Mozilla-based browsers.

Access the debugger via the Tools->Web Development menu. With the debugger open, any script error brings the debugger window to the front, with execution paused at the problem line. If the code is from an external `.js` file, that file's source code is displayed, with the problem line highlighted. This debugger automatically tracks objects and their property values in one of the window's panes. You may also set breakpoints in code so that you can single-step through code and observe values at each step.

For more information about Venkman, visit [www.mozilla.org/projects/venkman](http://www.mozilla.org/projects/venkman). To obtain the latest copy and pointers to documentation, visit [www.hacksrus.com/~glinda/venkman](http://www.hacksrus.com/~glinda/venkman).

## Using the embeddable Evaluator

As soon as a page loads or after some scripts run, the window contains objects whose properties very likely reveal a lot about the environment at rest (that is, not while scripts are running). Those values are normally disguised from you, and the only way to guarantee successful access to view those values is through scripting within the same window or frame. That's where the embeddable Evaluator comes in handy.

As you probably recall from Chapter 13 and the many example sections of Parts III and IV of this book, the code within the standalone Evaluator provides two text boxes for entry of expressions (in the top box) and object references (the bottom box). Results of expression evaluation and object property dumps are displayed in the Results textarea between the two input boxes. A compact version of The Evaluator is contained by a separate library version called `evaluator.js` (located in the Chapter 45 folder of listings on the CD-ROM). As you embark on any substantial page development project, you should link in the library with the following tag at the top of your head section:

```
<script type="text/javascript" src="evaluator.js"></script>
```

Be sure to either have a copy of the `evaluator.js` file in the same directory as the document under construction or specify a complete file: URL to the library file on your hard drive for the SRC attribute.

Immediately above the closing `body` tag of your document, include the following:

```
<script type="text/javascript">
printEvaluator();
</script>
```

If your page contains lots of positioned content, you'll need to put The Evaluator into its own positioned layer, out of the way of your primary content. For example:

```
<div style="position:absolute; top:800px; left:100px">
  <script type="text/javascript">
    printEvaluator();
  </script>
</div>
```

The `printEvaluator()` function draws a horizontal rule (`hr`) followed by the complete control panel of The Evaluator, including the codebase principal support for NN4+/Moz. From this control panel, you can reference any document object supported by the browser's object model or global variable. You can even invoke functions located in other scripts of the page by entering them into the top text box. Whatever references are available to other scripts on the page are also available to The Evaluator, including references to other frames of a frame-set and even other windows (provided a reference to the newly opened window has been preserved as a global variable, as recommended in Chapter 16).

If you are debugging a page on multiple browsers, you can switch between the browsers and enter property references into The Evaluator on each browser and make sure all browsers return the same values. Or, you can verify that a DOM object and property are available on all browsers under test. If you are working on W3C DOM-compatible browsers, invoke the `walkChildNodes()` function of The Evaluator to make sure that modifications your scripts make to the node tree are achieving the desired goals. Experiment with direct manipulation of the page's objects and node tree by invoking DOM methods as you watch the results on the page.

You should be aware of only two small cautions when you embed The Evaluator into the page. First, The Evaluator declares its own one-letter lowercase global variable names (a through z) for use in experiments. Your own code should therefore avoid one-letter global variables (but local variables, such as the `i` counter of a `for` loop, are fine provided they are initialized inside a function with a `var` keyword). Second, while embedding The Evaluator at the bottom of the page should have the least impact on the rest of your HTML and scripts, any scripts that rely on the length of the `document.forms` array will end up including the form that is part of The Evaluator. You can always quickly turn off The Evaluator by commenting out the `printEvaluator()` statement in the bottom script to test your page on its own.

The embeddable Evaluator is without question the most valuable and frequently used debugging tool in my personal arsenal. It provides x-ray vision into the object model of the page at any resting point.

## Emergency evaluation

Using The Evaluator assumes that you thought ahead of time that you want to view property values of a page. But what if you haven't yet embedded The Evaluator, and you encounter a state that you'd like to check out without disturbing the currently loaded page?

To the rescue comes the `javascript: URL` and the Location/Address box in your browser's toolbar. By invoking the `alert()` method through this URL, you can view the value of any property. For example, to find out the content of the cookie for the current document, enter the following into the Location/Address box in the browser:

```
javascript:alert(document.cookie)
```

Object methods or script functions can also be invoked this way, but you must be careful to prevent return values from causing the current page to be eliminated. If the method or function is known to return a value, you can display that value in an alert dialog box. The syntax for a function call is:

```
javascript:alert(myFunction("myParam1"))
```

And if you want to invoke a function that does not necessarily return a value, you should also protect the current page by using the void operator, as follows:

```
javascript:void myFunction("myParam1")
```

One more way to grab a “snapshot” of the current document tree, complete with all tags, is to use the following pseudo-URL in the Location/Address box:

```
javascript: "<textarea cols=120 rows=40>" + document.body.parentNode.innerHTML + "</textarea>"
```

When you execute this script, the current page goes away, replaced by a page containing a `textarea` filled with the current HTML state of the entire document (except for the `<html>` tag). If your scripts perform document tree modification, and you want to observe the current tree state, this command acts as a cross-browser x-ray into the document. You should consider making a bookmark out of the above URL, and keep it handy.

## A Simple Trace Utility

Single-stepping through running code with a JavaScript debugger is a valuable aid when you know where the problem is. But when the bug location eludes you, especially in a complex script, you may find it more efficient to follow a rapid trace of execution and viewing intermediate values along the way. The kinds of questions that this debugging technique addresses include:

- ♦ How many times is that loop executing?
- ♦ What are the values being retrieved each time through the loop?
- ♦ Why won't the while loop exit?
- ♦ Are comparison operators behaving as I'd planned in `if...else` constructions?
- ♦ What kind of value is a function returning?

A bonus feature of the embeddable Evaluator is a simple trace utility that lets you control where in your running code values can be recorded for viewing after the scripts run. The resulting report you get after running your script can answer questions like these and many more.

### The `trace()` function

Listing 45-1 shows the `trace()` function that is built into the `evaluator.js` library file. By embedding the Evaluator into your page under construction, you can invoke the `trace()` function wherever you want to capture an interim value.

#### Listing 45-1: `trace()` function

```
function trace(flag, label, value) {
  if (flag) {
    var msg = "";
    if (trace.caller) {
      var funcName = trace.caller.toString();
      funcName = funcName.substring(9, funcName.indexOf("(") + 1);
      msg += "In " + funcName + ": ";
    }
    msg += label + "=" + value + "\n";
    document.forms["ev_evaluator"].ev_output.value += msg;
  }
}
```

The `trace()` function takes three parameters. The first, `flag`, is a Boolean value that determines whether the trace should proceed (I show you a shortcut for setting this flag later). The second parameter is a string used as a plain-language way for you to identify the value being traced. The value to be displayed is passed as the third parameter. Virtually any type of value or expression can be passed as the third parameter — which is precisely what you want in a debugging aid.

Only if the flag parameter is `true` does the bulk of the `trace()` function execute. The first task is to extract the name of the function from which the `trace()` function was called. By retrieving the rarely used `caller` property of a function, the script grabs a string copy of the entire function that has just called `trace()`. A quick extraction of a substring from the first line yields the name of the function. That information becomes part of the message text that records each trace. The message identifies the calling function followed by a colon; after that comes the label text passed as the second parameter plus an equal sign and the value parameter. The format of the output message adheres to the following syntax:

```
In <funcName>: <label>=<value>
```

The results of the trace—one line of output per invocation—are appended to the Results textarea in The Evaluator. It's a good idea to clear the textarea before running a script that has calls to `trace()` so that you can get a clean listing.

## Preparing documents for trace.js

As you build your document and its scripts, you need to decide how granular you want tracing to be: global or function-by-function. This decision affects at what level you place the Boolean “switch” that turns tracing on and off.

You can place one such switch as the first statement in the first script of the page. For example, specify a clearly named variable and assign either `false` or `zero` to it so that its initial setting is off:

```
var TRACE = 0;
```

To turn debugging on at a later time, simply edit the value assigned to `TRACE` from `zero` to `one`:

```
var TRACE = 1;
```

Be sure to reload the page each time you edit this global value.

Alternatively, you can define a local `TRACE` Boolean variable in each function for which you intend to employ tracing. One advantage of using function-specific tracing is that the list of items to appear in the Results textarea will be limited to those of immediate interest to you, rather than all tracing calls throughout the document. You can turn each function's tracing facility on and off by editing the values assigned to the local `TRACE` variables.

## Invoking trace()

All that's left now is to insert the one-line calls to `trace()` according to the following syntax:

```
trace(TRACE, "label", value);
```

By passing the current value of `TRACE` as a parameter, you let the library function handle the decision to accumulate and display the trace. The impact on your running code is kept to a one-line statement that is easy to remember. To demonstrate how to make the calls to `trace()`, Listing 45-2 shows a pair of related functions that convert a time in milliseconds to the string format “hh:mm”. To help verify that values are being massaged correctly, the script inserts a few calls to `trace()`.

**Listing 45-2: Calling trace()**

```
function timeToString(input) {
    var TRACE = 1;
    trace(TRACE,"input",input);
    var rawTime = new Date(eval(input));
    trace(TRACE,"rawTime",rawTime);
    var hrs = twoDigitString(rawTime.getHours());
    var mins = twoDigitString(rawTime.getMinutes());
    trace(TRACE,"result", hrs + ":" + mins);
    return hrs + ":" + mins;
}

function twoDigitString(val) {
    var TRACE = 1;
    trace(TRACE,"val",val);
    return (val < 10) ? "0" + val : "" + val;
}
```

After running the script, the Results box in The Evaluator shows the following trace:

```
In timeToString(input): input=976767964655
In timeToString(input): rawTime=Wed Dec 13 20:26:04 GMT-0800 2000
In twoDigitString(val): val=20
In twoDigitString(val): val=26
In timeToString(input): result=20:26
```

Having the name of the function in the trace is helpful in cases in which you might justifiably reuse variable names (for example, `i` loop counters). You can also see more clearly when one function in your script calls another.

One of the most valuable applications of the `trace()` function comes when your scripts accumulate HTML that gets written to other windows or frames, or replaces HTML segments of the current page. Because the source view may not display the precise HTML that you assembled, you can output it via the `trace()` function to the Results box. From there, you can copy the HTML and paste it into a fresh document to test in the browser by itself. You can also verify that the HTML content is being formatted the way that you want it.

## Browser Crashes

Each new browser generation is less crash-prone than its predecessor, which is obviously good news for everyone. It seems that most crashes, if they occur, do so as the page loads. This can be the result of some ill-advised HTML, or something happening as the result of script statements that either run immediately as the page loads or in response to the `onload` event handler.

Finding the root of a crash problem is perhaps more time consuming because you must relaunch the browser each time (and in some cases, even reboot your computer). But the basic tactics are the same. Reduce the page's content to the barest minimum HTML by commenting out both scripts and all but `head` and `body` tags. Then begin enabling small chunks to test reloading of the page. Be suspicious of `meta` tags inserted by authoring tools. Their removal can sometimes clear up all crash problems. Eventually you will add something into the mix that will cause the crash. It means that you are close to finding the culprit.

## Preventing Problems

Even with help of authoring and debugging tools, you probably want to avoid errors in the first place. I offer a number of suggestions that can help in this regard.

### Getting structure right

Early problems in developing a page with scripts tend to be structural: knowing that your objects are displayed correctly on the page; making sure that your `<script>` tags are complete; and completing brace, parenthesis, and quoted pairs. I start writing my page by first getting down the HTML parts — including all form definitions. Because so much of a scripted page tends to rely on the placement and naming of interface elements, you will find it much easier to work with these items after you lay them out on the page. At that point, you can start filling in the JavaScript.

When you begin defining a function, repeat loop, or `if` construction, fill out the entire structure before entering any details. For example, when I define a function named `verifyData()`, I enter the entire structure for it:

```
function verifyData() {
}

```

I leave a blank line between the beginning of the function and the closing brace in anticipation of entering at least one line of code.

After I decide on a parameter to be passed and assign a variable to it, I may want to insert an `if` construction. Again, I fill in the basic structure:

```
function verifyData(form) {
    if (form.checkbox.checked) {
    }
}

```

This method automatically pushes the closing brace of the function lower, which is what I want — putting it securely at the end of the function where it belongs. It also ensures that I line up the closing brace of the `if` statement with that grouping. Additional statements in the `if` construction push down the two closing braces.

If you don't like typing or don't trust yourself to maintain this kind of discipline when you're in a hurry to test an idea, you should prepare a separate document that has templates for the common constructions: `<script>` tags, `function`, `if`, `if...else`, `for` loop, `while` loop, and conditional expressions. Then if your editor and operating system support it, drag and drop the necessary segments into your working script.

## Build incrementally

The worst development tactic you can follow is to write tons of code before trying any of it. Error messages may point to so many lines away from the source of the problem that it could take hours to find the true source of difficulty. The save-switch-reload sequence is not painful, so the better strategy is to try your code every time you have written a complete thought — or even enough to test an intermediate result in an alert dialog box — to make sure that you're on the right track.

## Test expression evaluation

Especially while you are learning the ins and outs of JavaScript, you may feel unsure about the results that a particular string, math, or date method yields on a value. The longer your scripted document gets, the more difficult it will be to test the evaluation of a statement. You're better off trying the expression in a more controlled, isolated environment, such as The Evaluator. By doing this kind of testing in the browser, you save a great deal of time experimenting by going back and forth between the source document and the browser.

## Build function workbenches

A similar situation exists for building and testing functions, especially generalizable ones. Rather than test a function inside a complex scripted document, drop it into a skeletal document that contains the minimum number of user interface elements that you need to test the function. This task gets difficult when the function is closely tied to numerous objects in the real document, but it works wonders for making you think about generalizing functions for possible use in the future. Display the output of the function in a text or textarea object or include it in an alert dialog box.

## Testing Your Masterpiece

If your background strictly involves designing HTML pages, you probably think of testing as determining your user's ability to navigate successfully around your site. But a JavaScript-enhanced page — especially if the user enters input into fields or implements Dynamic HTML techniques — requires a substantially greater amount of testing before you unleash it to the online masses.

A large part of good programming is anticipating what a user can do at any point and then being sure that your code covers that eventuality. With multiframe windows, for example, you need to see how unexpected reloading of a document affects the relationships between all the frames — especially if they depend on each other. Users will be able to click Reload at any time or suspend document loading in the middle of a download from the server. How do these activities affect your scripting? Do they cause script errors based on your current script organization?

The minute you enable a user to type an entry into a form, you also invite the user to enter the wrong kind of information into that form. If your script expects only a numeric value from a field, and the user (accidentally or intentionally) types a letter, is your script ready to handle that “bad” data? Or no data? Or a negative floating-point number?

Just because you, as author of the page, know the “proper” sequence to follow and the “right” kind of data to enter into forms, your users will not necessarily follow your instructions. In days gone by, such mistakes were relegated to “user error.” Today, with an increasingly consumer-oriented Web audience, any such faults rest solely on the programmer — you.

If I sound as though I’m trying to scare you, I have succeeded. I was serious in the early chapters of this book when I said that writing JavaScript is *programming*. Users of your pages are expecting the same polish and smooth operation (no script errors and certainly no crashes) from your site as from the most professional software publisher on the planet. Don’t let them or yourself down. Test your pages extensively on as many browsers and as many operating systems as you can and with as wide an audience as possible before putting the pages on the server for all to see.

# Security and Netscape Signed Scripts

---

The paranoia levels about potential threats to security and privacy on the Internet are at an all-time high. As more people rely on e-mail and Web site content for their daily lives and transactions, the fears will only increase for the foreseeable future (an indeterminate number of Web Weeks). As a jokester might say, though, “I may be paranoid, but how do I know someone really isn’t out to get me?” The answer to that question is that you don’t know, and such a person may be out there.

But Web software developers are doing their darnedest to put up roadblocks to those persons out to get you—hence, the many levels of security that pervade browsers. Unfortunately, these roadblocks also get in the way of scripters who have completely honest intentions. Designing a Web site around these barriers is one of the greatest challenges that many scripters face.

## Battening Down the Hatches

When Navigator 2 first shipped to the world way back in the previous century (February 1996), it was the first browser released to include support for Java applets and scripting—two entirely different but often confused technologies. It didn’t take long for clever programmers in the Internet community to find the ways in which one or the other technology provided inadvertent access to client computer information (such as reading file directories) and Web surfer activities (such as histories of where you’ve been on the Net and even the passwords you may have entered to access secure sites).

JavaScript, in particular, was the avenue that many of these programmers used to steal such information from Web site visitors’ browsers. The sad part is that the same features that provide the access to the information were intentionally made a part of the initial language to aid scripters who would put those features to beneficial use in controlled environments, such as intranets. But out in the Wild Wide Web, a scripter could capture a visitor’s e-mail address by having the site’s home page surreptitiously send a message to the site’s author without the visitor even knowing it.

### In This Chapter

Exploring browser security policies

Applying JavaScript to Navigator security mechanisms

Using Netscape signed scripts

Word of security breaches of this magnitude not only circulated throughout the Internet, but also reached both the trade and mainstream press. As if the security issues weren't bad enough on their own, the public relations nightmare compounded the sense of urgency to fix the problem. To that end, Netscape released two revised editions of Navigator 2. The final release of that generation of browser, Navigator 2.02, took care of the scriptable security issues by turning off some of the scripted capabilities that had been put into the original 2.0 version. No more capturing visitors' browser histories; no more local file directory listings; no more silent e-mail. Users could even turn off JavaScript support entirely if they so desired.

The bottom line on security is that scripts are prevented from performing automated processes that invade the private property of a Web author's page or a client's browser. Thus, any action that may be suspect, such as sending an e-mail message, requires an explicit action on the part of the user — clicking a Submit button, in this case — to carry it out. Security restrictions must also prevent a Web site from tracking your activity beyond the boundaries of that Web site.

## When Worlds Collide

If a script tries to do something that is not allowed or is a potential personal security breach, the browser reports the situation to the user. For example, browsers display a warning to the user when a script in a subwindow tries to close the main window.

Another security error message often confuses scripters who don't understand the possible privacy invasions that can accrue from one window or frame having access to the URL information in another window or frame. In WinIE5+, for example, an ominous error message — "Access denied" — warns users of an attempt to access URL information from another frame if that URL is from a different Web site.

Despite the fact that a scripted Web site may have even loaded the foreign URL into the other frame, the security restrictions guard against unscrupulous usage of the ability to snoop in other windows and frames.

## The Java Sandbox

Much of the security model for JavaScript is similar to that originally defined for Java applets. Applets had a potentially dangerous facility of executing Java code on the client machine. That is a far cry from the original deployment of the World Wide Web as a read-only publishing medium on the Internet. Here were mini-programs downloaded into a client computer that, if unchecked, could have the same access to the system as a local software program.

Access of this type would clearly be unacceptable. Imagine the dismay caused by someone clicking a link that said "Free Money," only to have the linked page download an applet that read or damaged local disk files unbeknownst to the user. In anticipation of pranksters, the designers of Java and the Java virtual machine built in a number of safeguards to prevent applets from gaining access to local machines. This mechanism is collectively referred to as the *sandbox*, a restricted area in which applets can operate. Applets cannot extend their reach outside of the sandbox to access local file systems and many sensitive system preferences. Any applet runs only while its containing page is still loaded in the browser. When the page goes away, so does the applet, without being saved to the local disk cache.

JavaScript adopted similar restrictions. The language provided no read or write access to local files beyond the highly regulated cookie file. Moreover, because JavaScript works more closely with the browser and its documents than applets typically do, the language had to build in extra restrictions to prevent browser-specific privacy invasions. For example, it was not possible for a script in one window to monitor the user's activity in another window, including the URL of the other window, if the page didn't come from the same server as the first window. Sometimes the restrictions on the JavaScript side are even more severe than in Java. For example, while a Java applet is permitted to access the network anytime after the applet is loaded, an applet is prevented from reaching out to the Net if the trigger for that transaction comes from JavaScript via LiveConnect (see Chapter 44). Only partial workarounds are available.

Neither the Java nor JavaScript security blankets were fully bug-free at the outset. Some holes were uncovered by the languages' creators and others in the community. To their credit, Sun, Netscape, and Microsoft are quick to plug any holes that are discovered. Although the plugs don't necessarily fix existing copies of insecure browsers out there, it means that a Bad Guy can't count on every browser to offer the same security hole for exploitation. That generally makes the effort not worth the bother.

## Security Policies

Netscape has defined security mechanism under the term *policies*. This usage of the word mirrors that of institutions and governments: A policy defines the way potentially insecure or invasive requests are handled by the browser or scripting language. NN4+/Mozilla includes two different security policies: *same origin* and *signed script* policies. The same origin policy dates back to Navigator 2, although some additional rules have been added to that policy as Navigator has matured. The signed script policy started with NN4 and utilizes the state of the art in cryptographic signatures of executable code inside a browser, whether that code is a plug-in, a Java applet, or a JavaScript script. Because of the signed script facilities, NN4 was designed to allow scripts to have wider range of control over the browser's interior working parts, provided the user granted permission for such activity (more about this later in the chapter). These same facilities are built into today's Mozilla-based browsers. NN3 included a partially implemented prototype of another policy known as data tainting. Signed scripts supersede data tainting, so if you encounter any writings about data tainting, you can ignore them because the technology was abandoned long ago.

By and large, the same origin policy is in force inside IE3 and after. Precise details may not match up with NN one-for-one, but the most common features are identical. The signed script policy is implemented only in NN4+. While Microsoft offers digital signatures for some items that may be embedded within an HTML page (such as ActiveX controls and other components), scripts that are in an HTML page's source code or linked in as a `.js` library cannot be signed for IE. Although everything you read in this chapter about signed scripts applies only to NN4+, you should find the next couple of sections informative even if you develop solely for IE.

## The Same Origin Policy

The "origin" of the same origin policy means the protocol and domain of a source document. If all of the source files currently loaded in the browser come from the same server and domain, scripts in any one part of the environment can poke around the other documents. Restrictions come into play when the script doing the poking and the document being poked come from different origins. The potential security and privacy breaches this kind of access can cause put this access out of bounds within the same origin policy.

An origin is not the complete URL of a document. Consider the two popular URLs for Netscape's Web sites:

```
http://home.netscape.com
http://devedge.netscape.com
```

The protocol for both sites is `http:`. Both sites also share the same domain name: `netscape.com`. But the sites run on two different servers: `home` and `devedge` (at least this is how the sites appear to browsers accessing them; the physical server arrangement may be quite different).

If a frameset contains documents from the same server at `netscape.com`, and all frames are using the same protocol, they have the same origin. Completely open and free access to information, such as `location` object properties, is available to scripts in any frame's document. But if one of those frames contains a document from the other server, their origins don't match. A script in a document from one server would display an "access disallowed" or "permission denied" error message if it tried to get the `location` property of that other document.

A similar problem occurs if you were creating a Web-based shopping service that displays the product catalog in one window and displays the order form from a secure server in another window. The order form, whose protocol might be `https:`, would not be granted access to the `location` object properties in a catalog page whose protocol is `http:`, even though both share the same server and domain name.

## Setting the `document.domain`

When both pages in an origin-protected transaction are from the same domain (but different servers or protocols), you can instruct JavaScript to set the `document.domain` properties of both pages to the domain that they share. When this property is set to that domain, the pages are treated as if from the same origin. Making this adjustment is safe, because JavaScript doesn't allow setting the `document.domain` property to any domain other than the origin of the document making the setting. See the `document.domain` property entry in Chapter 18 for further details.

## Origin checks

Scattered throughout the language reference chapters are notes about items that undergo what you now know to be origin checks. For the sake of convenience, I list them all here to help you get a better feeling for the kind of information that is protected. The general rule is that any object property or method that exposes a local file in a user's system or can trace Web surfing activity in another window or frame undergoes an origin check. Failure to satisfy the same origin rule yields an "access disallowed" or "permission denied" error message on the client's machine.

## Window object checks

The document object models of windows and frames that don't share the same origin are not available to each other. Each separate origin window or frame is its own little world that has very little ability to communicate with another window or frame. IE sometimes takes this to the extreme, causing problems between a main window and a subwindow whose content is entirely dynamically generated from the main window's scripts.

## Location object checks

All `location` object properties are restricted to same origin access. Of all same origin policy restrictions, this one seems to interfere with well-meaning page authors' plans when they want to provide a frame for users to navigate around the Web. Such access, however, would allow spying on your users.

## Document object checks

A `document` object's properties are by necessity loaded with information about the content of that document. Just about every property other than the ones that specify color properties are off-limits if the origin of the target document is different from the one making the request:

```
anchors[]    lastModified
applets[]    length
cookie       links[]
domain       referrer
embeds       title
forms[]      URL
```

In addition, no normally modifiable `document` property can be modified if the origin check fails. This, of course, does not prevent you from using `document.write()` to write an entirely new page of content to the frame to replace a document from a different origin. But in IE4+ and W3C DOM browsers, scripts from one origin won't be able to modify (or even copy) partial content from a frame whose content comes from another origin.

## NN4 layer object checks

Although most of a NN4 layer's content is protected by the restrictions that apply to the `document` object inside, a layer object also has a potentially revealing `src` property. This is essentially similar to the `location.href` property of a frame. Thus the `src` property requires an origin check before yielding its information.

## Form object checks

Form data is generally protected by the restriction to a document's `forms[]` array. But should a script in another window or frame also know the name of the form, that, too, won't enable access unless both documents come from the same origin.

## Applet object checks

The same goes for named Java applets. A script cannot retrieve information about the class filename unless both documents are from the same origin (although the applet can be from anywhere).

LiveConnect access from a Java applet to JavaScript is not an avenue to other windows and frames from other origins. Any calls from the applet to the objects and protected properties described here undergo origin checks when those objects are in other frames and windows. The applet assumes the origin of the document that contains the applet, not the applet codebase.

## Image object checks

While image objects are accessible from other origins, their `src` and `lowsrc` properties are not. These URLs could reveal some or all the URL info about the document containing them.

## Linked script library checks

To prevent a network-based script from hijacking a local script library file, NN4+ prevents a page from loading a `file:` protocol library in the `src` attribute of a `<script>` tag unless the main document also comes from a `file:` protocol source. If you are beginning to think that security engineers are a suspicious and paranoid lot, you are starting to get the idea. It's not easy to curb potential abuses of Bad Guys in a networked environment initially established for openness and free exchange of information among trusted individuals.

## The Netscape Signed Script Policy

Just as there are excellent reasons to keep Web pages from poking around your computer and browser, there are equally good reasons to allow such access to a Web site you trust not to be a Bad Guy. To permit trusted access to the client machine and browser, Sun Microsystems and Netscape (in cooperation with other sources) developed a way for Web application authors to identify themselves officially as authors of the pages and to request permission of the user to access well-defined parts of the computer system and browser.

The technology is called object *signing*. In broad terms, object signing means that an author can electronically lock down a chunk of computer code (whether it be a Java applet, a plug-in, or a script) with the electronic equivalent of a wax seal stamped by the author's signet ring. At the receiving end, a user is informed that a sealed chunk of code is requesting some normally protected access to the computer or browser. The user can examine the "seal" to see who authored the code and the nature of access being requested. If the user trusts the author not to be a Bad Guy, the user grants permission for that code to execute; otherwise the code does not run at all. Additional checks take place before the code actually runs. That electronic "seal" contains an encrypted, reduced representation of the code as it was locked by the author. If the encrypted representation cannot be re-created at the client end (it takes only a fraction of a second to check), it means the code has been modified in transit and will not run.

In truth, nothing prevents an author from being a Bad Guy, including someone you may normally trust. The point of the object signing system, however, is that a trail leads back to the Bad Guy. An author cannot use this technology to sneak into your computer or browser without your explicit knowledge and permission.

### Signed objects and scripts

A special version of the signed object technology is the one that lets scripts be locked down by their author and electronically signed. Virtually any kind of script in a document can be signed: a linked `.js` library, scripts in the document, event handlers, and JavaScript entities. As described later in this chapter, you must prepare your scripts for being signed, and then run the entire page through a special tool that attaches your electronic signature to the scripts within that page.

### What you get with signed scripts

If you sign your scripts and the user grants your page permission to do its job, signed scripts open up your application to a long list of capabilities, some of which border on acting like genuine local applications. Because the designers of NN4+ know that signed scripts are available to authors, a huge number of properties and actions are exposed to authors.

The most obvious power you get with signed scripts is freedom from the restrictions of the same origin policy. All object properties and methods that perform origin checks for access in other frames and windows become available to your scripts without any special interaction with the user beyond the dialog box that requests the one-time permission for the page.

Some operations that normally display warnings about impending actions—sending a form to a `mailto:` URL or closing the main browser window under script control—lose those warning dialog boxes if the user grants the appropriate permission to a signed script. Object properties considered private information, such as individual URLs stored in the history object and browser preferences, are opened up, including the possibility of altering browser preferences.

Existing windows can have their chrome elements hidden. New windows can be set to be always raised or lowered, sized to very small sizes, or positioned offscreen. The `dragdrop` event of a window reveals its URL. All of these are powerful points of access, provided the user grants permission.

Again, however, I emphasize that these capabilities are accessible via Netscape's signed script policy only. Internet Explorer, at least through Version 6, does not support Netscape's signed script policy.

## The Digital Certificate

Before you can sign a script or other object, you must apply for a digital certificate. A digital certificate (also called a digital `id`) is a small piece of software that gets downloaded and bound to the developer's Navigator browser on a particular computer. Each downloaded digital certificate is accessible from the Privacy & Security window of Navigator 7's Preferences, which are found by selecting Preferences from the Edit menu. Open the Privacy & Security category by double-clicking it, which reveals a list of subcategories. The Certificates category contains a button named Manage Certificates, which leads you to the Certificate Manager. The Certificate Manager displays a list of the certificates currently available on your system. If you have not yet applied for a certificate, the list is empty. When you sign a page with the certificate, information about the certificate is included in the file generated by the signing tool.

Possession of a certificate makes you what is known as a principal. If a user loads a page that has signed "stuff" in it, a security alert advises the user that a Web site is requesting enhanced privileges.

Certificates are issued by organizations established as certificate authorities. A certificate authority (known as a `ca` for short), or a certificate server authorized by a `ca`, registers applicants and issues certificates to individuals and software developers. When you register for a certificate, the `ca` queries you for identification information, which it verifies as best it can. The certificate that is issued to you identifies you as the holder of the certificate. Under the "Authorities" category of the Security Manager window are the certificate authorities loaded into the browser when you installed the browser. These are organizations that issue certificates. The `ca` of the organization that issues your certificate must be listed for you to sign scripts.

### How to get a certificate

You must visit a certificate vendor to obtain your certificate. The cost ranges from about \$20 to many hundreds of dollars depending on the vendor and the type of certificate you want to obtain. One vendor that is aware of the needs of Netscape object signing is Thawte Digital Certificate Services ([www.thawte.com](http://www.thawte.com)). This `ca` offers a certificate expressly for developers performing Netscape object signing. Verisign ([www.verisign.com](http://www.verisign.com)) is also recommended.

Because one of the foundations of a certificate is the identity of the certificate owner, registration requires submitting documentation that proves the identity of your organization. Each `ca` has different requirements, so check the latest information at the `ca`'s enrollment Web site. After the `ca` processes your application, the company sends you an e-mail message with a code number to pick up your certificate at the `ca`'s Web site. The act of picking up the certificate is actually downloading the certificate into your browser. Therefore, be sure you are using the Navigator browser on the computer with which you will use to sign your pages.

## Activating the codebase principal

If you want to try out the capabilities available to signed scripts from a server without purchasing a certificate (or without going through the signing process described later in this chapter during script development and debugging), you can set up your copy of Navigator to accept what is called a *codebase* principal in place of a genuine certificate. A codebase principal means that the browser accepts the source file as a legitimate principal, although it contains no identification as to the owner or certificate.

### Note

You can experiment with properties and methods that normally require signed scripts without modifying the codebase principal preferences or signing scripts with a certificate. Each time you activate the Privilege Manager (as The Evaluator does when you check the “Use NN Codebase Security” checkbox), a security alert lets you elect to continue with the untrusted access to your browser or system. **Do not check the box in the alert dialog that remembers this choice** because it could leave your browser and system vulnerable to other unsigned scripts without your knowledge.

Depending on which version of Navigator you are running, if you set up your browser for codebase principals, you may not be able to verify a certificate that is presented to you when accessing someone else’s Web site — even if it is a valid cryptographic certificate. Therefore, even though secure requests won’t slip past you silently, your Navigator won’t necessarily have the protective shield it normally does to identify certificate holders beyond the URL of the code. Enable codebase principals only on a copy of Navigator that doesn’t venture beyond your development environment. To activate codebase principals for your copy of Navigator, follow these steps:

1. Quit Navigator.
2. Search your hard disk for a Navigator 4 support file named `prefs.js` or Navigator 6+ support file named `all.js`.
3. Edit the version-specific file in a text editor as follows:
  - a. For NN4, add the following line to the end of the `prefs.js` file:
 

```
user_pref("signed.applets.codebase_principal_support", true);
```
  - b. For NN6+, change the `codebase_principal` preference in `all.js` from `false` to `true`:
 

```
pref("signed.applets.codebase_principal_support", true);
```
4. Save the file.

To deactivate codebase principals, quit Navigator and then change the `true` setting of the affected line to `false`. Because NN/Moz rebuilds the preference file upon quitting, the entry will be in alphabetical order rather than at the end of the file where you first entered it. This preferences setting does not affect your ability to sign scripts with your certificate as described in the rest of this chapter.

## Signing Scripts

The process of signing scripts entails some new concepts for even experienced JavaScript authors. You must use a separate signing tool program. You must also prepare the page that bears scripts so that the tool and the object signing facilities of the browser can do their jobs.

## Signing tool

Download the latest version of Netscape's SignTool from links you find at <http://developer.netscape.com:80/software/signedobj/jarpack.html> (you find different versions for a variety of Windows and UNIX versions). This tool includes a utility program called a JAR Packager. A JAR file is a special kind of zipped file collection that has been designed to work with the Navigator security infrastructure. The letters of the name stand for Java ARchive, which is a file format standard developed primarily by Sun Microsystems in cooperation with Netscape and others.

A JAR file's extension is `.jar`, and when it contains signed script information, it holds at least one file, known as the *manifest*, or list of items zipped together in the file. Among the items in the manifest is certificate information and data (a hash value code) about the content of the signed items at the instant they were signed. In the case of a single page containing signed scripts, the JAR file contains only the certificate and hash values of the signed scripts within the document. If the document links in an external `.js` script library file, that library file is also packaged in the JAR file. Thus, a page with signed scripts occupies space on the server for the HTML file and its companion JAR file.

The SignTool program combines the JAR Packager with the script signing functions (originally a separate program called `zigbert.exe`). Follow links on the SignTool download page to the latest instructions on packaging and signing your finished files from the command line (there is no GUI for this tool). But before you reach that point, you need to compose your pages in a way that the security mechanism can protect your scripts.

## Preparing scripts for signing

Signifying which items in a page are script items that require signing is up to the page author. It is important to remember that if you want to sign even one script element in a document, *every* script in the document must be signed. By "document," I mean an object model document. Because the content of an NN4-only `<layer>` tag exists in its own document, you don't have to sign its scripts if they don't require it, nor communicate with the signed scripts in the main document.

The first concept you have to master is recognizing what a script is. For signing purposes, a script is more than just the set of statements between a `<script>` and `</script>` tag boundary. An event handler—even one that calls a function living in a `<script>` tag—is also a script that needs signing. So, too, is a JavaScript entity used to supply a value to an HTML tag attribute. Each one of these items is a script as far as script signing is concerned.

Your job is to mark up the file with special tag attributes that do two things: 1) help SignTool know what items to sign in a file; and 2) help the browser loading the signed document know what items to run through the hash routine again to compare against the values stored in the JAR file.

## The archive attribute

The first attribute goes in the first `<script>` tag of the file, preferably near the very top of the document in the `<head>` portion. This attribute is the `archive` attribute, and its value is the name of the JAR file to be associated with the HTML file. For example:

```
<script type="text/javascript" archive="myArchive.jar" id="1">
```

You can add script statements to this tag or immediately end it with a `</script>` tag.

The SignTool utility uses the `archive` attribute to assign a name to its archive output file. After the signed page loads into the visitor's browser, the attribute points to the file containing signed script information. Having more than one JAR archive file associated with a signed page is possible. Typically, such a situation calls for a second JAR archive overseeing a confined portion of the page. That second archive file may even be embedded in the primary archive file, allowing a script segment signed by one principal to be combined with scripts signed by a different principal.

## The `id` attribute

More perplexing to scripters coming to script signing for the first time is the `id` attribute. The `id` attribute is merely a label for each script. Each script must have a label that is unique among all labels specified for a JAR archive file.

As with the `archive` attribute, the `id` plays a dual role. When you run your page through SignTool, the utility scans the page for these `id` attributes. When SignTool encounters one, it calculates a hash value (something like a checksum) on the content of the script. For a `<script>` tag set, it is for the entire content of the tag set; for an event handler, it is for the event handler text. The hash value is associated with the `id` attribute label and stored inside the JAR file. After the document loads into the client's browser, the browser also scans for the `id` attributes and performs the same hash calculations on the script items. Then the browser can compare the `id`/hash value pairs against the list in the JAR file. If they match, then the file has arrived without being modified by a Bad Guy (or a dropped bit in the network).

Most examples show `id` attribute values to be numbers, but the attributes are actually strings. No sequence or relationship exists among `id` attribute values: you can use the names of your favorite cartoon show characters, as long as no two `id` attributes are given the same name. The only time the same `id` attribute value may appear in a document is if another JAR file is embedded within the main JAR file. Even so, I recommend avoiding reusing names inside the same HTML file, no matter how many JAR files are embedded.

With one exception, each script item in a document must have its own `id` attribute. The exception is a `<script>` tag that specifies a `src` attribute for an external `.js` file. That file is part of the JAR file, so the browser knows it's a signed script.

For other `<script>` tags, include the `id` attribute anywhere within the opening tag, as follows:

```
<script type="text/javascript" id="3">
  statements
</script>
```

For a function handler, the `id` attribute comes after the event handler inside the object tag, as follows:

```
<input type="button" value="Calculate" onclick="doCalc(this.form)" id="bart" />
```

And for a JavaScript entity, the `id` attribute must be specified in an empty `<script>` tag immediately before the tag that includes the entity for an attribute value, as follows:

```
<script id="20">
<input type="text" name="date" value=&{getToday()}; />
```

Listing 46-1 shows a skeletal structure of a document that references a single JAR file and includes five signed scripts: one external `.js` file and four script items in the document itself. The `fetchFile()` function invokes a function imported from `access.js`. Notice that the `archive` attribute appears in the very first `<script>` tag in the document. This also happens to be a tag that imports an external `.js` file, so that no `id` attribute is required. If there were

no external library file for this page, the `archive` attribute would be located in the main `<script>` tag, which also has the `id` attribute. I arbitrarily assigned increasing numbers as the `id` attribute values, but I could have used any identifiers. Notice, too, that each script has its own `id` value. Just because an event handler invokes a function in a `<script>` tag that has an `id` value doesn't mean a relationship exists between the `id` attribute values in the `<script>` tag and in the event handler that invokes a function there.

### Listing 46-1: Basic Signed Script Structure

```
<html>
  <head>
    <title>Signed Scripts Testing</title>
    <script type="text/javascript" archive="myArchive.jar" src="access.js">
    </script>
    <script type="text/javascript" id="1">
      function fetchFile(form) {
        form.output.value = getFile();
      }
      function newRaisedWindow() {
        // statements for this function
      }
    </script>
  </head>
  <body>
    A Source Code Example Only
    <form>
      <textarea name="output" cols="60" rows="10" wrap="virtual">
      </textarea><br />
      <input type="button" value="Read File"
      onclick="this.form.output.value = ''; fetchFile(this.form);"
      id="2" /><br />
      <textarea name="input" cols="60" rows="10" wrap="virtual">
      </textarea><br />
      <input type="button" value="Save File"
      onclick="setFile(this.form.input.value);" id="3" />
      <p><input type="button" value="New Window&#201;"
      onclick="newRaisedWindow();" id="4" /></p>
    </form>
  </body>
</html>
```

## Editing and moving signed scripts

The nature of the script signing process requires that even the slightest modification you make to a signed script source code requires re-signing the page. For this reason, enabling codebase principals while you create and debug your early code is a convenient alternative.

The rigid link between the hash value of a script element at both the signing and visitor loading times means that you must exercise care when shifting an HTML file that contains signed script elements between servers of differing operating systems. Windows, UNIX, and Macintosh have different ways of treating carriage returns. If you change the representation of an HTML source file when you move the source from, say, a Windows machine to a UNIX server, the

signature may no longer work. However, if you perform a purely binary transfer of the HTML files, every byte is the same, and the signature should work. This operating system-specific text representation affects only how files are stored on servers, not how various client platforms interpret the source code.

## Accessing Protected Properties and Methods

For the browser to allow access to protected properties or methods, it must have its privileges enabled. Only the user can grant permission to enable privileges, but it is up to your code to request those privileges of the user.

### Gaining privileges

NN4+ comes with some Java classes that allow signed scripts and other signed objects to display the privilege request alert windows, and then turn on the privileges if the user clicks the “OK” or “Grant” button. A lot of these classes show up in the `netscape.security` package, but scripters only work directly with one class and three of its methods:

```
netscape.security.PrivilegeManager.enablePrivilege(["targetName"])
netscape.security.PrivilegeManager.revertPrivilege(["targetName"])
netscape.security.PrivilegeManager.disablePrivilege(["targetName"])
```

The `enablePrivilege()` method is the one that displays the security alert for the user. In NN4, the specific target named as a parameter influenced the details of the security alert message; for NN6+, the security alert is generic (and far less intimidating).

If the user grants the privilege, script processing continues with the next statement. But if the user denies access, then processing stops, and the `PrivilegeManager` class throws a Java exception that gets displayed as a JavaScript error message. Later in this chapter I show you how to gracefully handle the user’s denial of access.

Enabling a privilege in JavaScript is generally not as risky as enabling a Java applet. The latter can be more easily hijacked by an alien class to piggyback on the trusted applet’s privileges. Even though the likelihood of such activity taking place in JavaScript is very low, turning privileges off after the statement that requires privileges is always a good idea. Use the `revertPrivilege()` method to temporarily turn off the privilege; another statement that enables the same privilege target will go right ahead without asking the user again. Disable privileges only when the script requiring privileged access won’t be run again until the page reloads.

### Specifying a target

Rather than opening blanket access to all protected capabilities in one blow, the Netscape security model defines narrow capabilities that are opened up when privileges are granted. Each set of capabilities is called a target. Netscape defines dozens of different targets, but not all of them are needed to access the kinds of methods and properties available to JavaScript. You will likely confine your targets to the nine discussed here.

Because NN4’s security alerts provided (at times excruciating) detail about the nature of the privilege being requested by the Web site, targets had various risk levels and categories. These concerns are less of an issue in NN6+, but they are provided here for your more complete understanding of the mechanisms beneath the Privilege Manager.

Each target has associated with it a risk level (low, medium, or high) and two plain-language descriptions about the kinds of actions the target exposes to code. This information appears in the NN4 security privilege dialog box that faces a user the first time a particular signature requests privileges. All of the targets related to scripted access are medium or high risk, because they tend to open up local hard disk files and browser settings.

Netscape has produced two categories of targets: primitive and macro. A *primitive target* is the most limited target type. It usually confines itself to either reading or writing of a particular kind of data, such as a local file or browser preference. A *macro target* usually combines two or more primitive targets into a single target to simplify the user experience when your scripts require multiple kinds of access. For example, if your script must both read and write a local file, it could request privileges for each direction, but the user would be presented with a quick succession of two similar-looking security dialog boxes. Instead, you can use a macro target that combines both reading and writing into the privilege. The user sees one security dialog box, which, in NN4, explains that the request is for both read and write access to the local hard disk.

Likely targets for scripted access include a combination of primitive and macro targets. Table 46-1 shows the most common script-related targets and the information that appears in the security dialog box.

For each call to `netscape.security.PrivilegeManager.enablePrivilege()`, you specify a single target name as a string, as in

```
netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserRead");
```

This specification allows you to enable, revert, and disable individual privileges as required in your script.

---

**Table 46-1: Scripting-Related Privilege Targets**

---

<i>Target Name</i>		
<i>Risk</i>	<i>Short Description</i>	<i>Long Description</i>
		Universal BrowserAccess
High	Reading or modifying browser data	Reading or modifying browser data that may be considered private, such as a list of Web sites visited or the contents of Web forms you may have filled in. Modifications may also include creating windows that look like they belong to another program or positioning windows anywhere on the screen.
		Universal BrowserRead
Medium	Reading browser data	Access to browser data that may be considered private, such as a list of Web sites visited or the contents of Web page forms you may have filled in.
		Universal BrowserWrite
High	Modifying the browser	Modifying the browser in a potentially dangerous way, such as creating windows that may look like they belong to another program or positioning windows anywhere on the screen.

*Continued*

**Table 46-1** (continued)

<i>Target Name</i>		
<i>Risk</i>	<i>Short Description</i>	<i>Long Description</i>
	<code>Universal FileAccess</code>	
High	Reading, modifying, or deleting any of your files	This form of access is typically required by a program such as a word processor or a debugger that needs to create, read, modify, or delete files on hard disks or other storage media connected to your computer.
	<code>Universal FileRead</code>	
High	Reading files stored in your computer	Reading any files stored on hard disks or other storage media connected to your computer.
	<code>Universal FileWrite</code>	
High	Modifying files stored in your computer	Modifying any files stored on hard disks or other storage media connected to your computer.
	<code>Universal PreferencesRead</code>	
Medium	Reading preferences settings	Access to read the current settings of your preferences.
	<code>Universal PreferencesWrite</code>	
High	Modifying preferences settings	Modifying the current settings of your preferences.
	<code>Universal SendMail</code>	
Medium	Sending e-mail messages on your behalf	

## Blending Privileges into Scripts

The implementation of signed scripts in Navigator protects scripters from many of the potential hazards that Java applet and plug-in developers must watch for. The chance that a privilege enabled in a script can be hijacked by code from a Bad Guy is very small. Still, exercising safe practices in case you someday work with other kinds of signed objects is good practice.

### Keep the window small

Privilege safety is predicated on limiting exposure according to two techniques. The first technique is to enable only the level of privilege required for the protected access your scripts need. For example, if your script only needs to read a normally protected `document` object property, enable the `UniversalBrowserRead` target rather than the wider `UniversalBrowserAccess` macro target.

The second technique is to keep privileges enabled only as long as the scripts need them enabled. If a statement calls a function that invokes a protected property, enable the privilege for that property in the called function, not at the level of the calling statement. If a privilege is enabled inside a function, the browser automatically reverts the privilege at the end of the function. Even so, if the privilege isn't needed all the way to the end of the function, you should explicitly revert it after you are through with the privilege.

## Think of the users

One other deployment concern focuses more on the user's experience with your signed page. You should recognize that the call to the Java `PrivilegeManager` class is a LiveConnect call from JavaScript in NN4. Because the Java virtual machine does not start up automatically when Navigator 4 does, a brief delay occurs the first time a LiveConnect call is made in a session (the status bar displays "Starting Java..."). Such a delay may interrupt the user flow through your page if, for example, a click of a button needs access to a privileged property. Therefore, consider gaining permission for protected access as the page loads. Execute an `enablePrivilege()` and `revertPrivilege()` method in the very beginning. If Java isn't yet loaded into the browser, the delay is added to the other loading delays for images and the rest of the page. Thereafter, when privileges are enabled again for a specific action, neither the security dialog box nor the startup delay get in the way for the user.

Also remember that users don't care for security dialog boxes to interrupt their navigation. If your page utilizes a couple of related primitive targets, at the outset enable the macro target that encompasses those primitive targets. The user gets one security dialog box covering all potential actions in the page. Then let your script enable and revert each primitive target as needed.

## Example

To demonstrate signed scripts in action, I show a page that accesses a typical target that allows the script to open an always-raised new window. No error checking occurs for the user's denial of privilege in this example. Therefore, if you experiment with this page (either with codebase principals turned on or signing them yourself), you will see the JavaScript error that displays the Java exception. Error detection is covered later in the chapter.

## Accessing a protected window property

Listing 46-2 is a small document that contains one button. The button calls a function that opens a new window with the NN-proprietary `alwaysRaised` parameter turned on. Setting `protected window.open()` parameters in NN4+ requires the `UniversalBrowserWrite` privilege target. Inside the function, the privilege is enabled only for the creation of the new window. For this simple example, I do not enable the privilege when the document loads.

### Listing 46-2: Creating an alwaysRaised Window

```
<html>
  <head>
    <title>Simple Signed Script</title>
    <script type="text/javascript" archive="myJar.jar" id="1">
      function newRaisedWindow() {
        netscape.security.PrivilegeManager.enablePrivilege(
          "UniversalBrowserWrite");
        var newWindow =
          window.open("", "", "HEIGHT=100,WIDTH=300,alwaysRaised");
        netscape.security.PrivilegeManager.disablePrivilege(
          "UniversalBrowserWrite");
      }
    </script>
  </head>
</html>
```

*Continued*

## Listing 46-2 (continued)

```

var newContent = "<html><body><b>It\\'s good to be the King!</b>";
newContent += "<form><center><input type='button' value='OK'";
newContent +=
    "onclick='self.close()'></center></form></body></html>";
newWindow.document.write(newContent);
newWindow.document.close();
}
</script>
</head>
<body>
<b>This button generates an always-raised new window.</b>
<form>
  <input type="button" value="New 'Always Raised' Window"
    onclick="newRaisedWindow()" id="2" />
</form>
</body>
</html>

```

Listing 46-2 has two script items that need signing: the `<script>` tag and the event handler for the button. Also, the `archive` attribute points to the JAR file that contains the script signature. Note that this example file is not signed, and therefore does not include a companion JAR archive on the CD-ROM.

## Handling Privilege Manager Errors

The change between the ways NN4 and NN6+ allows scripts to intercept errors causes no small problem if you need to serve both browser versions. The primary reason you want to handle errors is that when a user denies access to advanced privileges, the `PrivilegeManager` generates an error. Although the error is not destructive in any way, and it appears only in the JavaScript Console window (NN4.5+), accounting for such factors is good coding practice. Unfortunately, the mechanism that works for NN4 doesn't work in NN6+; the mechanism that works in NN6+ cannot even be placed in a page that loads into NN4 without generating syntax errors. So, if you plan on still supporting NN4, you'll need to serve up different pages for NN4 and NN6+.

For NN4, you can define an `onerror()` function that looks for the specific error message thrown by the `PrivilegeManager` class through `LiveConnect`. That function looks like the following:

```

function onerror(msg, URL, lineNum) {
    var errorMsg = msg;
    if (msg.indexOf("ForbiddenTargetException") != -1) {
        errorMsg = "You have elected not to grant privileges to this script.";
    }
    alert(errorMsg);
    return true;
}

```

Of course, you don't have to display any message, but it may be a good place to advise users about what they're missing by not granting privilege.

For NN6+, you can use the native `try...catch` exception handling, which means that the calls to the `enablePrivilege()` method of the `PrivilegeManager` class must be wrapped inside a `try` block. The function from Listing 46-2 is modified as follows:

```
function newRaisedWindow() {
  try {
    netscape.security.PrivilegeManager.enablePrivilege(
      "UniversalBrowserWrite");
  }
  catch(err) {
    alert("You have elected not to grant privileges to this script.");
    return;
  }
  var newWindow = window.open("", "", "HEIGHT=100,Width=300,alwaysRaised");
  netscape.security.PrivilegeManager.disablePrivilege("UniversalBrowserWrite")
  var newContent = "<html><body><b>It's good to be the King!</b>";
  newContent += "<form><center><input type='button' value='OK'";
  newContent += "onclick='self.close()' /></center></form></body></html>";
  newWindow.document.write(newContent);
  newWindow.document.close();
  return;
}
```

## Signed Script Miscellany

In this last section of the chapter, I list some of the more esoteric issues surrounding signed scripts. Three in particular are: 1) how to allow unsigned scripts in other frames, windows, or layers to access signed scripts; 2) how to make sure your signed scripts are not stolen and reused; and 3) special notes about international text characters.

### Exporting and importing signed scripts

JavaScript provides an escape route that lets you intentionally expose functions from signed scripts for access by unsigned pages. If such a function contains a trusted privilege without careful controls on how that privilege is used, a page that is not as well intentioned as yours could hijack the trust.

The command for exposing this function is `export`. The following example exports a function named `fileAccess()`:

```
export fileAccess;
```

A script in another window, frame, or layer can use the `import` command to bring that function into its own set of scripts:

```
import fileAccess;
```

Even though the function is now also a part of the second document, it executes within the context of the original document, whose signed script governs the privilege. For example, if you exported a function that did nothing but enable a file access privilege, a Bad Guy who studies your source code could write a page that imports that function into a page that now has unbridled file access.

If you wish to share functions from signed scripts in unsigned pages loaded into your own frames or layers, avoid exporting functions that enable privileges. Other kinds of functions, if hijacked, can't do the same kind of damage as a privileged function can.

## Locking down your signed pages

Speaking of hijacking scripts, it would normally be possible for someone to download your HTML and JAR archive files and copy them to another site. When a visitor comes to that other site and loads your copied page and JAR file, your signature is still attached to the scripts. Although this may sound good from a copyright point of view, you may not want your signature to appear as coming from someone else's Web server. You can, however, employ a quick trick to ensure that your signed scripts work only on your server. By embedding the domain of the document in the code, you can branch execution so that scripts work only if the file comes from your server.

The following script segment demonstrates one way to employ this technique:

```
<script type="text/javascript" archive="myPage.jar" id="1">
if (document.URL.match(/^http:\\\\www.myDomain.com\\/\\/)) {
    privileges statements execute only from my server
}
</script>
```

Even though this branching code is visible in the HTML file, the hash value of your code is saved and signed in the archive. If someone modifies the HTML, the hash value that is recalculated when a visitor loads the page won't match the JAR file manifest, and the script signature fails.

## International characters

Although international characters are fine for HTML content, they should not be used in signed scripts. The problem is that international characters are often converted to other character sets for display. This conversion invalidates the signature, because the signed and recalculated hash values don't match. Therefore, do not put international characters in any signable script item. If you must include such a character, you can escape it or, in NN4, put such scripts in unsigned layers.

# Cross-Browser Dynamic HTML Issues

---

**V**ersion 4 browsers — NN4 and IE4 — were the first browsers to include World Wide Web technologies that gave page authors far more control over the display and interactive behavior of Web page content. Lumped together under the heading of Dynamic HTML (DHTML), these technologies dramatically extended the simple formatting of standard HTML that page authors had used for years. These days, scripters and designers coming to Web development for the first time take DHTML capabilities for granted; they are probably unaware that plain ol' HTML is little more than a specification to assign context to static text and images on a page.

A lot of what the user gets with DHTML had previously been accomplished only via Java applets and plug-ins, such as early versions of Shockwave (pre-Flash). Not that DHTML eliminates these technologies from the Web author's arsenal (DHTML doesn't do sound or video, for example), but because DHTML can accomplish much more of what authors look for in assembling page content and layout without the long downloads of applets or plug-in content, it becomes an attractive way for nonprogrammers to spice up Web applications.

Perhaps categorizing DHTML authors as “nonprogrammers” is not quite right. DHTML also adds significantly to the vocabulary required to incorporate dynamic content into pages. Suddenly HTML becomes a lot more programming than simply adding tags to existing content. And if you want to do dynamic positioning of elements, be prepared to put your JavaScript skills to use.

## What Is DHTML?

You can practically find as many definitions of Dynamic HTML as there are people to ask. My definition covers a broad range, because DHTML is not really any one “thing.” Instead it is an amalgam of several technologies, each of which has a standards effort in varying stages of readiness. The key technologies are as follows: Cascading Style Sheets (CSS); Document Object Model (DOM); and client-side scripting. It will help your authoring skills if you have a little historical perspective on how the Web arrived at DHTML.

### In This Chapter

Introducing  
Dynamic HTML

The common  
denominator of  
DHTML functionality  
across browsers

Upgrading to modern  
compatibility techniques

For many years, the HTML standard was intended for the rendering of static content — not much more than an electronic version of a printed page. The most interactive part of a page was a form, which included buttons to click and text boxes to fill in. But for anything to change on the page, the content had to be served up again from the host computer.

Client-side scripting, as first implemented through JavaScript in NN2, opened the way for HTML pages to not only contain some “smarts,” but also control individual pieces of content on the page without fetching a modified page from the server. At first, only form control elements were scriptable. Soon thereafter, images could be swapped, although the rectangular space for the image was fixed when the page loaded. More dynamism accrued to pages in NN4 by way of the layer, which acted like a borderless, transparent or opaque window that could contain its own HTML document content and be positioned anywhere on the page, including overlapping content on the main page or other layers. A layer’s entire content could be modified without touching the rest of the page or other layers.

But the real breakthrough in dynamism came in IE4, whose rendering engine permitted any element to be modified, inserted, or removed on the fly, while the rest of the page reflowed its content quickly and automatically in response to the change. At the same time, an accepted standard for stylesheets (Cascading Style Sheets) opened the way for scripts to modify the look of content already on the page. Text could change colors when a cursor rolled atop it by either adjusting the stylesheet property associated with the text or changing the stylesheet rule that applies to the text.

Development activity at both Netscape and Microsoft eventually led to a standard for the Document Object Model as a way for scripts to control HTML content directly. Unfortunately, the browser makers frequently implemented first, and only then tried to establish their implementations as standards. Sometimes the implementations were not as complete as the standards became, leaving the browsers in states that only partially implement the standards, while paying homage to legacy implementations. Netscape used the occasion of developing an entirely new code base for what became the Mozilla browser family to try to sever some ties with the past. In many respects the Mozilla browser represents the state of the standard art as implemented so far. Newest versions of IE, on the other hand, must try to cater to both the legacy implementation and the standards, creating a massive DOM implementation with significant overlap in functionality with different syntaxes. Thus, the result of proprietary explorations and industry standards is a choice of modern browsers that permit a wide range of dynamic activity on content that reaches the browser. Browsers that had started life as sleepy renderers of a tiny HTML vocabulary have grown into powerful front ends for server applications, if not self-contained applications of a sort that execute entirely on the client computer.

Standards for CSS, DOM, and ECMA scripting have been well covered earlier in this book. The purpose of this chapter is to demonstrate approaches to accommodating the sometimes vast differences in specific implementations of these technologies (including browser-specific variations) to produce content that runs on as many DHTML-capable browsers as possible. Most of the problems, as you are well aware from Chapters 15 and 39, are caused by page authors trying to develop for essentially three different document object models: NN4, IE4+, and W3C DOM (as implemented in IE5+/NN6+/Mozilla/Safari).

## Striving for Compatibility

With as many as three object models to support (you can, of course, elect to support only a subset of browsers if you like) you should look for ways to minimize your pain. If the NN4 object model is in your mix, you will very likely experience moments of sheer torture, as you try to get even the CSS-supported HTML to behave as it does in browsers of the other object models. Thankfully, the NN4 browser's installed base is quickly becoming a remnant of the past.

Two keys to survival are among the object models: knowing each DOM's limitations and finding common denominators.

In the area of DHTML limitations, NN4 is the clear winner. Compared to the automatic content reflowing of IE4+ and W3C DOM browsers, the NN4 object model is painfully static. For example, dynamically changing the color of a chunk of text in response to a rollover is a difficult task in NN4 requiring the careful positioning of a layer atop main page text; and making any inline modification to content (other than swapping an image of the same size) is completely out of the question. Between the IE4+ and W3C DOMs, the biggest differences fall more along operating system and browser brand lines. Microsoft takes advantage of the integration of the IE browser and the Windows operating system to such an extent that it can provide IE services that work only on Windows versions of IE. MacIE users are out of luck (for text filters, for instance), as are users of any other browser brand.

Looking for areas of commonality — or at least gaining a clear understanding of where the models diverge — can be a tedious, yet personally rewarding pursuit. For example, one of the biggest problems facing designers for all three DOMs is the way scripts must reference elements that are to be moved or hidden (something that all three object models can do). NN4 requires references that take the layer object structure into account; IE4+ has the Microsoft syntax of `document.all`, which provides a reference avenue to any element whose `id` attribute is set; and the W3C DOM (as implemented in IE5+/NN6+/Mozilla/Safari) uses a finger-twisting (albeit now industry standard) `document.getElementById()` method to obtain a reference to any ID'd element.

As soon as your script has a valid reference to an element, the next step is to read or write some property, or invoke some method of that object that governs the element's position (and possibly other style) attributes. Here, again, the object models diverge, but not quite as severely. NN4 has a singular implementation that provides properties and methods of positioned elements (layer objects) directly; the IE4+ and W3C DOMs, on the other hand, work their positioning magic through the `style` property of a positioned element. In some cases the "last-dot" property names are identical across all three models (for example, `document.myLayer.zIndex`, `document.all.myLayer.style.zIndex`, and `document.getElementById("myLayer").style.zIndex`). Building a reference to reach that last dot, though, is where some of your hard work must go.

Each DOM also has its own event model. Whereas IE5+ overlaps its DOM features with both the IE4+ and to some extent the W3C DOM, the event models don't follow the same lines of implementation. As of WinIE6 and MacIE5, IE does not implement any of the W3C DOM event model, although Mozilla-based browsers do.

The bottom line, then, is letting your scripts decide how to perform actions based on the browser version is not a good idea. Instead, the scripts should be smart enough to act based on the capabilities of the browser that is currently running the script. As you see in the rest of this chapter, it is possible to develop fairly sophisticated DHTML into a page and make it work with all three DOMs without one iota of browser version detection.

## Working Around Incompatibilities

To create DHTML for multiple DOMs, you must find ways to accommodate incompatible object references and occasionally incompatible property names. Scripting gives you several alternatives to working your way around these potential problems. Some of the approaches you can take are now passe, but they are described here partly for the sake of historical reference, but also because you will see many instances of these approaches taken in legacy DHTML applications from the days when authors had to worry about only two DOMs (NN4 and IE4). The real “meat” of this discussion comes later, when you learn more about object detection and custom APIs.

### Old-fashioned compatibility tricks

In a simpler time (until late 2000), it was possible to write cross-browser DHTML applications that had to run on only two classes of browser: NN4 and IE4. Two approaches to writing code for these two DOMs grew in popularity: inline branching and platform equivalency. They are described here, not for you to apply, but for you to understand what the pioneers did, in case you encounter their code in your Web surfing.

#### Inline branching

The idea behind inline branching is that your scripts will use `if...else` decisions to execute one branch of code for one browser and another branch for the other browser. Before you can begin to write code that creates branches for each browser, you should define two global variables at the top of the page that act as Boolean flags for your `if...else` constructions later. Therefore, at the first opportunity for a `<script>` tag in a page, include the following code fragment to set flags named `isNav4` and `isIE4`:

```
var isNav4, isIE4;
if (parseInt(navigator.appVersion) == 4) {
    if (navigator.appName == "Netscape") {
        isNav4 = true;
    } else if (navigator.appVersion.indexOf("MSIE") != -1) {
        isIE4 = true;
    }
}
```

Version checking here is quite specific. First of all, it intentionally limits access to browsers whose versions come back as version 4. This code, written when the browsers were still at version 4, was remarkably prescient. My concern at the time was that DHTML was so volatile that it was unknown if future browser versions would be backward compatible with the code to be run inside branches governed by the two global variables. As it turned out, NN6 (whose `navigator.appVersion` reports 5) is not backward compatible with the layer structure of NN4, so that locking the NN4 branches to NN4 became a good thing. On the IE side, the `navigator.appVersion` property continues to report 4, even through IE6, which is backward compatible

with IE4. Thus, any branch dedicated to IE4 executes under this scheme and remains syntactically accurate.

Another aspect of the flag-setting script I should mention is that the example provides no escape route for browsers that aren't level 4 or aren't either Navigator or Internet Explorer (should there be a level 4 browser from another brand). In a production environment, I would either prefilter access to the page or redirect ill-equipped users to a page that explains why they can't view the page. In the structure of the preceding script, redirection would have to be made in two places, as follows:

```
var isNav4, isIE4;
if (parseInt(navigator.appVersion) == 4) {
    if (navigator.appName == "Netscape") {
        isNav4 = true;
    } else if (navigator.appVersion.indexOf("MSIE") != -1) {
        isIE4 = true;
    } else {
        location = "sorry.html";
    }
} else {
    location = "sorry.html";
}
```

Later in this chapter, I discuss the issue of designing DHTML pages that degrade gracefully in pre-DHTML browsers.

With the global variables defined in the document (and unsupported browsers redirected elsewhere), you can use them as condition values in branching statements that address an object according to the reference appropriate for each platform. For example, to change the visibility property of an object named `instructions`, you use the flags as follows:

```
if (isNav4) {
    document.instructions.visibility = "hidden";
} else {
    document.all.instructions.style.visibility = "hidden";
}
```

As the browser DOMs evolve, expand, and fragment, inline branching becomes increasingly less practical. With so many permutations of DOM according to browser brand, browser version, and operating system, you can drive yourself crazy trying to accommodate them all and maintain the code going forward. This approach also eliminates from consideration any non-NN or non-IE browser (such as Opera), which may have the capabilities needed to play your DHTML scripts. This approach also limits the possibility that future browsers with higher `navigator.appVersion` values can take advantage of your scripts.

## Platform equivalency

Another technique attempts to limit the concern for the different ways each platform refers to a positionable element (because cross-browser DHTML is pretty much limited to the properties affecting positionable elements). If you examine the formats for each platform's object references, you see that all formats contain a reference to the `document` and to the object name or ID. The IE4+ DOM syntax also includes property words, such as `all` and `style`. If you assign these extra property names to variables for IE4 and leave those variables as empty strings for NN4, you can assemble an object reference for those two platforms in one statement.

To begin using this technique, set two global variables that store reference components for the scope (`all` in IE4) and the `style` object (`style` in IE4):

```
var range = "";
var styleObj = "";
if (parseInt(navigator.appVersion) == 4) {
    if (navigator.appVersion.indexOf("MSIE") != -1) {
        range = "all.";
        styleObj = ".style";
    }
}
```

From this point, you can assemble an object reference with the help of the JavaScript `eval()` function, as follows:

```
var instrux = eval("document." + range + "instructions" + styleObj);
instrux.visibility = "hidden";
```

Or, you can use the `eval()` function to handle the entire property assignment in one statement, as follows:

```
eval("document." + range + "instructions" + styleObj +
    ".visibility = 'hidden'");
```

If your page does not have a lot of objects that your scripts will be adjusting, you can use this platform equivalency approach to create global variables holding references to your positionable objects at load time (triggered by the `onload` event handler so that all objects exist and can be referenced by the `eval()` function). Then, use those variables for object references throughout the scripts.

Unfortunately, the platform equivalency methodology breaks down when an NN4 layer object is nested inside another layer. The platform equivalency formulas assume that each object is directly addressable from the outermost `document` object. If your objects have a variety of nested locations, you can use either the inline branching method described earlier, or batch-assign objects to global variables at load time using platform branching techniques along the lines of the following example:

```
var instrux;
function initObjectVars() {
    if (isNav4) {
        instrux = document.outerLayer.document.instructions;
    } else {
        instrux = document.all.instructions.style;
    }
}
```

As soon as the variable contains a valid reference to the object for the current platform, your scripts can treat the object without further concern for platform when addressing properties that have the same name in both platforms:

```
instrux.visibility = "hidden";
```

The nested layer situation is not the only potential problem for the platform equivalency approach. In fact, the W3C DOM format for referencing objects (using the `document.getElementById()` method) makes for some hair-raising string assembly and global variable assignment. Another truly negative aspect is the frequent usage of the `eval()` function. As mentioned in Chapter 34, this function is a performance speed thief.

## Modern approaches to compatibility

Although in-line branching and platform equivalency were suitable for their generations, the profusion of browser versions calls for better approaches to simplifying authoring for multiple DOMs. “Browser sniffing” is no longer a workable strategy except in rare instances. Techniques more suitable for today — object detection and custom APIs — are not really new. But these techniques are the preferred way to build cross-browser scripts with an eye to compatibility both backward and forward.

### Object detection

The subject of object detection has been mentioned in several places in earlier chapters of this book. The technique has been used for a long time to let a browser not equipped to handle image objects gracefully skip over image swapping script segments:

```
if (document.images) {
    // statements to work with image objects
}
```

If there is no `document.images` property for a browser, the condition evaluates to `undefined`, which the condition treats as being `false`.

But object detection has also been misused in the past, especially in the DHTML realm, to substitute for browser version detection. For example, if a browser supported the `document.all` collection, a global variable was set to indicate that the browser was IE4 or later; the existence of `document.layers` supposedly meant that the browser was NN4. While both of those assertions are true (as of the browsers released so far), it was a mistake to link a browser version with the existence of an object or property. Instead, object detection should be used only if your script statements will be addressing that object, just as the `document.images` condition does in the previous example.

To demonstrate this tactic, consider the need to assemble a reference to an object so that it is ready to have one of its DHTML properties adjusted. Each of the three DOMs has its own syntax for assembling such a reference, and each syntax relies on the existence of a particular object or property. The function shown in Listing 47-1 (not by itself, but included in Listing 47-2) lets you pass the name or ID of a positioned element (either in string form or object form) to receive back a valid reference to the object with which style-related properties are associated — all without resorting to the `eval()` function in any form:

#### Listing 47-1: Using Object Detection to Assemble an Element Object Reference

```
function getObject(obj) {
    var theObj;
    if (document.layers) {
        if (typeof obj == "string") {
            // just one layer deep
            return document.layers[obj];
        } else {
            // can be a nested layer
            return obj;
        }
    }
}
```

*Continued*

## Listing 47-1 (continued)

```

if (document.all) {
    if (typeof obj == "string") {
        return document.all(obj).style;
    } else {
        return obj.style;
    }
}
if (document.getElementById) {
    if (typeof obj == "string") {
        return document.getElementById(obj).style;
    } else {
        return obj.style;
    }
}
return null;
}

```

The primary object detection for each of the three sections of this function looks for the presence of categories of objects (`document.layers` and `document.all`) or a particular method (`document.getElementById()`), and then — this is the important part — the script uses those detected objects in the statements. The script doesn't know IE4 from NN7; it *does* know how to derive valid references for three different object models, and employs the syntax of the first one for which the associated object property or method is supported.

In practice, the order of the three sections should have no bearing on your scripts, but you should be aware of one subtlety: IE5+ can work with either of the last two sections, because those browsers detect `document.all` and `document.getElementById` as valid references. If you were to switch the position of the last two sections, IE5+ would be using W3C DOM terminology. The results, however, are the same: A valid reference to the `style` object associated with an element.

## Custom APIs

Notions of object detection and simplifications of your scripts come together in the final approach to building cross-browser DHTML: Writing a custom API (Application Programming Interface). A JavaScript custom API is a library of functions you design to act as an intermediary between your scripts and other scriptable entities. Ideally, an API simplifies access to, or control of, other entities. In the context of designing a cross-browser DHTML page, an API can offer a single function that smoothes over the differences in object references and/or property names among several platforms. Your custom function provides a single access point that is consistent across all platforms. In essence, you are creating your own metavocabulary for methods and property settings.

The element object reference maker in Listing 47-1 is a good start for such an API, because all other functions for moving, hiding, showing, and changing the stacking order of a positionable element need a valid style-oriented reference to the element. Now look at a function from an API whose job is to alter the stacking order of a positionable element:

```
// set the z-order of an object
function setZIndex(obj, zOrder) {
    var theObj = getObject(obj);
    theObj.zIndex = zOrder;
}
```

Your main page script would use the ID of the positioned `div` element as the first parameter to this function, with an integer indicating the value that would be assigned to the element's stylesheet `z-Index` attribute:

```
setZIndex("myLayer", 100);
```

All of the branching for the various DOMs in this function is done in the `getObject()` function (Listing 47-1), which returns the valid reference for whichever of the three supported DOMs is running the script. All three DOMs, it turns out, have the same `zIndex` property representing the `z-Index` style attribute, so that no further branching is needed here.

As one more example, the next API function offers an interface to incompatible ways of adjusting the location of a positionable element. In this case, the act of moving an element has different syntax in different DOMs. One group (NN4 for layers) uses the `moveTo()` method; the rest support `left` and `top` properties of their `style` object:

```
// position an object at a specific pixel coordinate
function shiftTo(obj, x, y) {
    var theObj = getObject(obj);
    if (theObj.moveTo) {
        theObj.moveTo(x,y);
    } else if (typeof theObj.left != "undefined") {
        theObj.left = x + "px";
        theObj.top = y + "px";
    }
}
```

Notice one workaround, which, on the surface, isn't pretty: The second branch must perform an odd way of object detection. We're stuck with having to make a tradeoff when it comes to checking for the existence of a style property. If the page uses stylesheets defined in `<style>` tags (or imported into the page from external stylesheet files), the element affected by the rule does not yield the rule's property values through the element's `style` property. The property exists, but its value in this case (or until it is set by script) is an empty string. IE5+ provides a `currentStyle` property to give us the effective values, but that property is not (yet) a part of the DOM standard. It's true that you can derive the effective style property of an element (see Chapter 26), but even if you assign the stylesheet via the element's `style` attribute (in which case the style property values come through), detecting the presence of the property with the conditional expression

```
if (theObj.left)
```

is not practical here anyway. If the effective value of the `left` and `top` properties were an empty string (or zero for a numeric style property value), the conditional expression would evaluate to the equivalent of `false`, making it appear as though the property doesn't exist. To validate the existence of the property, the conditional expression verifies that the value of a named property has a type other than "undefined." It may seem like a long way to go to prove the existence of a property, but it works, even if the value is an empty string or zero.

It is important that both branches perform object detection. Although it is unlikely (but, as we learned from the transition between NN4 and NN6, not impossible), if a future browser should completely alter its vocabulary, omitting the objects being detected here, the function ends gracefully, without generating script errors.

An API is usually best deployed as an external `.js` file. One such API file is described later in this chapter. Bear in mind, however, that a lengthy API gets downloaded to the browser, no matter how much or how little of it your main scripts use. Blindly linking in a big library just to use a few of its functions is a mistake. You serve your users better if you create a subset of the API, and link the subset to the page (or drop the few functions directly into the page's scripts if the combination is not reused on a lot of pages).

## Handling non-DHTML browsers

An important question to ask yourself as you embark on a DHTML-enhanced page is how you intend to treat visitors whose browsers aren't up to the task. In many respects the problem is similar to the problem of treating nonscriptable browsers when your page relies on scripting (see Chapter 13).

The moment your page uses DHTML to position an element, you must remember that non-DHTML browsers display the content according to traditional HTML rendering rules. No elements are allowed to overlap. Any block-level tag is rendered at the left margin of the page, unless some other non-DHTML alignment (center or right) is at work. This goes for elements that you design to be DHTML-positioned to sit offscreen (perhaps with a clickable tab) until called by the user. An element defined as being hidden or not displayed in DHTML will be visible. In most cases, your carefully designed DHTML page will look terrible.

However, a page that does not use too radical a layout strategy may still be usable in non-DHTML browsers. You should always check your DHTML-enabled page in an older browser to see how it looks. Perhaps there isn't too much you need to do to degrade the DHTML so that the page is acceptable in older browsers.

The ultimate responsibility for deciding your compatibility strategy with older browsers rests with you and your perceptions about your page visitors. If they are in need of vital information from your site and that information is readable in non-DHTML browsers, that may be enough. Otherwise, you must provide a separate content path for both levels of browsers, much as you may be doing for scriptable versus nonscriptable browsers.

## A DHTML API Example

Now it's time to get to a real DHTML API that you can use and build upon for your own applications. Listing 47-2 contains the API code, which is most likely to be deployed as an external `.js` library file. In fact, this API is used as-is in a map puzzle game application in Chapter 56. You can see there how it is used to control element positioning, dragging, and layering for the three DOM families. The code in Listing 47-2 is longer than most listings in this book, so for your convenience, I interlace commentary amid the long listing.

No global variables are needed for this API. Because all browser branching is performed via object detection, there is no need for browser version detection. Instead, the library starts with the `getObject()` function shown earlier in this chapter. Virtually every other function in this library makes a trip to `getObject()` to convert the name of the object passed as a parameter to an object reference whose positionable (or other style-related property) can be adjusted.

**Listing 47-2: The Custom API (DHTMLapi.js)**

```

// convert object name string or object reference
// into a valid object reference ready for style change
function getObject(obj) {
    var theObj;
    if (document.layers) {
        if (typeof obj == "string") {
            return document.layers[obj];
        } else {
            return obj;
        }
    }
    if (document.all) {
        if (typeof obj == "string") {
            return document.all(obj).style;
        } else {
            return obj.style;
        }
    }
    if (document.getElementById) {
        if (typeof obj == "string") {
            return document.getElementById(obj).style;
        } else {
            return obj.style;
        }
    }
    return null
}

```

A pair of functions handles all motion of positionable elements. The first function, `shiftTo()` takes three parameters: the ID of the object being moved, and the horizontal and vertical pixel coordinates of the top-left corner of the element. The assumption is that the main page script that invokes this library function performs the calculation of the coordinates. You see that code in Chapter 56. Branches inside this function handle the NN4 `layer.moveTo()` method or the setting of style properties for other DOMs. In these other browsers, moving the element requires adjusting two positional properties, left and top. Even though the adjustments are made in separate statements, the action on the screen does not follow the action statement-by-statement. Between screen buffering and quick execution, the repositioning appears as a single shift.

```

// position an object at a specific pixel coordinate
function shiftTo(obj, x, y) {
    var theObj = getObject(obj);
    if (theObj.moveTo) {
        theObj.moveTo(x,y);
    } else if (typeof theObj.left != "undefined") {
        theObj.left = x + "px";
        theObj.top = y + "px";
    }
}

```

The `shiftBy()` function mimics NN4's `layer.moveBy()` method. The second and third parameters represent the number of pixels that the object should be moved on the page. A positive number means to the right or down; a negative number means to the left or up; a value of zero means no change to the axis. For NN4, the script uses the `layer.moveBy()` method. But for the rest, the passed values are added to the `left` and `top` properties. Notice that because these properties return strings that include the units for the measurements, the incremental values are added to integer extractions from the current settings. And because the units being used here are the default (pixels), no units have to be assigned with the new values (although they could without penalty).

```
// move an object by x and/or y pixels
function shiftBy(obj, deltaX, deltaY) {
    var theObj = getObject(obj);
    if (theObj.moveBy) {
        theObj.moveBy(deltaX, deltaY);
    } else if (typeof theObj.left != "undefined") {
        theObj.left = parseInt(theObj.left) + deltaX + "px";
        theObj.top = parseInt(theObj.top) + deltaY + "px";
    }
}
```

Both platforms use the same property name for setting the stacking order of positionable things. Therefore, the `setZIndex()` function does little more than convert the object reference and assign the incoming value to the `zIndex` property.

```
// set the z-order of an object
function setZIndex(obj, zOrder) {
    var theObj = getObject(obj);
    theObj.zIndex = zOrder;
}
```

NN4 and browsers with style objects have their own way of referring to the background color. The `setBGColor()` function applies the correct syntax based on whichever property is detected in the object.

```
// set the background color of an object
function setBGColor(obj, color) {
    var theObj = getObject(obj);
    if (theObj.bgColor) {
        theObj.bgColor = color;
    } else if (typeof theObj.backgroundColor != "undefined") {
        theObj.backgroundColor = color;
    }
}
```

Allowable values for the `visibility` property are very unprogrammatic in my opinion. I expect a Boolean value rather than strings. To accede to reality while making the process of showing and hiding elements more logical to me, I created API functions called `show()` and `hide()`.

```
// set the visibility of an object to visible
function show(obj) {
    var theObj = getObject(obj);
    theObj.visibility = "visible";
}

// set the visibility of an object to hidden
function hide(obj) {
    var theObj = getObject(obj);
    theObj.visibility = "hidden";
}
```

Although the `left` and `top` properties of NN4 layers do not include unit values, it is still safe to use `parseInt()` on the values returned from the properties, whether they be retrieved in NN4 or browsers that have `style` objects (whose properties return units). The need for these API functions came from the way the map puzzle application in Chapter 56 works. For a couple of operations, it calculates the destination for an object with respect to the position of one of the other positioned elements. These functions return the values needed for the main program's calculation. This is also an example of how you may need to embellish the API for your own application.

```
// retrieve the x coordinate of a positionable object
function getObjectLeft(obj) {
    var theObj = getObject(obj);
    return parseInt(theObj.left);
}

// retrieve the y coordinate of a positionable object
function getObjectTop(obj) {
    var theObj = getObject(obj);
    return parseInt(theObj.top);
}
```

The previous API is generalizable enough to be used as a library with any cross-platform DHTML application using positioning. The API can even be used with a platform-specific page. It is more efficient, however, to use a browser's native objects, properties, and methods if you know for sure that users will have only one brand of browser.

# Internet Explorer Behaviors

---

Internet Explorer 5 for Windows was the first browser to deploy what Microsoft calls *behaviors*. Microsoft and others have proposed the behaviors concept to the W3C, and it could some day become one of the W3C standard recommendations. Such a standard might not be implemented exactly the way Microsoft currently implements behaviors, but most of the concepts are the same, and the syntax being discussed so far is similar. While there is no guarantee that the W3C will adopt behaviors as a standard, you will see that the concept seems to be a natural extension to the work that has already been adopted for both CSS and XML.

The W3C effort is called Behavioral Extensions to CSS. For the latest document describing the work of the participants of the standards discussions, visit <http://www.w3.org/TR/becss>.

## Stylesheets for Scripts

You can best visualize what a behavior is in terms of the way you use stylesheets. Consider a stylesheet rule whose selector is a tag or a class name. The idea behind the stylesheet is that one rule, which can define dozens of rendering characteristics of a chunk of HTML content, can be applied to perhaps dozens, if not hundreds, of elements within the document. A corporation may design a series of rules for the way its Web documents will look throughout the Web site. If the designer decides to alter the font family or color for, say, `h1` elements, that change is made in one place (the external stylesheet file), and the impact is felt immediately across the entire site. Any page that includes an `h1` element renders the header with the newly modified style.

Imagine now that instead of visual styles associated with an element, you want to define a *behavioral style* for a particular group of elements. A behavioral style is the way an element responds to predominantly user interaction with the element. For example, if the design specifications for a Web site indicate that all links should have their text colored a certain way when at rest, but on mouse rollovers, the text color changes to a more contrasting color, the font weight increases to bold, and the text becomes underlined. Those modifications require scripts to change the style properties of the element in response to the mouse action of the user. The scripts that fire in response to specific user actions (events) are written in an external file known as a behavior, and a behavior is associated with an element, class, or tag through the same CSS syntax that you use for other style properties.

### In This Chapter

Introducing IE behaviors

Understanding the structure of behavior XML files

Exploring behavior samples

A behavior, of course, assumes that its scripts can work with whatever HTML element is associated with the behavior. Just as it would be illogical to associate the `tableLayout` style property with an element that wasn't a `table`, so, too, would it be illogical to associate a behavior, whose scripts employed `table` object properties and methods, to a `p` element. Even so, a well-designed behavior can obtain details about the element being manipulated through the element object's properties. The better you are at writing generalizable JavaScript functions, the more successful you will be in implementing behaviors.

## Embedding Behavior Components

IE treats each behavior as a component, or add-on building block for the browser. IE5+ comes equipped with a handful of behaviors built into the browser (the so-called default behaviors, which happen to rely on specific XML elements embedded in a document). Behaviors that you create most likely exist as separate files on the server, just like external `.css` and `.js` files do. The file extension for a behavior file is `.htc` (standing for HTML Component).

### Linking in a behavior component

To associate a behavior with any single element, class of elements, or tag as the page loads, use CSS rule syntax and the IE-specific `behavior` attribute. The basic syntax is as follows:

```
selector {behavior:url(componentReference)}
```

As with any stylesheet rule, you can combine multiple rule properties, delimiting them with semicolons. The format of the *componentReference* depends on whether you are using one of the IE default behaviors or a behavior you've written to an external file. For default behaviors, the reference is in the format:

```
#default#componentName
```

For example, if you want to associate the `download` behavior with any element of class `downloads` use:

```
.downloads {behavior:url(#default#download)}
```

Relative or absolute URIs to external `.htc` files can also be specified. For example, if your site contains a directory named `behaviors` and a file named `hilite.htc`, the stylesheet rule from the root directory is:

```
.hilite {behavior:url(behaviors/hilite.htc)}
```

As with all Cascading Style Sheet rules, behaviors can be specified in a `style` element of the page, in the `style` attribute of an individual element, or in a rule defined inside an imported `.css` file.

### Enabling and disabling behaviors

In Chapter 15, you can find details of WinIE5+ methods for all HTML elements that let scripts manage the association of a behavior with an element after the page has loaded. Invoking the `addBehavior()` method on an element assigns an external `.htc` file to that element. When you no longer need that behavior associated with the element, invoke the `removeBehavior()` method.

## Component Structure

An `.htc` behavior file is a text file consisting of script statements inside a `<script>` tag set and some special XML tags that WinIE5+ knows how to parse. You create `.htc` files in the same kind of plain text editor that you use for external `.js` or `.css` files.

### Script statements

Unlike external `.js` files, an `.htc` behavior file includes `<script>` tags, which surround any JavaScript (or VBScript, if you like) statements that control the behavior. Because a behavior most typically is written to control one or more aspects of the HTML element to which it is connected, statements tend to operate only on the associated object element. A special reference—`element`—is used to refer to the element object itself (much like the way the `this` keyword in a custom object's method self-refers to the object associated with the method).

If your behavior will be modifying either the content or style of the element, use the `element` reference as a foundation to the reference to one of that element object's properties or methods. For example, if a statement in a behavior needs to set the `style.visibility` property so that the element hides itself, the statement in the behavior script is:

```
element.style.visibility = "hidden";
```

Any valid reference from the point of view of the element object is fair game, including references to the element's `parentElement`, even though the parent element is not explicitly associated with the behavior.

### Variable scope

Except for the special `element` reference, script content of a behavior is completely self-contained. You can define global variables in the behavior that are accessible to any script statement in the behavior. But a global variable in a behavior does not become a global variable for the main document's scripts to use. You can expose variables so that scripts outside of the behavior can get to them (as described later in the chapter), but this exposure is not automatic.

Most of the script content of a behavior consists of functions that usually interact in some fashion with the associated element (via the element's properties and/or methods). Local variables in functions have the same scope and operate just like they do in regular script functions. Global variables you define in a behavior, if any, are usually there for the purpose of preserving values between separate invocations of the functions.

### Assigning event handlers

Functions in a behavior are triggered from outside the behavior through two means: event handlers and direct invocation of functions declared as public (described in the next section). Event handler binding is performed in a way that is not used elsewhere in the IE4+ DOM. Each event type (for example, `onmouseover`, `onkeypress`) requires its own special XML tag at the top of the behavior file. The format for the event handler tag is as follows:

```
<public:attach event="eventName" onevent="behaviorFunctionName()" />
```

As the behavior loads, the `public:attach` tag instructs the browser to expose to the “public” (that is, the world outside of the behavior) an event type (whose name always begins with the “on” prefix in the IE4+ event model); whenever an event of that type reaches the behavior’s element, the function (defined within the behavior file) is invoked. In XML terminology, the `public:` part of the tag is known as a *namespace*, and IE includes a built-in parser for the `public` namespace. Notice, too, the XML syntax at the end of the tag that allows a single set of angle brackets to act as a start and end tag set (there is no content for this tag, just the attributes and their values).

To demonstrate, imagine that a behavior has a function named `underlineIt()`, which sets the `element.style.textDecoration` property to `underline`. To get the element to display the underline decoration as the user rolls the mouse atop the element, bind this function to the element’s `onmouseover` event handler as follows:

```
<public:attach event="onmouseover" onevent="underlineIt()" />
```

If you compare the wording of the opening part of the tag, you may recognize a connection to the IE4+ event model’s `attachEvent()` method of all HTML elements (see Chapter 15). You can have as many event binding tags as your element needs. To invoke multiple functions in response to a single event type, simply add the subsequent function invocation statements to the `onevent` attribute, separating the calls by semicolons (the same as with regular JavaScript statement delimiters).

## Exposing properties and methods

XML tags with the `public:` namespace are also used (with different attributes) to expose a behavior’s global variables as properties of the element and a behavior’s functions as methods of the element. The syntax for both types of “public” announcements is as follows:

```
<public:property name="globalVarName" />
<public:method name="functionName" />
```

Values for both items are string versions of references to the variable and function (no parentheses). Again, you can define as many properties and methods for a behavior as you need.

As soon as a property and/or method is made public in a behavior, scripts from outside the behavior can access those items as if they were properties or methods of the element associated with the behavior:

```
document.all.elementID.behaviorProperty
document.all.elementID.behaviorMethod()
```

If you associate a behavior with a stylesheet class selector, and several document elements share that class name, each one of those elements gains the public properties and methods of that behavior, accessible through references to the individual elements. That’s because a behavior’s scripts are written to read or modify properties of whatever element receives a bound event or is referenced along the way to the public property or method.

## Behavior Examples

The two following examples are intentionally simple to help you grasp the concepts of behaviors if they are new to you. The first example interacts with multiple elements strictly through event binding; the second example exposes a property and method that the main page’s scripts access to good effect.

## Example 1: Element dragging behavior

This book contains several examples of how to script a page to let a user drag an element around the browser window (Chapters 39 and 56 in particular). In all those examples, the dragging code and event handling was embedded in some fashion into the page's scripts. The first example of a behavior, however, drives home the notion of separating an element's behavior from its content (just as a CSS2 style sheet separates an element's appearance from its content).

Imagine that it's your job to design a page that employs three draggable elements. Two of the elements are images, while the third is a panel layer that also includes a form. If you haven't scripted DHTML before, this may sound like a daunting task at first, one rife with the possibility of including multiple versions of the same scripts to accommodate different kinds of draggable elements.

Now imagine that to the rescue comes a scripter who has built a behavior that takes care of all of the dragging scripting for you. All you do is assign that behavior by way of one attribute of each draggable element's stylesheet rule. Absolutely no other scripting is required on the main page to achieve the element dragging.

Listing 48-1 shows the behavior file (`drag.htc`) that controls basic dragging of a positionable element on the page. You may recognize some of the code as an IE4+ version of the cross-browser dragging code used elsewhere in this book (for a blow-by-blow account of these functions, see the description of the map puzzle game in Chapter 56). The names of the three operative functions and the basic way they do their jobs are identical to the other dragging scripts. Event binding, however, follows the behavior format through the XML tags. All interaction with the outside world occurs through the "public" event handlers.

### Listing 48-1: An Element Dragging Behavior

```
<public:attach event="onmousedown" onevent="engage()" />
<public:attach event="onmousemove" onevent="dragIt()" />
<public:attach event="onmouseup" onevent="release()" />
<public:attach event="onmouseover" onevent="setCursor()" />
<public:attach event="onmouseout" onevent="release();restoreCursor()" />

<script type="text/javascript">
// global declarations
var offsetX = 0;
var offsetY = 0;
var selectedObj;
var oldZ, oldCursor;

// initialize drag action on mousedown
function engage() {
    selectedObj = (element == event.srcElement) ? element : null;
    if (selectedObj) {
        offsetX = event.offsetX - element.document.body.scrollLeft;
        offsetY = event.offsetY - element.document.body.scrollTop;
        oldZ = element.runtimeStyle.zIndex;
        element.style.zIndex = 10000;
        event.returnValue = false;
    }
}
```

*Continued*

## Listing 48-1 (continued)

```

// move element on mousemove
function dragIt() {
    if (selectedObj) {
        selectedObj.style.pixelLeft = event.clientX - offsetX;
        selectedObj.style.pixelTop = event.clientY - offsetY;
        event.cancelBubble = true;
        event.returnValue = false;
    }
}

// restore state on mouseup
function release() {
    if (selectedObj) {
        selectedObj.style.zIndex = oldZ;
    }
    selectedObj = null;
}

// make cursor look draggable on mouseover
function setCursor() {
    oldCursor = element.runtimeStyle.cursor;
    element.style.cursor = "hand";
}

// restore cursor on mouseout
function restoreCursor() {
    element.style.cursor = oldCursor;
}
</script>

```

Notice a subtlety in Listing 48-1 that is implied by the element-specific scope of a behavior. Two statements in the `engage()` function need to reference scroll-related properties of the `document.body` object. Because the only connection between the behavior and the document is via the element reference, that reference is used along with the `document` property (a property of every HTML element object in IE4+, as shown in Chapter 15). From there, the `body` object and the required properties can be accessed.

Listing 48-2 is a simple page that contains three elements that are associated with the `drag.htc` behavior through a stylesheet rule definition (for the `draggable` class). The document is incredibly uncomplicated. Even the `drag.htc` file isn't very big. But together they produce a far more interesting page for the user than a couple of static images and a form.

## Listing 48-2: Three Draggable Elements Using the Behavior

```

<html>
<head>
    <title>IE5+ Behavior Demo (Dragging)</title>
    <style type="text/css">
        .draggable {position:absolute; behavior:url(drag.htc)}
        #img1 {left:150px; top:150px}
        #img2 {left:170px; top:170px}
    </style>

```

```

        #txt1 {left:190px; top:190px; background-color:aqua; width:150px;
            height:50px; text-align:center}
    </style>
</head>
<body>
    <h1>IE5+ Behavior Demo (Dragging)</h1>
    <hr />
     
    <div class="draggable" id="txt1">
        A form inside a div element.
        <form>
            <input type="button" value="Does Nothing" />
        </form>
    </div>
</body>
</html>

```

Obviously, the dragging example here is very rudimentary. It isn't clear from the sample code what the user gets from the page, other than the joy of moving things around. If you were designing an application that genuinely benefits from draggable objects (for example, the map puzzle in Chapter 56), you can easily enhance the behavior to perform actions, such as snapping a dragged element into place when it is within a few pixels of its proper destination. For such an implementation, the behavior can be given some extra global variables, akin to the values assigned to the state objects in Chapter 56, including the pixel coordinates of the ideal destination for a dragged element. An `onload` event handler for the page can fire a public `init()` function in each element's behavior to assign those coordinate values. Any event that can bubble (such as mouse events) does so from the behavior to the target. Therefore, you can extend the event action of the behavior by adding a handler for the same event to the element outside of the behavior.

## Example 2: Text rollover behavior

In the second example, you see how a behavior exposes a global variable and function as a public property and method, respectively. The demonstration reinforces the notion that even if a single behavior file is associated with multiple elements (for example, the elements share the same class, and the behavior is assigned to the class), each behavior maintains its own variable values, independent of the other elements and their behaviors.

The nature of this behavior is to set the `color` style property of the associated element to either a default color (red) or to another color that has been passed into the behavior via one of its public methods. The color setting is preserved in one of the behavior's global variables, and that variable is exposed as a public property.

Listing 48-3 shows the `.htc` behavior file's content. Only two events are bound to this behavior: `onmouseover` and `onmouseout` — the typical rollover events. The `onmouseover` event invokes the `makeHot()` function, while the `onmouseout` event invokes the `makeNormal()` function. Before the `makeHot()` function makes any changes to the `color` and `fontWeight` style properties of the element, existing settings are preserved in (non-public) global variables in the behavior. This allows the `makeNormal()` function to restore the original settings, regardless of what document styles may be applied to the element in a variety of pages. That's something to keep in mind when you design behaviors: they can be deployed in pages controlled by any number of stylesheets. Don't assume any basic style setting; instead, use the `currentStyle` property to read and preserve the effective property values before touching them with your behavior's modification scripts.

Neither of the event handler functions are exposed as public methods. This was a conscious decision for a couple of reasons. The most important reason is that both functions rely on being triggered by a known event occurring on the element. If either function were invoked externally, the event object would contain none of the desired information. Another reason behind this is from a common programming style for components that protects inner workings, while exposing only those methods and properties that are “safe” for others to invoke. For this code, the public method does little more than set a property. It’s an important property, to be sure, and one of the protected functions relies on it. But by allowing the public method little room to do any damage other than execution of the behavior, the design makes the behavior component that more robust.

Assigning a color value to the public property and passing one as a parameter to the public method accomplishes the same result in this code. As you will see, the property gets used in the demonstration page to retrieve the current value of the global variable. In a production behavior component, the programmer would probably choose to expose this value strictly as a read/write property or expose two methods, one for getting and one for setting the value. The choice would be at the whim of the programmer’s style and would likely not be both. Using a method, however, especially for setting a value, creates a framework in which the programmer can also perform validation of the incoming value before assigning it to the global variable (something the example here does not do).

### Listing 48-3: Rollover Behavior (makeHot.htc)

```
<public:attach event="onmouseover" onevent="makeHot()" />
<public:attach event="onmouseout" onevent="makeNormal()" />
<public:property name="hotColor" />
<public:method name="setHotColor" />
<script type="text/javascript">
var oldColor, oldWeight;
var hotColor = "red";

function setHotColor(color) {
    hotColor = color;
}

function makeHot() {
    if (event.srcElement == element) {
        oldColor = element.currentStyle.color;
        oldWeight = element.currentStyle.fontWeight;
        element.style.color = hotColor;
        element.style.fontWeight = "bold";
    }
}

function makeNormal() {
    if (event.srcElement == element) {
        element.style.color = oldColor;
        element.style.fontWeight = oldWeight;
    }
}
</script>
```

To put the public information and the behavior, itself, to work, a demonstration page includes three spans within a paragraph that are associated with the behavior. Listing 48-4 shows the code for the demo page.

In addition to the text with rollover spans, the page contains two `select` controls, which let you assign a separate color to each of the three elements associated with the behavior. The first `select` element lets you choose one of the three elements. Making that choice invokes the `readColor()` function in the same page. This is the function that reads the `hotColor` public property of the chosen span. That color value is used to select the color name for display in the second `select` element. If you make a choice in the list of colors, the `applyVals()` function invokes the public `setHotColor()` method of the element currently selected from the list of elements. Rolling the mouse over that element now highlights in the newly selected color, while the other elements maintain their current settings.

#### Listing 48-4: Applying the Rollover Behavior

```
<html>
  <head>
    <title>IE5+ Behavior Demo (Styles)</title>
    <style type="text/css">
      .hotStuff {font-weight:bold; behavior:url(makeHot.htc)}
    </style>
    <script type="text/javascript">
      function readColor(choice) {
        var currColor = document.all(choice.value).hotColor
        var colorList = choice.form.color
        for (var i = 0; i < colorList.options.length; i++) {
          if (colorList.options[i].value == currColor) {
            colorList.selectedIndex = i
            break
          }
        }
      }
      function applyVals(form) {
        var elem = form.elem.value
        document.all(elem).setHotColor(form.color.value)
      }
    </script>
  </head>
  <body>
    <h1>IE5+ Behavior Demo (Styles)</h1>
    <hr />
    <form>
      Choose Hilited Element: <select name="elem"
        onchange="readColor(this)">
        <option value="elem1">First</option>
        <option value="elem2">Second</option>
        <option value="elem3">Third</option>
      </select> Choose Hilite Color: <select name="color"
        onchange="applyVals(this.form)">
        <option value="red" selected="selected">Red</option>
        <option value="blue">Blue</option>
        <option value="green">Green</option>
    </form>
  </body>
</html>
```

*Continued*

**Listing 48-4 (continued)**

```

        </select>
    </form>
    <p>Lorem ipsum dolor sit amet, <span id="elem1"
        class="hotStuff">consectetur</span> adipisicing elit, sed do eiusmod
        tempor incididunt ut <span id="elem2" class="hotStuff">labore et
        dolore magna aliqua</span>. Ut enim adminim veniam, quis nostrud
        exercitation ullamco laboris <span id="elem3" class="hotStuff">nisi ut
        aliquip ex ea commodo consequat</span>.</p>
    </body>
</html>

```

Behaviors are not the solution for every scripting requirement. As demonstrated here, they work very well for generic style manipulation, but you are certainly not limited to that sphere. By having a reference back to the element associated with the behavior, and then to the document that contains the element, a behavior's scripts can have free run over the page — provided the actions are either generic among any page or generic among a design template that is used to build an entire Web site or application.

Even if you don't elect to use behaviors now (perhaps because you must support browsers other than WinIE5+), they may be in your future. Behaviors are fun to think about and also instill good programming practice in the art of creating reusable, generalizable code.

## For More Information

In addition to the address of W3C activity on behaviors, Microsoft devotes many pages of its developer site to behaviors. Here are some useful pointers.

**Overview:**

<http://msdn.microsoft.com/workshop/author/behaviors/overview.asp>

**Using DHTML Behaviors:**

<http://msdn.microsoft.com/workshop/author/behaviors/howto/using.asp>

**Default Behaviors Reference:**

<http://msdn.microsoft.com/workshop/author/behaviors/reference/reference.asp>

**IE5.5 Element Behaviors (an extension to the original behaviors):**

Each of these locations ends with yet more links to related pages at the Microsoft Developer Network (MSDN) Web site.

# Application: Tables and Calendars

---

**W**orking with HTML tables is a lot of fun, especially if, like me, you are not a born graphics designer. By adding a few tags to your page, you can make your columnar data look more organized, professional, and appealing. Having this power under scripting control is even more exciting, because it means that in response to a user action or other variable information (such as the current date or time), a script can do things to the table as the table is being built. In IE4+ and W3C DOMs, scripts can modify the content and structure of a table even after the page has loaded, allowing the page to almost “dance.”

You have three options when designing scripted tables for your pages, although only two are backward compatible with non-DHTML browsers:

- ◆ Static tables
- ◆ Dynamic tables
- ◆ Dynamic HTML tables

The design path you choose is determined by whether you need to dynamically update some or all fields of a table (data inside `<td> . . . </td>` tags) and which browser levels you need to support. To highlight the differences among the three styles, this chapter traces the implementation of a monthly calendar display in all three formats.

## About the Calendars

Because the emphasis here is on the way tables are scripted and displayed, I quickly pass over structural issues of the calendar versions described in the following sections. The first two examples are backward compatible to all but the first-generation scriptable browsers. The final example, however, is a much more modern affair, utilizing table-related DOM objects and methods to simplify the code. It requires WinIE4+ (unfortunately, a bug in MacIE causes problems with the amount of `table` object modification the script does) or a W3C-compatible browser.

### In This Chapter

Accommodating older browsers

Scripted tables

Date calculations

All three calendars follow similar (if not over-simplified) rules for displaying calendar data. English names of the months are coded into the script, so that they can be plugged into the calendar heading as needed. To make some of the other calendar calculations work (such as figuring out which day of the week is the first day of a given month in a given year), I define a method for my month objects. The method returns the JavaScript date object value for the day of the week of a month's first date. Virtually everything I do to implement the month objects is adapted from the custom objects discussion of Chapter 27.

## Static Tables

The issue of updating the contents of a table's fields is tied to the nature of an HTML document being loaded and fixed in the browser's memory. Recall that for early browsers, you can modify precious few elements of a document and its objects after the document has loaded. That case certainly applies for typical data points inside a table's `<td>` tag pair. After a document loads — even if JavaScript has written part of the page — none of its content (except for text and textarea field contents and a few limited form element properties) can be modified without a complete reload.

Listing 49-1 contains the static version of a monthly calendar. The scripted table assembly begins in the Body portion of the document. Figure 49-1 shows the results.

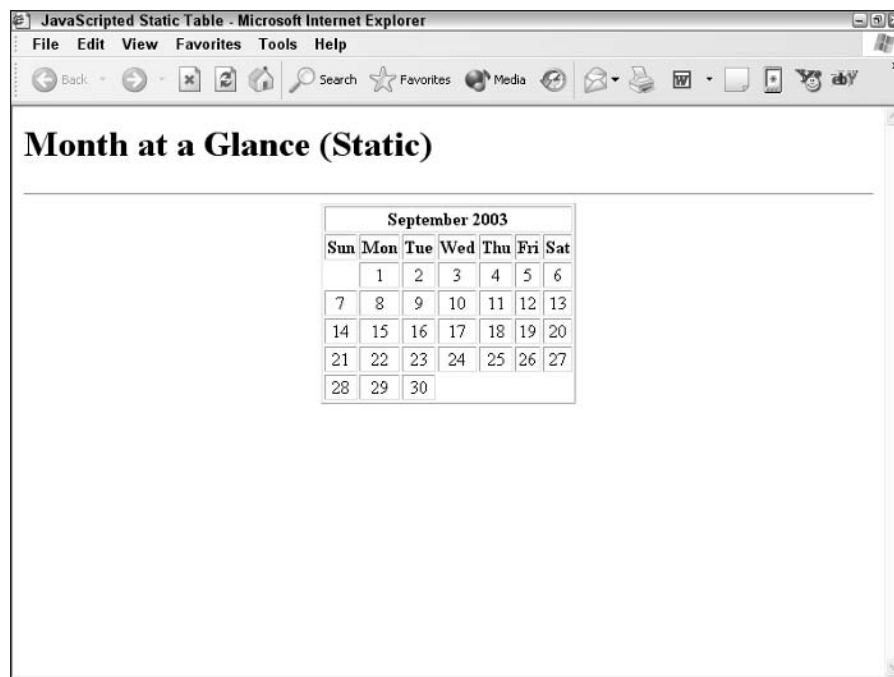

Figure 49-1: The static table calendar generated by Listing 49-1.

## Listing 49-1: A Static Table Generated by JavaScript

```

<html>
  <head>
    <title>JavaScripted Static Table</title>
    <script type="text/javascript">
      // function becomes a method for each month object
      function getFirstDay(theYear, theMonth){
        var firstDate = new Date(theYear,theMonth,1);
        return firstDate.getDay() + 1;
      }
      // number of days in the month
      function getMonthLen(theYear, theMonth) {
        var oneHour = 1000 * 60 * 60;
        var oneDay = oneHour * 24;
        var thisMonth = new Date(theYear, theMonth, 1);
        var nextMonth = new Date(theYear, theMonth + 1, 1);
        var len = Math.ceil((nextMonth.getTime() -
          thisMonth.getTime() - oneHour)/oneDay);
        return len;
      }
      // correct for Y2K anomalies
      function getY2KYear(today) {
        var yr = today.getYear();
        return ((yr < 1900) ? yr + 1900 : yr);
      }
      // create array of month names
      theMonths = new Array("January", "February", "March", "April", "May",
        "June", "July", "August", "September", "October", "November",
        "December");
    </script>
  </head>
  <body>
    <h1>Month at a Glance (Static)</h1>
    <hr />
    <script type="text/javascript">
      // initialize some variables for later
      var today = new Date();
      var theYear = getY2KYear(today);
      var theMonth = today.getMonth(); // for index into our array

      // which is the first day of this month?
      var firstDay = getFirstDay(theYear, theMonth);
      // total number of <TD>...</TD> tags needed in for loop below
      var howMany = getMonthLen(theYear, theMonth) + firstDay;

      // start assembling HTML for table
      var content = "<center><table border='1'>";
      // month and year display at top of calendar
      content += "<tr><th colspan='7'>" + theMonths[theMonth] + " " + theYear +
        "</th></tr>";
    </script>
  </body>
</html>

```

*Continued*

## Listing 49-1 (continued)

```

// days of the week at head of each column
content += "<tr><th>Sun</th><th>Mon</th><th>Tue</th><th>Wed</th>";
content += "<th>Thu</th><th>Fri</th><th>Sat</th></tr>";
content += "<tr>";

// populate calendar
for (var i = 1; i < howMany; i++) {
    if (i < firstDay) {
        // 'empty' boxes prior to first day
        content += "<td></td>";
    } else {
        // enter date number
        content += "<td align='center'>" + (i - firstDay + 1) + "</td>";
    }
    // start new row after each week
    if (i % 7 == 0 && i != howMany) {
        content += "</tr><tr>";
    }
}
content += "</table></center>";

// blast entire table's HTML to the document
document.write(content);
</script>
</body>
</html>

```

In this page, a little bit of the HTML—the `<h1>` heading and `<hr>` divider—is unscripted. The rest of the page consists entirely of the table definition, all of which is constructed in JavaScript. Most of the work for assembling the calendar's data points occurs inside of the `for` loop. Because not every month starts on a Sunday, the script determines the day of the week on which the current month starts. For all fields prior to that day, the `for` loop writes empty `<td></td>` tags as placeholders. After the numbered days of the month begin, the `for` loop writes the date number inside the `<td>...</td>` tags. Whatever the script puts inside the tag pair is written to the page as flat HTML. Under script control like that in the example, however, the script can designate what goes into each data point—rather than writing fixed HTML for each month's calendar.

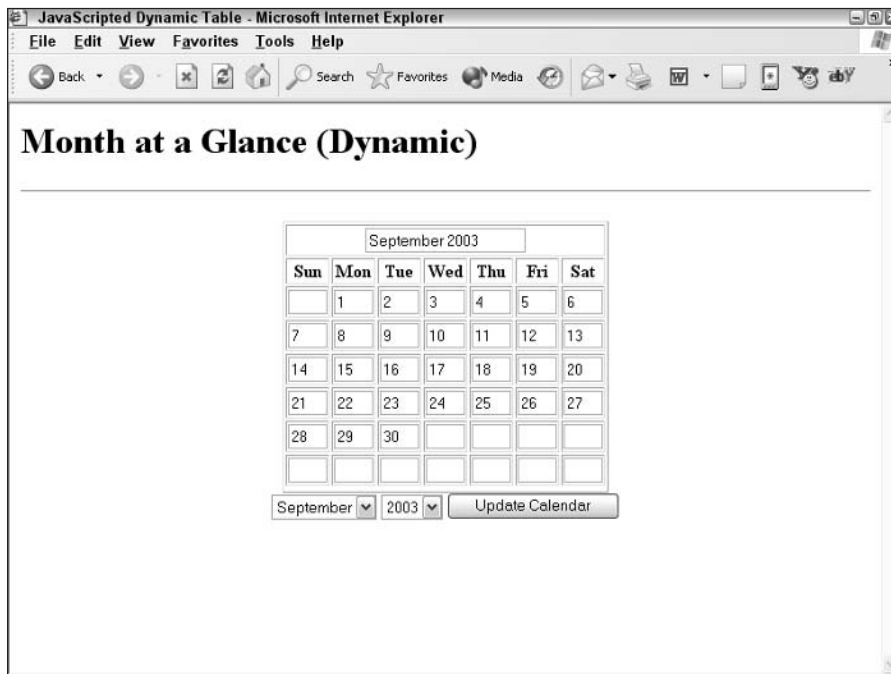

The important point to note in this example is that although the content of the page may change automatically over time (without having to redo any HTML for the next month), after the page is written, its contents cannot be changed. If you want to add controls or links that are to display another month or year, you have to rewrite the entire page. This can be accomplished by passing the desired month and year as a search string for the current page's URL and then assigning the combination to the `location.href` property. You also have to add script statements to the page that look for a URL search string, extract the passed values, and use those values to generate the calendar while the page loads (see Chapter 17 for examples of how to accomplish this feat). But to bring a calendar such as this even more to life (while avoiding page reloading between views), you can implement it as a dynamic table.

## Dynamic Tables

The only way to make data points of a table dynamically updatable in backward-compatible browsers is to turn those data points into text (or `textarea`) objects. The approach to this implementation is different from the static table because it involves the combination of *immediate* and *deferred* scripting. Immediate scripting facilitates the building of the table framework, complete with fields for every modifiable location in the table. Deferred scripting enables users to make choices from other interface elements, causing a new set of variable data to appear in the table's fields.

Listing 49-2 turns the preceding static calendar into a dynamic one by including controls that enable the user to select a month and year to display in the table. As testament to the support for absolute backward compatibility, a button triggers the redrawing of the calendar contents, rather than `onchange` event handlers in the `select` elements; a bug in NN2 for Windows caused that event not to work for the `select` object. Don't worry, the last example you see a bit later in the chapter does away with backward compatibility in favor of a sleeker design.

Form controls aside, the look of this version is quite different from the static calendar. Compare the appearance of the dynamic version shown in Figure 49-2 against the static version in Figure 49-1.

**Figure 49-2:** Dynamic calendar generated by Listing 49-2.

## Listing 49-2: A Dynamic Calendar Table

```

<html>
  <head>
    <title>JavaScripted Dynamic Table</title>
    <script type="text/javascript">
      // function becomes a method for each month object
      function getFirstDay(theYear, theMonth){
        var firstDate = new Date(theYear,theMonth,1);
        return firstDate.getDay();
      }
      // number of days in the month
      function getMonthLen(theYear, theMonth) {
        var oneHour = 1000 * 60 * 60;
        var oneDay = oneHour * 24;
        var thisMonth = new Date(theYear, theMonth, 1);
        var nextMonth = new Date(theYear, theMonth + 1, 1);
        var len = Math.ceil((nextMonth.getTime() -
          thisMonth.getTime() - oneHour)/oneDay);
        return len;
      }
      // correct for Y2K anomalies
      function getY2KYear(today) {
        var yr = today.getYear();
        return ((yr < 100) ? yr + 1900 : yr);
      }
      // create array of month names
      theMonths = new Array("January", "February", "March", "April", "May",
        "June", "July", "August", "September", "October", "November",
        "December"); // deferred function to fill fields of table
      function populateFields(form) {
        // initialize variables for later from user selections
        var theMonth = form.chooseMonth.selectedIndex;
        var theYear =
          form.chooseYear.options[form.chooseYear.selectedIndex].value;
        // initialize date-dependent variables

        // which is the first day of this month?
        var firstDay = getFirstDay(theYear, theMonth);
        // total number of <TD>...</TD> tags needed in for loop below
        var howMany = getMonthLen(theYear, theMonth);

        // set month and year in top field
        form.oneMonth.value = theMonths[theMonth] + " " + theYear;
        // fill fields of table
        for (var i = 0; i < 42; i++) {
          if (i < firstDay || i >= (howMany + firstDay)) {
            // before and after actual dates, empty fields
            // address fields by name and [index] number
            form.oneDay[i].value = "";
          } else {
            // enter date values
            form.oneDay[i].value = i - firstDay + 1;
          }
        }
      }
    </script>
  </head>

```

```

<body>
  <h1>Month at a Glance (Dynamic)</h1>
  <hr />
  <script type="text/javascript">
    // initialize variable with HTML for each day's field
    // all will have same name, so we can access via index value
    // empty event handler prevents
    // reverse-loading bug in some platforms
    var oneField = "<input type='text' name='oneDay' size='2' onfocus=''>";
    // start assembling HTML for raw table
    var content = "<form><center><table border='1'>";
    // field for month and year display at top of calendar
    content += "<tr><th colspan='7'><input type='text'
      name='oneMonth'></th></tr>";
    // days of the week at head of each column
    content += "<tr><th>Sun</th><th>Mon</th><th>Tue</th><th>Wed</th>";
    content += "<th>Thu</th><th>Fri</th><th>Sat</th></tr>";
    content += "<tr>";

    // layout 6 rows of fields for worst-case month
    for (var i = 1; i < 43; i++) {
      content += "<td align='middle'>" + oneField + "</td>";
      if (i % 7 == 0) {
        content += "</tr><tr>";
      }
    }

    content += "</table>";
    // blast empty table to the document
    document.write(content);
  </script>
  <select name="chooseMonth">
    <option value="January" selected="selected">January</option>
    <option value="February">February</option>
    <option value="March">March</option>
    <option value="April">April</option>
    <option value="May">May</option>
    <option value="June">June</option>
    <option value="July">July</option>
    <option value="August">August</option>
    <option value="September">September</option>
    <option value="October">October</option>
    <option value="November">November</option>
    <option value="December">December</option>
  </select> <select name="chooseYear">
    <option value="2003" selected="selected">2003</option>
    <option value="2004">2004</option>
    <option value="2005">2005</option>
    <option value="2006">2006</option>
    <option value="2007">2007</option>
    <option value="2008">2008</option>
    <option value="2009">2009</option>
    <option value="2010">2010</option>
  </select>
  <br /><input type="button" name="updater" value="Update Calendar"
    onclick="populateFields(this.form)" />
  </form> <!-- start tag written by script -->
</body>
</html>

```

When you first load Listing 49-2, it creates an empty table along with numerous text objects. An `onload` event handler in the `Body` definition also could easily set the necessary items to load the current month.

From a cosmetic point of view, the dynamic calendar may not be as pleasing as the static one in Figure 49-1. Several factors contribute to this appearance.

From a structural point of view, creating a table that can accommodate any possible layout of days and dates that a calendar may require is essential. That means a basic calendar consisting of six rows of fields. For many months, the last row remains completely empty. But because the table definition must be fixed when the page loads, this layout cannot change on the fly.

The more obvious cosmetic comparison comes from the font and alignment of data in text objects. Except for capabilities of browsers capable of using stylesheets, you're stuck with what the browser presents in both categories. In the static version, you can define different font sizes and colors for various fields, if you want (such as coloring the entry for today's date). Not so in text objects in a backward-compatible program.

This cosmetic disadvantage, however, is a boon to functionality and interactivity on the page. Instead of the user being stuck with an unchanging calendar month, this version includes pop-up menus from which the user can select a month and year of choice. Clicking the Update Calendar button refills the calendar fields with data from the selected month.

One more disadvantage to this dynamic table surfaces, however: All text objects can be edited by the user. For many applications, this capability may not be a big deal. But if you're creating a table-based application that encourages users to enter values in some fields, be prepared (in other words, have event handlers in place) to either handle calculations based on changes to any field or to alert users that the fields cannot be changed (and restore the correct value).

## Hybrids

It will probably be the rare scripted table that is entirely dynamic. In fact, the one in Figure 49-2 is a hybrid of static and dynamic table definitions. The days of the week at the top of each column are hard-wired into the table as static elements. If your table design can accommodate both styles, implement your tables that way. The fewer the number of text objects defined for a page, the better the performance for rendering the page, and the less confusion for the page's users.

## Dynamic HTML Tables

If you have the luxury of developing for IE4+ or NN6+/W3C, you have all the resources of the `table` and related element objects, as described in Chapter 37. The resulting application will appear to be much more polished, because not only does your content flow inside a table (which you can style to your heart's delight), but the content is dynamic within the table.

Listing 49-3 blends the calendar calculations from the earlier two calendar versions with the powers of IE4+ and W3C DOMs. A change to a requested calendar month or year instantly redraws the body of the table, without disturbing the rest of the page (see Figure 49-3).

**Figure 49-3:** DHTML table.

Basic date calculations are identical to the other two versions. Because this page has to be used with more modern browsers, it can use the shortcut array creation syntax for the month names array. Also, the way the table must be constructed each time is very different from two previous versions. In this version, the script creates new table rows, creates new cells for those rows, and then populates those cells with the date numbers. Repeat loop logic is quite different, relying on a combination of `while` and `for` loops to get the job done.

Other features made possible by more modern browsers include automatic population of the list of available years. This page will never go out of style (unless browsers in 2050 no longer use JavaScript). There is also more automation in the triggers of the function that populates the table.

```

## Further Thoughts

The best deployment of an interactive calendar requires the kind of Dynamic HTML currently available in IE4+ and NN6+/W3C DOMs. Moreover, the cells in those DOMs can receive mouse events so that a user can click a cell and it will highlight perhaps in a different color or display some related, but otherwise hidden, information.

A logical application for such a dynamic calendar would be in a pop-up window or frame that lets a user select a date for entry into a form date field. It eliminates typing in a specific date format, thereby ensuring a valid date entry every time. Without DHTML, you can create a static version of the calendar that renders the numbers in the calendar cells as HTML links. Those links can use a `javascript: URL` to invoke a function call that sets a date field in the main form.

# Application: A Lookup Table

---

One of the first ideas that intrigued me about JavaScript was the notion of delivering CGI-like functionality along with an HTML document. On the Web, numerous, small data collections currently require CGI scripting and a back-end database engine to drive them. Of course, not everyone who has information to share has access to the server environment (or the expertise) to implement such a solution. JavaScript provides that power.

## A Serverless Database

Before you get too carried away with the idea of letting JavaScript take the place of your SQL database, you need to recognize several limitations that prevent JavaScript from being a universal solution. First, any database that you embed into an HTML document is read-only. Although you can script an interface and lookup routines for the user, no provisions are available for writing revised information back to the server, if that is your intention.

A second consideration is the size of the data collection. Unlike databases residing on servers, the entire JavaScript database (or subset you define for inclusion into a single HTML document) must be downloaded to the user's browser before the user can work with the data. As a point of reference, think about image files. At 56.6 Kbps through a dial-up connection, how large an image file would you tolerate downloading? Whatever that limit may be (anywhere from 10 to 35K, depending on your patience) is what your database size limit should be. For many special-purpose collections, this is plenty of space, assuming one byte per character. Unlike what happens when the user downloads an embedded image file, the user doesn't see special status bar messages about your database: To the browser, these messages are all part of the HTML coming in with the document.

The kind of data I'm talking about here is obviously text data. That's not to say you can't let your JavaScript-enhanced document act as a front end to data files of other types on your server. The data in your embedded lookup table can be URLs to images that get swapped into the page as needed.

### In This Chapter

Serverless data  
collection lookup

Data-entry validation

## The Database

As I was thinking about writing a demonstration of a serverless database, I encountered a small article in the *Wall Street Journal* that related information I had always suspected. The Social Security numbers assigned to virtually every U.S. citizen are partially coded to indicate the state in which you registered for your Social Security number. This information often reveals the state in which you were born (another study indicates that two-thirds of U.S. citizens live their entire lives in the same state). The first three digits of the nine-digit number comprise this code.

When the numbering system was first established, each state was assigned a block of three-digit numbers. Therefore, if the first three digits fall within a certain range, the Social Security Administration has you listed as being registered in the corresponding state or territory. I thought this would be an interesting demonstration for a couple of reasons: first, the database is not that large, so it can be easily embedded into an HTML document without making the document too big to download, even on slow Internet connections; second, it offers some challenges to data-entry validation, as you see in a moment.

**Note**

Before young people from populous states write to tell me that their numbers are not part of the database, let me emphasize that I am well aware that several states have been assigned number blocks not reflected in the database. This example is only a demonstration of scripting techniques, not an official Social Security Administration page.

## The Implementation Plan

For this demonstration, all I started with was a printed table of data. I figured that the user interface for this application would probably be very plain: a text field in which the user can enter a three-digit number, a clickable button to initiate the search, and a text field to show the results of the lookup. Figure 50-1 shows the page. Pretty simple by any standards.

Given that user interface (I almost always start a design from the *interface* — how my page's users will experience the information presented on the page), I next planned the internals. I needed the equivalent of two tables: one for the numeric ranges, and one for the state names. Because most of the numeric ranges are contiguous, I could get by with a table of the high number of each range. This meant that the script would have to trap elsewhere for the occasional numbers that fall outside of the table's ranges — the job of data validation.

Because the two tables were so closely related to each other, I had the option of creating two separate arrays, so that any given index value would correspond to both the numeric and state name entries in both tables (*parallel arrays*, I call them). The other option was to create a two-dimensional array (see Chapter 30), in which each array entry has data points for both the number and state name. For purposes of demonstration to first-time database builders, I decided to stay with two parallel arrays. This method makes visualizing how the lookup process works with two separate arrays a little easier.

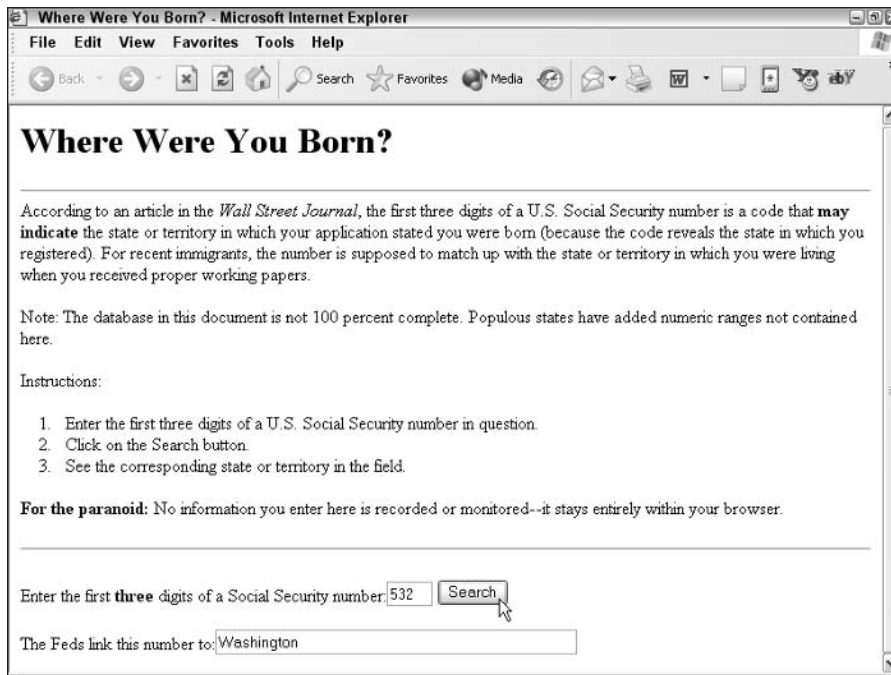

Figure 50-1: The Social Security number lookup page.

## The Code

The HTML document starts normally through the definition of the document title:

```
<html>
  <head>
    <title>Where Were You Born?</title>
```

In this application, you will see that I place utility function definitions close to the top of the script sections and put any action-oriented scripts (functions acting in response to event handlers) closer to the bottom of the script sections. My preference is to have all dependencies resolved before the script needs them. This philosophy carries over from the logic that dictates putting as many scripts in the Head as possible, so that even if the user (or network) should interrupt downloading of a page before every line of HTML reaches the browser, any user interface element relying on scripts will have those scripts loaded and ready to go. The order of functions in this example is not critical, because as long as they all reside in the Head section, they are defined and loaded by the time the field and button appear at the bottom of the page. But after I develop a style, I find it easier to stick with it — one less matter to worry about while scripting a complex application.

After creating an array (named `ssn`) with 57 empty slots, the script populates all 57 data points of the array, starting with the first entry going into the slot numbered 0. These data numbers correspond to the top end of each range in the 57-entry table. For example, any number greater than 3 but less than or equal to 7 falls into the range of the second data entry of the array (`ssn[1]`).

```
<script type="text/javascript">
// create array listing all the top end of each numeric range
var ssn = new Array(57);
ssn[0] = 3;
ssn[1] = 7;
ssn[2] = 9;
ssn[3] = 34;
ssn[4] = 39;
ssn[5] = 49;
ssn[6] = 134;
ssn[7] = 158;
ssn[8] = 211;
ssn[9] = 220;
ssn[10] = 222;
ssn[11] = 231;
ssn[12] = 236;
ssn[13] = 246;
ssn[14] = 251;
ssn[15] = 260;
ssn[16] = 267;
ssn[17] = 302;
ssn[18] = 317;
ssn[19] = 361;
ssn[20] = 386;
ssn[21] = 399;
ssn[22] = 407;
ssn[23] = 415;
ssn[24] = 424;
ssn[25] = 428;
ssn[26] = 432;
ssn[27] = 439;
ssn[28] = 448;
ssn[29] = 467;
ssn[30] = 477;
ssn[31] = 485;
ssn[32] = 500;
ssn[33] = 502;
ssn[34] = 504;
ssn[35] = 508;
ssn[36] = 515;
ssn[37] = 517;
ssn[38] = 519;
ssn[39] = 520;
ssn[40] = 524;
ssn[41] = 525;
ssn[42] = 527;
ssn[43] = 529;
ssn[44] = 530;
ssn[45] = 539;
ssn[46] = 544;
ssn[47] = 573;
ssn[48] = 574;
```

```

ssn[49] = 576;
ssn[50] = 579;
ssn[51] = 580;
ssn[52] = 584;
ssn[53] = 585;
ssn[54] = 586;
ssn[55] = 599;
ssn[56] = 728;

```

I do the same for the array containing the states and territory names. Both of these array populators seem long but pale in comparison to what you would have to do with a database of many kilobytes. Unfortunately, JavaScript doesn't give you the power to load existing data files into arrays (but see the recommendations at the end of the chapter), so any time you want to embed a database into an HTML document, you must go through this array-style assignment frenzy:

```

// create parallel array listing all the states/territories
// that correspond to the top range values in the first array
var geo = new Array(57);
geo[0] = "New Hampshire";
geo[1] = "Maine";
geo[2] = "Vermont";
geo[3] = "Massachusetts";
geo[4] = "Rhode Island";
geo[5] = "Connecticut";
geo[6] = "New York";
geo[7] = "New Jersey";
geo[8] = "Pennsylvania";
geo[9] = "Maryland";
geo[10] = "Delaware";
geo[11] = "Virginia";
geo[12] = "West Virginia";
geo[13] = "North Carolina";
geo[14] = "South Carolina";
geo[15] = "Georgia";
geo[16] = "Florida";
geo[17] = "Ohio";
geo[18] = "Indiana";
geo[19] = "Illinois";
geo[20] = "Michigan";
geo[21] = "Wisconsin";
geo[22] = "Kentucky";
geo[23] = "Tennessee";
geo[24] = "Alabama";
geo[25] = "Mississippi";
geo[26] = "Arkansas";
geo[27] = "Louisiana";
geo[28] = "Oklahoma";
geo[29] = "Texas";
geo[30] = "Minnesota";
geo[31] = "Iowa";
geo[32] = "Missouri";
geo[33] = "North Dakota";
geo[34] = "South Dakota";
geo[35] = "Nebraska";
geo[36] = "Kansas";
geo[37] = "Montana";
geo[38] = "Idaho";

```

```

geo[39] = "Wyoming";
geo[40] = "Colorado";
geo[41] = "New Mexico";
geo[42] = "Arizona";
geo[43] = "Utah";
geo[44] = "Nevada";
geo[45] = "Washington";
geo[46] = "Oregon";
geo[47] = "California";
geo[48] = "Alaska";
geo[49] = "Hawaii";
geo[50] = "District of Columbia";
geo[51] = "Virgin Islands";
geo[52] = "Puerto Rico";
geo[53] = "New Mexico";
geo[54] = "Guam, American Samoa, N. Mariana Isl., Philippines";
geo[55] = "Puerto Rico";
geo[56] = "Long-time or retired railroad workers";

```

Now comes the beginning of the data validation functions. Under control of a master validation function shown in a minute, the `stripZeros()` function removes any leading 0s that the user may have entered. Notice that the instructions tell the user to enter the first three digits of a Social Security number. For 001 through 099, that means the numbers begin with one or two 0s. JavaScript, however, treats any numeric value starting with 0 as an octal value. Because I have to do some numeric comparisons for the search through the `ssn[]` array, the script must make sure that the entries (which are strings to begin with, coming as they do from text objects) can be converted to decimal numbers. The `parseInt()` function, with the all-important second parameter indicating Base 10 numbering, does the job. But because the remaining validations assume a string value, the integer is reconverted to a string value before it is returned:

```

// **BEGIN DATA VALIDATION FUNCTIONS**
// JavaScript sees numbers with leading 0's as octal values, so strip 0's
function stripZeros(inputStr) {
    return parseInt(inputStr, 10).toString();
}

```

The next three functions are described in full in Chapter 43, which discusses data validation. In the last function, a copy of the input value is converted to an integer to enable the function to make necessary comparisons against the boundaries of acceptable ranges:

```

// general purpose function to see if an input value has been entered
function isEmpty(inputStr) {
    if (inputStr == "" || inputStr == null) {
        return true;
    }
    return false;
}

// general purpose function to see if a suspected numeric input
// is a positive integer
function isNumber(inputStr) {
    for (var i = 0; i < inputStr.length; i++) {
        var oneChar = inputStr.substring(i, i + 1);
        if (oneChar < "0" || oneChar > "9") {
            return false;
        }
    }
}

```

```

    return true;
}

// function to determine if value is in acceptable range
function inRange(inputStr) {
    num = parseInt(inputStr);
    if (num < 1 || num > 586 && num < 596 || num > 599 &&
        num < 700 || num > 728) {
        return false;
    }
    return true;
}

```

The master validation controller function (named `isValid()` in this application) is also covered in depth in Chapter 43. A statement that wants to know if it should proceed with the lookup process calls this function. If any one validation test fails, the function returns `false`, and the search does not proceed:

```

// Master value validator routine
function isValid(inputStr) {
    if (isEmpty(inputStr)) {
        alert("Please enter a number into the field before clicking the
            button.");
        return false;
    } else {
        if (!isNumber(inputStr)) {
            alert("Please make sure entries are numbers only.");
            return false;
        } else {
            if (!inRange(inputStr)) {
                alert("Sorry, the number you entered is not part of our
                    database. Try another three-digit number.");
                return false;
            }
        }
    }
    return true;
}
// **END DATA VALIDATION FUNCTIONS**

```

The `search()` function is invoked by two different event handlers (and indirectly by a third). The two direct calls come from the input field's `onchange` event handler and the Search button's `onclick` event handler. The handler passes a reference to the form, which includes the button and both text objects.

To search the database, the script repeatedly compares each succeeding entry of the `ssn[]` array against the value entered by the user. For this process to work, a little bit of preliminary work is needed. First comes an initialization of a variable, `foundMatch`, which comes into play later. Initially set to `false`, the variable is set to `true` only if there is a successful match—information you need later to set the value of the result text object correctly for all possible conditions:

```

// Roll through ssn DB to find index; apply index to geography DB
function search(form) {
    var foundMatch = false;
    var inputStr = stripZeros(form.entry.value);
    if (isValid(inputStr)) {
        inputValue = inputStr;
    }
}

```

```

        for (var i = 0; i < ssn.length; i++) {
            if (inputValue <= ssn[i]) {
                foundMatch = true;
                break;
            }
        }
    }
    form.result.value = (foundMatch) ? geo[i] : "";
    form.entry.focus();
    form.entry.select();
}

```

Next comes all the data preparation. After the entry is passed through the zero stripper, a copy is dispatched to the master validation controller, which, in turn, sends copies to each of its special-purpose minions. If the master validator detects a problem from the results of any of those minions, it returns `false` to the condition that wants to know if the input value is valid. Should the value not be valid, processing skips past the `for` loop and proceeds immediately to an important sequence of three statements.

The first is a conditional statement that relies on the value of the `foundMatch` variable that was initialized at the start of this function. If `foundMatch` is still `false`, that means that something is wrong with the entry and it cannot be processed. To prevent any incorrect information from appearing in the result field, that field is set to an empty string if `foundMatch` is `false`. The next two statements set the focus and selection to the entry field, inviting the user to try another number.

On the other hand, if the entry is a valid number, the script finally gets to perform its lookup task. Looping through every entry of the `ssn[]` array starting with entry 0 and extending until the loop counter reaches the last item (based on the array's `length` property), the script compares the input value against each entry's value. If the number is less than or equal to a particular entry, the value of the loop counter (`i`) is frozen, the `foundMatch` variable is set to `true`, and execution breaks out of the `for` loop.

This time through the conditional expression, with `foundMatch` being `true`, the statement plugs the corresponding value of the `geo[]` array (using the frozen value of `i`) into the result field. Focus and selection are set to the entry field to make it easy to enter another value.

Browsers that recognize keyboard events benefit by allowing the search to be initiated if the user presses the Enter key after entering a number. An `onkeypress` event handler for the input text box invokes the `searchOnReturn()` function. This function employs cross-browser event parsing to find out if the Return key had been pressed while the text pointer was in the text box. If so, the `search()` function, described earlier, is asked to do its job. Any characters other than the Return key are allowed to pass unchanged to the input box:

```

// start search if input field receives a Return character
function searchOnReturn(form, evt) {
    evt = (evt) ? evt : (window.event) ? window.event : "";
    if (evt) {
        var theKey = (evt.charCode) ? evt.charCode :
            ((evt.which) ? evt.which : evt.keyCode);
        if (theKey == 13) {
            search(form);
            return false;
        }
    }
}
return true;

```

```

    }
  </script>
</head>

```

The balance of the code is the Body part of the document. The real action takes place within the Form definition:

```

<body>
  <h1>Where Were You Born?</h1>
  <hr />
  According to an article in the <cite>Wall Street Journal</cite>, the
  first three digits of a U.S. Social Security number is a code that <b>may
  indicate</b> the state or territory in which your application stated you
  were born (because the code reveals the state in which you registered).
  For recent immigrants, the number is supposed to match up with the state
  or territory in which you were living when you received proper working
  papers.
  <p>Note: The database in this document is not 100 percent complete.
  Populous states have added numeric ranges not contained here.</p>
  <p>Instructions:</p>
  <ol>
    <li>Enter the first three digits of a U.S. Social Security number in
    question.</li>
    <li>Click on the Search button.</li>
    <li>See the corresponding state or territory in the field.</li>
  </ol>
  <p><b>For the paranoid:</b> No information you enter here is recorded or
  monitored--it stays entirely within your browser.</p>
  <hr />

```

The form's `onsubmit` event handler is set to prevent accidental submission (or pseudo-submission, because no `action` attribute is specified for the form) that MacIE does from any form's text box (other browsers submit on Return from only a single-field form). Each of the text objects is sized to fit the expected data. A handful of event handlers invoke the `search()` function (directly and indirectly), passing a reference to the form as a parameter:

```

  <form onsubmit="return false">
    Enter the first <b>three</b> digits of a Social Security number:<input
    type="text" name="entry" size="3"
    onkeypress="return searchOnReturn(this.form, event)"
    onchange="search(this.form)" /> <input type="button" value="Search"
    onclick="search(this.form)" />
    <p>The Feds link this number to:<input type="text" name="result"
    size="50" /></p>
  </form>
</body>
</html>

```

## Further Thoughts

If I were doing this type of application for production purposes, I would turn each pairing of range high number and geographical location into separate objects and store the objects in an array. Making that technique work requires one extra function and a different way of populating the data. The following is an example using the same variable names as the preceding listing:

```

// specify an array entry with two items
function dataRecord(ssn, geo) {
    this.ssn = ssn;
    this.geo = geo;
    return this;
}

// initialize basic array
var numberState = new Array(57);

// populate main array with smaller arrays
numberState[0] = new dataRecord(3,"New Hampshire");
numberState[1] = new dataRecord(7,"Maine");
numberState[2] = new dataRecord(9,"Vermont");

```

The other changes (marked in boldface) occur in the `search()` function, which must address this data in a slightly different way than it did before:

```

function search(form) {
    var foundMatch = false;
    var inputStr = stripZeros(form.entry.value);
    if (isValid(inputStr)) {
        inputValue = inputStr;
        for (var i = 0; i < numberState.length; i++) {
            if (inputValue <= numberState[i].ssn) {
                foundMatch = true;
                break;
            }
        }
    }
    form.result.value = (foundMatch) ? numberState[i].geo : "";
    form.entry.focus();
    form.entry.select();
}

```

All references to data are to the `numberState[]` array and properties of its objects (either `ssn` or `geo`). With the data for each record arranged in a comma-delimited fashion, it may be easier to transfer data exported from an existing database to your script with less copying and pasting or dragging and dropping.

Another possibility would be to use JavaScript's capability to load `.js` files that have the arrays already populated or have variables preloaded with comma-delimited values. By using the `string.split()` method (see Chapter 27), you can easily assign data in this format to an array.

From a user interface perspective, the `searchOnReturn()` function can do more with the event object. For instance, it could filter data entry so that only numbers ever reach the input text field. You would still want to perform the data-entry validation in case someone were to paste some non-numeric text into the text box.

I truly believe that serverless data lookups offer a great opportunity to many creative JavaScripters.

# Application: A “Poor Man’s” Order Form

---

I hesitate to call the application described in this chapter an “order form” because it is not in any way intended for use as a client-side shopping cart or some of the more advanced e-commerce applications you see on the Web. No, the goal here is to demonstrate how JavaScript can be used to assist users with column-and-row arithmetic, very much like the kinds of arithmetic needed to calculate the total for an order of goods.

Although this order form is not linked to any particular online catalog, some or all of it can be used as a piece for a small e-commerce site. The form in the example here requires that users input product descriptions and prices, but there is no reason that a client-side JavaScript shopping cart can’t accumulate the shopper’s choices from catalog pages, and then present them in an order form with product descriptions and prices hard-wired into the table. There still are entry boxes for quantity and selecting local sales tax rates. But all the arithmetic products and sums are calculated quickly on the client with JavaScript.

Along the way, you should also discover how to design code—more specifically, JavaScript data structures—in such a way that they are easily editable by non-scripters who are responsible for updating the embedded data. Therefore, even if you prefer to leave professional e-commerce order processing to server CGIs, you may still pick up a scripting tip or two from this “poor man’s” version of an order form.

## Defining the Task

I doubt that any two order forms on the Web are executed precisely the same way. Much of the difference has to do with the way a CGI program on the server wants to receive the data on its way to an order-entry system or database. The rest has to do with how clever the HTML programmer is. To come up with a generalized demonstration, I had to select a methodology and stay with it.

### In This Chapter

Live math on table rows and columns

Number formatting

Code reusability

Because the intended goal of this demonstration is to focus on the rows and columns of an order form, I omit the usual name-and-address input elements. Instead, the code deals exclusively with the tabular part of the form, including the footer “stuff” of a form for subtotals, sales tax, shipping, and the grand total.

Another goal is to design the order form with an eye to as much reusability as possible. In other words, I may design the form for one page, but I also want to adapt it to another order form quickly without having to muck around too deeply in complicated HTML and JavaScript code. One giant annoyance that this approach eliminates is the normal HTML repetition of row after row of tags for input fields and table cells. JavaScript can certainly help you out there.

The order form code also demonstrates how to perform math and display results in two decimal places, use the `String.split()` method to make it easy to build arrays of data from comma-delimited lists, and enable JavaScript arrays to handle tons of repetitive work.

## The Form Design

Figure 51-1 shows a rather simplified version of an order form as provided in the listings. Many elements of the form are readily adjustable by changing only a few characters near the top of the JavaScript listing. At the end of the chapter, I provide several suggestions for improving the user experience of a form, such as this one.

Figure 51-1: The order form display.

## Form HTML and Scripting

Because this form is generated as the document loads, JavaScript writes most of the document to reflect the variable choices made in the reusable parts of the script. In fact, in this example, only the document heading is hard-wired in HTML.

The order form example page starts innocently enough:

```
<html>
  <head>
    <title>Scripted Order Form</title>
```

### Global adjustments

The first important section of the example is the start of the JavaScript statements and functions that do most of the work. The script begins by initializing three very important global variables. This location is where the author, defining the details for the order form, also enters information about the column headings, column widths, and number of data entry rows:

```
<script type="text/javascript">
  // ** BEGIN GLOBAL ADJUSTMENTS ** //
  // Order form columns and rows specifications
  // **Column titles CANNOT CONTAIN PERIODS
  var columnHeads = "Qty,Stock#,Description,Price,Total".split(",");
  var columnWidths = "3,7,20,7,8".split(",");
  var numberOfRows = 5;
```

The first two assignment statements perform double duty. Not only do they provide the location for customized settings to be entered by the HTML author, but they use the *string*.split() method to literally create arrays out of their series of comma-delimited strings. At first, this may seem to be a roundabout way to generate an array, because you can also create the array directly with

```
var columnHeads = new Array("Qty","Stock",...);
```

But the way shown here minimizes the possibility of goofing up the quotes and commas when modifying the data, especially if modification might be attempted by a non-scripter.

So much of the repetitive work to come in this application is built around arrays that it will prove to be extraordinarily convenient to have the column title names and column widths in parallel arrays. The number-of-rows value also plays a role in not only drawing the form, but calculating it as well.

Notice the caveat about periods in column heading strings. You will soon see that these column names are assigned as text object names, which, in turn, are used to build object references to text boxes. Object names cannot have periods in them, so for these column headings to perform their jobs, you have to leave periods out of their names.

As part of the global adjustment area, the extendRow() method requires knowledge about which columns are to be multiplied to reach a total for any row:

```
// data entry row math
function extendRow(form,rowNum) {
  // **change 'Qty' and 'Price' to match your column names
  var rowSum = form.Qty[rowNum].value * form.Price[rowNum].value;
  // **change 'Total' to match your corresponding column name
  form.Total[rowNum].value = formatNum(rowSum,2);
}
```

This example uses the `Qty`, `Price`, and `Total` fields for math calculations. Those field names are inserted into the references within this function. To calculate the total for each row, the function receives the form object reference and the row number as parameters. As described later, the order form is generated as a kind of array. Each field in a column intentionally has the same name. This scheme enables scripts to access a given field in that column by row number when using the row number as an index to the array of objects bearing the same name. For example, for the first row (row 0), you calculate the total by multiplying the quantity field of row 0 (`form.Qty[0].value`) times the price field of row 0 (`form.Price[0].value`). You then format that value to two places to the right of the decimal and plug that number into the value of the total field for row 0 (`form.Total[0].value`).

The final place where you have to worry about customized information is in the function that adds up the total columns. The function must know the name that you assigned to the total column:

```
function addTotals(form) {
    var subTotal = 0;
    for (var i = 0; i < numberOfRows; i++) {
        // **change 'Total' in both spots to match your column name
        subTotal += (form.Total[i].value != "")?
            parseFloat(form.Total[i].value) : 0;
    }
    form.subtotal.value = formatNum(subTotal,2);
    form.tax.value = formatNum(getTax(form,subTotal),2);
    form.total.value = "$" + formatNum((parseFloat(form.subtotal.value) +
        parseFloat(form.tax.value) + parseFloat(form.shipping.value)),2);
}
// ** END GLOBAL ADJUSTMENTS ** //
```

The `addTotals()` function receives the form reference as a parameter, which it uses to read and write data around the form. The first task is to add up the values of the total fields from each of the data-entry rows. Here you need to be specific about the name you assign to that column. To keep code lines to a minimum, you use a conditional expression inside the `for` loop to make additions to the `subTotal` amount only when a value appears in a row's total field. Because all values from text fields are strings, you use `parseFloat()` to convert the values to floating-point numbers before adding them to the `subTotal` variable.

Three more assignment statements fill in the subtotal, tax, and total fields. The subtotal is nothing more than a formatted version of the amount reached at the end of the `for` loop. The task of calculating the sales tax is passed off to another function (described in a following section), but its value is also formatted before being plugged into the sales tax field. For the grand total, you add floating-point-converted values of the subtotal, tax, and shipping fields before slapping a dollar sign in front of the result. Even though the three fields contain values formatted to two decimal places, any subsequent math on such floating-point values incurs the minuscule errors that send formatting out to 16 decimal places. Thus, you must reformat the results after the addition.

## Do the math

As you can see from Figure 51-1, the user interface for entering the sales tax is a pair of `select` elements. This type of interface minimizes the possibility of users entering the value in all kinds of weird formats that, in some cases, would be impossible to parse. The function that calculates the sales tax of the subtotal looks to these `select` objects for their current settings:

```
function getTax(form,amt){
    var chosenPercent = form.percent[form.percent.selectedIndex].value;
    var chosenFraction = form.fraction[form.fraction.selectedIndex].value;
    var rate = parseFloat(chosenPercent + "." + chosenFraction) / 100;
    return amt * rate;
}
```

After receiving the form object reference and subtotal amount as parameters, the function reads the two values chosen in the `select` elements. The string `value` properties of the `select` objects are temporarily stored in local variables. To arrive at the actual rate, you concatenate the two portions of the string (joined by an artificial decimal point) and `parseFloat()` the string to get a number that you can then divide by 100. The product of the subtotal times the rate is returned to the calling statement (in the preceding `addTotals()` function).

All of the calculation that ripples through the order form is controlled by a single `calculate()` function:

```
function calculate(form,rowNum) {
    extendRow(form,rowNum);
    addTotals(form);
}
```

This function is called by any object that affects the total of any row. Such a request includes both the form object reference and the row number. This information lets the single affected row, and then the totals column, be recalculated. Changes to some objects, such as the sales tax `select` objects, affect only the totals column, so they will call `addTotals()` function directly rather than this function (the rows don’t need recalculation).

Number formatting, as explained in Chapter 28, is a detail that scripters must handle themselves (unless you are designing for IE5.5+ and NN6+/W3C, which include the *number*.`toFixed()` method for number formatting). We can borrow the formatting code from Chapter 28, and use it here as-is:

```
function formatNum(expr,decplaces) {
    var str = (Math.round(parseFloat(expr) *
        Math.pow(10,decplaces))).toString();
    while (str.length <= decplaces) {
        str = "0" + str;
    }
    var decpoint = str.length - decplaces;
    return str.substring(0,decpoint) + "." +
        str.substring(decpoint,str.length);
}
```

Being able to pick up this function from a different application should reinforce the advantage to writing functions to be as generalizable as possible. Rather than building page-specific references into the formatting function, it accepts parameters that could come from anywhere. Page specifics are left to another function that deals with reading and writing text box values.

## Cooking up some HTML

As we near the end of the scripting part of the document’s Head section, we come to two functions that are invoked later to assemble some table-oriented HTML based on the global settings made at the top. One function assembles the row of the table that contains the column headings:

```

function makeTitleRow() {
    var titleRow = "<tr>";
    for (var i = 0; i < columnHeads.length; i++) {
        titleRow += "<th>" + columnHeads[i] + "<\th>";
    }
    titleRow += "<\tr>";
    return titleRow;
}

```

The heart of the `makeTitleRow()` function is the `for` loop, which makes simple `<th>` tags out of the text entries in the `columnHeads` array defined earlier. All this function does is assemble the HTML. A `document.write()` method in the `Body` puts this HTML into the document.

```

function makeOneRow(rowNum) {
    var oneRow = "<tr>";
    for (var i = 0; i < columnHeads.length; i++) {
        oneRow += "<td align=middle><input type=text size=" +
            columnWidths[i] + " name=\'" + columnHeads[i] +
            "\' onchange='calculate(this.form," + rowNum + ")'\><\td>";
    }
    oneRow += "<\tr>";
    return oneRow;
}

```

Creating a row of entry fields is a bit more complex, but not much. Instead of assigning just a word to each cell, you assemble an entire `<input>` object definition. You use the `columnWidths` array to define the size for each field (which therefore defines the width of the table cell in the column). `columnHead` values are assigned to the field's `name` attribute. Each column's fields have the same name, no matter how many rows exist. Finally, the `onchange` event handler invokes the `calculate()` method, passing the form and, most importantly, the row number, which comes into this function as a parameter (see the following section).

The next block of code closes up the head, opens up the body, and prepares the page for a table to hold the order form:

```

</script>
</head>
<body>
    <center>
        <h1>ORDER FORM</h1>
        <form>
            <table border='2'>

```

## Tedium lost

Believe it or not, all of the rows of data-entry fields in the table are defined by the handful of JavaScript statements that follow:

```

<script type="text/javascript">
    document.write(makeTitleRow());
    // order form entry rows
    for (var i = 0; i < numberOfRows; i++) {
        document.write(makeOneRow(i));
    }

```

The first function to be called is the `makeTitleRow()` function, which returns the HTML for the table's column headings. Then a very simple `for` loop writes as many rows of the field cells

as defined in the global value near the top of the document. Notice how the index of the loop, which corresponds to the row number, is passed to the `makeOneRow()` function, so that it can assign that row number to its relevant statements. Therefore, these few statements generate as many entry rows as you need.

## Tedium regained

What follows in the script writes the rest of the form to the screen. To make these fields as intelligent as possible, the scripts must take the number of columns into consideration. A number of empty-space cells must also be defined (again, calculated according to the number of columns). Finally, the code-consuming `select` element definitions must also be in this segment of the code:

```
// order form footer stuff (subtotal, sales tax, shipping, total)
var colSpacer = "<tr><td colspan=" + (columnWidths.length - 2) +
"></td>";
document.write(colSpacer);
document.write("<th>Subtotal:</th>");
document.write("<td><input type=text size=" +
columnWidths[columnWidths.length - 1] +
" name=subtotal></tr>");
document.write("<tr><td colspan=" + (columnWidths.length - 3) +
"></td>");
var tax1 = "<select name=percent
onchange='addTotals(this.form)''><option value=0>0";
tax1 += "<option value=1>1<option value=2>2<option value=3>3";
tax1 += "<option value=4>4<option value=5>5<option value=6>6";
tax1 += "<option value=7>7<option value=8>8<option value=9>9";
tax1 += "</select>";
var tax2 = "<select name=fraction
onchange='addTotals(this.form)''>";
tax2 += "<option value=0>00<option value=25>25";
tax2 += "<option value=50>50<option value=75>75</select>";
document.write("<th align=right>" + tax1 + "." + tax2 +
"%</th>");
document.write("<th align=right>Sales Tax:</th>");
document.write("<td><input type=text size=" +
columnWidths[columnWidths.length - 1] +
" name=tax value=0.00></tr>");
document.write(colSpacer);
document.write("<th>Shipping:</th>");
document.write("<td><input type=text size=" +
columnWidths[columnWidths.length - 1] +
" name=shipping value=0.00
onchange='addTotals(this.form)''></tr>");
document.write(colSpacer);
document.write("<th>Total:</th>");
document.write("<td><input type=text size=" +
columnWidths[columnWidths.length - 1] + " name=total></tr>");
</script>
</table>
</form>
</center>
</body>
</html>
```

To gain a better understanding of how the script assembles the HTML for this part of the table, start by looking at the `colSpacer` variable. This variable contains a table cell definition that must span all but the rightmost two columns. Thus, the `colspan` attribute is calculated based on the length of the `columnWidths` array (minus two for the columns we need for data). Therefore, to write the line for the subtotal field, you start by writing one of these column spacers, followed by the `<th>` type of cell with the label in it. For the actual field, you must size it to match the fields for the rest of the column. That's why you summon the value of the last `columnWidths` value for the `size` attribute. You use similar machinations for the Shipping and Total lines of the form footer material.

In between these locations, you define the Sales Tax `select` objects (and a column spacer that is one cell narrower than the other one you used). To reduce the risk of data-entry error and to allow for a wide variety of values without needing a 40-item pop-up list, I divided the choices into two components and then display the decimal point and percentage symbol in hard copy. Both `select` objects trigger the `addTotals()` function to recalculate the rightmost column of the form.

Sometimes, it seems odd that you can script 4 lines of code to get 20 rows of a table, yet it takes 20 lines of code to get only 4 more complex rows of a table. Such are the incongruities of the JavaScripter's life.

## Further Thoughts

Depending on the catalog of products or services being sold through this order form, the first improvement I would make is to automate the entry of stock number and description. For example, if the list of all product numbers isn't that large, you may want to consider dropping a `select` element into each cell of the Description column. Then, after a user makes a selection, the `onchange` event handler performs a lookup through a product array and automatically plugs in the description and unit price. In any version of this form, you also need to perform data validation for crucial calculation fields, such as quantity.

Some of the other online order forms I've seen include reset buttons for every row or a column of checkmarks that lets users select one or more rows for deletion or resetting. Remember that people make mistakes and change their minds while ordering online. Give them plenty of opportunity to recover easily. If getting out of jam is too much trouble, they will head for the History list or Back button, and that valued order will be, well, history.

# Application: Outline-Style Table of Contents

---

**I**n your Web surfing, you may have encountered sites that implement an expandable, outline type of table of contents. I've long thought that these elements were great ideas, especially for sites with lots of information. An outline, such as the Windows Explorer or text-style Macintosh Finder windows, enables the author to present a large table of contents in a way that doesn't necessarily take up a ton of page space or bandwidth. From listings of top-level entries, a user can drill down to reveal only those items of interest.

No matter how much I like the idea, however, I dislike visiting these sites. A CGI program on the server responds to each click, chews on my selection, and then sends back a completely new screen, showing my choice expanded or collapsed. After working with outlines in the operating system and outliner programs on personal computers, the delays in this processing seem interminable. It occurred to me that implementing the outline interface as a client-side JavaScript can significantly reduce the delay problem and make outlines a more viable interface to a site's table of contents. This chapter documents the process that went into an early version of the outliner, which works with most older browsers. Some newer versions are also presented.

## Design Challenges

The more I looked into implementing an outline in the early scripting days, the more challenges I found ahead of me.

The first problem was making the little icons (widgets) clickable so that they respond to user mouse actions. Even though images are objects in NN3 and IE4+, NN images don't have mouse-oriented event handlers until you reach NN6 (although you can make some mouse events work in some versions of WinNN4). Therefore, it was necessary to surround each image with a link object whose `href` attribute called a `javascript: URL` and function to do the job. This technique also helped solve the next problem.

### In This Chapter

Multiple frames

Clickable images

Custom objects

Image caching

Persistent data

Dynamic HTML  
positioning

Reading XML data

After a user clicks an outline widget, the script must update the window or frame containing the outline to expand or collapse a portion of the outline. The original design predated dynamically updated pages of IE4+ and NN6+/W3C DOM, so the entire page had to be rewritten. But to make that work, the script needed a way to represent and temporarily preserve the current state of the outline—a line-by-line rundown on whether a line was currently expanded or collapsed. If the script could save that state somewhere, the widget's link `href` attribute could summon a JavaScript function whose job is to perform a soft reload of the current page without reopening it—with the `history.go()` method. Therefore, as a user clicked a widget, the state of the outline created by that click would be generated in the script, saved, and then used to specify the expanded or collapsed state of each line as the page reloaded.

Just when I was congratulating myself on how clever I was, I realized that any attempt to save the state of the new outline in a variable was doomed: Even a soft reload restores variables to their original state. I'd have to find another way to maintain the data.

The first method I used was to store the outline state (a string of 0s and 1s, in which a 1 indicated that the item was expanded) in a text box. Text and `textarea` objects in early browsers maintain their contents even through a document reload (but not a reopen). Although this method was convenient, it was ugly because it meant that the field would have to be in the frame. One tactic was to make the frame a non-scrolling frame and stuff the field out of sight by pushing it to the far right with padding spaces inside a `<pre>...</pre>` tag.

Next, it was time to try Netscape's mechanism for storing persistent data on the client computer: the `document.cookie` property. Cookies are not unique to JavaScript. Any CGI can also store data, such as a user's login name and password for a site, in a cookie. The cookie did the trick. Information about the outline lasts in the cookie of any user's computer only as long as the browser stays running.

Another detail that I wanted to overcome was the initial delay experienced the first time a user clicked one of the collapsed widgets in the outline. At that point, only one of three icon image files had been loaded and cached in the browser. In the very first version of this application for NN2, I arranged to display all three widgets as decoration on the page to get them loaded up front. But with NN3+ and IE4+, I can precache all the widget art files and deploy them instantly when needed.

## The Implementation Plan

I admit to approaching the outline technique the first time without a specific data-display goal in mind—not always the best way to go about it. In search of some logical and public domain data that I could use as an example, I came upon the tables of information about food composition (grams of protein, fat, calories, and so on) published by the U.S. government. For this demonstration, I created one HTML document containing data for two hierarchical categories of foods: peas and pickles. At the beginning of each food category, I assigned an anchor to which the text entries of the outline point.

My design for this implementation calls for two frames set up as columns (see Figure 52-1). The narrower left column houses the outline interface. After the frameset loads, the wider right frame initially shows an introductory HTML document. Clicking any of the links in the outline changes the view of the right-hand frame from the introductory document to the food data document. A link at the bottom of the food data document enables the user to view the introductory document again in the same frame, if desired.

**Figure 52-1:** The outline in the left frame is dynamic and local.

In addition to image caching, modern browsers gave me reason to make some other improvements to the outliner over a version originally created for NN2. They include

- ♦ Adjustable indentation spacing
- ♦ Easier specification of widget art files
- ♦ Easier way to specify a target frame for the results
- ♦ Additional array field for status bar display text

All adapter-adjustable elements appear near the top of the script to make it easy for scripters without a lot of experience to modify the application for their own sites.

## The Code

All files for this implementation of the outline are on the CD-ROM accompanying this book, so I display here only the code for the framesetting document (`index.htm`) and the outline (`toc4.htm`). Earlier numbered filenames were used for previous editions of this book.

### Setting the frames

To establish the frames, the script creates a two-column format, assigning 35 percent of the page as a column to contain the outline:

```

<html>
  <head>
    <title>Outline Table of Contents</title>
  </head>
  <frameset cols="35%,*">
    <noframes>
      <body>
        <h1>It's really cool...</h1>
        <h2>...but only if you have a frames-capable browser.</h2>
        <hr />
        <a href="../index.html">Back</a>
      </body>
    </noframes>
    <frame name="Frame1" src="toc4.htm" />
    <frame name="Frame2" src="intro.htm" />
  </frameset>
</html>

```

Because pages designed for multiple frames and JavaScript don't fare well in browsers incapable of displaying frames, a good approach is to surround HTML with a `<noframes>` tag for display to users of old browsers or browsers on portable devices that have limited feature sets. You can substitute any link you like for the one shown here, which goes back to the main JavaScript page at my Web site.

The names that I assign to the two frames aren't very original or clever, but they help me remember which frame is which. Because the nature of the contents of the second frame changes (either the introductory document or the data document), I couldn't think of a good name to reflect its purpose.

## Outline code

Now we come to some lengthy code for the outline (in file `toc4.htm`). Much of the code deals with managing the binary representation of the current state of the outline. For each line of the completely exploded outline, the code designates a 0 for a line that has no nested items showing and a 1 for a line that has a nested item showing. This sequence of 0s and 1s (as one string) is the road map that the script follows when redrawing the outline. Cues from the 0 and 1 settings let the script know whether it should display a nested item (if one exists) or leave that item collapsed.

To help me visualize the inner workings of these scripts, I developed a convention that calls any item with nested items beneath it a *mother*. Any nested item is that mother's *daughter*. A daughter can also be a mother if it has an item nested beneath it. You see how this plays out in the code shortly.

The food outline document starts out simply enough, with the standard opening of a JavaScript script. The first specification set apart for easy modification is the size of the indentation level in pixels:

```

<html>
  <head>
    <title>Food Selection Outline</title>
    <script type="text/javascript">
      // ** BEGIN OUTLINE AUTHOR-ADJUSTABLE SPECIFICATIONS **//

      // size of horizontal indent per level
      var indentPixels = 20;

```

Outline level indentations are controlled by the width of a transparent image file. Indentation size is uniform throughout the outline, and the value is controlled via the `indentPixels` global variable. The image file is actually only a single pixel large, but by setting the width as needed (see the following example), it occupies a known amount of space, without affecting the font characteristics of the outline text.

Two more groups of adjustable items come next. The first group takes care of the widget images. This group is where you specify the filenames for the three widgets and provide the script with their height and width measurements:

```
// art files and sizes for three widget styles
// (all three widgets must have same height/width)
var collapsedWidget = "plus.gif";
var expandedWidget = "minus.gif";
var endpointWidget = "end.gif";
var widgetWidth = 12;
var widgetHeight = 12;

// Target for documents loaded when user clicks on a link.
// Specify your target frame name here.
var displayTarget = "Frame2";
```

When you design your widget art (if you don't like mine), be sure to design all three to be the same size. This practice prevents scaling of the images later.

If you deploy the outliner for your site, be sure to change the name of the frame assigned to the `displayTarget` global variable. This value eventually becomes part of the text links in the outline. If you want a click of a link to completely replace the current frameset with a different page, specify `_top` as the display target.

## Assembling outline content

The last of the easily modifiable areas defines the content of the outline. After defining the primary array (`db`), a second dimension is added to create an array of custom objects. The `dbRecord` array (defined in the following listing) helps populate the `db` array with specifics provided in the comma-delimited statements here:

```
// Create array object containing outline content and attributes.
// To adapt outline for your use, modify this table.
// Start the array with [1], and continue without gaps to your last item.
// The order of the five parameters:
// 1. Boolean (true or false) whether _next_ item is indented.
// 2. String to display in outline entry (including <font> or style
//    tags).
// 3. URL of link for outline entry; Use empty string ("") for no link
// 4. Integer of indentation level (0 is leftmost margin level)
// 5. String for status line during onMouseOver (apostrophes require
//    \\'')
var db = new Array();
db[db.length] = new dbRecord(true, "Peas", "",0,"");
db[db.length] = new dbRecord(false, "Boiled", "foods.htm#boiled",1,
    "Mmm, boiled peas...");
db[db.length] = new dbRecord(true, "Canned", "foods.htm#canned",1,
    "Check out canned peas...");
db[db.length] = new dbRecord(false, "Alaska","foods.htm#alaska",2,
    "Alaska\\'s finest...");
```

```

db[db.length] = new dbRecord(false, "Low-Sodium", "foods.htm#lowosodium", 2,
    "A healthy treat...");
db[db.length] = new dbRecord(true,
    "<font color=red size=+2>Pickles</font>", "", 0, "");
db[db.length] = new dbRecord(true, "Cucumber", "foods.htm#cucumber", 1,
    "What\\'s new in cukes...");
db[db.length] = new dbRecord(false, "Dill", "foods.htm#dill", 2,
    "Pucker up...");
db[db.length] = new dbRecord(false, "Fresh", "foods.htm#fresh", 2,
    "You\\'d prefer stale?");
db[db.length] = new dbRecord(false, "Sour", "foods.htm#sour", 2,
    "For sweeties...");
// add more records to complete your outline
// ** END AUTHOR-ADJUSTABLE SPECIFICATIONS **//

```

Each record consists of five items. The first item is a Boolean value, which denotes whether the item is a mother item (that is, the next item in the list is nested one level deeper). The HTML that displays in the outline comes next. This text can be multiple-word strings, or any HTML that you like (some users have assigned `<img>` tags to show pictures instead of text). For the third item, you can insert any valid URL, whether it be to a separate site, an anchor in another document (as shown here), or even a `javascript: URL` to execute another function. If you don't want an entry in the outline to be a link—just plain, flat text—leave this third item as an empty string, as I do here for the topmost items in both categories. The fourth item is a number representing how many nested levels the item has. And finally, the last item is a string containing the text that appears in the status bar when the user rolls the mouse over the item in the outline. Because of a quirk in the way the status bar responds to quoted characters, any string literal character (normally preceded with a backslash) requires two backslashes (one to alert the browser of the other).

Be sure to keep the items for the `db` array in the same top-to-bottom order as you'd expect to see in a fully expanded outline. Notice that the index values of the array are automatically inserted for you: The `length` property of an array is always one more than the highest index. By inserting references to the `db.length` property in the brackets, you instruct JavaScript to “walk the ladder” upward from zero. If you move things around the outline, however, don't forget to adjust the indentation levels if they are affected by the content changes.

The bottom of the array creation section marks the end of the code that you need to modify after you deploy the outliner. The rest of the JavaScript code works silently for you, but if you intend to perform further customizations to the outliner, understanding how it all works will help.

On to the constructor function for the `dbRecord` entries. This function is the classic JavaScript way to build a custom object (see Chapter 33):

```

// object constructor for each outline entry
function dbRecord(mother, display, URL, indent, statusMsg){
    this.mother = mother; // is this item a parent?
    this.display = display; // text to display
    this.URL = URL; // link tied to text; if empty string, item
    // appears as straight text
    this.indent = indent; // how many levels nested?
    this.statusMsg = statusMsg; // descriptive text for status bar
    return this;
}

```

To preload all the images into the browser's image cache, you create new `Image` objects for each and assign the filenames to their `src` properties. Notice that these statements are not in functions, but rather execute as the page loads:

```

// pre-load all images into cache
var fillerImg = new Image(1,1);
fillerImg.src = "filler.gif";
var collapsedImg = new Image(widgetWidth,widgetHeight);
collapsedImg.src = collapsedWidget;
var expandedImg = new Image(widgetWidth,widgetHeight);
expandedImg.src = expandedWidget;
var endpointImg = new Image(widgetWidth,widgetHeight);
endpointImg.src = endpointWidget;

```

## Cookie storage

To preserve the binary digit string between redraws of the outline, this script must save the string to a place that won't be overwritten or emptied during the document reload. The `document.cookie` fills that requirement nicely. Excerpting and adapting parts of Bill Dortch's cookie functions (see Chapter 18), this script simplifies the writing of a cookie that disappears when the user quits the browser:

```

// ** functions that get and set persistent cookie data **
// set cookie data
var mycookie = document.cookie;
function setCurrState(setting) {
    mycookie = document.cookie = "currState=" + escape(setting);
}
// retrieve cookie data
function getCurrState() {
    var label = "currState=";
    var labelLen = label.length;
    var cLen = mycookie.length;
    var i = 0;
    while (i < cLen) {
        var j = i + labelLen;
        if (mycookie.substring(i,j) == label) {
            var cEnd = mycookie.indexOf(";",j);
            if (cEnd == -1) {
                cEnd = mycookie.length;
            }
            return unescape(mycookie.substring(j,cEnd));
        }
        i++;
    }
    return "";
}

```

A global variable is used to act as a speedy intermediary between the actual browser cookie and the functions here that need to access cookie data. The `setCurrState()` function contains a construction that you don't see much in this book, but is quite valid. Notice the three-piece assignment statement. Evaluation of this statement works from right to left. The rightmost expression concatenates a cookie label and the value passed in as a parameter to the function. Note, too, that the value is passed through the `escape()` function to properly URL-encode the data for the sake of data integrity (so that spaces and odd punctuation don't mess up the mechanism). The concatenated value is assigned to the `document.cookie` property. With the value safely dropped into the cookie (it may be just one of several name/value pairs for this domain), the value of the `document.cookie` property (which includes all name/value pairs for the domain) is assigned to the `mycookie` global variable.

Retrieving information from the cookie still requires a bit of parsing to be on the safe side. If other cookie writing were to come from the current server path, more than one cookie would be available to the current document. Parsing the entire cookie for just the portion that corresponds to the `currState` labeled cookie ensures that the script gets only the data previously saved to that label.

## The focal point

The `toggle()` function, which is pivotal in this outline scheme, receives as a parameter the index number of the `db` array element whose content the user just clicked. The purpose of this function is to grab a copy of the current outline state from the cookie, alter the binary representation of the clicked item, and feed the revised binary number back to the cookie (where it governs the display of the outline after the document reloads):

```
// **function that updates persistent storage of state**
// toggles an outline mother entry, storing new value in the cookie
function toggle(n) {
    var newString = "";
    var currState = getCurrState();
    var expanded = currState.charAt(n); // of clicked item
    newString += currState.substring(0,n);
    newString += expanded ^ 1; // Bitwise XOR clicked item
    newString += currState.substring(n+1,currState.length);
    setCurrState(newString); // write new state back to cookie
}
```

To make this happen, you must extract two pieces of information before any processing: the current state from the cookie and the current setting of the clicked item. The latter is saved in a local variable named `expanded` because its 0 or 1 value represents the expanded state of that particular entry in the outline.

With those information morsels in hand, the script starts building the new binary string that gets written back to the cookie. The new string consists of three pieces: the front part of the existing string up to (but not including) the digit representing the clicked item, the changed entry, and the rest of the original string.

Changing the setting of the clicked item from a 0 to a 1, or vice versa, is necessary. Although I can implement this task a few different ways (for example, using a conditional expression or an `if...else` construction), I thought I'd exercise an operator that otherwise gets little use: the bitwise XOR operator (^). Because the values involved here are 0 and 1, performing an XOR operation with the value of 1 inverts the original value:

```
0 ^ 1 = 1
1 ^ 1 = 0
```

Okay, perhaps using an XOR operator is showing off. But the experience forced me to understand a JavaScript power that may come in handy for the future.

## Selecting a widget image for an entry

At this point, the script starts defining functions to help the script statements in the `Body` write the HTML for the new version of the outline. The `getGIF()` function determines which of the three widget image files needs to be specified for a particular entry in the outline. The function receives the index value to the `db` array of entries created earlier in the script. As the `Body` script assembles the HTML for the outline, it calls this function once for each item in the outline. In return, the function provides a reference to one of three `Image` objects created earlier:

```

// **functions used in assembling updated outline**
// returns the proper GIF file name for each entry's control
function getGIF(n, currState) {
  var mom = db[n].mother; // is entry a parent?
  var expanded = currState.charAt(n); // of clicked item
  if (!mom) {
    return endpointWidget;
  } else {
    if (expanded == 1) {
      return expandedWidget;
    }
  }
  return collapsedWidget;
}

```

The decision process for this function first tries to eliminate any item that ends a mother-daughter chain. Any item that is as deeply nested as it can be (which means the item is not a mother) automatically gets the `endpointWidget` image.

Now you're left with trying to figure out whether the item in the display should get an expanded or collapsed icon. The holder of this information is the cookie. Thus, the script extracts the binary setting for the entry under scrutiny. If the cookie shows that entry to be a 1, it means that the item has nested items showing and that it should get the `expandedWidget` image; otherwise, it should get the `collapsedWidget` image. Notice that you're returning *references* to the Image objects, not the names of the image files.

A similar excursion through each item determines what status message is assigned to the `onmouseover` event handler for each of the widget images. The decision tree is identical to that of the `getGIF()` function:

```

// returns the proper status line text based on the icon style
function getGIFStatus(n, currState) {
  var mom = db[n].mother; // is entry a parent
  var expanded = currState.charAt(n); // of rolled item
  if (!mom) {
    return "No further items";
  } else {
    if (expanded == 1) {
      return "Click to collapse nested items";
    }
  }
  return "Click to expand nested items";
}

```

## Initialize the cookie

The final task of the script running in the Head is to initialize the cookie if it's empty. Using the length of the `db` array as a counter, you build a string of 0s, with one 0 for each item in the outline:

```

// initialize 'current state' storage field
if (getCurrState() == "" || getCurrState().length != (db.length)) {
  initState = "";
  for (i = 0; i < db.length; i++) {
    initState += "0";
  }
  setCurrState(initState);
}
</script>
</head>

```

Each of those 0s in the parameter to the `setCurrState()` function corresponds to a collapsed setting for an entry in the outline. In other words, the first time the outline appears, all items are in the collapsed mode. If you modify the outline for your own use by creating your own `db` array of data, the initial state of the cookie will be set for you automatically based on the length of the `db` array.

## Writing the outline

At last we reach the document `Body`, where the outline is assembled and written to the page. Script statements here are immediate, meaning that they execute while the page loads. I have you begin by initializing some variables that you will need in a moment. The most important variable is `newOutline`, which will be used to accumulate the contents of the outline for eventual writing to the page:

```
<body>
  <script type="text/javascript" language="JavaScript1.1">
    // build new outline based on the values of the cookie
    // and data points in the outline data array.
    // This fires each time the user clicks on a control,
    // because the HREF for each one reloads the current document.
    var newOutline = "";
    var prevIndentDisplayed = 0;
    var showMyDaughter = 0;
    var currState = getCurrState(); // get whole state string
    document.write("<center><h3>Composition of Selected Foods</h3>
      <hr /></center>");
```

The following section is the real beef of this script: the part that assembles the HTML for the outline that displays as the document loads. In other words, this part must read the current state data from the cookie and assemble widget images and text links according to the map of expanded and collapsed items in the cookie data. These activities take place within a `for` loop that cycles through every item in the database. Each value of the `i` index refers to one listing in the `db` array. Trace the logic of one entry:

```
// cycle through each entry in the outline array
for (var i = 0; i < db.length; i++) {
  var theGIF = getGIF(i, currState); // get the image
  var theGIFStatus = getGIFStatus(i, currState); // get the status msg
  var currIndent = db[i].indent; // get the indent level
  var expanded = currState.charAt(i); // current state

  // display entry only if it meets one of three criteria
  if (currIndent == 0 || currIndent <= prevIndentDisplayed ||
    (showMyDaughter == 1 && (currIndent - prevIndentDisplayed == 1))) {
    newOutline += "<img src=\"filler.gif\" height='1' width='" +
      (indentPixels * currIndent) + "' />";
    newOutline += "<a href=\"javascript:history.go(0)\" \" +
      \"onmouseover=\"window.status='\" + theGIFStatus +
      \"';return true;\" onclick=\"toggle(\" + i + \");return \" +
      (theGIF != endpointWidget) + "\">";
    newOutline += "<img src=\"\" + theGIF + "\" height='" +
      widgetHeight + "' width='" + widgetWidth +
      "' border='0' /></a>";
    if (db[i].URL == "" || db[i].URL == null) {
      newOutline += " " + db[i].display + "<br />"; // no link
    } else {
      newOutline += " <a href=\"\" + db[i].URL + "\" target=\"\" +
```

```

        displayTarget + "\" onmouseover=\"window.status=\'" +
        db[i].statusMsg + "\';return true;\">" + db[i].display +
        "</a><br />";
    }
    prevIndentDisplayed = currIndent;
    showMyDaughter = expanded;
    if (db.length > 25) {
        document.write(newOutline);
        newOutline = "";
    }
}
}
}

```

First, you call upon two previously defined functions to grab the widget image object and corresponding `onmouseover` message for the status bar. Two more variables contain the indent property for the item (that is, how many steps indented the item will appear in the outline structure) and the current expanded state, based on the cookie's entry for that item.

Not every entry in the outline database is displayed. For instance, a nested item whose mother is collapsed won't need to be displayed. To find out if an entry should be displayed, the script performs a number of tests on some of its values. An item can be displayed if any of the following conditions are met:

- ♦ The item is a topmost item, with an indentation factor of 0.
- ♦ The item is at the same or smaller indentation level as the previous item displayed.
- ♦ The previous item was tagged as being expanded, and the current item is indented from the previous item by one level.

Over the next few statements, the script pieces together the HTML for the outline entry, starting with the width necessary for the transparent filler image (based on the number of pixels specified for indentations near the top of the script). Next comes the link definition that wraps around the widget image. The following concepts apply to each link:

- ♦ The `href` attribute is the `javascript: URL` to invoke the `history.go()` method.
- ♦ The `onmouseover` event handler is set to adjust the status message to the previously retrieved message (notice the `return true` statement to make the setting take effect).
- ♦ The `onclick` event handler is set to call the `toggle()` function, passing the number of the item within the outline database. An `onclick` event handler is carried out before the browser responds to the click of the link by navigating to the URL. Therefore, the `toggle()` function changes the setting of the cookie a fraction of a second before the browser refreshes the document (which relies on that new cookie setting). But click events on widgets that have no children do not need to hit the `toggle()` function. Therefore, the content of the `return` statement is influenced by whether or not the widget image is an endpoint image.

In the next statement, the `newOutline` string accumulation continues with the `<img>` tag specifications for the widget art. Specifying the `height` and `width` attributes for the image is important, partly to help the browser lay out the page more quickly, partly to avoid pesky performance inconsistencies.

Next comes a decision about whether to display the item text as a link or as plain text. The script inspects the `db[i].URL` property to see if it is empty. If so, that means no URL is specified for a link, and the item should be built as plain text.

If a URL is specified for the item, the script instead constructs a link around the text. In this HTML assembly process, numerous calls to properties of the `db` array fetch properties of the entry for the URL, the status bar message, and the text to display. Notice, too, that the link sets the target of the link to the frame name assigned to `displayTarget` near the top of the script.

As you near the end of the loop, two variable values, `prevIndentDisplayed` and `showMyDaughter`, are updated with settings from the current traversal through the loop. These values influence the display of nested items for the next entry's journey through the loop.

But before looping around again, the script inspects whether the outline is longer than 25 entries. If so, the script writes the outline entries that have accumulated so far, resetting the `newOutline` variable to empty for the next time through the loop. The reasoning behind this last routine is to help long outlines start to display their goods faster. I have seen Web site authors use this outline for literally hundreds of entries. At that quantity, the usually fast JavaScript begins to bog down a bit. By writing lines from a big outline to the page early, the user gets visual feedback that something is happening.

Once outside the loop, the script writes whatever last items may have accumulated in the `newOutline` variable. For outlines with less than 25 items, the whole outline is written in one push; for longer outlines, the value is empty at this point, because the intermediate writings have completed the job.

All that's left is to close up standard tags to finish the document definition:

```
        document.write(newOutline);
    </script>
</body>
</html>
```

Notice that the `document.write()` statement here is not followed by `document.close()`. Because this content is being written as the page loads, the output stream is closed at the end of the page's HTML.

## Customization possibilities

Although this DHTML-free outliner is not the fanciest to be found on the Web, it is, nevertheless, quite popular probably due to its ease of customizability and backward compatibility to all but the earliest browsers (you can find the very original version at my Web site). Other page authors have pushed and pulled on this code to tailor it to a variety of special needs.

### Alternative displays

At the root of almost all significant customization jobs lie modifications to the `dbRecord` object constructor near the beginning of the page and the HTML assembly portion in the Body. They work hand in hand. For example, one user wants different links in the outline to load pages into different targets. Most links are to load content into another frame of the same frameset, while others are to replace the frameset entirely. In the version provided previously, one target is assumed, and it is set as a global variable. But if you need to provide different targets for each item, you can add a new property (perhaps named `target`) to the `dbRecord` constructor, and assign the string name of the target (for example, "Frame2", "\_top") to the property for each item. Then, in the HTML accumulation portion, assign the value of `db[i].target` to that `target` attribute (watching out for the necessary pairings of quote symbols, as shown in other attribute assignments).

Another request asked that the text associated with the plus/minus images be clickable, not to navigate to another page, but to expand and collapse the nested content. All the pieces for this variation are already in place. By performing minor reconstructive surgery on the HTML accumulator script, you can add a branch that looks for the `db[i].mother` property. If it's true, don't write the closing `</a>` tag after the widget. Instead, branch to write the `db[i].display` text without its own URL link, and write the widget's `</a>` tag after the text. Now the widget and text share the same link as the widget originally had.

## Cookie-free zones

Not everyone likes to develop with cookies. That's not a problem for this outliner, even though the previous example uses them liberally. The data that preserves the state of the outline is nothing but a string of 1s and 0s. If you are using a frameset, that string can be preserved as a global variable in the framesetting document.

To minimize the changes needed to the existing code, you can continue to use the same functions — `setCurrState()` and `getCurrState()` — as the interfaces to the reading and writing of the state. Begin by defining a global variable in the Head portion of the framesetting document, initializing it as an empty string:

```
<script type="text/javascript">
outlineState = "";
</script>
```

Now you can modify the two functions in the outliner page as follows:

```
// ** functions that get and set state data **
// set cookie data
var mycookie = document.cookie;
function setCurrState(setting) {
    mycookie = parent.outlineState = setting;
}
// retrieve cookie data
function getCurrState() {
    return parent.outlineState;
}
```

Notice that there is no need for the label that has to be assigned to a cookie. The variable name keeps this data separate from the rest of the script space.

The only downside to not using a cookie is that the outline state is not preserved if the frameset goes away. If the user revisits the frameset in the same session, the outline state will be reinitialized at its beginning state.

## Expanding/collapsing all at once

If you have an extensive outline, you may want to provide a shortcut to the user to expand everything at once or close up the entire outline. Because the string of 1s and 0s maintains the state of the outline, you can use the `db` array to help you create a new state string, and then apply it to the page. Here are two functions that do the job:

```
function expandAll() {
    expState = "";
    for (i = 1; i < db.length; i++) {
        expState += (db[i].mother) ? "1" : "0";
    }
}
```

```

    setCurrState(expState);
    history.go(0);
}

function collapseAll() {
    collState = "";
    for (i = 1; i < db.length; i++) {
        collState += "0";
    }
    setCurrState(collState);
    history.go(0);
}

```

All you need are a couple of buttons to invoke these functions, and you're in business.

## Reducing server access

Through the lifetime of this outliner application, it has seen wildly different behaviors of the various browsers with regard to how much the browser reaches out to the server for each redisplay of the outline. Although the `history.go(0)` type of reloading is supposed to be the least onerous, some browsers seem to read the entire file from scratch. This approach is still faster than having a CGI script completely reconfigure a page, but for an extensive outline and a slow Internet connection, the results can be objectionable.

One possible solution is to avoid reloading the page at all. Instead, place all of the code for the outliner management and creation in the framesetting document. Code that currently writes the outline as the page loads can be encapsulated in a function that writes to the frame designated as the outline frame (don't forget the `document.close()` for this writing!). Function calls from the outliner (to `toggle()`, for instance) have to be modified so that the reference is to the function in the parent frame (`parent.toggle(n)`).

Distributing the code around frames may not be as convenient as keeping it all together, but user experience should weigh more heavily than programmer expedience. This practice also opens the possibility for putting all of the outliner code, except for the calls to the constructor functions, in an external `.js` library. You can then put multiple outline contents into multiple `.js` libraries and load the pairs that you need into a frameset.

Using `document.write()` to another frame may still not avoid server access entirely. It is not uncommon for the application of any image file—including those that have been precached—to check the cached version against the modification date of the file on the server. This activity is much faster than downloading the image again, but if you see network activity even after shifting the outliner's scripts to the frameset, at least you understand what's happening. A version of the application directed from the parent window is contained on the CD-ROM.

## Multiple outlines

The example in this chapter assumes that a site will be using only one outline-style table of contents. You can, of course, have multiple outlines for different sections of a Web site or application. But if the outlines all share the same cookie data, the state of the most recent outline will be applied to the next one that loads. Items will be magically opened. And if the number of items between the two outlines is different, the cookie data can get a bit messy.

To solve this problem, assign a different cookie label for each outline. That prevents one outline's state from stepping on another.

## Cascading Style Sheet Version

The advent of Cascading Style Sheets (CSS) brought a number of intriguing possibilities for an application, such as the outliner. Not only can stylesheets be used to control the look of the items in the outline, but additional properties make it possible to hide and show elements, including inserting or removing elements from the rendered content. Alas, not all of these features work in NN4, so the version under discussion in this section resorts to redrawing the outline for NN4. But for IE4+ and NN6+/W3C DOMs, the response is very fast, and no page reloading is necessary. One of the goals, too, in this application was to reuse as much of the code from earlier versions as possible. Note that this version does not work (or work correctly) with browsers prior to NN4 or IE4.

### CSS implementation plan

Many of the compromises in this version resulted from quirky behavior of NN4 with some types of elements and stylesheets. I chose to render the outline content as a series of nested `div` elements. If this were being implemented strictly in more well-behaved browsers, style-sheet control over `ul` and `li` elements would be even more convenient because those elements already have an indentation scheme built into them. With so much HTML code needed to generate the `div` elements and their contents, I decide to trade the cleverness of multidimensional array storage of outline content for the better performance of straight HTML. Each row of content in the outline is set in its own `<div>` block tag set. Any row that had children nested inside contains those items as a nested block.

Stylesheets afforded the design a handy behavior. Hiding and showing blocks via the CSS-Positioning `visibility` property (see Chapter 26) is not an apt solution here, because hiding an item does not remove it from the page rendering. Therefore, unless the page included a ton of positioning code to overlap hidden items with visible items (which would have worked in NN4, but at the price of substantial increases in code and inflexibility), the outline would not cinch up if a branch is collapsed. To the rescue comes the `display` property of a style. One value of this property (`none`) not only hides the block, but it temporarily removes it from the rendering order of the page. Any items rendered below it that are visible (that is, whose `display` property is set to `block`) scoot up to render after the previous visible item.

Setting the `display` property has slightly different results in NN4 and more modern DOMs. In NN4, you can set the property after the block has been rendered on the page, but its appearance does not change; in both the IE4+ and NN6+/W3C DOMs, the change is immediate, with the rest of the page reflowing to adjust to the change in the block's visibility and presence. Therefore, for NN4, the page still needs to reload itself and remember the state of the outline between reloads (via the same cookie mechanism used for the earlier version) so that the page can set the property value as the page loads. And except for only a couple of places in the code, both the IE4+ and NN6+/W3C DOMs share positioning code.

The CSS version uses the same cookie value (a sequence of 1 and 0 values) to represent the visible or hidden state of each item as in the old version. To convey the change of state, however, the function called by the click of an icon widget must pass the index values of the child items affected by the expansion or collapse of a node. This means that more of the HTML — in this case, the parameters of the functions — has to be hard-wired to the structure of the outline, as you see shortly. Less of this would be necessary if NN4's implementation of CSS offered the same level of scriptable introspection into HTML elements as IE4's implementation:

We'd be able to employ the style property inheritance behavior to simplify the way blocks are shown and hidden. Because the two classes of browsers supported in this example are so different in this regard, the scripting reflects the lowest common denominator for controlling the toggle of expanded and collapsed states.

## The CSS code

By putting so much of the content directly into HTML, the scripting component of the CSS outliner version is significantly smaller than the older version. Where possible, I stayed with the same function and variable naming schemes of the previous version.

At the top of the document, I define three styles for the amount of indentation required by the three indentation levels of my sample outline. If the outline were to go to more levels, I would add styles accordingly:

```
<html>
  <head>
    <title></title>
    <style type="text/css">
      div.indent0 {margin-left:0}
      div.indent1 {margin-left:10}
      div.indent2 {margin-left:20}
    </style>
```

Scripting begins by setting some global variables. Browser-specific branching comes into play later, but in an effort to stamp out explicit version detection, the code here relies on object detection to set the requisite flags. Only browsers capable of the CSS style scripting needed here have a `document.styleSheets` property, so flags are set for the two supported browser classes. These flags are set here primarily as a convenience for writing branching code later. Rather than constantly retesting for the presence of the property, the global flags are shorter and marginally faster. Two more variables hold their respective browser class state values, with the NN4 version maintaining a copy of the cookie as a variable for performance reasons:

```
<script type="text/javascript">
  // global variables
  var isNN4, isCSS, CSScurrState, NN4Cookie = document.cookie;
  if (document.styleSheets) {
    isCSS = true;
    isNN4 = false;
  } else {
    isCSS = false;
    isNN4 = true;
  }
}
```

To each of the cookie storage functions from the original version, I add a branch to handle the storage and retrieval of state data for CSS browsers, simply setting and getting the global variable. This may seem to be more indirect than is necessary, but it is essential to allow the reuse of many functions in other parts of the code so that those areas don't have to worry about browser platform. Notice that the label for this outline's cookie is slightly different from that of the earlier version. This difference allows you to open both outliners with NN4 in the same session and not worry about one cookie value overlapping with the other:

```
// ** functions that get and set persistent data **
// set persistent data
function setCurrState(setting) {
  if (isNN4) {
    NN4Cookie = document.cookie = "currState2=" + escape(setting);
  } else {
```

```

        // for CSS, data is saved as a global variable instead of cookie
        CSScurrState = setting;
    }
}

// retrieve persistent data
function getCurrState() {
    if (isCSS) {
        // for CSS, data is in global var instead of cookie
        return CSScurrState;
    }
    var label = "currState2=";
    var labelLen = label.length;
    var cLen = NN4Cookie.length;
    var i = 0;
    while (i < cLen) {
        var j = i + labelLen;
        if (NN4Cookie.substring(i,j) == label) {
            var cEnd = NN4Cookie.indexOf(";",j);
            if (cEnd == -1) {
                cEnd = NN4Cookie.length;
            }
            return unescape(NN4Cookie.substring(j,cEnd));
        }
        i++;
    }
    return "";
}

```

The `toggle()` function is called by the `onclick` event handler of the links surrounding the widget icon art in the outline. A variable number of parameters are passed to this function, so that the parameters are extracted and analyzed via the `arguments` property of the function. Both browsers with only a few small browser-specific branches use a great deal of the code. Inside the large `for` loop, a CSS branch dynamically changes the setting of the `style.display` property. For NN4, the page is reloaded after all changes to the cookie version of the state are saved. After the NN4 version goes off to reload the page, the CSS version swaps the image of the toggled widget. As a final touch, the window is given focus so that WinIE browsers lose the dotted rectangle around the clicked image:

```

// **function that updates persistent storage of state**
// toggles an outline mother entry, storing new value
function toggle() {
    var newString = "";
    var expanded, n;
    // get all <DIV> tag objects in IE4/W3C DOMs
    if (document.all) {
        var allDivs = document.all.tags("div");
    } else if (document.getElementsByTagName) {
        var allDivs = document.getElementsByTagName("div");
    }
    var currState = getCurrState() // of whole outline
    // assemble new state string based on parameters passed from link
    for (var i = 0; i < arguments.length; i++) {
        n = arguments[i];
        expanded = currState.charAt(n); // of clicked item
        newString += currState.substring(0,n);
        newString += expanded ^ 1; // Bitwise XOR clicked item
        newString += currState.substring(n+1,currState.length);
    }
}

```

```

        currState = newString;
        newString = "";
        if (isCSS) {
            // dynamically change display style without reloading
            if (expanded == "0") {
                allDivs[n].style.display = "block";
            } else {
                allDivs[n].style.display = "none";
            }
        }
    }
    setCurrState(currState); // write new state back to cookie
    if (isNN4) {
        location.reload();
    }
    // swap images in CSS versions
    var img = document.images["widget" + (arguments[0]-1)];
    img.src = (img.src.indexOf("plus.gif") != -1) ?
        "minus.gif" : "plus.gif";
    window.focus();
}

```

A prerequisite for loading the page to begin with is setting the initial value of the state. This is the only part of the script that must be hard-wired based on the structure of the outline—string assigned to `initState` will be different with each outline. The goal here is to set each block assigned to the `indent0` style class to 1 while all others are set to 0. These settings allow the first display of the outline to show all the root nodes, with all other items collapsed:

```

// initialize 'current state' storage field
if (!getCurrState()) {
    // must be hard-wired to outline structure with "1" for
    // each indent0 class item, "0" for all others
    initState = "1000010000";
    setCurrState(initState);
}

```

With the initial outline state saved in the preceding code, the following statements execute at load time to write a `<style>` tag set for NN4. This tag sets the `display` property of all collapsed blocks to none. As you see in the HTML coming up, blocks are assigned `id` attributes with the letter “a” followed by a sequence number starting with zero:

```

// for Navigator 4, set display style for flagged IDs to 'none'
// each time the page (re)loads
if (isNN4) {
    document.write("<style type='text/css'>");
    var visState = getCurrState();
    for (var i = 0; i < visState.length; i++) {
        if (visState.charAt(i) == "0") {
            document.write("#a" + i + " {display:none}\n");
        }
    }
    document.write("</style>");
}

```

Initial settings of the `display` property for IE4+ can be done programmatically only after the document loads (the tags must exist before their properties can be adjusted). The following `init()` function is called from the `onload` event handler. Each browser class has a different set of initialization tasks. Both branches rely on the current state setting, so that value is

retrieved just once. In the CSS branch, the `style.display` properties for hidden blocks are set to `none`. For NN4, on the other hand, the `style.display` properties are set as the page reloads, but this loop swaps the widget image for expanded blocks to the `minus.gif` version:

```
// for CSS, initialize flagged tags to style display = "none"
// for NN4, set affected images to minus.gif
function init() {
    var visState = getCurrState();
    if (isCSS) {
        for (var i = 0; i < visState.length; i++) {
            if (visState.charAt(i) == "0") {
                if (document.all) {
                    document.all("a" + i).style.display = "none";
                } else if (document.getElementsByTagName) {
                    document.getElementById("a" + i).style.display = "none";
                }
            }
        }
    } else if (isNN4) {
        for (i = 0; i < visState.length; i++) {
            if (visState.charAt(i) == "1") {
                if (i+1 < visState.length && visState.charAt(i+1) == "1") {
                    if (document.images["widget" + i]) {
                        document.images["widget" + i].src = "minus.gif";
                    }
                }
            }
        }
    }
}
</script>
</head>
<body onload="init()">
    <center>
        <h3>Composition of Selected Foods</h3>
        <hr />
    </center>
```

Now begins the HTML that defines the content of the outline. For readability, I have formatted the `<div>` tag sets to follow the indentation of the outline data (this listing looks much better if you open the file from the CD-ROM in your text editor with word wrap turned off). Each tag includes a `class` attribute pointing to a class defined in the first `<style>` tag of the page. Each tag also includes an `id` attribute whose name begins with the letter “a” and a sequential serial number, starting with zero. Navigator uses the `id` attributes to help it assign `display` property settings during each reload.

Like the older version of the outliner, each entry includes an image (surrounded by a clickable link) and a text entry (which may or may not be a link to a document). The link around the image includes a `javascript: URL` for the `href` attribute. When a link is for a widget that is a mother item, the parameters to the `toggle()` function are the serial numbers of the immediate children IDs whose display properties are to be adjusted in the `toggle()` function. These passed items only need to be in the immediate children, because any of their children inherit the `display` property of their parents. For example, the first widget toggles items 1 and 2 (ids `a1` and `a2`). Item 2 happens to be a parent to items 3 and 4. But when the `display` property of item 2 is set to `none`, none of its children (items 3 and 4) are displayed, no matter how their display properties are set.

`img` elements associated with each toggled `div` are named along similar lines, with the name starting with “`widget`” and the same serial number as the containing `div`. If you look at the end of the `toggle()` function again, you’ll see that the name for the `img` element is derived from the first parameter received by the `toggle()` function. That first parameter will always be one number higher than the serial number for the widget image to swap. To help you visualize the numbering scheme used within the example, the numbered identifiers and methods that relay associated numbers are shown in boldface:

```
<div class="indent0" id="a0">
  <a href="javascript:toggle(1,2)"
    onmouseover="status='Click to expand/collapse nested items';
      return true"
    onmouseout="status='';return true">
  </a>&nbsp;Peas<br />
  <div class="indent1" id="a1">
    <a href="javascript:void(0)"
      onmouseover="status='No further items';return true"
      onmouseout="status='';return true"></a>&nbsp;<a
      href="foods.htm#boiled" target="Frame2">Boiled</a><br />
  </div>
  <div class="indent1" id="a2">
    <a href="javascript:toggle(3,4)"
      onmouseover="status='Click to expand/collapse nested items';
        return true"
      onmouseout="status='';return true"></a>&nbsp;<a
      href="foods.htm#canned" target="Frame2">Canned</a><br />
    <div class="indent2" id="a3">
      <a href="javascript:void(0)"

</div>
<div class="indent2" id="a9">
  <a href="javascript:void(0)"
onmouseover="status='No further items';return true"
onmouseout="status='';return true"></a>&nbsp;<a
href="foods.htm#sour" target="Frame2">Sour</a><br />
</div>
</div>
</div>
</body>
</html>

```

The CSS version (for the identical outline content) is a slightly smaller file size than the older, compatible one, but not so big a difference as to influence your choice. Browser compatibility should be your number one criterion. Ease of modification for changing content and improved user experience for browsers following the CSS branch are tied in second.

## A Futuristic (XML) Outline

Only a handful of browsers — WinIE5+ and Mozilla-based browsers — are capable of working directly with XML data, but I believe this capability will grow more important as the concept of “Web services” becomes more ingrained in the mainstream internet. Therefore, I’ve modernized the many generations of scriptable outliner described earlier in this chapter to use the XMLHttpRequest object described in Chapter 41. The data for this outline version is set apart in a more easily maintainable XML data file. At the same time, I’ve “prettied up” the hierarchical interface of the outliner display.

### Birth of an XML specification

Collapsible outlines provide convenient ways to organize hierarchical information all around us. You’d be hard-pressed to find a more active proponent of the outline than Dave Winer, founder of UserLand Software, Inc. (<http://www.userland.com>). Dave is a veteran software developer, as well as author and outspoken Web publisher. His [www.scripting.com](http://www.scripting.com) Web site is a popular destination if you want to find out the latest Internet and computing technology “buzz.”

As an outgrowth of development for his company's Web tools, Dave looked to the XML structure to assist in representing outline content in a shareable, easily parseable format. The result is a specification called Outline Processor Markup Language, or OPML for short. You can read all about the formal specification at <http://www.opml.org/spec>. Like virtually all XML, OPML is intended to be written by software, not humans (although humans input the data via a user-friendly front-end provided by the software). Even so, the format of an OPML outline is extremely readable by humans, and, with little more trouble than writing basic HTML tags manually, you can represent an outline in this format yourself.

A plain OPML file, saved as an `.xml` file, can be viewed through the native XML parsers of IE5+ and NN6+/Moz. These parsers automatically render XML tags in the same hierarchical fashion as OPML encourages outlines to be structured. But such rendering is under strict control of the browser, unless you also get involved with XML stylesheets (the XSL and XSLT standards), at which point, browser implementation incompatibilities can make the going tough.

I liked the OPML data format when I first saw it, and I think it's a convenient way to convey an outline's data to the client, at which point JavaScript and the browser's DOM can take over to provide interesting visuals for the content and interaction with the content. Thus was born this last example of the chapter, in which the outliner's data is delivered not in the form of scripted arrays or hard-wired HTML `div` elements. Instead, the data arrives in its native XML (OPML) format from a separate file. Scripts take over to do the rest.

## OPML outliner prep

The appearance of widgets and text for the new outliner has changed to more closely emulate the kinds of outline presentations that you see in some Windows programs (see Figure 52-2). For demonstration purposes, the same frameset structure and outline content from earlier examples are used for the OPML version so that you can more easily see the differences in implementations and grasp new concepts presented here. For example, the comparison of how the outline data is delivered in the form of JavaScript objects (the first example) and OPML is enlightening.

As you recall, a custom object constructor function generated one JavaScript object for each outline entry. The properties of the object are completely under your control, so that you can add properties (such as the target of an entry's link) whose values influence the way the entry is rendered and the way it behaves. OPML has a similar extensibility feature. Each outline entry is nothing more than a tag. An entry that does not have any nested child nodes can use the XML shortcut of combining a start and end tag inside one set of angle brackets:

```
<tagName attribute="value" ... />
```

And any entry that has nested nodes contains the nested nodes between its start and end tags, as shown here with the actual tag names used in OPML (indentation is optional, but increases readability):

```
<outline text="text">
  <outline text="text" />
  <outline text="text" />
</outline>
```

If you want to associate more information about an entry, simply add an attribute. For example, if an entry is to behave as a link, you can convey that information with an attribute whose name you determine. When it comes time for your scripts to render the content in HTML, the scripts access the attribute values and generate the associated HTML for the attributes (you see an example of this in the code).

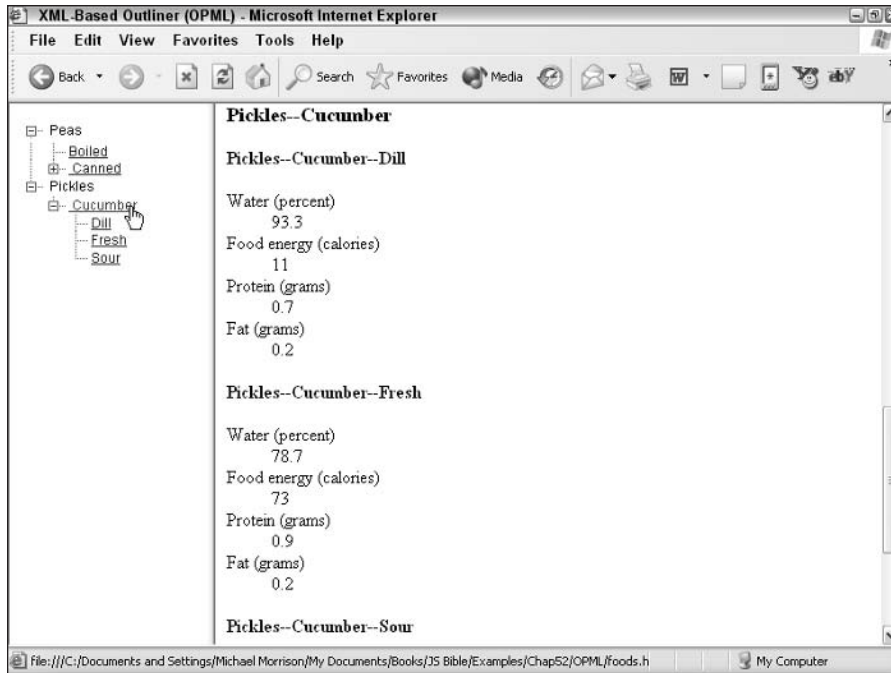

Figure 52-2: OPML-based outliner style.

The true beauty of the OPML structure (and XML in general) is that the parent–child relationships are automatically implied by the element containment. Unlike the JavaScript custom object in the first example, the author does not have to specify how many levels deep an entry is, or whether it has any child nodes: The XML containment hierarchy describes all of that information. Suddenly, all of the W3C DOM gobbledygook about nodes, child nodes, and attributes become your friend, as your scripts convert the element hierarchy into a renderable hierarchy of your design.

## The XML and HTML code

Because our focus is so tight on the outliner content, the first code to view is that of the XML document, named `outlineData.xml`:

```
<?xml version="1.0" ?>
<opml version="1.0">
  <head>
    <title>A Modern Outline</title>
    <dateCreated>Thu, 13 Nov 2003 02:40:00 GMT</dateCreated>
    <dateModified>Fri, 19 Dec 2003 19:35:00 GMT</dateModified>
    <ownerName>Danny Goodman</ownerName>
    <ownerEmail>dannyg@dannyg.com</ownerEmail>
    <expansionState></expansionState>
    <vertScrollState>1</vertScrollState>
    <windowTop></windowTop>
    <windowLeft></windowLeft>
    <windowBottom></windowBottom>
    <windowRight></windowRight>
```

```

</head>
<body>
  <outline text="Peas">
    <outline text="Boiled" uri="foods.htm#boiled"/>
    <outline text="Canned" uri="foods.htm#canned">
      <outline text="Alaska" uri="foods.htm#alaska"/>
      <outline text="Low-Sodium" uri="foods.htm#losodium"/>
    </outline>
  </outline>
  <outline text="Pickles">
    <outline text="Cucumber" uri="foods.htm#cucumber">
      <outline text="Dill" uri="foods.htm#dill"/>
      <outline text="Fresh" uri="foods.htm#fresh"/>
      <outline text="Sour" uri="foods.htm#sour"/>
    </outline>
  </outline>
</body>
</opml>

```

This file is textbook OPML version 1.0 form. Notice that the OPML syntax reuses element names that are found in all HTML files (for example, `head`, `title`, `body`). This element name duplication makes it essential to isolate the XML from any HTML rendering area (such as an `iframe`), which would automatically add its own `body` element and thus destroy the OPML node tree.

The HTML body of the `toc6.html` file is sparse to say the least:

```

<body onload="init('outlineData.xml')">
  <div id="content"></div>
</body>

```

The only other HTML delivered in the document body is an empty `div` element, which is used as the container for the outline HTML that the scripts generate as a result of the `onload` event handler's invocation of the `init()` function.

## Setting the scripted stage

All scripts for this page are in the Head (although they could also be linked in from an external `.js` file). First on the docket is establishing several global variables that get used a lot within the rest of the code and make it easy to customize important visible properties, especially widget art. Due to the art choices made for this version, there are separate versions for items that appear as first, middle, and end items for different nesting states:

```

<script type="text/javascript">
// global variables
// art files and sizes for widget styles and spacers
// (all images must have same height/width)
var collapsedWidget = "oplus.gif";
var collapsedWidgetStart = "oplusStart.gif";
var collapsedWidgetEnd = "oplusEnd.gif";
var expandedWidget = "ominus.gif";
var expandedWidgetStart = "ominusStart.gif";
var expandedWidgetEnd = "ominusEnd.gif";
var nodeWidget = "onode.gif";
var nodeWidgetEnd = "onodeEnd.gif";
var emptySpace = "oempty.gif";
var chainSpace = "ochain.gif";

```

```

var widgetWidth = "20";
var widgetHeight = "16";
var currState = "";
var displayTarget = "Frame2";

```

The `init()` function, invoked by the `onload` event handler, starts the content creation in motion. The basic sequence is to first load the external XML data into a scripted document object global variable (named `xDoc`). If the data loads successfully, a reference to the Body portion of the outline data is retrieved so that many other functions are able to dive into the outliner hierarchy. The reference to the OPML body element is passed to the `makeHTML()` function, which returns the entire outline HTML to be assigned to the `innerHTML` property of the empty `div` element delivered with the document:

```

// initialize first time
function init(outlineDataURL) {
    loadXMLDoc(outlineDataURL);
    if (xDoc) {
        // demo how to get outline head elements
        var hdr = xDoc.getElementsByTagName("head")[0];
        // get outline body elements for iteration and conversion to HTML
        var ol = xDoc.getElementsByTagName("body")[0];
        // wrap whole outline HTML in a span
        var olHTML = "<span id='renderedOL'>" + makeHTML(ol) + "</span>";
        // throw HTML into 'content' div for display
        document.getElementById("content").innerHTML = olHTML;
        initExpand();
    }
}

```

Loading the XML file is performed in the `loadXMLDoc()` function. The function also handles alerts to users due to a missing XML file, connection problems, or lack of support for the feature:

```

// XML document
var xDoc;

// retrieve XML document as document object
function loadXMLDoc(url) {
    var req;
    if (window.XMLHttpRequest) {
        req = new XMLHttpRequest();
        req.open("GET", url, false);
        req.send(null);
    } else if (window.ActiveXObject) {
        req = new ActiveXObject("Microsoft.XMLHTTP");
        if (req) {
            req.open("GET", url, false);
            req.send();
        }
    }
    if (req) {
        if (req.status == 200) {
            xDoc = req.responseXML;
            if (xDoc && typeof xDoc.childNodes != "undefined" &&
                xDoc.childNodes.length == 0) {
                xDoc = null;
            }
        }
    }
}

```

```

    } else {
        alert("There was a problem retrieving the XML data:\n" +
            req.statusText);
    }
} else {
    alert("Sorry, this browser isn't equipped to read XML data.");
}
}

```

## Accumulating the HTML

From the `init()` function, a call to the `makeHTML()` function starts the most complex actions of the scripts on this page. This function walks the node hierarchy of the outline's body elements, deciphering which ones are containers and which ones are end points.

Two global variables are used to keep track of how far the node walk progresses because this function calls itself from time to time to handle nested branches of the node tree. Because a reflexive call to a function starts out with new values for local variables, the globals operate as pointers to let statements in the function know which node is being accessed. The numbers get applied to an `id` attribute assigned to the `div` elements holding the content.

One of the fine points of the design of this outline is the way space to the left of each entry is assembled. Unlike the earlier outlines in this chapter, this one displays vertical dotted lines connecting nodes at the same level. There isn't a vertical line for every clickable node appearing above the item, because a clickable node may have no additional siblings, meaning that the space is blank. To see what I mean, open the OPML example, and expand the Peas and Canned nodes (or see Figure 52-2). The Canned node is the end of the second "column," so the space beneath the icon is blank. That's what some of the code in `makeHTML()` named "prefix" is dealing with: Accumulating just the right combination of dotted line (`chain.gif`) and blank (`empty.gif`) images in sequence before the outline entry.

Another frequent construction throughout this function is a three-level conditional expression. This construction is used to determine whether the image just to the left of the item's text should be a start, middle, or end version of the image. The differences among them are subtle (having to do with how the vertical dotted line extends above or below the widgets). All of these decisions are made from information revealed by the inherent structure of the OPML element nesting. The listing in the book looks longer than it truly is because so many long or deeply nested lines must be wrapped to the next line. Viewing the actual file in your text editor should calm your fears a bit.

```

// counters for reflexive calls to makeHTML()
var currID = 0;
var blockID = 0;
// generate HTML for outline
function makeHTML(outlineID, ol, prefix) {
    var output = "";
    var nestCount, link, nestPrefix;
    prefix = (prefix) ? prefix : "";
    for (var i = 0; i < ol.childNodes.length; i++) {
        nestCount = ol.childNodes[i].childNodes.length;
        output += "<div class='row' id='line" + currID++ + "'>\n";
        if (nestCount > 0) {
            output += prefix;
            output += "<img id='widget" + (currID-1) + "' src='" +

```

```

        ((i== ol.childNodes.length-1) ? collapsedWidgetEnd : (blockID==0) ?
        collapsedWidgetStart : collapsedWidget);
    output += " height=" + widgetHeight + " width=" + widgetWidth;
    output += " title='Click to expand/collapse nested items.'
        onclick='toggle(this," + blockID + ")'>";
    link = (ol.childNodes[i].getAttribute("uri")) ?
        ol.childNodes[i].getAttribute("uri") : "";
    if (link) {
        output += "&nbsp;<a href='" + link + "'
            class='itemTitle' title='" +
            link + "' target='" + displayTarget + "'>";
    } else {
        output += "&nbsp;<a class='itemTitle' title='" + link + "'>";
    }
    output += "&nbsp;" + ol.childNodes[i].getAttribute("text") + "</a>";
    currState += calcBlockState(outlineID, currID-1);
    output += "<span class='OLBlock' blocknum='" + blockID +
        "' id='OLBlock" + blockID++ + "'>";
    nestPrefix = prefix;
    nestPrefix += (i == ol.childNodes.length - 1) ?
        "<img src='" + emptySpace + "' height=16 width=20>" :
        "<img src='" + chainSpace + "' height=16 width=20>";
    output += makeHTML(outlineID, ol.childNodes[i], nestPrefix);
    output += "</span></div>\n";
} else {
    output += prefix;
    output += "<img id='widget" + (currID-1) + "' src='" +
        ((i == ol.childNodes.length - 1) ? nodeWidgetEnd : nodeWidget);
    output += "' height=" + widgetHeight + " width=" + widgetWidth + ">";
    link = (ol.childNodes[i].getAttribute("uri")) ?
        ol.childNodes[i].getAttribute("uri") : "";
    if (link) {
        output += "&nbsp;<a href='" + link + "'
            class='itemTitle' title='" +
            link + "' target='" + displayTarget + "'>";
    } else {
        output += "&nbsp;<a class='itemTitle' title='" + link + "'>";
    }
    output += ol.childNodes[i].getAttribute("text") + "</a>";
    output += "</div>\n";
}
}
return output;
}

```

As with the HTML assembly code of the first outliner, if you were to add attributes to outline elements in an OPML outline (for example, a URL for an icon to display in front of the text), it is in `makeHTML()` that the values would be read and applied to the HTML being created.

The only other function invoked by the `makeHTML()` function is `calcBlockState()`. This function looks into one of the OPML outline's head elements, called `expansionstate`. This element's values can be set to a comma-delimited list of numbers corresponding to nodes that are to be shown expanded when the outline is first displayed. The `calcBlockState()` function is invoked for each parent element. The element's location is compared against values in the `expansionstate` element, if there are any, and returns the appropriate 1 or 0 value for the state string being assembled for the rendered outline:

```

// apply default expansion state from outline's header
// info to the expanded state for one element to help
// initialize currState variable
function calcBlockState(outlineID, n) {
    var ol = document.getElementById(outlineID).getElementsByTagName("body")[0];
    var outlineLen = ol.getElementsByTagName("outline").length;
    // get OPML expansionState data
    var expandElem = document.getElementById(
        outlineID).getElementsByTagName("expansionState")[0];
    var expandedData = (expandElem.childNodes.length) ?
        expandElem.firstChild.nodeValue.split(",") : null;
    if (expandedData) {
        for (var j = 0; j < expandedData.length; j++) {
            if (n == expandedData[j] - 1) {
                return "1";
            }
        }
    }
    return "0";
}

```

The final act of the initialization process is a call to the `initExpand()` function. This function loops through the `currState` global variable (whose value was written in `makeHTML()` with the help of `calcBlockState()`) and sets the `display` property to `block` for any element designed to be expanded at the outset. HTML element construction in `makeHTML()` is performed in such a way that each parent `div` has a `span` nested directly inside of it; and inside that `span` are all the child nodes. The `display` property of the `span` determines whether all of those children are seen or not.

```

// expand items set in expansionState XML tag, if any
function initExpand(outlineID) {
    for (var i = 0; i < currState.length; i++) {
        if (currState.charAt(i) == 1) {
            document.getElementById("OLBlock" + i).style.display = "block";
        }
    }
}

```

By the time the `initExpand()` function has run—a lot of setup code that executes pretty quickly—the rendered outline is in a steady state. Users can now expand or collapse portions by clicking the widget icons.

## Toggling node expansion

All of the widget images in the outline have `onclick` event handlers assigned to them. The handlers invoke the `toggle()` function, passing parameters consisting of a reference to the `img` element object receiving the event and the serial number of the `span` block nested just inside the `div` that holds the image. With these two pieces of information, the `toggle()` function sets in motion the act of inverting the expanded/collapsed state of the element and the plus or minus version of the icon image. The `blockNum` parameter corresponds to the position within the `currState` string of 1s and 0s holding the flag for the expanded state of the block. With the current value retrieved from `currState`, the value is inverted through `swapState()`. Then, based on the new setting, the `display` property of the block is set accordingly, and widget art is changed through two special-purpose functions:

```

// toggle an outline mother entry, storing new state value;
// invoked by onclick event handlers of widget image elements
function toggle(img, blockNum) {
    var newString = "";
    var expanded, n;
    // modify state string based on parameters from img
    expanded = currState.charAt(blockNum);
    currState = swapState(currState, expanded, blockNum);
    // dynamically change display style
    if (expanded == "0") {
        document.getElementById("OLBlock" + blockNum).style.display = "block";
        img.src = getExpandedWidgetState(img.src);
    } else {
        document.getElementById("OLBlock" + blockNum).style.display = "none";
        img.src = getCollapsedWidgetState(img.src);
    }
}

```

Swapping the state of the `currState` variable utilizes the same XOR operator employed by the first outliner in this chapter. The entire `currState` string is passed as a parameter. The indicated digit is segregated and inverted, and the string is reassembled before being returned to the calling statement in `toggle()`:

```

// invert state
function swapState(currState, currVal, n) {
    var newState = currState.substring(0,n);
    newState += currVal ^ 1; // Bitwise XOR item n
    newState += currState.substring(n+1,currState.length);
    return newState;
}

```

As mentioned earlier, each of the clickable widget icons (plus and minus) can be one of three states, depending on whether the widget is at the start, middle, or end of a vertical-dotted chain. The two image swapping functions find out (by inspecting the URLs of the images currently occupying the `img` element) which version is currently in place so that, for instance, a starting plus (collapsed) widget is replaced with a starting minus (expanded) widget. This is a case of going the extra mile for the sake of an improved user interface:

```

// retrieve matching version of 'minus' images
function getExpandedWidgetState(imgURL) {
    if (imgURL.indexOf("Start") != -1) {
        return expandedWidgetStart;
    }
    if (imgURL.indexOf("End") != -1) {
        return expandedWidgetEnd;
    }
    return expandedWidget;
}

// retrieve matching version of 'plus' images
function getCollapsedWidgetState(imgURL) {
    if (imgURL.indexOf("Start") != -1) {
        return collapsedWidgetStart;
    }
    if (imgURL.indexOf("End") != -1) {
        return collapsedWidgetEnd;
    }
    return collapsedWidget;
}

```

## Wrap up

There's no question that the amount and complexity of the code involved for the OPML version of the outliner are significant. The "pain" associated with developing an application such as this is all up front. After that, the outline content is easily modifiable in the OPML format (or perhaps by some future editor that produces OPML output).

Even if you don't plan to implement an OPML outline, the explanation of how this example works should drive home the importance of designing data structures that assist not only the visual design but also the scripting that you use to manipulate the visual design.

## Further Thoughts

The advent of CSS and element positioning has prompted numerous JavaScripters to develop another kind of hierarchical system of pop-up or drop-down menus. You can find examples of this interface at many of the JavaScript source Web sites listed in Appendix D. Making these kinds of menus work well in NN4, IE4+, and NN6+/W3C DOM browsers is a lot of hard work, and if you can adopt code already ironed out by others, then all the better.

Most of the code you find, however, will require a fair amount of tweaking to blend the functionality into the visual design that you have or are planning for your Web site. Finding two implementations on the Web that look or behave the same way is rare. As long as you're aware of what you'll be getting yourself into, you are encouraged to check out these interface elements. By hiding menu choices except when needed, valuable screen real estate is preserved for more important, static content.

# Application: Calculations and Graphics

---

**W**hen the scripting world had its first pre-release peeks at JavaScript (while Netscape was still calling the language LiveScript), the notion of creating interactive HTML-based calculators captured the imaginations of many page authors. Somewhere on the World Wide Web, you can find probably every kind of special-purpose calculation normally done by scientific calculators and personal computer programs — leaving only weather-modeling calculations to the supercomputers of the world.

In the search for my calculator gift to the JavaScript universe, I looked around for something more graphical. Numbers, by themselves, are pretty boring; so any way the math could be enlivened was fine by me. Having been an electronics hobbyist since I was a kid, I recalled the color-coding of electronic resistor components. The values of these gizmos aren't printed in plain numbers anywhere. You have to know the code and the meaning of the location of the colored bands to arrive at the value of each one. I thought that this calculator would be fun to play with, even if you don't know what a resistor is.

assembly

## The Calculation

To give you an appreciation for the calculation that goes into determining a resistor's value, here is the way the system works. Three closely spaced color bands determine the resistance value in ohms. The first (leftmost) band is the tens digit; the second (middle) band is the ones digit. Each color has a number from 0 through 9 assigned to it (black = 0, brown = 1, and so on). Therefore, if the first band is brown and the second band is black, the number you start off with is 10. The third band is a multiplier. Each color determines the power of ten by which you multiply the first digits. For example, the red color corresponds to a multiplier of 102, so that  $10 \times 102$  equals 1,000 ohms.

A fourth band, if present, indicates the tolerance of the component—how far, plus or minus, the resistance measurement can fluctuate due to variations in the manufacturing process. Gold means a tolerance of plus-or-minus 5 percent; silver means plus-or-minus 10 percent; and no band means a 20 percent tolerance. A pinch of extra space typically appears between the main group of three-color bands and the one tolerance band.

## User Interface Ideas

The quick-and-dirty, non-graphical approach for a user interface was to use a single frame with four `select` elements defined as pop-up menus (one for each of the four color bands on a resistor), a button to trigger calculation, and a field to show the numeric results.

How dull.

It occurred to me that if I design the art carefully, I can have JavaScript assemble an updated image of the resistor consisting of different slices of art: static images for the resistor's left and right ends, and variable slivers of color bands for the middle. Rather than use the brute force method of creating an image for every possible combination of colors (3,600 images total!), a far more efficient approach is to have one image file for each color (12 colors plus 1 empty) and enable JavaScript to call them from the server, as needed, in the proper order. If not for client-side JavaScript, a CGI script on the server would have to handle this kind of intelligence and user interaction. But with this system, any dumb server can dish up the image files as called by the JavaScript script.

The first generation of this resistor calculator used two frames, primarily because I needed a second frame to update the calculator's art dynamically while keeping the pop-up color menus stationary. Images couldn't be swapped back in those frontier days, so the lower frame had to be redrawn for each color choice. Fortunately, modern browsers enabled me to update individual image objects in a loaded document without any document reloading. Moreover, with all the images precached in memory, page users experience no (or virtually no) delay in making a change from one value to another.

The design for the new version is a simple, single-document interface (see Figure 53-1). Four pop-up menus let you match colors of a resistor, whereas the `onchange` event handler in each menu automatically triggers an image and calculation update. To hold the art together on the page, a table border surrounds the images on the page, whereas the numeric value of the component appears in a text field.

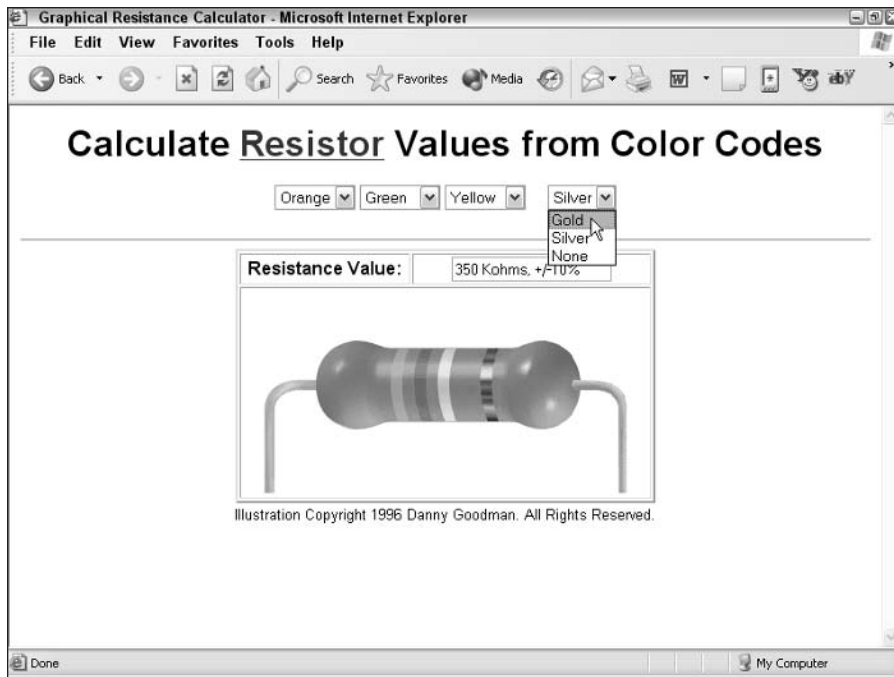

Figure 53-1: The Resistor Calculator with images inside a table border.

## The Code

All the action takes place in the file named `resistor.htm`. A second document is an introductory HTML text document that explains what a resistor is and why you need a calculator to determine a component's value. The article, called *The Path of Least Resistance*, can be viewed in a secondary window from a link in the main window. Here you will be looking only at `resistor.htm`, which has been updated to include stylesheets.

The document begins in the traditional way without any surprises:

```
<html>
  <head>
    <title>Graphical Resistance Calculator</title>
    <style type="text/css">
      body {font-family:Arial, Helvetica, serif}
    </style>
    <script type="text/javascript">
```

## Basic arrays

In calculating the resistance, the script needs to know the multiplier value for each color. If not for the last two multiplier values actually being negative multipliers (for example, 10-1 and 10-2), I could have used the index values without having to create this array. But the two out-of-sequence values at the end make it easier to work with an array rather than to try special-casing these instances in later calculations:

```
// create array listing all the multiplier values
var multiplier = new Array();
multiplier[0] = 0;
multiplier[1] = 1;
multiplier[2] = 2;
multiplier[3] = 3;
multiplier[4] = 4;
multiplier[5] = 5;
multiplier[6] = 6;
multiplier[7] = 7;
multiplier[8] = 8;
multiplier[9] = 9;
multiplier[10] = -1;
multiplier[11] = -2;

// create array listing all tolerance values
var tolerance = new Array();
tolerance[0] = "+/-5%";
tolerance[1] = "+/-10%";
tolerance[2] = "+/-20%";
```

Although the script doesn't do any calculations with the tolerance percentages, it needs to have the strings corresponding to each color for display in the pop-up menu. The `tolerance` array is there for that purpose.

## Calculations and formatting

Before the script displays the resistance value, it needs to format the numbers in values that are meaningful to those who know about these values. Just as measures of computer storage bytes, high quantities of ohms are preceded with “kilo” and “meg” prefixes, commonly abbreviated with the “K” and “M” letters. The `format()` function determines the order of magnitude of the final calculation (from another function shown in the following section) and formats the results with the proper unit of measure:

```
// format large values into kilo and meg
function format(ohmage) {
    if (ohmage >= 1e6) {
        ohmage /= 1e6;
        return "" + ohmage + " Mohms";
    } else {
        if (ohmage >= 1e3) {
            ohmage /= 1e3;
            return "" + ohmage + " Kohms";
        } else {
            return "" + ohmage + " ohms";
        }
    }
}
```

The selections from the pop-up menus meet the calculation formulas of resistors in the `calcOhms()` function. Because this function is triggered indirectly by each of the `select` objects, sending any of their parameters to the function is a waste of effort. Moreover, the `calcOhms()` function is invoked by the `onload` event handler, which is not tied to the form or its controls. Therefore, the function obtains the reference to the form and then extracts the necessary values of the four `select` objects by using explicit (named) references. Each value is stored in a local variable for convenience in completing the ensuing calculation.

Recalling the rules used to calculate values of the resistor bands, the first statement of the calculation multiplies the “tens” pop-up value times 10 to determine the tens digit and then adds the ones digit. From there, the combined value is multiplied by the exponent value of the selected multiplier value. Notice that the expression first assembles the value as a string to concatenate the exponent factor and then evaluates it to a number. Although I try to avoid the `eval()` function because of its slow performance, the one call per calculation is not a performance issue at all. The evaluated number is passed to the `format()` function for proper formatting (and setting of order of magnitude). In the meantime, the tolerance value is extracted from its array, and the combined string is plugged into the result text field (which is in a separate form, as described later):

```
// calculate resistance and tolerance values
function calcOhms() {
    var form = document.forms["input"];
    var d1 = form.tensSelect.selectedIndex;
    var d2 = form.onesSelect.selectedIndex;
    var m = form.multiplierSelect.selectedIndex;
    var t = form.toleranceSelect.selectedIndex;
    var ohmage = (d1 * 10) + d2;
    ohmage = eval("'" + ohmage + "e" + multiplier[m]);
    ohmage = format(ohmage);
    var tol = tolerance[t];
    document.forms["output"].result.value = ohmage + ", " + tol;
}
```

## Preloading images

As part of the script that runs when the document loads, the next group of statements pre-caches all possible images that can be displayed for the resistor art. For added scripting convenience, the color names are loaded into an array. With the help of that just-created array of color names, you then create another array (`imageDB`), which both generates `Image` objects for each image file and assigns a URL to each image. Notice an important subtlety about the index values being used to create each entry of the `imageDB` array: Each index is a `colorArray` entry, which is the name of the color. As you found out in Chapter 30, if you create an array element with a named index, you must use that style of index to retrieve the data thereafter; you cannot switch arbitrarily between numeric indexes and names. As you see in a moment, this named index provides a critical link between the choices a user makes in the pop-up lists and the image objects being updated with the proper image file.

```
// pre-load all color images into image cache
var colorArray = new Array("Black","Blue","Brown","Gold","Gray",
    "Green","None","Orange","Red","Silver","Violet","White","Yellow");
var imageDB = new Array();
for (i = 0; i < colorArray.length; i++) {
    imageDB[colorArray[i]] = new Image(21,182);
    imageDB[colorArray[i]].src = colorArray[i] + ".gif";
}
```

The act of assigning a URL to the `src` property of an `Image` object instructs the browser to pre-load the image file into memory. This pre-loading happens as the document is loading, so another few seconds of delay won't be noticed by the user.

## Changing images on the fly

The next four functions are invoked by their respective `select` object's `onchange` event handler. For example, after a user makes a new choice in the first `select` object (the “tens” value color selector), that `select` object reference is passed to the `setTens()` function. Its job is to extract the text of the choice and use that text as the index into the `imageDB` array. Alternatively, the color name can also be assigned to the `value` attribute of each option, and the `value` property read here. You need this connection to assign the `src` property of that array entry to the `src` property of the image that you see on the page (defined in the following section). This assignment is what enables the images of the resistor to be updated instantaneously—just the one image “slice” affected by the user's choice in a `select` object:

```
function setTens(choice) {
    var tensColor = choice.options[choice.selectedIndex].value;
    document.tens.src = imageDB[tensColor].src;
    calcOhms();
}
function setOnes(choice) {
    var onesColor = choice.options[choice.selectedIndex].value;
    document.ones.src = imageDB[onesColor].src;
    calcOhms();
}
function setMult(choice) {
    var multColor = choice.options[choice.selectedIndex].value;
    document.mult.src = imageDB[multColor].src;
    calcOhms();
}
function setTol(choice) {
    var tolColor = choice.options[choice.selectedIndex].value;
    document.tol.src = imageDB[tolColor].src;
    calcOhms();
}
```

The rest of the script for the `Head` portion of the document merely provides the statements that open the secondary window to display the introductory document:

```
function showIntro() {
    window.open("resintro.htm","", "width=400,height=320,
        left=100,top=100");
}
</script>
</head>
```

## Creating the select objects

A comparatively lengthy part of the document is consumed with the HTML for the four `select` objects. Notice, however, that the document contains an `onload` event handler in the `<body>` tag. This handler calculates the results of the currently selected choices whenever the document loads or reloads. If it weren't for this event handler, you would not see the resistor art

## Further Thoughts

I am very pleased with the improvements to performance and perceived quality that swappable images and image precaching bring to the current version of this calculator. Images change crisply. Network latency is no longer an issue.

In the layout department, however, annoying differences still exist among different platforms. At one point in the design process, I considered trying to align the pop-up menus with images of the resistor (or callout line images), but the differences in platform rendering of pop-up menus made that idea impractical. At best, I now separate the three left `select` objects from the right one by way of hard-coded spaces (`&nbsp;`).

You should notice from this exercise that I look for ways to blend JavaScript object data structures with my own data's structure. For example, the `select` objects serve multiple duties in these scripts. Not only does the text of each option point to an image file of the same name, but the index values of the same options are applied to the calculations. Things don't always work out that nicely, but whenever your scripts bring together user interface elements and data elements, look for algorithmic connections involving names or index integers that you can leverage to create elegant, concise code.

# Application: Intelligent “Updated” Flags

---

It happens to every active Web user all the time: You visit a site periodically and never know for sure what material is new since your last visit. Often, Web page authors may flag items with “New” or “Updated” .gif images after they update those items themselves. But if you fail to visit the site over a few modification sessions, the only items you find flagged are those that are new as of the most recent update by the page’s author. Several new items from a few weeks back may be of vital interest to you, but you won’t have the time to look through the whole site in search of material that is more recent than *your* last visit. Even if the items display their modification dates, do you remember for sure the date and time of your last visit to the page?

As much as I might expect a CGI program and database on a Web site to keep track of my last visit, that really is asking a great deal of the Web site. Besides, not every Web site has the wherewithal to build such a database system — if it can even put up its own CGIs. Plus, some users won’t visit sites if they need to identify themselves or register.

After surveying the way scriptable browsers store cookie information and how time calculations are performed under popular Web browsers, I found that a feasible alternative is to build this functionality into HTML documents and let the scripting manage the feature for users. The goal is to save in the visitor’s cookie file the date and time of the last visit to a page and then use that point as a measure against items that have an authorship time stamp in the HTML document.

## The Cookie Conundrum

Managing the cookie situation in this application is a bit more complicated than you may think. The reason is that you have to take into account the possible ways visitors may come and go from your site while surfing the Web. You cannot use just one cookie to store the last time a user visits the site, because you cannot predict when you should update that information with today’s date and time. For example, if you have a cookie with the previous visit in it, you eventually

### In This Chapter

Temporary and persistent cookies

World time calculations

CGI-like intelligence

need to store today's visit. But you cannot afford to overwrite the previous visit immediately (say, in `onload`) because your scripts need that information to compare against items on the page not only right now, but even after the visitor vectors off from a link and comes back later. That also means you cannot update that last visit cookie solely via an `onunload` event handler, because that, too, would overwrite information that you need when the visitor comes back a minute later.

To solve the problem, I devised a system of two cookies. One is written to the cookie that is given an expiration date of some time out in the future—the *hard cookie*, I call it. The other is a temporary cookie—the *soft cookie*—which stays in cookie memory but is never written to the file. Such temporary cookies are automatically erased as the browser quits.

The hard cookie stores the time stamp when a visitor first loads the page since the last launch of the browser. In other words, the hard cookie contains a time stamp of the current visit. Before the previous entry is overwritten, however, it is copied into the soft cookie. That soft cookie maintains the time stamp of the previous visit and becomes the measure against which author time stamps in the HTML document are compared. To guard against inadvertent overwriting of both cookies, a function triggered by the document's `onload` event handler looks to see if the soft cookie has any data in it. If so, the function knows that the visitor has been to this page in the current session and leaves the current settings alone. Thus, the visitor can come to the site and see what's new, vector off to some other location, and come back to see the same new items flagged and pick up from there.

One potential downside to this system is that if a user never quits the browser (or if the browser quits only by crashing), the cookies will never be updated. If you discover that a great deal of your users keep their computers and browsers running all the time, you can build in a kind of timeout that invalidates the soft cookie if the hard cookie is more than, say, 12 hours old.

## Time's Not on Your Side

Thanks to more than 15 years' experience programming applications that involve tracking time, I am overly sensitive to the way computers and programming languages treat time on a global basis. This issue is a thorny one, what with the vagaries of Daylight Savings Time and time zones in some parts of the world that differ from their neighbors by increments other than whole hours.

To accomplish a time tracking scheme for this application, I had to be aware of two times: the local time of the visitor and the local time of the page author. Making times match up in what can be widely disparate time zones, I use one time zone—GMT—as the reference point.

When a visitor arrives at the page, the browser needs to save that moment in time so that it can be the comparison measure for the *next* visit. Fortunately, whenever you create a new date object in JavaScript, it does so internally as the GMT date and time. Even though the way you attempt to read the date and time created by JavaScript shows you the results in your computer's local time, the display is actually filtered through the time zone offset as directed by your computer's time control panel. In other words, the millisecond value of every date object you create is maintained in memory in its GMT form. That's fine for the visitor's cookie value.

For the page author, however, I was presented with a different problem. Rather than force the author to convert the time stamps throughout the document to GMT, I wanted to let the author enter dates and times in local time. Aside from the fact that many people have trouble doing time zone conversions, looking at an existing item in the HTML with a local time stamp and instantly recognizing when that was last updated is much easier.

The problem, then, is how to let the visitor’s browser know what time the author’s time stamp is in GMT terms. To solve the issue, the author’s time stamp needs to include a reference to the author’s time zone relative to GMT. An Internet convention provides a couple of ways to do this: specifying the number of hours and minutes difference from GMT or, where supported by the browser, the abbreviation of the time zone. In JavaScript, you can create a new date object out of one of the specially formatted strings containing the date, time, and time zone. Three examples follow for the Christmas Eve dinner that starts at 6 p.m. in the Eastern Standard Time zone of North America:

```
var myDate = new Date("24 Dec 1997 23:00:00 GMT");
var myDate = new Date("24 Dec 1997 18:00:00 GMT-0500");
var myDate = new Date("24 Dec 1997 18:00:00 EST");
```

The first assumes you know the Greenwich Mean Time for the date and time that you want to specify. But if you don’t, you can use the GMT designation and offset value. The syntax indicates the date and time is in a time zone exactly five hours west of GMT (values to the east would be positive numbers) in `hhmm` format. Browsers also know all of the time zone abbreviations for North America (EST, EDT, CST, CDT, MST, MDT, PST, and PDT, where “S” is for standard time and “D” is for daylight time).

When a user visits a page with this application embedded in it, the visitor’s browser converts the author’s time stamp to GMT (with the help of the author’s zone offset parameter), so that both the author time stamp and last visit time stamp (in the soft cookie) are comparing apples to apples.

## The Application

All of this discussion may make the application sound complicated. That may be true, internally. But the goal, as in most of the samples in this book, is to make the application easy to use in your site, even if you’re not sure how everything works inside.

The sample page described in this chapter and on the CD-ROM (`whatsnew.htm`) is pretty boring to look at, because the power all lies in the scripting that users don’t see (see Figure 54-1). Though this figure may be the most uninspired graphic presentation of the book, the functionality may be the most valuable addition that you make to your Web site.

When you first open the document (do so from a copy on your hard disk so that you can modify the author time stamp in a moment), all you see are the two items on the page without any flags. Although both entries have author time stamps that pre-date the time you’re viewing the page, a soft cookie does not yet exist against which to compare those times. But the act of making the first visit to the page has created a hard cookie of the date and time that you first opened the page.

**Figure 54-1:** An item flagged as being new since my last visit to the page.

Quit the browser to get that hard cookie officially written to the cookie file. Then open the `whatsnew.htm` file in your script editor. Scroll to the bottom of the document, where you see the `<body>` tag and the interlaced scripts that time stamp anything that you want on the page. This application is designed to display a special `.gif` image that says “NEW 4U” whenever an item has been updated since your last visit.

Each interlaced script looks like this:

```
<script type="text/javascript">
document.write(newAsOf("12 Oct 2003 13:36:00 PDT"))
</script>
```

The `document.write()` method writes to the page whatever HTML comes back from the `newAsOf()` function. The parameter to the `newAsOf()` function is what holds the author time stamp and zone offset information. The time stamp value must be in the string format, as shown in the preceding example, with the date and time following the exact order (“dd mmm yyyy hh:mm:ss”). Month abbreviations are in English (Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, Dec).

As you see in the code that follows, the `newAsOf()` function returns an `<img>` tag with the “NEW 4U” image if the author time stamp (after appropriate conversion) is later than the soft cookie value. This image can be placed anywhere in a document. For example, at my Web site, I sometimes place the image before a contents listing rather than at the end. This means, too, that if part of your page is written by `document.write()` methods, you can just insert the `newAsOf()` function call as a parameter to your own `document.write()` calls.

If you want to see the author time stamping work, edit one of the time stamps in the `whatsnew.htm` file to reflect the current time. Save the document and relaunch the browser to view the page. The item whose author time stamp you modified should now show the bright “NEW 4U” image.

## The Code

The sample page starts by initializing three global variables that are used in the statements that follow. One variable is a Boolean value indicating whether the visitor has been to the page before. Another variable, `lastVisit`, holds the value of the soft cookie whenever the visitor is at this page. One other variable, `dateAdjustment`, is (unfortunately) necessary to take into account a date bug that persists in Macintosh versions of Navigator (times of new date objects can be off by one hour). I use this variable to automatically handle any discrepancies:

```
<html>
  <head>
    <title>Showing What's New</title>
    <script type="text/javascript">
      // globals
      var repeatCustomer = false;
      var lastVisit = 0; // to hold date & time of previous access in GMT ms
      var dateAdjustment = 0; // to accommodate date bugs on some platforms
```

For reading and writing cookie data, I use virtually the same cookie functions from the outline table of contents (see Chapter 52). The only difference is that the cookie writing function includes an expiration date, because I want this cookie to hang around in the cookie file for a while—at least until the next visit, whenever that may be:

```
// shared cookie functions
var mycookie = document.cookie;
// read cookie data
function getCookieData(name) {
  var label = name + "=";
  var labelLen = label.length;
  var cLen = mycookie.length;
  var i = 0;
  while (i < cLen) {
    var j = i + labelLen;
    if (mycookie.substring(i,j) == label) {
      var cEnd = mycookie.indexOf(";",j);
      if (cEnd == -1) {
        cEnd = mycookie.length;
      }
      return unescape(mycookie.substring(j,cEnd));
    }
    i++;
  }
  return "";
}

// write cookie data
function setCookieData(name,dateData,expires) {
  mycookie = document.cookie = name + "=" + dateData + "; expires=" +
    expires;
}
```

Notice that the `setCookieData()` function still maintains a level of reusability by requiring a name for the cookie to be passed as a parameter along with the data and expiration date. I could have hard-wired the name into this function, but that goes against my philosophy of designing for reusability.

Next comes a function that figures out if any problems with JavaScript date accuracy exist on any platform. Essentially, the function creates two date objects, one to serve as a baseline. Even the baseline date can be bad, so to test against it, you want to use the second object to create another date using the first date object's own values as a parameter. If any major discrepancies occur, they will show up loud and clear:

```
// set dateAdjustment to accommodate Mac bug in Navigator 3
function adjustDate() {
    var base = new Date();
    var testDate = base;
    testDate = testDate.toLocaleString();
    testDate = new Date(testDate);
    dateAdjustment = testDate.getTime() - base.getTime();
}
```

In truth, this function always shows some adjustment error, because both the baseline date and test date cannot be created simultaneously. Even in an accurate system, the two will vary by some small number of milliseconds. For the purposes here, this amount of variance is insignificant.

## Setting the stage

Functions in the next part of the script get your cookies all in a row. The first function (`saveCurrentVisit()`) deals with the visitor's local time, converting it to a form that will be useful on the next visit. Although one of the local variables is called `nowGMT`, all the variable does is take the new date object and convert it to the GMT milliseconds value (minus any `dateAdjustment` value) by invoking the `getTime()` method of the date object. I use this name in the variable to help me remember what the value represents:

```
// write date of current visit (in GMT time) to cookie
function saveCurrentVisit() {
    var visitDate = new Date();
    var nowGMT = visitDate.getTime() - dateAdjustment;
    var expires = (nowGMT + (180 * 24 * 60 * 60 * 1000));
    expires = new Date(expires);
    expires = expires.toGMTString();
    setCookieData("lastVisit", nowGMT, expires);
}
```

From the current time, I create an expiration date for the cookie. The example shows a date roughly six months (180 days, to be exact) from the current time. I leave the precise expiration date up to your conscience and how long you want the value to linger in a user's cookie file.

The final act of the `saveCurrentVisit()` function is to pass the relevant values to the function that actually writes the cookie data. I assign the name `lastVisit` to the cookie. If you want to manage this information for several different pages, assign a different cookie name for each page. This setup can be important in case a user gets to only part of your site during a visit. On the next visit, the code can point to page-specific newness of items.

The “temporary” cookie also needs to set an expiration date for itself. Normally, temporary cookies disappear when the user quits the browser. But these days, it's not uncommon for users to keep their computers and applications running for days (with fewer crashes than not too long ago). To force the browser to visit the site after awhile as if coming fresh (to look for new flags), the `nextPrevVisit` cookie is set to expire one hour after it is set:

```
// set cookie with next previous visit with one-hour expiration
function saveNextPrevVisit(lastStoredVisit) {
    var visitDate = new Date();
    var nowGMT = visitDate.getTime() - dateAdjustment;
    var expires = (nowGMT + (60*1000));
    expires = new Date(expires);
    expires = expires.toGMTString();
    setCookieData("nextPrevVisit", lastStoredVisit, expires);
}

```

The bulk of what happens in this application takes place in an initialization function. All the cookie swapping occurs there, as well as the setting of the `repeatCustomer` global variable value:

```
// set up global variables and establish whether user is repeat customer
function initialize() {
    var lastStoredVisit = getCookieData("lastVisit");
    var nextPrevStoredVisit = getCookieData("nextPrevVisit");

    adjustDate();

    if (!lastStoredVisit) { // never been here before
        saveCurrentVisit();
        repeatCustomer = false;
    } else { // been here before...
        if (!nextPrevStoredVisit) { // but first time this session
            saveNextPrevVisit(lastStoredVisit); // expires in one hour
            lastVisit = parseFloat(lastStoredVisit);
            saveCurrentVisit();
            repeatCustomer = true;
        } else { // back again during this session (perhaps reload or Back)
            lastVisit = parseFloat(nextPrevStoredVisit);
            repeatCustomer = true;
        }
    }
}

initialize();

```

The first two statements retrieve both hard (`lastVisit`) and soft (`nextPrevVisit`) cookie values. After calling the function that sets any necessary date adjustment, the script starts examining the values of the cookies to find out where the visitor stands upon coming to the page.

The first test is whether the person has ever been to the page before. You do this by checking whether a hard cookie value (which would have been set in a previous visit) exists. If no such cookie value exists, the current visit time is written to the hard cookie and `repeatCustomer` is set to `false`. These actions prepare the visitor’s cookie value for the *next* visit.

Should a user already be a repeat customer, you have to evaluate whether this visit is the user’s first visit since launching the browser. You do that by checking for a value in the soft cookie. If that value doesn’t exist, it means the user is here for the first time “today.” You then grab the hard cookie and drop it into the soft cookie before writing today’s visit to the hard cookie.

For repeat customers who have been here earlier in this session, you update the `lastVisit` global variable from the cookie value. The variable value will have been destroyed when the user left the page just a little while ago, whereas the soft cookie remains intact, enabling you to update the variable value now.

Outside of the function definition, the script automatically executes the `initialize()` function by that single statement. This function runs every time the page loads.

## The date comparison

Every interlaced script in the body of the document calls the `newAsOf()` function to find out if the author's time stamp is after the last visit of the user to the page. This function is where the time zone differences between visitor and author must be neutralized so that a valid comparison can be made:

```
function newAsOf(authorDate) {
    authorDate = new Date(authorDate);
    var itemUpdated = authorDate.getTime();
    alert(itemUpdated + ":" + lastVisit);
    return ((itemUpdated > lastVisit) && repeatCustomer) ?
        "<img src='updated.gif' height=10 width=30 \\/>" : "";
}
</script>
</head>
```

As you saw earlier, calls to this function require one parameter: a specially formatted date string that includes time zone information. The first task in the function is to re-cast the author's date string to a date object. You reuse the variable name (`authorDate`) because its meaning is quite clear. The date object created here is stored internally in the browser in GMT time, relative to the time zone data supplied in the parameter. To assist in the comparison against the `lastVisit` time (stored in milliseconds), the `getTime()` method converts `authorDate` to GMT milliseconds.

The last statement of the function is a conditional expression that returns the `<img>` tag definition for the “NEW 4U” image only if the author's time stamp is later than the soft cookie value and the visitor has been here before. Otherwise, the function returns an empty string. Any `document.write()` method that calls this function and executes via this branch writes an empty string — nothing — to the page.

## A live <body>

For the sample document, I have you create a simple bulleted list of two entries, imaginatively called “First item” and “Second item.” Interlaced into the HTML are scripts that are ready to insert the “NEW 4U” image if the author time stamp is new enough:

```
<body>
  <ul>
    <li>First item <script type="text/javascript">
      document.write(newAsOf("19 Nov 2003 19:55:00 PST"))</script></li>
    <li>Second item <script type="text/javascript">
      document.write(newAsOf("18 Nov 2003 13:36:00 PST"))</script></li>
  </ul>
</body>
</html>
```

All these script tags make the HTML a bit hard to read, but I believe the functionality is worth the effort.

## Further Thoughts

You can, perhaps, go overboard with the way that you use this technique at a Web site. Like most features in JavaScript, I recommend using it in moderation and confining the flags to high-traffic areas that repeat visitors frequent. One hazard is that you can run out of the 20 cookies if you have too many page-specific listings.

You can share the same cookie among documents in related frames. Locate all the functions from the script in this chapter’s Head section into a Head section of a framesetting document. Then, modify the call to the `newAsOf()` function by pointing it to the parent:

```
document.write(parent.newAsOf("18 Nov 2003 17:40:00 PDT"));
```

That way, one cookie can take care of all documents that you display in that frameset.

# Application: Decision Helper

---

The list of key concepts for this chapter's application looks like the grand finale to a fireworks show. As JavaScript implementations go, the application is, in some respects, over the top, yet not out of the question for presenting a practical interactive application on a Web site without any server programming.

## The Application

I wanted to implement a classic application often called a *decision support system*. My experience with the math involved here goes back to the first days of Microsoft Excel. Rather than design a program that had limited appeal (covering only one possible decision tree), I set out to make a completely user-customizable decision helper. All the user has to do is enter values into fields on a series of screens; the program performs the calculations to let the user know how the various choices rank against each other.

Although I won't be delving too deeply into the math inside this application, you will find it helpful to understand how a user approaches this program and what the results look like. The basic scenario is a user who is trying to evaluate how well a selection of choices measure up to his or her expectations of performance. User input includes:

- ◆ The name of the decision
- ◆ The names of up to five alternatives (people, products, ideas, and so on)
- ◆ The factors or features of concern to the user
- ◆ The importance of each of the factors to the user
- ◆ A user ranking of the performance of every alternative in each factor

What makes this kind of application useful is that it forces the user to rate and weigh a number of often-conflicting factors. By assigning hard numbers to these elements, the user leaves the difficult process of figuring out the weights of various factors to the computer.

### In This Chapter

Multiple frames

Multiple-document applications

Multiple windows

Persistent storage (cookies)

Scripted image maps

Scripted charts

Results come in the form of floating-point numbers between 0 and 100. As an extra touch, I've added a graphical charting component to the results display.

## The Design

With so much user input necessary for this application, conveying the illusion of simplicity was important. Rather than lump all text objects on a single scrolling page, I decided to break them into five pages, each consisting of its own HTML document. As an added benefit, I could embed information from early screens into the HTML of later screens, rather than having to create all changeable items out of text objects so that the application would work with older browsers. This “good idea” presented one opportunity and one rather large challenge.

The opportunity was to turn the interface for this application into something resembling a multimedia application using multiple frames. The largest frame would contain the forms the user fills out as well as the results page. Another frame would contain a navigation panel with arrows for moving forward and backward through the sequence of screens, plus buttons for going back to a home page and getting information about the program. I also thought a good idea would be to add a frame that provides instructions or suggestions for the users at each step. And so, the three-frame window was born, as shown in the first entry screen in Figure 55-1.

Using a navigation bar also enables me to demonstrate how to script a client-side image map — not an obvious task with JavaScript.

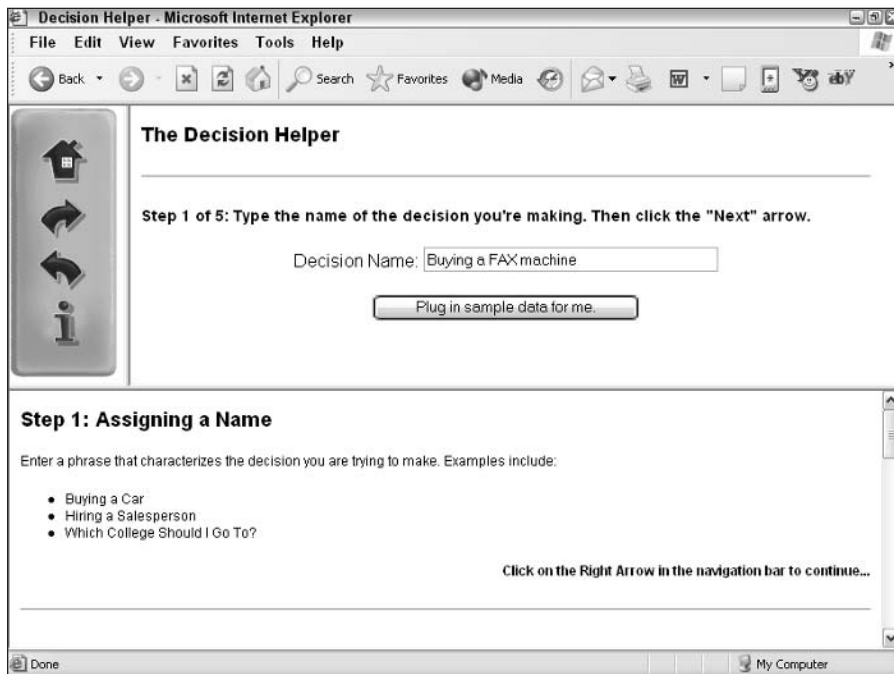

Figure 55-1: The Decision Helper window consists of three frames.

On the challenge side of this design, finding a way to maintain data globally as the user navigates from screen to screen was necessary. Every time one of the entry pages unloads, none of its text fields is available to a script. My first attack at this problem was to store the data as global variable data (mostly arrays) in the parent document that creates the frames. Because JavaScript enables you to reference any parent document's object, function, or variable (by preceding the reference with `parent`), I thought this task would be a snap. A nasty bug in Navigator 2 (the prominent browser when this application was first developed) got in the way at the time: If a document in any child window unloaded, the variables in the parent window got jumbled. The other hazard here is that a reload of the frameset could erase the current state of those variables.

My next hope was to use the `document.cookie` as the storage bin for the data. A major problem I faced was that this program needs to store a total of 41 individual data points, yet no more than 20 uniquely named cookies can be allotted to a given domain. But the cookie proved to be the primary solution for this application (although see the "Further Thoughts" section at the end of the chapter about a non-cookie version on the CD-ROM). For some of the data points (which are related in an array-like manner), I fashioned my own data structures so that one named cookie could contain up to five related data points. That reduced my cookie demands to 17. Note that the application with cookies works only from a Web server (not locally) with Safari 1.0.

## The Files

Before I get into the code, let me explain the file structure of this application. Table 55-1 gives a rundown of the files used in the Decision Helper.

**Table 55-1: Files Comprising the Decision Helper Application**

<i>File</i>	<i>Description</i>
<code>index.htm</code>	Framesetting parent document
<code>dhNav.htm</code>	Navigation bar document which contains some scripting
<code>dhNav.gif</code>	Image displayed in <code>dhNav.htm</code>
<code>dh1.htm</code>	First Decision Helper entry page
<code>dh2.htm</code>	Second Decision Helper entry page
<code>dh3.htm</code>	Third Decision Helper entry page
<code>dh4.htm</code>	Fourth Decision Helper entry page
<code>dh5.htm</code>	Results page
<code>chart.gif</code>	Tiny image file used to create bar charts in <code>dh5.htm</code>
<code>dhHelp.htm</code>	Sample data and instructions document for lower-right frame
<code>dhAbout.htm</code>	Document that loads into a second window

A great deal of interdependence exists among these files. As you see later, assigning the names to some of these files was strategic for the implementation of the image map.

## The Code

With so many JavaScript-enhanced HTML documents in this application, you can expect a great deal of code. To best grasp what's going on here, first try to understand the structure and interplay of the documents, especially the way the entry pages rely on functions defined in the parent document. My goal in describing this structure is not to teach you how to implement this application, but rather how to apply the lessons I learned while building this application to the more complex ideas that may be aching to get out of your head and into JavaScript.

### index.htm

Taking a top-down journey through the JavaScript and HTML of the Decision Helper, start at the document that loads the frames. Unlike a typical framesetting document, however, this one contains JavaScript code in its Head section — code that many other documents rely on:

```
<html>
  <head>
    <title>Decision Helper</title>
```

An important consideration to remember is that in a multiple-frame environment, the title of the parent window's document is the name that appears in the window's title bar, no matter how many other documents are open inside its subframes.

The first items of the script control a global variable, `currTitle`, which is set by a number of the subsidiary files as the user navigates through the application. This variable ultimately helps the navigation bar buttons do their jobs correctly. Because this application relies on the `document.cookie` so heavily, the cookie management functions (slightly modified versions of Bill Dortch's Cookie Functions — see Chapter 18) are located in the parent document so they load only once. I simplified the cookie writing function because this application uses default settings for pathname and expiration. With no expiration date, the cookies don't survive the current browser session, which is perfect for this application:

```
<script type="text/javascript">
// global variable settings of current dh document number
var currTitle = "";
function setTitleVar(titleVal) {
    currTitle = "" + titleVal;
}
function getCookieVal(offset) {
    var endstr = document.cookie.indexOf(";", offset);
    if ((" " + endstr) == " " || endstr == -1)
        endstr = document.cookie.length;
    return unescape(document.cookie.substring(offset, endstr));
}

function getCookie(name) {
    var arg = name + "=";
    var alen = arg.length;
    var clen = document.cookie.length;
    var i = 0;
    while (i < clen) {
        var j = i + alen;
        if (document.cookie.substring(i, j) == arg)
            return getCookieVal(j);
        i = document.cookie.indexOf(" ", i) + 1;
        if (i == 0)
            break;
    }
}
```

```

    return null;
}

function setCookie(name, value) {
    document.cookie = name + "=" + escape (value) + ";";
}

```

When this application loads (or a user elects to start a new decision), it's important to grab the cookies you need and initialize them to basic values that the entry screens will use to fill entry fields when the user first visits them. All statements inside the `initializeCookies()` function call the `setCookie()` function, defined in the preceding listing. The parameters are the name of each cookie and the initial value—mostly empty strings. Before going on, study the cookie labeling structure carefully. I refer to it often in discussions of other documents in this application:

```

function initializeCookies() {
    setCookie("decName", "");
    setCookie("alt0", "");
    setCookie("alt1", "");
    setCookie("alt2", "");
    setCookie("alt3", "");
    setCookie("alt4", "");
    setCookie("factor0", "");
    setCookie("factor1", "");
    setCookie("factor2", "");
    setCookie("factor3", "");
    setCookie("factor4", "");
    setCookie("import", "0");
    setCookie("perf0", "");
    setCookie("perf1", "");
    setCookie("perf2", "");
    setCookie("perf3", "");
    setCookie("perf4", "");
}

```

The following functions should look familiar to you. They were borrowed either wholesale or with minor modification from the data-entry validation section of the Social Security number database lookup in Chapter 50. I'm glad I wrote these as generic functions, making them easy to incorporate into this script. Because many of the entry fields on two screens must be integers between 1 and 100, I brought the data validation functions to the parent document rather than duplicating them in each of the subdocuments:

```

// JavaScript sees numbers with leading zeros as octal values, so strip
// zeros
function stripZeros(inputStr) {
    var result = inputStr;
    while (result.substr(0,1) == "0") {
        result = result.substr(1,result.length);
    }
    return result;
}

// general purpose function to see if a suspected numeric input
// is a positive integer
function isNumber(inputStr) {
    for (var i = 0; i < inputStr.length; i++) {
        var oneChar = inputStr.substr(i, i + 1);
        if (oneChar < "0" || oneChar > "9") {
            return false;
        }
    }
}

```

```

    }
    return true;
}

// function to determine if value is in acceptable range for this
// application
function inRange(inputStr) {
    num = parseInt(inputStr);
    if (num < 1 || num > 100) {
        return false;
    }
    return true;
}

```

To control the individual data-entry validation functions in the master controller, I again was able to borrow heavily from the application in Chapter 50:

```

// Master value validator routine
function isValid(inputStr) {
    if (inputStr != "" ) {
        inputStr = stripZeros(inputStr);
        if (!isNumber(inputStr)) {
            alert("Please make sure entries are numbers only.");
            return false;
        } else {
            if (!inRange(inputStr)) {
                alert("Entries must be numbers between 1 and 100. Try
                    another value.");
                return false;
            }
        }
    }
    return true;
}

```

Each of the documents containing entry forms retrieves and stores information in the cookie. Because all cookie functions are located in the parent document, it simplifies coding in the subordinate documents to have functions in the parent document acting as interfaces to the primary cookie functions. For each category of data stored as cookies, the parent document has a pair of functions for getting and setting data. The calling statements pass only the data to be stored when saving information; the interface functions handle the rest, such as storing or retrieving the cookie with the correct name.

In the following pair of functions, the decision name (from the first entry document) is passed back and forth between the cookie and the calling statements. Not only must the script store the data, but if the user returns to that screen later for any reason, the entry field must retrieve the previously entered data:

```

function setDecisionName(str) {
    setCookie("decName",str);
}
function getDecisionName() {
    return getCookie("decName");
}

```

The balance of the storage and retrieval pairs does the same thing for their specific cookies. Some cookies are named according to index values (*factor1*, *factor2*, and so on), so their cookie-accessing functions require parameters for determining which of the cookies to access, based on the request from the calling statement. Many of the cookie retrieval functions are called to fill in data in tables of later screens during the user's trip down the decision path:

```

function setAlternative(i,str) {
    setCookie("alt" + i,str);
}
function getAlternative(i) {
    return getCookie("alt" + i);
}
function setFactor(i,str) {
    setCookie("factor" + i,str);
}
function getFactor(i) {
    return getCookie("factor" + i);
}
function setImportance(str) {
    setCookie("import",str);
}
function getImportance(i) {
    return getCookie("import");
}
function setPerformance(i,str) {
    setCookie("perf" + i,str);
}
function getPerformance(i) {
    return getCookie("perf" + i);
}
}

```

One sequence of code that runs when the parent document loads is the one that looks to see if a cookie structure is set up. If no such structure is set up (the retrieval of a designated cookie returns a null value), the script initializes all cookies via the function described earlier:

```

    if (getDecisionName() == null) {
        initializeCookies();
    }
</script>
</head>

```

The balance of the parent document source code defines the frameset for the browser window. It establishes some hard-wired pixel sizes for the navigation panel. This ensures that the entire .gif file is visible whenever the frameset loads, without a ton of unwanted white space if the browser window is large:

```

<frameset rows="250,*">
  <frameset cols="104,*">
    <frame name="navBar" src="dhNav.htm" scrolling="no" marginheight="2"
      marginwidth="1" />
    <frame name="entryForms" src="dh1.htm" />
  </frameset>
  <frameset rows="100%">
    <frame name="instructions" src="dhHelp.htm" />
  </frameset>
</frameset>
<noframes>
  <body>
    <h1>It's really cool...</h1>
    <h2>...but only if your browser handles frames</h2>
    <hr />
    <a href="../index.html">Back</a>
  </body>
</noframes>
</frameset>
</html>

```

I learned an important lesson about scripting framesets along the way. Older browsers, especially NN through version 4, do not respond to changes in framesetting size attributes through a simple reload of the page. I found it necessary to reopen the frameset file from time to time. I also found it necessary to sometimes quit early Navigators altogether and relaunch to make some changes visible. Therefore, if you seem to be making changes, but reloading the frameset doesn't make the changes appear, try reopening or — as a last resort — quitting the browser.

## dhNav.htm

Because of its crucial role in controlling the activity around this program, look into the navigation bar's document next. To accomplish the look and feel of a multimedia program, this document was designed as a client-side image map that has four regions scripted corresponding to the locations of the four buttons (see Figure 55-1). One function is connected to each button.

The first function is linked to the graphical Home button. For the listing here, I just present an alert dialog box replicating the action of navigating back to a real Web site's home page:

```
<html>
  <head>
    <title>Navigation Bar</title>
    <script type="text/javascript">
      function goHome() {
        alert("Navigate back to home page on a real site.");
      }
    </script>
  </head>
</html>
```

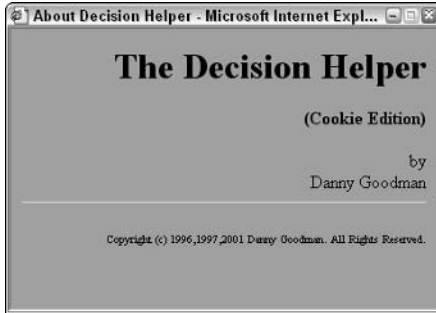

Each of the arrow navigation buttons brings the user to the next or previous entry screen in the sequence. To facilitate this without building tables of document titles and names, you call upon the `currTitle` global variable in the parent document. This value contains an integer in the range between 1 and 5, corresponding to the main content documents, `dh1.htm`, `dh2.htm`, and so on. As long as the offset number is no higher than the next-to-last document in the sequence, the `goNext()` function increments the index value by one and concatenates a new location for the frame. At the same time, the script advances the help document (in the bottom frame) to the anchor corresponding to the chosen entry screen by setting the `location.hash` property of that frame. Similar action navigates to the previous screen of the sequence through the `goPrev()` function. This time, the index value is decremented by one, and an alert warns the user if the current page is already the first in the sequence:

```
function goNext() {
  var currOffset = parseInt(parent.currTitle);
  if (currOffset <= 4) {
    ++currOffset;
    parent.entryForms.location.href = "dh" + currOffset + ".htm";
    parent.instructions.location.hash = "help" + currOffset;
  } else {
    alert("This is the last form.");
  }
}

function goPrev() {
  var currOffset = parseInt(parent.currTitle);
  if (currOffset > 1) {
    --currOffset;
    parent.entryForms.location.href = "dh" + currOffset + ".htm";
    parent.instructions.location.hash = "help" + currOffset;
  } else {
    alert("This is the first form.");
  }
}
```

Clicking the Info button displays a smaller window containing typical About-box data for the program (see Figure 55-2):

```
function goInfo() {
    var newWindow = window.open("dhAbout.htm", "", "HEIGHT=250,WIDTH=380");
}
</script>
</head>
```

**Figure 55-2:** The About Decision Helper screen appears in a separate window.

The Body of the navigation document contains the part that enables you to script a client-side image map. Mouse click events weren't available to area elements until version 4 browsers, so to let these image maps work with older versions, mouse action is converted to script action by assigning a `javascript:` pseudo-URL to the `HREF` attribute for each area element. Instead of pointing to an entirely new URL (as area elements usually work), the attributes point to the JavaScript functions defined in the Head portion of this document. After a user clicks the rectangle specified by an `<area>` tag, the browser invokes the function instead.

```
<body bgcolor="white">
  <map id="navigation" name="navigation">
    <area shape="rect" coords="23,22,70,67" href="javascript:goHome()" />
    <area shape="rect" coords="25,80,66,116" href="javascript:goNext()" />
    <area shape="rect" coords="24,125,67,161"
      href="javascript:goPrev()" />
    <area shape="rect" coords="35,171,61,211"
      href="javascript:goInfo()" />
  </map> 
</body>
</html>
```

Although not shown here, you can assign `onmouseover` event handlers to each area element for NN3+ and IE4+ to display a friendly message about the action of each button.

## dh1.htm

Of the five documents that display in the main frame, `dh1.htm` is the simplest (refer to Figure 55-1). It contains a single entry field in which the user is invited to enter the name for the decision.

Only one function adorns the Head. This function summons one of the cookie interface functions in the parent window. A test is located here in case there is a problem with initializing the cookies. Rather than show `null` in the field, the conditional expression substitutes an empty string:

```

<html>
  <head>
    <title>DH1</title>
    <style type="text/css">
      body {font-family:Arial, Helvetica, serif}
      h2 {font-size:18px}
      h4 {font-size:14px}
    </style>
    <script type="text/javascript">
      function loadDecisionName() {
        var result = parent.getDecisionName();
        result = (result == null) ? "" : result;
        document.forms[0].decName.value = result;
      }
    </script>
  </head>

```

After the document loads, it performs three tasks (in the `onload` event handler). The first task is to set the global variable in the parent to let it know which number of the five main documents is currently loaded. Next, the script must fill the field with the decision name stored in the cookie. This task is important because users will want to come back to this screen to review what they entered previously. A third statement in the `onload` event handler sets the focus of the entire browser window to the one text object. This task is especially important in a multi-frame environment, such as this design. After a user clicks on the navigation panel, that frame has the focus. To begin typing into the field, the user has to tab (repeatedly) or click the text box to give the text box focus for typing. By setting the focus in the script when the document loads, you save the user time and aggravation:

```

<body onload="parent.setTitleVar(1);
loadDecisionName();document.forms[0].decName.focus()">
  <h2>The Decision Helper</h2>
  <hr />
  <h4>Step 1 of 5: Type the name of the decision you're making. Then click
the "Next" arrow.</h4>

```

In the text field itself, an `onchange` event handler saves the value of the field in the parent's cookie for the decision name. No special Save button or other instruction is necessary here because any navigation that the user does via the navigation bar automatically causes the text field to lose focus and triggers the `onchange` event handler:

```

  <center>
    <form>
      Decision Name: <input type="text" name="decName" size="40"
onchange="parent.setDecisionName(this.value)" />
    </form>
  </center>
</body>
</html>

```

The copy of this file on the CD-ROM also has code that allows for plugging in sample data (as seen on my Web site) and a (commented out) `textarea` object that you can use for debugging cookie data.

## dh2.htm

For the second data-entry screen (shown in Figure 55-3), five fields invite the user to enter descriptions of the alternatives under consideration. As with the decision name screen, the scripting for this page must both retrieve and save data displayed or entered in the fields.

Figure 55-3: The second data-entry screen.

In one function, the script retrieves the alternative cookies (five total) and stuffs them into their respective text fields (as long as their values are not null). This function script uses a `for` loop to cycle through all five items—a common process throughout this application. Whenever a cookie is one of a set of five, the parent function has been written (in the following example) to store or extract a single cookie, based on the index value. Text objects holding like data (defined in the following listing) are all assigned the same name, so that JavaScript lets you treat them as array objects—greatly simplifying the placement of values into those fields inside a `for` loop:

```
<html>
  <head>
    <title>DH2</title>
    <style type="text/css">
      body {font-family:Arial, Helvetica, serif}
      h2 {font-size:18px}
      h4 {font-size:14px}
    </style>
    <script type="text/javascript">
      function loadAlternatives() {
        for (var i = 0; i < 5; i++) {
          var result = parent.getAlternative(i);
          result = (result == null) ? "" : result;
          document.forms[0].alternative[i].value = result;
        }
      }
    </script>
  </head>
```

After the document loads, the document number is sent to the parent's global variable, its fields are filled by the function defined in the Head, and the first field is handed the focus to assist the user in entering data the first time:

```
<body onload="parent.setTitleVar(2);
loadAlternatives();document.forms[0].alternative[0].focus()">
  <h2>The Decision Helper</h2>
  <hr />
  <h4>Step 2 of 5: Type up to five alternatives you are considering.</h4>
```

Any change that a user makes to a field is stored in the corresponding cookie. Each onchange event handler passes its indexed value (relative to all like-named fields) plus the value entered by the user as parameters to the parent's cookie-saving function:

```
<center>
  <form>
    Alternative 1: <input type="text" name="alternative" size="25"
onchange="parent.setAlternative(0,this.value)" /><br />
    Alternative 2: <input type="text" name="alternative" size="25"
onchange="parent.setAlternative(1,this.value)" /><br />
    Alternative 3: <input type="text" name="alternative" size="25"
onchange="parent.setAlternative(2,this.value)" /><br />
    Alternative 4: <input type="text" name="alternative" size="25"
onchange="parent.setAlternative(3,this.value)" /><br />
    Alternative 5: <input type="text" name="alternative" size="25"
onchange="parent.setAlternative(4,this.value)" /><br />
  </form>
</center>
</body>
</html>
```

## dh3.htm

With the third screen, the complexity increases a bit. Two factors contribute to this increase in difficulty. One is that the limitation on the number of cookies available for a single domain forces you to join into one cookie the data that might normally be distributed among five cookies. Second, with the number of text objects on the page (see Figure 55-4), it becomes more efficient (from the standpoint of tedious HTML writing) to let JavaScript deploy the fields. The fact that two sets of five related fields exist facilitates using `for` loops to lay out and populate them.

One initial function here is reminiscent of Head functions in previous entry screens. This function retrieves a single factor cookie from the set of five cookies:

```
<html>
  <head>
    <title>DH3</title>
    <style type="text/css">
      body {font-family:Arial, Helvetica, serif}
      h2 {font-size:18px}
      h4 {font-size:14px}
    </style>
    <script type="text/javascript">
      function getdh3Factor(i) {
        var result = parent.getFactor(i);
        if (result == null) {
          return "";
        }
        return result;
      }
    </script>
  </head>
</html>
```

**The Decision Helper**

**Step 3 of 5: List the factors that will influence your decision, and assign a weight (from 1 to 100) to signify the importance of each factor in your decision.**

Factor 1-->	Cost	80	<--Weight 1
Factor 2-->	Size	40	<--Weight 2
Factor 3-->	Paper Handling	60	<--Weight 3
Factor 4-->	Warranty	70	<--Weight 4
Factor 5-->			<--Weight 5

**Step 3: Assigning Factors and Weights**

**Factors** are the kinds of items you might find in a product feature checklist. But they can also be subjective items, such as the prestige you might attach to the neighborhoods in which houses you're considering are located. Whatever you enter here, the items should be factors that you can measure either by some hard measure (e.g., the size of a computer model's hard disk) or by subjective measure (e.g., what the buzz is around campus about a potential college course's prospects are for meeting members of the opposite sex).

**Weights** are a measure of how important a particular factor is to you. For instance, when buying a car, interior space may be very important to you (rating, say, a 90), but fuel economy is further down the list of considerations (rating perhaps a 30). Each value you enter here is independent of the others: consider each factor individually, and assign a weight value between 1 and 100.

**Continue clicking the Right Arrow to advance...**

**Figure 55-4:** Screen for entering decision factors and their weights.

Values for the five possible weight entries are stored together in a single cookie. To make this work, I had to determine a data structure for the five “fields” of a single cookie “record.” Because all entries are integers, I can choose any nonnumeric character. I arbitrarily selected the period:

```
function setdh3Importance() {
    var oneRecord = "";
    for (var i = 0; i < 5; i++) {
        var dataPoint = document.forms[0].importance[i].value;
        if (!parent.isValid(dataPoint)) {
            document.forms[0].importance[i].focus();
            document.forms[0].importance[i].select();
            return;
        }
        oneRecord += dataPoint + ".";
    }
    parent.setImportance(oneRecord);
    return;
}
```

The purpose of the `setdh3Importance()` function is to assemble all five values from the five Weight entry fields (named “importance”) into a period-delimited record that is ultimately sent to the cookie for safekeeping. Another of the many `for` loops in this application cycles through each of the fields, checking for validity and then appending the value with its trailing period to the variable (`oneRecord`) that holds the accumulated data. As soon as the loop finishes, the entire record is sent to the parent function for storage.

Although the function shows two `return` statements, the calling statement does not truly expect any values to be returned. Instead, I use the `return` statement inside the `for` loop as a way to break out of the `for` loop without any further execution whenever an invalid entry is found. Just prior to that, the script sets the focus and select to the field containing the invalid entry. JavaScript, however, is sensitive to the fact that a function with a `return` statement in one possible outcome doesn't have a `return` statement for other outcomes (an error message to this effect appears in some browsers if you try the function without balanced returns). By putting a `return` statement at the end of the function, all other possibilities are covered to the browser's satisfaction.

The inverse of storing the weight entries is retrieving them. Because the `parent.getImportance()` function returns the entire period-delimited record, this function must break apart the pieces and distribute them into their corresponding `Weight` fields. A combination of string methods determines the offset of the period and how far the data extraction should go into the complete record. Before the `for` loop repeats each time, it is shortened by one "field's" data. In other words, as the `for` loop executes, the copy of the cookie data returned to this function is pared down one entry at a time as each entry is stuffed into its text object for display:

```
function getdh3Importance() {
    var oneRecord = parent.getImportance();
    if (oneRecord != null) {
        for (var i = 0; i < 5; i++) {
            var recLen = oneRecord.length;
            var offset = oneRecord.indexOf(".");
            var dataPoint = (offset >= 0) ?
                oneRecord.substring(0,offset) : "";
            document.forms[0].importance[i].value = dataPoint;
            oneRecord = oneRecord.substring(offset+1,recLen);
        }
    }
}
</script>
</head>
```

Upon loading the document, the only tasks that the `onload` event handler needs to do are to update the parent global variable about the document number and to set the focus to the first entry field of the form:

```
<body onload="parent.setTitleVar(3);document.forms[0].factor[0].focus()">
<h2>The Decision Helper</h2>
<hr />
<h4>Step 3 of 5: List the factors that will influence your decision, and
    assign a weight (from 1 to 100) to signify the importance of each
    factor in your decision.</h4>
```

Assembling the HTML for the form and its 10 data-entry fields needs only a few lines of JavaScript code. Performed inside a `for` loop, the script assembles each line of the form, which consists of a label for the `Factor` (and its number), the factor input field, the importance input field, and the label for the `Weight` (and its number). A `document.write()` method writes each line to the document:

```
<p>
<script type="text/javascript">
    var output = "<center><form>";
    for (i = 0; i < 5; i++) {
        output += "Factor " + (i+1) + "--><input type='text' name='factor'
            size='25' ";
```

```

var eHandler = " onchange=\`parent.setFactor(" + i +
    ",this.value)\`";
output += eHandler + "value='" + getdh3Factor(i) + "'";

output += "<input type='text' name='importance' size='3' ";
var eHandler = " onchange=\`setdh3Importance()\`";
output += eHandler + "value=''";

output += "--Weight " + (i+1) + "<br \\/>";
document.write(output);
output = "";
}
document.write("<\/form><\/center>");
getdh3Importance();
<\/script>
<\/p>
<\/body>
<\/html>

```

Each of the scripted text objects has an event handler. Notice that each event handler is first defined as a variable on a statement line just above its insertion into the string being assembled for the `input` object definition. One reason for this fact is that the nested quote situation gets quite complex when you are doing these tasks all in one massive assignment statement. Rather than mess with matching several pairs of deeply nested quotes, I found it easier to break out one portion (the event handler definition) as a variable value and then insert that preformatted expression into the concatenated string for the `input` definition.

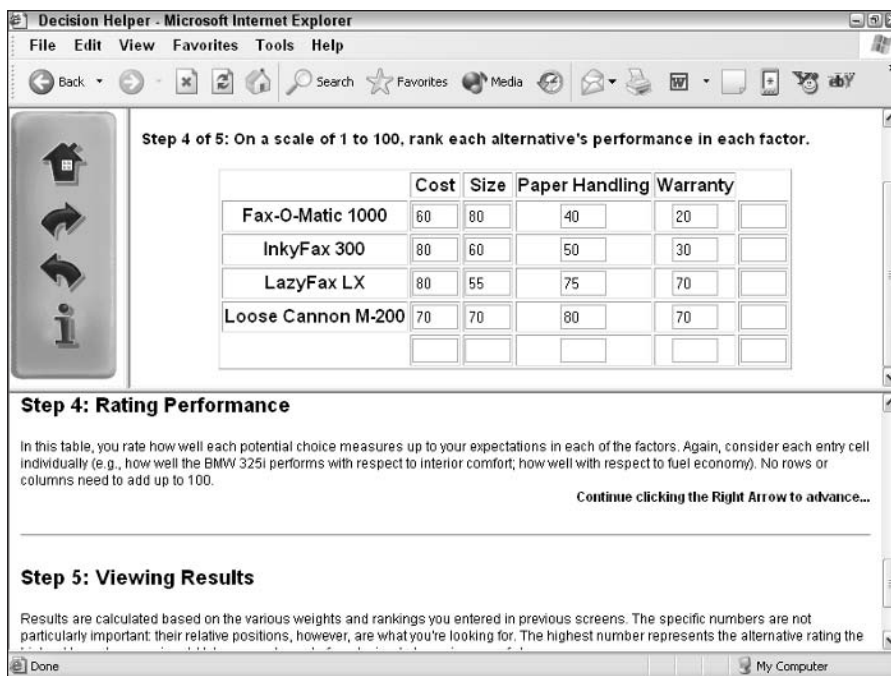

Notice, too, how the different ways of storing the data in the cookies influence the ways the existing cookie data is filled into the fields as the page draws itself. For the factors, which have one cookie per factor, the `value` attribute of the field is set with a specific indexed call to the parent factor cookie retriever, one at a time. But for the importance values, which are stored together in the period-delimited chunk, a separate function call (`getdh3Importance()`) executes after the fields are already drawn (with initial values of empty strings) and fills all the fields in a batch operation.

## dh4.htm

Step 4 of the decision process (shown in Figure 55-5) is the most complex step because of the sheer number of entry fields: 25 in all. Notice that this screen retrieves data from two of the previous screens (or rather from the cookies preserving the entries) and embeds the values into the fixed parts of the table. All these tasks are possible when you create those tables with JavaScript.

Functions for getting and setting performance data are complex because of the way I was forced to combine data into five “field” records. In other words, one parent cookie exists for each row of data cells in the table. To extract cell data for storage in the cookie, I use nested for loop constructions. The outer loop counts the rows of the table, whereas the inner loop (with the `j` counter variable) works its way across the columns for each row.

Because all cells are named identically, they are indexed with values from 0 to 24. Calculating the row (`i * 5`) plus the column number establishes the cell index value. After you check for validity, each cell’s value is added to the row’s accumulated data. Each row is then saved to its corresponding cookie. As in the code for `dh3.htm`, the `return` statement is used as a way to break out of the function if an entry is deemed invalid.

**Figure 55-5:** A massive table includes label data from earlier screen entries.

Retrieving the data and populating the cells for the entire table requires an examination of each of the five performance cookies, and for each labeled cookie's data, a parsing for each period-delimited entry. After a given data point is in hand (one entry for a cell), it must go into the cell with the proper index:

```
<html>
  <head>
    <title>DH4</title>
    <style type="text/css">
      body {font-family:Arial, Helvetica, serif}
      h2 {font-size:18px}
      h4 {font-size:14px}
    </style>
    <script type="text/javascript">
      function getdh4Performance() {
        var oneRecord = "";
        var recLen = 0;
        var offset = 0;
        var dataPoint = "";
        var cellNum = 0;
        for (var i = 0; i < 5; i++) {
          oneRecord = parent.getPerformance(i);
          if (oneRecord == null) {
            continue;
          }
        }
      }
    </script>
  </head>
</html>
```

```

        for (var j = 0; j < 5; j++) {
            recLen = oneRecord.length;
            offset = oneRecord.indexOf(".");
            dataPoint = oneRecord.substring(0,offset);
            cellNum = j + (i * 5);
            document.forms[0].ranking[cellNum].value = dataPoint;
            oneRecord = oneRecord.substring(offset+1,recLen);
        }
    }
}
function setdh4Performance() {
    var oneRecord = "";
    var cellNum = 0;
    var dataPoint = "";
    for (var i = 0; i < 5; i++) {
        oneRecord = "";
        for (var j = 0; j < 5; j++) {
            cellNum = j + (i * 5);
            dataPoint = document.forms[0].ranking[cellNum].value;
            if (!parent.isValid(dataPoint)) {
                document.forms[0].ranking[cellNum].focus();
                document.forms[0].ranking[cellNum].select();
                return;
            }
            oneRecord += dataPoint + ".";
        }
        parent.setPerformance(i,oneRecord);
    }
    return;
}
</script>
</head>

```

After the document is loaded, the `onload` event handler sends the document number to the parent global variable and brings focus to the first field of the table:

```

<body onload="parent.setTitleVar(4);document.forms[0].ranking[0].focus()">
  <h2>The Decision Helper</h2>
  <hr />
  <h4>Step 4 of 5: On a scale of 1 to 100, rank each alternative's
  performance in each factor.</h4>

```

To lessen the repetitive HTML for all tables, JavaScript again assembles and writes the HTML that defines the tables. In the first batch, the script uses yet another `for` loop to retrieve the factor entries from the parent cookie so that the words can be embedded into `<th>` tags of the first row of the table. If every factor field is not filled in, the table cell is set to empty:

```

<p>
  <script type="text/javascript">
    var output = "<div align='center'><form name='perfRankings'><table
      border='1'>";
    output += "<tr><td></td>";
    for (var i = 0; i < 5; i++) {
        var oneFactor = parent.getFactor(i);
        oneFactor = (oneFactor == null) ? "" : oneFactor;
        output += "<th>" + oneFactor + "</th>";
    }
  </script>

```

Next comes the assembly of subsequent rows of the table. The first column displays the name of each alternative (within `<th>` tags). The remaining columns are text boxes, all with the same name and event handler. As each row of table definition is completed, it is written to the document. After the table and form closing tags are also written, the `getdh4Performance()` function retrieves all cookie data for the fields and distributes it accordingly:

```

    for (var i = 0; i < 5; i++) {
        var oneAlt = parent.getAlternative(i);
        oneAlt = (oneAlt == null) ? "" : oneAlt;
        output += "<tr><th>" + oneAlt + "<\th>";
        for (var j = 0; j < 5; j++) {
            output += "<td align='center'><input type='text' size='3'
                name='ranking' value=''
                onchange='setdh4Performance()'><\td>";
        }
        output += "<\tr>";
        document.write(output);
        output = "";
    }
    document.write("<\table><\form><\div>");
    getdh4Performance();
</script>
</p>
</body>
</html>

```

## dh5.htm

From a math standpoint, `dh5.htm`'s JavaScript gets pretty complicated. But because the complexity is attributed to the decision support calculations that turn the user's entries into results, I treat the calculation script shown here as a black box. You're free to examine the details, if you're so inclined.

Results appear in the form of a table (see Figure 55-6) with columns showing the numeric results and an optional graphical chart.

For the purposes of this example, you only need to know a couple of things about the `calculate()` function. First, this function calls all the numeric data stored in parent cookies to fulfill values in its formulas. Second, results are tabulated and placed into a five-entry indexed array called `itemTotal[i]`. This array is defined as a global variable, so that its contents are available to scripts coming up in the Body portion of the document:

```

<html>
  <head>
    <title>DH5</title>

    <style type="text/css">
      body {font-family:Arial, Helvetica, serif}
      h2 {font-size:18px}
      h4 {font-size:14px}
    </style>
    <script type="text/javascript">
      var itemTotal = new Array();

      function calculate() {
        var scratchpad = "";
        var importanceSum = 0;
        var oneRecord = parent.getImportance();
        var weight = new Array();

```

```

for (i = 0; i < 5; i++) {
    var recLen = oneRecord.length;
    var offset = oneRecord.indexOf(".");
    scratchpad = oneRecord.substring(0,offset);
    importanceSum += (scratchpad == "" || scratchpad == "NaN") ?
        0 : parseInt(scratchpad);
    oneRecord = oneRecord.substring(offset+1,recLen);
}
oneRecord = parent.getImportance();
for (i = 0; i < 5; i++) {
    recLen = oneRecord.length;
    offset = oneRecord.indexOf(".");
    scratchpad = oneRecord.substring(0,offset);
    weight[i] = (scratchpad == "" || scratchpad == "NaN") ?
        0 : parseInt(scratchpad)/importanceSum * 100;
    oneRecord = oneRecord.substring(offset+1,recLen);
}
for (i = 0; i < 5; i++) {
    oneRecord = parent.getPerformance(i);
    if (oneRecord == null) {
        continue;
    }
    scratchpad = 0;
    for (var j = 0; j < 5; j++) {
        var recLen = oneRecord.length;
        var offset = oneRecord.indexOf(".");
        var dataPoint = oneRecord.substring(0,offset);
        scratchpad += (dataPoint != "" || dataPoint == "NaN") ?
            parseInt(dataPoint) * weight[j] / 100 : 0;
        oneRecord = oneRecord.substring(offset+1,recLen);
    }
    itemTotal[i] = scratchpad;
}
}
calculate();
</script>
</head>

```

Constructing this function served up many reminders about keeping data types straight. Because the data stored in cookies was in the form of strings, when it comes time to do some real math with those values, careful placement of the `parseInt()` function is essential for getting the math operators to work.

An `onload` event handler sends the document number to the global variable, as usual. The results display in this document relies heavily on stored and calculated values, so the table is constructed entirely out of JavaScript. That also means it can redisplay the decision name as part of the page:

```

<body onload="parent.setTitleVar(5)">
  <h2>The Decision Helper</h2>
  <hr />
  <script type="text/javascript">
    document.write("<h4>" + parent.getDecisionName() + "</h4><br \\/>
      <br \\/>");
    var output = "<div align='center'><form name='Results'><table
      border='1'>";
    output += "<tr><td></td><th>Results</th><th>Ranking</th>";
    document.write(output);
    output = "";
  </script>

```

Figure 55-6: The results screen for a decision.

I need to break up the discussion of the `for` loop that produces the results because there are two distinct parts of this HTML assembly. The first, shown in the following script segment, assembles the first two cells of each row of the table. The first cell contains an embedded listing of the alternative name (in `<th>` tags). To highlight the calculated values—and enable the `size` attribute to do the artificial job of truncating the floating-point number—the results are shown in text boxes. For each row, the corresponding result in `itemTotal[i]` is inserted as the `value` attribute of the text box. The `size` attribute is set to 7, which allows the typical double-digit results, a decimal point, and four digits to the right of the decimal (an extra pixel shows on the Macintosh version, however):

```
for (var i = 0; i < 5; i++) {
    var oneAlt = parent.getAlternative(i);
    oneAlt = (oneAlt == null || oneAlt == "") ? "" : oneAlt;
    itemTotal[i] = (oneAlt == "") ? 0 : itemTotal[i];
    output += "<tr><th>" + oneAlt + "</th>";
    output += "<td align='center'><input type='text' size='7'
        name='ranking' value=" + itemTotal[i] + "></td>";
}
```

For extra pizzazz, a third column “draws” a bar chart within a 100-pixel-wide cell. The bars are actually scalings of a one-pixel-wide `.gif` file (an orange line, 12 pixels tall). A single-color `.gif` image scales to fill whatever width is assigned in the `width` attribute. This method is faster and far better than a more tedious method (tedious from the Web page author’s point

of view) of creating 100 different .gif files, one for each possible width of the bar. I also could have used a one-pixel square .gif file with equal ease:

```

        output += "<td width='100'>";
        chartWidth = Math.round(itemTotal[i]);
        if (chartWidth > 0) {
            output += "<img src='chart.gif' height='12' width='" + chartWidth +
                "' \/>";
        }
        output += "<\td><\tr>";
        document.write(output);
        output = "";
    }
    document.write("<\table><\form><\div>");
</script>
</body>
</html>

```

## dhHelp.htm

The only other code worth noting in this application is in the `dhHelp.htm` document, which appears in the lower-right frame of the window. At the end of this document are two links that call separate JavaScript functions in this document's Head section. The Head functions are as follows:

```

<html xmlns="http://www.w3.org/1999/xhtml">
  <head>
    <title>Decision Helper Help</title>
    <style type="text/css">
      body {font-family:Arial, Helvetica, serif; font-size:12px}
      h4 {font-size:18px}
      div {align:right}
    </style>
    <script type="text/javascript">
      function goFirst() {
        parent.entryForms.location = "dh1.htm";
        self.location.hash = "help1";
      }
      function restart() {
        if (confirm("Erase current decision and start a new one?")) {
          parent.initializeCookies();
          parent.entryForms.location = "dh1.htm";
          self.location.hash = "help1";
        }
      }
    </script>
  </head>

```

One function merely returns the user to the beginning of the sequences for both the entry screens and the help screen. The second function is a rare instance in which a confirm dialog box makes sense: It is about to erase all entered data. If the user says it's okay to go ahead, the parent window's function for initializing all cookies is called, and the navigation for both the entry and help screens goes back to the beginning.

The links at the bottom of the document (see Figure 55-6) are coded to trigger JavaScript functions (rather than navigate to URLs) and include `onmouseover` event handlers to provide more information about the link in the status bar:

```
<a href="javascript:goFirst()"
onmouseover="window.status='Go back to beginning to review
data...';return true">
Review This Decision</a> || <a href="javascript:restart()"

## Further Thoughts

If you've managed to follow through with this application's discussions, you will agree that it's quite a JavaScript workout. But this application proves that, without a ton of code, JavaScript provides enough functionality to add a great deal of interactivity and pseudo-intelligence to an otherwise flat HTML document.

As an alternative to using cookies for data storage, I have also implemented a version of the application that uses text boxes defined in a frame defined with a row height of 0. This technique further challenges the synchronization of frames during reloading when a user resizes the browser window or navigates with the Back or Forward browser buttons. This alternate version is located on the CD-ROM for your own investigation and comparison.

Dynamic HTML also offers some possibilities for this application. The entire program can be presented in a no-frame window, with the navigation, interactive content, and instructions frames incorporated into individual positionable objects. The interactive content area can be treated almost like a slide show, with successive pages flying in from one edge.

Not only is this application instructive for many JavaScript techniques, but it is also fun to play with as a user. Some financial Web sites have adapted it to assist visitors with investment decisions. You can use it to dream about where to go on a dream vacation, or help you decide the most ethical of a few paths confronting you in a personal dilemma. There's something about putting in data, turning a crank, and watching results (with a bar chart to boot!) magically appear on the screen.

# Application: Cross-Browser DHTML Map Puzzle

---

**D**ynamic HTML allows scripts to position, overlap, and hide or show elements under the control of stylesheets and scripting. To demonstrate modern cross-browser DHTML development techniques, this chapter describes the details of a jigsaw puzzle game using pieces of a map of the “lower 48” United States (I think everyone would guess where Alaska and Hawaii go on a larger map of North America). I chose this application because it allows me to demonstrate several typical tasks you might want to script in DHTML: hiding and showing elements; handling events for multiple elements; tracking the position of an element with the mouse cursor; absolute positioning of elements; changing the z-order of elements; changing element colors; and animating movement of elements.

As with virtually any programming task, the example code here is not laid out as the quintessential way to accomplish a particular task. Each author brings his or her own scripting style, experience, and implementation ideas to a design. Very often, you have available several ways to accomplish the same end. If you find other strategies or tactics for the operations performed in these examples, it means you are gaining a good grasp of both JavaScript and Dynamic HTML.

## The Puzzle Design

Figure 56-1 shows the finished map puzzle with the game in progress. To keep the code to a reasonable length, the example provides positionable state maps for only seven western states. Also, the overall design is intentionally Spartan so as to place more emphasis on the positionable elements and their scripting, rather than on fancy design.

### In This Chapter

Applying a DHTML API

Scripting, dragging, and layering of multiple elements

Event handling for three DOMs at once

**Figure 56-1:** The puzzle map game DHTML example.  
*(Images courtesy Map Resources — [www.mapresources.com](http://www.mapresources.com))*

When the page initially loads, all the state maps are presented across the top of the puzzle area. The state labels all have a red background, and the silhouette of the continental United States has no features in it. To the right of the title is a question mark icon. A click of this icon causes a panel of instructions to glide to the center of the screen from the right edge of the browser window. That panel has a button that hides the panel.

To play the game (no scoring or time keeping is in this simplified version), a user clicks and drags a state with the goal of moving it into its rightful position on the silhouette. While the user drags the state, its label background to the right of the main map turns yellow to highlight the name of the state being worked on. To release the state in its trial position, the user releases the mouse button. If the state is within a 4-pixel square region around its true location, the state snaps into its correct position and the corresponding label background color turns green. If the state is not dropped close enough to its destination, the label background reverts to red, meaning that the state still needs to be placed.

After the last state map is dropped into its proper place, all the label backgrounds will be green, and a congratulatory message is displayed where the state map pieces originally lay. Should a user then pick up a state and drop it out of position, the congratulatory message disappears.

I had hoped that all versions of the application would look the same on all platforms. They do, with one small exception. Because the labels are generated as positioned `div` elements for all browsers, NN4 (especially on the Windows version) doesn't do as good a rendering job as other browsers. If I were to use genuine `layer` elements for the labels just for NN4, they'd

look better. And, while the code could use scripts to generate `layers` for NN4 and `divs` for others, the choice here was to stay with `div` elements alone. If you try this game on NN4 and other DHTML browsers, you will see minor differences in the way the labels are colored (red, yellow, and green) during game play. All other rendering and behavior is identical (although a rendering bug in NN6 is discussed later).

## Implementation Details

Due to the number of different scripted properties being changed in this application, I decided to implement a lot of the cross-platform scripting as a custom API loaded from an external `.js` file library. The library, whose code is dissected and explained in Chapter 47, contains functions for most of the scriptable items you can access in DHTML. Having these functions available simplified what would have been more complex functions in the main part of the application.

Although I frown on using global variables except where absolutely necessary, I needed to assign a few globals for this application. All of them store information about the state map currently picked up by the user and the associated label. This information needs to survive the invocations of many functions between the time the state is picked up until it is dropped and checked against the “database” of state data.

That database is another global object—a global that I don’t mind using at all. Constructed as a multidimensional array, each “record” in the database stores several fields about the state, including its destination coordinates inside the outline map and a Boolean field to store whether the state has been correctly placed in position.

Out of necessity for NN4, the state map images are encased in individual `div` elements. This makes their positionable characteristics more stable, as well as making it possible to capture mouse events that NN4’s image objects do not recognize. If the application were being done only for IE4+ and W3C DOMs, the images themselves could be positionable, and the DHTML API could be used without modification. You could certainly argue that it’s time to let go of version 4 browsers and move forward, but to maximize compatibility across the broadest possible user base, supporting version 4 browsers whenever possible still isn’t a bad idea.

### The custom API

To begin the analysis of the code, you should be familiar with the API that is linked in from an external `.js` library file. Listing 47-2 contains that code and its description.

### The main program

Code for the main program is shown in Listing 56-1. The listing is a long document, so I interlace commentary throughout the listing. Before diving into the code, however, allow me to present a preview of the structure of the document. With two exceptions (the map silhouette and the help panel), all positionable elements have their styles set via stylesheets in the `head` of the document. Notice the way class and id selectors are used to minimize the repetitive nature of the styles across so many similar items. After the stylesheets come the scripts for the page. All of this material is inside the `<head>` tag section. I leave the `<body>` section to contain the visible content of the page. This approach is an organization style that works well for me, but you can adopt any style you like, provided various elements that support others on the page are loaded before the dependent items (for example, define a style before assigning its name to the corresponding content tag’s ID attributes).

**Listing 56-1: The Main Program (mapgame.htm)**

```
<html>
  <head>
    <title>Map Game</title>
```

Most of the positionable elements have their CSS properties established in the `<style>` tag at the top of the document. Positionable elements whose styles are defined here include a text label for each state, a map for each state, and a congratulatory message. Notice that the names of the label and state map objects begin with a two-letter abbreviation of the state. This labeling comes in handy in the scripts when synchronizing the selected map and its label.

The label objects are nested inside the background map object. Therefore, the coordinates for the labels are relative to the coordinate system of the background map, not the page. That's why the first label has a `top` property of zero.

While both the background map and help panel are also positionable elements, scripts need to read the positions of these elements without first setting the values. Recall that in the IE4+ and W3C DOMs, the `style` property of an object does not reveal property values that are set in remote stylesheet rules. Although there are ways to read the effective style properties applied to an element from stylesheets (the `currentStyle` property in IE5+ and the `window.getComputedStyle()` method in NN6+/Moz), neither IE4 nor Safari 1.0 afford that luxury. Therefore, the stylesheet rules for the background map and help panel are specified as `style` attributes in those two elements' tags later in the listing.

```
<style type="text/css">
  .labels {position:absolute;
    background-color:red; layer-background-color:red;
    width:100; height:28; border:none; text-align:center}
  #azlabel {left:310; top:0}
  #calabel {left:310; top:29}
  #orlabel {left:310; top:58}
  #utlabel {left:310; top:87}
  #walabel {left:310; top:116}
  #nvlabel {left:310; top:145}
  #idlabel {left:310; top:174}

  #camap {position:absolute; left:20; top:100; width:1;}
  #ormap {position:absolute; left:60; top:100; width:1;}
  #wamap {position:absolute; left:100; top:100; width:1;}
  #idmap {position:absolute; left:140; top:100; width:1;}
  #nvmap {position:absolute; left:180; top:100; width:1;}
  #azmap {position:absolute; left:220; top:100; width:1;}
  #utmap {position:absolute; left:260; top:100; width:1;}

  #congrats {position:absolute; visibility:hidden; left:20; top:100;
    width:1; color:red}
</style>
```

The next statement loads the external `.js` library file that contains the API described in Chapter 47. I tend to load external library files before listing any other JavaScript code in the page, just in case the main page code relies on global variables or functions in its initializations.

```
<script type="text/javascript" src="DHTMLapi.js"></script>
```

Now comes the main script, which contains all the document-specific functions and global variables. Global variables here are ready to hold information about the selected state object (and associated details), as well as the offset between the position of a click inside a map object and the top-left corner of that map object. You will see that this offset is important to allow the map to track the cursor at the same offset position within the map. And because the tracking is done by repeated calls to a function (triggered by numerous mouse events), these offset values must have global scope.

```
// global declarations
var offsetX = 0;
var offsetY = 0;
var selectedObj;
var states = new Array();
var statesIndexList = new Array();
var selectedStateLabel;
```

As you will see later in the code, an `onload` event handler for the document invokes an initialization function, whose main job is to build the array of objects containing information about each state. The fields for each `state` object record are for the two-letter state abbreviation, the full name (not used in this application, but included for use in a future version), the `x` and `y` coordinates (within the coordinate system of the background map) for the exact position of the state, and a Boolean flag to be set to `true` whenever a user correctly places a state. I come back to the last two statements of the constructor function in a moment.

Calculating the data for the `x` and `y` coordinates required some legwork during development. As soon as I had the pieces of art for each state and the code for dragging them around the screen, I disengaged the part of the script that tested for accuracy. Instead, I added a statement to the code that revealed the `x` and `y` position of the dragged item in the status bar (rather than being bothered by alerts). When I carefully positioned a state in its destination, I copied the coordinates from the status bar into the statement that created that state record. Sure, it was tedious, but after I had that info in the database, I could adjust the location of the background map and not have to worry about the destination coordinates, because they were based on the coordinate system inside the background map.

```
// object constructor for each state; preserves destination
// position; invokes assignEvents()
function state(abbrev, fullName, x, y) {
    this.abbrev = abbrev;
    this.fullName = fullName;
    this.x = x;
    this.y = y;
    this.done = false;
    assignEvents(this);
    statesIndexList[statesIndexList.length] = abbrev;
}
// initialize array of state objects
function initArray() {
    states["ca"] = new state("ca", "California", 7, 54);
    states["or"] = new state("or", "Oregon", 7, 24);
    states["wa"] = new state("wa", "Washington", 23, 8);
    states["id"] = new state("id", "Idaho", 48, 17);
    states["az"] = new state("az", "Arizona", 45, 105);
    states["nv"] = new state("nv", "Nevada", 27, 61);
    states["ut"] = new state("ut", "Utah", 55, 69);
}
```

The act of creating each `state` object causes all statements in the constructor function to execute. Moreover, they were executing within the context of the object being created. That opened up channels for two important processes in this application. One was to maintain a

list of abbreviations as its own array. This becomes necessary later on when the script needs to loop through all objects in the `states` array to check their `done` properties. Because the array is set up like a hash table (with string index values), a `for` loop using numeric index values is out of the question. So, this extra `statesIndexList` array provides a numerically indexed array that can be used in a `for` loop; values of that array can then be used as index values of the `states` array. Yes, it's a bit of indirection, but other parts of the application benefit greatly by having the state information stored in a hash-table-like array.

We now come to the functions that operate while the user interacts with the map puzzle pieces. The first function, acting as a vital behind-the-scenes utility function, is called `setSelectedMap()`. It receives as its sole parameter an event object that is of the proper type for the browser currently running (that's done in the `engage()` function, described next). This function has three jobs to do, two of which set global variables. The first global variable, `selectedObj`, maintains a reference to the layer (puzzle piece) being dragged by the user. At the same time, the `selectedStateLabel` variable holds onto a reference to the layer that holds the label (recall that its color changes during dragging and release). All of this requires DOM-specific references that are generated through the aid of object detecting branches of the function. The last job of this function is to set the stacking order of the selected map to a value higher than the others so that while the user drags the map, it is in front of everything else on the page.

To assist in establishing references to the map and label layers, naming conventions of the HTML objects (shown later in the code) play an important role. Despite the event handlers being assigned to the `divs` that hold the images, the mouse events are actually targeted at the image objects. The code must associate some piece of information about the event target with the `div` that holds it ("parent" types of references don't work across all browsers, so we have to make the association the hard way). To prevent conflicts with so many objects on this page named with the lowercase abbreviations of the states, the image objects are assigned uppercase abbreviations of the state names. As `setSelectedMap()` begins to execute, it uses object detection to extract a reference to the element object regarded as the target of the event (`target` in W3C DOM browsers, `srcElement` in IE). To make sure that the event being processed comes from an image, the next statement makes sure that the target has both `name` and `src` properties, in which case a lowercase version of the name is assigned to the `abbrev` local variable (if only IE4+ and W3C DOMs were in play here, a better verification is checking that the `tagName` property of the event target is `img`). That `abbrev` variable then becomes the basis for element names used in references to objects assigned to `selectedObj` and `selectedStateLabel`. Notice how the NN4 version requires a double-layer nesting to the reference for the label because labels are nested inside the `bgmap` layer.

The presence of a value assigned to `selectedObj` becomes an important case for all three drag-related functions later. That's why the `setSelectedMap()` function nulls out the value if the event comes from some other source.

```

/*****
BEGIN INTERACTION FUNCTIONS
*****/

// set global reference to map being engaged and dragged
function setSelectedMap(evt) {
    var target = (evt.target) ? evt.target : evt.srcElement;
    var abbrev = (target.name && target.src) ?
        target.name.toLowerCase() : "";
    if (abbrev) {
        if (document.layers) {
            selectedObj = document.layers[abbrev + "map"];
            selectedStateLabel =
                document.layers["bgmap"].document.layers[abbrev + "label"];

```

```

    } else if (document.all) {
        selectedObj = document.all(abbrev + "map");
        selectedStateLabel = document.all(abbrev + "label");
    } else if (document.getElementById) {
        selectedObj = document.getElementById(abbrev + "map");
        selectedStateLabel = document.getElementById(abbrev + "label");
    }
    setZIndex(selectedObj, 100);
    return;
}
selectedObj = null;
selectedStateLabel = null;
return;
}

```

Next comes the `engage()` function definition. This function is invoked by `mousedown` events inside any of the state map layers (event handler assignment code comes later). NN4+/W3C DOM browsers pass an event object as the sole parameter to the function (picked up by the `evt` parameter variable). If that parameter contains a value, it stands as the event object for the rest of the processing; but for IE, the `window.event` object is assigned to the `evt` variable. After setting the necessary object globals through `setSelectedMap()`, the next major task for `engage()` is to calculate and preserve in global variables the number of pixels within the state map layer at which the `mousedown` event occurred. By preserving these values, the `dragIt()` function makes sure that the motion of the state map layer keeps in sync with the mouse cursor at the very same point within the state map. If it weren't for taking the offset into account, the layer would jump unexpectedly to bring the top-left corner of the layer underneath the cursor. That's not how users expect to drag items on the screen.

The calculations for the offsets require a variety of DOM-specific properties. For example, both NN4 and NN6+ offer `pageX` and `pageY` properties of the event object, but the coordinates of the layer itself require `left/top` properties for NN4 and `offsetLeft/offsetTop` properties for NN6+. A nested object detection takes place in each assignment statement. The IE branch has some additional branching within each of the assignment statements. These extra branches cover a disparity in the way WinIE and MacIE report the offset properties of an event. WinIE ignores window scrolling, while MacIE takes scrolling into account. Later calculations for positioning must take window scrolling into account, so that scrolling is factored into the preserved offset global values if there are indications that the window has scrolled and the values are being affected by the scroll (in which case the offset values go very negative). The logic is confusing, and it won't make much sense until you see later how the positioning is invoked. Conceptually, all of these offset value calculations may seem like a can of worms, but they are essential, and are performed amazingly compactly.

After the offsets are established, the state's label layer's background color is set to yellow. The function ends with `return false` to make sure that the `mousedown` event doesn't propagate through the page (causing a contextual menu to appear on the Macintosh, for instance).

```

// set relevant globals onmousedown; set selected map
// object global; preserve offset of click within
// the map coordinates; set label color to yellow
function engage(evt) {
    evt = (evt) ? evt : event;
    setSelectedMap(evt);
    if (selectedObj) {
        if (evt.pageX) {
            offsetX = evt.pageX - ((selectedObj.offsetLeft) ?
                selectedObj.offsetLeft : selectedObj.left);
            offsetY = evt.pageY - ((selectedObj.offsetTop) ?
                selectedObj.offsetTop : selectedObj.top);

```

```

    } else if (evt.offsetX || evt.offsetY) {
        offsetX = evt.offsetX - ((evt.offsetX < -2) ?
            0 : document.body.scrollLeft);
        offsetY = evt.offsetY - ((evt.offsetY < -2) ?
            0 : document.body.scrollTop);
    }
    setBGColor(selectedStateLabel,"yellow");
    return false;
}
}

```

The `dragIt()` function, compact as it is, provides the main action in the application by keeping a selected state object under the cursor as the user moves the mouse. This function is called repeatedly by the `mousemove` events, although the actual event handling methodology varies with platform (precisely the same way as with `engage()`, as shown previously). Regardless of the event property detected, event coordinates (minus the previously preserved offsets) are passed the `shiftTo()` function in the API.

Before the dragging action branch of the function ends, the event object's `cancelBubble` property is set to `true`. In truth, only the IE4+ and W3C DOM event objects have such a property, but assigning a value to a nonexistent object property for NN4 does no harm. It's important that this function operate as quickly as possible, because it must execute with each `mousemove` event. Canceling event bubbling helps in a way, but more important, the cancellation allows the `mousemove` event to be used for other purposes, as described in a moment.

```

// move div on mousemove
function dragIt(evt) {
    evt = (evt) ? evt : event;
    if (selectedObj) {
        if (evt.pageX) {
            shiftTo(selectedObj, (evt.pageX - offsetX), (evt.pageY -
                offsetY));
        } else if (evt.clientX || evt.clientY) {
            shiftTo(selectedObj, (evt.clientX - offsetX), (evt.clientY -
                offsetY));
        }
        evt.cancelBubble = true;
        return false;
    }
}

```

When a user drops the currently selected map object, the `release()` function invokes the `onTarget()` function to find out if the current location of the map is within range of the desired destination. If it is in range, the background color of the state label object is set to green, and the `done` property of the selected state's database entry is set to `true`. One additional test (the `isDone()` function call) looks to see if all the `done` properties are `true` in the database. If so, the `congrats` object is shown. But if the object is not in the right place, the label reverts to its original red color. In case the user moves a state that was previously okay, its database entry is also adjusted. No matter what the outcome, however, the user has dropped the map, so key global variables are set to `null` and the layer order for the item is set to zero (bottom of the heap) so that it doesn't interfere with the next selected map.

One more condition is possible in the `release()` function. As shown later in the initialization function, the document object's `onmousemove` event handler is assigned to the `release()` function (to compare the `onmousemove` events for the state maps go to `dragIt()`). The reasoning behind this document-level event assignment is that no matter how streamlined the dragging function may be, it is possible for the user to move the mouse so fast that the map can't keep up. At that point, `mousemove` events are firing at the document (or other object,

eventually bubbling up to the document), and not the state map. If that happens while a state map is registered as the selected object, but the image is no longer the target of the event, the code performs the same act as if the user had released the map. The label reverts to red, and all relevant globals are set to null, preventing any further interaction with the map until the user mouses down again on the map.

```
// onmouseup, see if dragged map is near its destination
// coordinates; if so, mark it as 'done' and color label green
function release(evt) {
    evt = (evt) ? evt : event;
    var target = (evt.target) ? evt.target : evt.srcElement;
    var abbrev = (target.name && target.src) ?
        target.name.toLowerCase() : "";
    if (abbrev && selectedObj) {
        if (onTarget(evt)) {
            setBGColor(selectedStateLabel, "green");
            states[abbrev].done = true;
            if (isDone()) {
                show("congrats");
            }
        } else {
            setBGColor(selectedStateLabel, "red");
            states[abbrev].done = false;
            hide("congrats");
        }
    }

    setZIndex(selectedObj, 0);
} else if (selectedStateLabel) {
    setBGColor(selectedStateLabel, "red");
}
selectedObj = null;
selectedStateLabel = null;
}
```

To find out if a dropped map is in (or near) its correct position, the `onTarget()` function first calculates the target spot on the page by adding the location of the `bgmap` object to the coordinate positions stored in the `states` database. Because the `bgmap` object doesn't come into play in other parts of this script, it is convenient to pass merely the object name to the two API functions that get the object's left and top coordinate points.

Next, the script uses platform-specific properties to get the recently dropped state map object's current location. A large `if` condition checks whether the state map object's coordinate point is within a 4-pixel square region around the target point. If you want to make the game easier, you can increase the cushion values from 2 to 3 or 4.

If the map is within the range, the script calls the `shiftTo()` API function to snap the map into the exact destination position and reports back to the `release()` function the appropriate Boolean value.

```
// compare position of dragged element against the destination
// coordinates stored in corresponding state object; after shifting
// element to actual destination, return true if item is within
// 2 pixels.
function onTarget(evt) {
    evt = (evt) ? evt : event;
    var target = (evt.target) ? evt.target : evt.srcElement;
    var abbrev = (target.name && target.src) ?
        target.name.toLowerCase() : "";
```

```

    if (abbrev && selectedObj) {
        var x = states[abbrev].x + getObjectLeft("bgmap");
        var y = states[abbrev].y + getObjectTop("bgmap");
        var objX, objY;
        if (selectedObj.pageX) {
            objX = selectedObj.pageX;
            objY = selectedObj.pageY;
        } else if (selectedObj.style) {
            objX = parseInt(selectedObj.style.left);
            objY = parseInt(selectedObj.style.top);
        }
        if ((objX >= x-2 && objX <= x+2) && (objY >= y-2 && objY <= y+2)) {
            shiftTo(selectedObj, x, y);
            return true;
        }
        return false;
    }
    return false;
}
}

```

A for loop cycles through the states database (with the help of the hash table values stored indirectly in the statesIndexList array) to see if all of the done properties are set to true. When they are, the release() function (which calls the isDone() function) displays the congratulatory object.

```

// test whether all state objects are marked 'done'
function isDone() {
    for (var i = 0; i < statesIndexList.length; i++) {
        if (!states[statesIndexList[i]].done) {
            return false;
        }
    }
    return true;
}
}

```

The help panel is created differently than the map and label objects (details coming up in a moment). When the user clicks the Help button at the top of the page, the instructions panel flies in from the right edge of the window (see Figure 56-2). The showHelp() function begins the process by setting its location to the current right window edge, bringing its layer to the very front of the heap, showing the object. To assist moveHelp() in calculating the center position on the screen, the showHelp() function retrieves (just once per showing) the DOM-specific property for the width of the help panel. That value is passed as a parameter to moveHelp() as it is repeatedly invoked through the setInterval() mechanism.

```

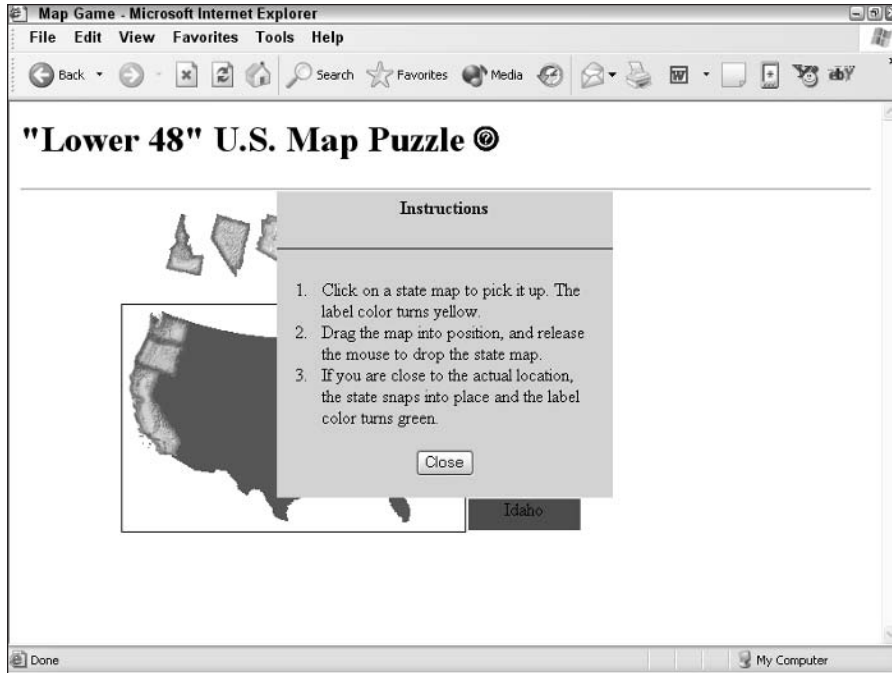

/*****
BEGIN HELP ELEMENT FUNCTIONS
*****/
// initiate show action
function showHelp() {
    var objName = "help";
    var helpWidth = 0;
    shiftTo(objName, insideWindowWidth, 80);
    setZIndex(objName,1000);
    show(objName);
    if (document.layers) {
        helpWidth = document.layers[objName].document.width;
    } else if (document.all) {
        helpWidth = document.all(objName).offsetWidth;
    }
}
}

```

```

    } else if (document.getElementById) {
        if (document.getElementById(objName).offsetWidth >= 0) {
            helpWidth = document.getElementById(objName).offsetWidth;
        }
    }
    intervalID = setInterval("moveHelp(" + helpWidth + ")", 1);
}

```

**Figure 56-2:** Instruction panel “flies” in from left to center screen.

In the `moveHelp()` function, the help object is shifted in 5-pixel increments to the left. The ultimate destination is the spot where the object is in the middle of the browser window. That midpoint must be calculated each time the page loads, because the window may have been resized. The width of the help object, received as a parameter to the function, gets a workout in the mid-point calculation.

This function is called repeatedly under the control of a `setInterval()` method in `showHelp()`. But when the object reaches the middle of the browser window, the interval ID is canceled, which stops the animation.

The help object processes a mouse event to hide the object. An extra `clearInterval()` method is called here in case the user clicks the object’s Close button before the object has reached mid-window (where `moveHelp()` cancels the interval). The script also shifts the position to the right edge of the window, but it isn’t absolutely necessary, because the `showHelp()` method positions the window there.

```

// iterative move help div to center of window
function moveHelp(w) {
    shiftBy("help",-5,0);
    var objectLeft = getObjectLeft("help");

```

```

        if (objectLeft <= (insideWindowWidth/2) - w/2) {
            clearInterval(intervalID);
        }
    }
    // hide the help div
    function hideMe() {
        clearInterval(intervalID);
        hide("help");
        shiftTo("help", insideWindowWidth, 80);
    }
}

```

The document's `onload` event handler invokes the `init()` function, which, in turn, calls two functions and assigns the document object's mouse event handlers. The first function is `initArray()`, which builds the `states[]` database and assigns event handlers to the state map layers. Because the layers are defined so late in the document, initializing their events after the page has loaded is safest.

For convenience in moving the help window to the center of the browser window, the `setWinWidth()` function sets a global variable (`insideWindowWidth`) to hold the width of the browser window. This function is also invoked by the `onresize` event handler for the window to keep the value up to date.

The most important parts of the `init()` function are the event handler assignments. The trio—engaging the map on `mousedown`, dragging it on `mousemove`, releasing it on `mouseup`—are assigned to the document object so that the events track correctly even if the cursor speeds past a puzzle piece's edge on a fast drag action.

```

// calculate center of window for help div
function setWinWidth() {
    if (window.innerWidth) {
        insideWindowWidth = window.innerWidth;
    } else if (document.body.scrollWidth) {
        insideWindowWidth = document.body.scrollWidth;
    } else if (document.width) {
        insideWindowWidth = document.width;
    }
}

/*****
INITIALIZE THE APPLICATION
*****/
// initialize application
function init() {
    initArray();
    setWinWidth();
    if (document.layers) {
        document.captureEvents(Event.MOUSEDOWN | Event.MOUSEMOVE |
Event.MOUSEUP);
    }
    document.onmousedown = engage;
    document.onmousemove = dragIt;
    document.onmouseup = release;
}
</script>
</head>

```

Now comes the part of the document that generates the visible content. The `<body>` tag contains the two event handlers just discussed. An image rollover for the help icon simply displays a message in the status bar.

```

<body onload="init()" onresize="setWinWidth()">
  <h1>"Lower 48" U.S. Map Puzzle<a href="javascript:void showHelp()"
    onmouseover="status='Show help panel...';return true"
    onmouseout="status='';return true"></a></h1>
  <hr />

```

Next come tags for all of the `div` elements. The `style` attribute for the `bgmap` `div` lets scripts read the positioned values to assist in calculating positions in the `onTarget()` function, as shown previously. The `bgmap` layer also contains all labels so that if the design calls for moving the map to another part of the page, the labels follow automatically. Notice how the lowercase state abbreviations are part of the names of both the label and map layers. As you saw in a few functions shown previously, a systematic approach to object naming can offer powerful shortcuts in determining references to elements.

```

<div id="bgmap" style="position:absolute; left:100; top:180; width:406">
  &nbsp;
  <div class="labels" id="azlabel">Arizona</div>
  <div class="labels" id="calabel">California</div>
  <div class="labels" id="orlabel">Oregon</div>
  <div class="labels" id="utlabel">Utah</div>
  <div class="labels" id="walabel">Washington</div>
  <div class="labels" id="nvlabel">Nevada</div>
  <div class="labels" id="idlabel">Idaho</div>
</div>
<div id="camap"></div>
<div id="ormap"></div>
<div id="wamap"></div>
<div id="idmap"></div>
<div id="azmap"></div>
<div id="nvmap"></div>
<div id="utmap"></div>
<div id="congrats"><h1>Congratulations!</h1></div>

```

In developing this application, I encountered an unfriendly NN4 bug. When defining the help panel as a positioned `div` element in NN4, the browser exhibited unwanted behavior after the instruction panel was shown and flown into place under script control. Even after hiding the help layer, the page no longer received mouse events, making it impossible to pick up a state map after the instructions appeared. The problem did not surface, however, if the help object was defined in the document with a `<layer>` tag.

Therefore, I did what I don't like to do unless absolutely necessary: I created branches in the content that used `document.write()` to create the same content with different HTML syntax, depending on the browser. For non-layer browsers, the page creates the same kind of block (with the `<div>` tag pair) used elsewhere in the document. Positioning properties are assigned to this block via a `style` attribute in the `<div>` tag. You cannot assign a style in the `<style>` tag that is visible to the entire document, because that specification and a like-named `<layer>` tag get confused.

For NN4, the page uses the `<layer>` tag and loads the content of the object from a separate HTML file (`instrux.htm`). One advantage I had with the `<layer>` tag was that I could assign an initial horizontal position of the help object with a JavaScript entity. The entity reaches into the `window.innerWidth` property to set the `left` attribute of the layer.

```

<script type="text/javascript">
var output = "";
if (document.layers) {
    output = "<layer id='help' top='80' left=&{window.innerWidth};
            width='300' visibility='hidden' src='instrux.htm'></layer>";
} else {
    output = "<div id='help' onclick='hideMe()' style='position:absolute;
            visibility:hidden; top:80; width:300; border:none;
            background-color:#98FB98;'>\n";
    output += "<p style='margin-top:5'>
            <center><b>Instructions</b></center></p>\n";
    output += "<hr color='seagreen' \\/>\n<ol style='margin-right:20''>";
    output += "<li>Click on a state map to pick it up. The label color
            turns yellow.</li>";
    output += "<li>Drag the map into position, and release the mouse to
            drop the state map.</li>";
    output += "<li>If you are close to the actual location, the state
            snaps into place and the label color turns green.</li>";
    output += "</ol>\n<form>\n<center><input type='button'
            value='Close'>\n</form></div>";
}
document.write(output);
</script>
</body>
</html>

```

This page has a lot of code to digest in one reading. Run the application, study the structure of the source code listing file, and re-read the previous explanations. It may take several readings for a mental picture of the application to form.

## Lessons Learned

As soon as the external cross-platform API was in place, it helped frame a lot of the other code in the main program. The APIs provided great comfort in that they encouraged me to reference a complex object fully in the main code as a platform-shared value (for example, the `selectedObj` and `selectedStateLabel` global variables). At the same time, I could reference top-level elements (that is, non-nested objects) simply by their names when passing them to API functions.

In many respects, the harder task was defining the stylesheet attributes and syntax that both browsers would treat similarly. In the case of the label objects, I couldn't reach complete parity in a cross-platform environment (the labels look different in NN4), and in the case of the help object, I had to code the HTML separately for each platform. Therefore, when approaching this kind of project, work first with the HTML and CSS syntax to build the look that works best for all platforms. Then start connecting the scripted wires. You may have to adjust the CSS code if you find odd behavior in one platform or the other with your scripting, but starting with a good layout is still easier.

But without a doubt the biggest lesson you learn from working on a project like this is how important it is to test an application on as many browsers and operating systems as possible. Designing a cross-platform application on one browser and having it run flawlessly on the other the first time is nearly impossible. Be prepared to go back and forth among multiple browsers, breaking and repairing existing working code along the way until you eventually reach a version that works on every browser that you can test.

# Application: Transforming XML Data

---

**C**hapter 52 ends with an example of an interactive outline whose data arrives from an external XML file, a feature supported by the Windows versions of IE5 or later and Mozilla-based browsers. The application described in this chapter picks up from there.

As you recall from the Chapter 52 outline, the node structure of the XML data was used as a guide to the structure for a one-time rendering of HTML elements. There was a one-to-one correlation between XML element nesting and the HTML element nesting. Adjusting stylesheet properties for displaying or hiding elements controlled all interactivity. What you're about to see here is a case for converting XML into JavaScript objects that can be used multiple times as a convenient data source for HTML that is displayed in any number of formats. In particular, you see how JavaScript's array sorting prowess supplies XML-supplied data with extraordinary flexibility in presentation.

You will see a lot of code in this chapter. The code is presented here as a way to demonstrate the potential for rich data handling. At the same time, the code may provide ideas for server-side processing of XML data being output to the client. If a server program can convert the XML data into the shortcut object and array notation of version 4 browsers or later, suddenly a broader range of browsers is capable of dealing with data stored as XML on the server.

# 57 CHAPTER

## In This Chapter

Mapping XML data to JavaScript objects

Complex JavaScript data structures

Advanced array sorting

Dynamic tables

## Application Overview

Understanding the data is a good place to start in describing this application. The scenario is a small American company (despite its grandiose name: GiantCo) that has divided the country into three sales regions. Two of the regions have two sales representatives, while the third region has three reps. The time is at the end of a fiscal year, at which point the management wants to review and present the performance of each salesperson. An XML report (`salesrpt.xml`) delivers the sales forecast and actual sales per quarter for each sales rep. An HTML and JavaScript page is charged with not only loading the XML data displaying the raw tabular data, but also allowing for a variety of views and sorting possibilities so that management can analyze performance by sales rep and region, as well as by quarter.

A server-based searching and reporting program collects the requested data and outputs each sales rep's record in an XML structure, such as the following one excerpted from the `salesrpt.xml` file:

```
<salesrep>
  <employeeid>12345</employeeid>
  <contactinfo>
    <firstname>Brenda</firstname>
    <lastname>Smith</lastname>
    <email>brendas@giantco.com</email>
    <phone>312-555-9923</phone>
    <fax>312-555-9901</fax>
  </contactinfo>
  <manager>
    <employeeid>02934</employeeid>
    <firstname>Alistair</firstname>
    <lastname>Renfield</lastname>
  </manager>
  <region>Central</region>
  <salesrecord>
    <period>
      <id>Q1_2000</id>
      <forecast>300000</forecast>
      <actual>316050</actual>
    </period>
    <period>
      <id>Q2_2000</id>
      <forecast>280000</forecast>
      <actual>285922</actual>
    </period>
    <period>
      <id>Q3_2000</id>
      <forecast>423000</forecast>
      <actual>432930</actual>
    </period>
    <period>
      <id>Q4_2000</id>
      <forecast>390000</forecast>
      <actual>399200</actual>
    </period>
  </salesrecord>
</salesrep>
```

As you can see, the data consists of several larger blocks, such as contact information, a pointer to the rep's manager, and then the details of each quarterly period's forecast and

actual sales. The goal is to present the data in table form with a structure similarly shown in Figure 57-1. Not only is the raw data presented, but numerous calculations are also made on the results, such as the percentage of quota attained for each reporting period, plus totals along each axis of the spreadsheet-like table.

Just above the table are two `select` elements. These controls' labels indicate that the table's data can be sorted by a number of criteria and the results of each sort can be ordered in different ways. Sorting in the example offers the following possibilities:

```

Representative's Name
Sales Region
Q1 Forecast
Q1 Actual
Q1 Performance
[the last three also for Q2, Q3, Q4]
Total Forecast
Total Actual
Total Performance

```

Ordering of the sorted results is a choice between “Low to High” or “High to Low.” While ordering of most sort categories is obviously based on numeric value, the sorting of the representatives' names is based on the alphabetical order of the last names. One other point about the user interface is that the design needs to signify via table cell background color the sales region of each representative. The colors aren't easily distinguishable in Figure 57-1, but if you open the actual example listing in WinIE5+ or NN7+/Moz on your computer, you will see the coloration.

The screenshot shows a web browser window titled "GiantCo Sales Analysis 2000 - Microsoft Internet Explorer". The page content is "GiantCo Sales Results 2000". Below the title, there are two dropdown menus: "Sort by: Representative" and "Ordered: Low to High". The "Ordered" dropdown is open, showing "Low to High" and "High to Low" options. Below the dropdowns is a table with the following structure:

Sales Rep	Q1 2000		Q2 2000		Q3 2000		Q4 2000		Total 2000	
	Fest/Act	Quota	Fest/Act	Quota	Fest/Act	Quota	Fest/Act	Quota	Fest/Act	Quota
Laura Almerson	145000 155090	106.9%	170000 189000	111.1%	205000 255030	124.4%	275000 268600	97.6%	795000 867720	109.1%
Jonathan Ames	270000 256050	94.8%	290000 295922	102%	305000 304030	99.6%	375000 382300	101.9%	1240000 1238302	99.8%
Stephen Borneo	255000 276050	108.2%	270000 225922	83.6%	305000 314030	102.9%	335000 354600	105.8%	1165000 1170602	100.4%
Esmerelda Hernandez	209000 210920	100.9%	195000 199200	102.1%	205000 235030	114.6%	255000 263700	103.4%	864000 908850	105.1%
Russell Kim	245000 241090	98.4%	245000 247800	101.1%	266000 277030	104.1%	255000 289000	113.3%	1011000 1054920	104.3%
Michael	285000 266000	103.7%	265000 266000	112.7%	315000 321000	106%	325000 316000	107.2%	1190000 1170000	107.3%

Figure 57-1: One view of the XML data output.

## Implementation Plan

Clearly all the data needed for numerous sorted and ordered views arrives in one batch from the XML file. Despite the element and node referencing properties and methods of the W3C DOM, trying to use the XML elements as the sole data store for scripts to sort the data each time would be impractical. For one thing, none of the elements have ID attributes—there's no need for it in the XML stored on the server database. And even if they did have IDs, how would scripts that you desire to write for generalizability make use of them unless the IDs were generated in a well-known sequence? Moreover, after a sales rep's record is rendered in the table, how easy would it be to dive back into that record and drill down for further information, such as the name of a representative's manager?

A solution that can empower the page author in this case is to use the node-walking properties and methods of the W3C DOM to assemble a JavaScript-structured database while the page loads. In other words, the conversion is performed just once during page loading, and the JavaScript version is preserved in an array (of XML “records” in this case) as a global variable. Any transformations on the data can be done from the JavaScript database with the help of additional powers of the language.

Given that route, the basic operation of the scripting of the page is schematically simple:

1. Convert the XML into an array of objects at load time.
2. Predefine all necessary sorting functions based on properties of those objects.
3. Provide a function that rebuilds the HTML table each time data is sorted.

With this sequence in mind, now look into the code that does the job.

## The Code

Rather than work through the long document in source code order, the following descriptions follow a more functional order. You can open the actual source code file (`salesrpt.htm`) to see where the various functions are positioned. To best understand this application, seeing the “how” rather than the “where” is more important. Also, many of the code lines (even some single expressions) are too wide for the printed page and therefore break unnaturally in the listings that follow. Trust the formatting of the source file on the CD-ROM.

### Style sheets

For the example provided on the CD-ROM, one set of stylesheet rules is embedded in the HTML document. As you can see from the rule selectors, many are tied to very specific classes of table-related elements used to render the content. In a production version of this application, I would expect that there would be more and quite different views of the data available to the users, such as bar charts for each salesperson or region. Each view would likely require its own unique set of stylesheet rules. In such a scenario, the proper implementation would be to use the LINK element to bring in a different external stylesheet file for each view type. All could be linked in at the outset, but only the current `styleSheet` object would be enabled.

```
<style type="text/css">
td {text-align:right}
td.rep, td.grandTotalLabel {text-align:center}
```

```
tr.East {background-color:#FFFFCC}
tr.Central {background-color:#CCFFFF}
tr.West {background-color:#FFCCCC}
tr.QTotal {background-color:#FFFF00}
td.repTotal {background-color:#FFFF00}
td.grandTotal {background-color:#00FF00}
h1 {font-family:"Comic Sans MS",Helvetica,sans-serif}
</style>
```

One stylesheet rule is essential: The one that suppresses the rendering of any XML element. That data is hidden from the user's view.

## Initialization sequence

An `onload` event handler invokes the `init()` function, which sets a lot of machinery in motion to get the document ready for user interaction. After loading the XML file into the `xDoc` global variable (via the `loadXMLDoc()` function), its most important job is running a `for` loop that builds the JavaScript database from the XML elements. Next, it sorts the database based on the current choice in the sorting `select` element. The sorting function ends by triggering the rendering of the table. These three actions correspond to the fundamental operation of the entire application.

```
// initialize global variable that stores JavaScript data
var db = new Array();

// Initialization called by onLoad
function init() {
    loadXMLDoc("salesrpt.xml");
    if (xDoc) {
        for (var i = 0; i < xDoc.getElementsByTagName("salesrep").length; i++) {
            db[db.length] = getOneSalesRep(i);
        }
        selectSort(document.getElementById("sortChooser"));
    }
}
```

## Converting the data

The controlling factor for creating the JavaScript database is the structure of the XML data. With the complete XML document stored in the `xDoc` variable, scripts can use DOM methods to look for elements bearing relevant tag names. Data for each sales rep is contained by a `salesrep` element. The number of `salesrep` elements determines how many records (JavaScript objects) are to be added to the `db` array. A call to the `getOneSalesRep()` function creates an object for each sales representative's data.

Despite the length of the `getOneSalesRep()` function, its operation is very straightforward. Most of the statements do nothing more than retrieve the data inside the various XML elements within a `salesrep` container and assign that data to a like-named property of the custom object. Following the structure of the XML example shown earlier in this chapter, you can see where some properties of a JavaScript object representing the data are, themselves, objects or arrays. For example, one of the properties is called `manager`, corresponding to the `manager` element. But that element has nested items inside. Then, making those nested elements properties of a `manager` object is only natural. Similarly, the repetitive nature of the data within each of the four quarterly periods calls for even greater nesting: The object property named `sales` is an array, with each item of the array

corresponding to one of the periods. Each period also has three properties (a period ID, forecast sales, and actual sales). Thus, the `sales` property is an array of objects.

```
function getOneSalesRep(i) {
    var oneRecord = new Object();
    var oneElem = xDoc.getElementsByTagName("salesrep")[i];
    oneRecord.id =
        oneElem.getElementsByTagName("employeeid")[0].firstChild.data;
    var contactInfoElem = oneElem.getElementsByTagName("contactinfo")[0];
    oneRecord.firstName =
        contactInfoElem.getElementsByTagName("firstname")[0].firstChild.data;
    oneRecord.lastName =
        contactInfoElem.getElementsByTagName("lastname")[0].firstChild.data;
    oneRecord.eMail =
        contactInfoElem.getElementsByTagName("email")[0].firstChild.data;
    oneRecord.phone =
        contactInfoElem.getElementsByTagName("phone")[0].firstChild.data;
    oneRecord.fax =
        contactInfoElem.getElementsByTagName("fax")[0].firstChild.data;
    oneRecord.manager = new Object();
    var oneMgrElem = oneElem.getElementsByTagName("manager")[0];
    oneRecord.manager.id =
        oneMgrElem.getElementsByTagName("employeeid")[0].firstChild.data;
    oneRecord.manager.firstName =
        oneMgrElem.getElementsByTagName("firstname")[0].firstChild.data;
    oneRecord.manager.lastName =
        oneMgrElem.getElementsByTagName("lastname")[0].firstChild.data;
    oneRecord.region =
        oneElem.getElementsByTagName("region")[0].firstChild.data;
    oneRecord.sales = new Array();
    var allPeriods = oneElem.getElementsByTagName("salesrecord")[0].childNodes;
    var temp;
    var accumForecast = 0, accumActual = 0;
    for (var i = 0; i < allPeriods.length; i++) {
        if (allPeriods[i].nodeType == 1) {
            temp = new Object();
            temp.period =
                allPeriods[i].getElementsByTagName("id")[0].firstChild.data;
            temp.forecast = parseInt(allPeriods[i].getElementsByTagName(
                "forecast")[0].firstChild.data);
            temp.actual = parseInt(allPeriods[i].getElementsByTagName(
                "actual")[0].firstChild.data);
            temp.quotaPct = getPercentage(temp.actual, temp.forecast);
            oneRecord.sales[temp.period] = temp;
            accumForecast += temp.forecast;
            accumActual += temp.actual;
        }
    }
    oneRecord.totalForecast = accumForecast;
    oneRecord.totalActual = accumActual;
    oneRecord.totalQuotaPct = getPercentage(accumActual, accumForecast);
    return oneRecord;
}

function getPercentage(actual, forecast) {
    var pct = (actual/forecast * 100) + "%";
    pct = pct.match(/\\d*\\.\\d/);
    return parseFloat(pct);
}
```

Assuming that the raw XML database stores only the sales forecast and actual dollar figures, it is up to analysis programs to perform their own calculations, such as how the actual sales compare against the forecasts. As you saw in the illustration of the rendered table, this application not only displays the percentage differences between the pairs of values, but it also provides sorting facilities on those percentages. To speed the sorting, the percentages are calculated as the JavaScript database is being accumulated, and the percentages are stored as properties of each object. Percentage calculation is called upon in two different statements of the `getOneSalesRep()` function, so that the calculation is broken out to its own function, `getPercentage()`. In that function, the two passed values are massaged to calculate the percentage value, and then the string result is formatted to no more than one digit to the right of the decimal (by way of a regular expression). The value returned for the property assignment is converted to a number data type, because sorting on these values needs to be done according to numeric sorting, rather than string sorting.

You can already get a glimpse at the contribution JavaScript is making to the scripted representation of the data transmitted in XML form. By virtue of planning for subsequent calculations, the JavaScript object contains considerably more information than was originally delivered, yet all the properties are derived from “hard” data supplied by the server database.

## Sorting the JavaScript database

With so many sorting keys for the user to choose from, it's no surprise that sorting code occupies a good number of script lines in this application. All sorting code consists of two major blocks: *dispatching* and *sorting*.

The dispatching portion is nothing more than one gigantic `switch` construction that sends execution to one of the 17 (!) sorting functions that match whichever sort key is chosen in the `select` element on the page. This dispatcher function, `selectSort()`, is also invoked from the `init()` function at load time. Thus, if the user makes a choice in the page, navigates to another page, and then returns with the page still showing the previous selection, the `onLoad` event handler will reconstruct the table precisely as it was. When sorting is completed, the table is drawn, as you see shortly.

```
function selectSort(chooser) {
    switch (chooser.value) {
        case "byRep" :
            db.sort(sortDBByRep);
            break;
        case "byRegion" :
            db.sort(sortDBByRegion);
            break;
        case "byQ1Fcst" :
            db.sort(sortDBByQ1Fcst);
            break;
        case "byQ1Actual" :
            db.sort(sortDBByQ1Actual);
            break;
        case "byQ1Quota" :
            db.sort(sortDBByQ1Quota);
            break;
        case "byQ2Fcst" :
            db.sort(sortDBByQ2Fcst);
            break;
        case "byQ2Actual" :
            db.sort(sortDBByQ2Actual);
            break;
    }
}
```

```

    case "byQ2Quota" :
        db.sort(sortDBByQ2Quota);
        break;
    case "byQ3Fcst" :
        db.sort(sortDBByQ3Fcst);
        break;
    case "byQ3Actual" :
        db.sort(sortDBByQ3Actual);
        break;
    case "byQ3Quota" :
        db.sort(sortDBByQ3Quota);
        break;
    case "byQ4Fcst" :
        db.sort(sortDBByQ4Fcst);
        break;
    case "byQ4Actual" :
        db.sort(sortDBByQ4Actual);
        break;
    case "byQ4Quota" :
        db.sort(sortDBByQ4Quota);
        break;
    case "byTotalFcst" :
        db.sort(sortDBByTotalFcst);
        break;
    case "byTotalActual" :
        db.sort(sortDBByTotalActual);
        break;
    case "byTotalQuota" :
        db.sort(sortDBByTotalQuota);
        break;
    }
    drawTextTable();
}

```

Each specific sorting routine is a function that automatically works repeatedly on pairs of entries of an array (see Chapter 30). Array entries here (from the `db` array) are objects — and rather complex objects at that. The benefit of using JavaScript array sorting is that the sorting can be performed on any property of objects stored in the array. For example, sorting on the `lastName` property of each `db` array object is based on a comparison of the `lastName` property for each of the pairs of array entries passed to the `sortDBByRep()` sort function. But looking down a little further, you can see that the mechanism allows sorting on even more deeply nested properties, such as the `sales.Q1_2000.forecast` property of each array entry. If a property in an object can be referenced, it can be used as a sorting property inside one of these functions.

```

function sortDBByRep(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.lastName < b.lastName) ? -1 : 1;
    } else {
        return (a.lastName > b.lastName) ? -1 : 1;
    }
}

function sortDBByRegion(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.region < b.region) ? -1 : 1;
    } else {
        return (a.region > b.region) ? -1 : 1;
    }
}

```

```

function sortDBByQ1Fcst(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q1_2000.forecast - b.sales.Q1_2000.forecast);
    } else {
        return (b.sales.Q1_2000.forecast - a.sales.Q1_2000.forecast);
    }
}
function sortDBByQ1Actual(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q1_2000.actual - b.sales.Q1_2000.actual);
    } else {
        return (b.sales.Q1_2000.actual - a.sales.Q1_2000.actual);
    }
}
function sortDBByQ1Quota(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q1_2000.quotaPct - b.sales.Q1_2000.quotaPct);
    } else {
        return (b.sales.Q1_2000.quotaPct - a.sales.Q1_2000.quotaPct);
    }
}
function sortDBByQ2Fcst(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q2_2000.forecast - b.sales.Q2_2000.forecast);
    } else {
        return (b.sales.Q2_2000.forecast - a.sales.Q2_2000.forecast);
    }
}
function sortDBByQ2Actual(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q2_2000.actual - b.sales.Q2_2000.actual);
    } else {
        return (b.sales.Q2_2000.actual - a.sales.Q2_2000.actual);
    }
}
function sortDBByQ2Quota(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q2_2000.quotaPct - b.sales.Q2_2000.quotaPct);
    } else {
        return (b.sales.Q2_2000.quotaPct - a.sales.Q2_2000.quotaPct);
    }
}
function sortDBByQ3Fcst(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q3_2000.forecast - b.sales.Q3_2000.forecast);
    } else {
        return (b.sales.Q3_2000.forecast - a.sales.Q3_2000.forecast);
    }
}
function sortDBByQ3Actual(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q3_2000.actual - b.sales.Q3_2000.actual);
    } else {
        return (b.sales.Q3_2000.actual - a.sales.Q3_2000.actual);
    }
}
function sortDBByQ3Quota(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q3_2000.quotaPct - b.sales.Q3_2000.quotaPct);
    } else {

```

```

        return (b.sales.Q3_2000.quotaPct - a.sales.Q3_2000.quotaPct);
    }
}
function sortDBByQ4Fcst(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q4_2000.forecast - b.sales.Q4_2000.forecast);
    } else {
        return (b.sales.Q4_2000.forecast - a.sales.Q4_2000.forecast);
    }
}
function sortDBByQ4Actual(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q4_2000.actual - b.sales.Q4_2000.actual);
    } else {
        return (b.sales.Q4_2000.actual - a.sales.Q4_2000.actual);
    }
}
function sortDBByQ4Quota(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q4_2000.quotaPct - b.sales.Q4_2000.quotaPct);
    } else {
        return (b.sales.Q4_2000.quotaPct - a.sales.Q4_2000.quotaPct);
    }
}
function sortDBByTotalFcst(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.totalForecast - b.totalForecast);
    } else {
        return (b.totalForecast - a.totalForecast);
    }
}
function sortDBByTotalActual(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.totalActual - b.totalActual);
    } else {
        return (b.totalActual - a.totalActual);
    }
}
function sortDBByTotalQuota(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.totalQuotaPct - b.totalQuotaPct);
    } else {
        return (b.totalQuotaPct - a.totalQuotaPct);
    }
}
}

```

For this application, all sorting functions branch in their execution based on the choice made in the “Ordered” select element on the page. The relative position of the two array elements under test in these simple subtraction comparison statements reverses when the sort order is from low to high (increasing) and when it is from high to low (decreasing). This kind of array sorting is extremely powerful in JavaScript and probably escapes the attention of most scripters.

## Constructing the table

As recommended back in Chapter 37’s discussion of `table` and related elements, it is often convenient to manipulate the structure of a `table` element by way of the specialized methods for tables, rather than mess with nodes and elements. The `drawTextTable()` function is devoted to employing those methods to create the rendered contents of the table below the

headers (which are hard-wired in the document's HTML). Composing an 11-column table requires a bit of code, and the `drawTextTable()`'s length attests to that fact. You can tell by just glancing at the code, however, that for big chunks of it, there is a comfortable regularity that is aided by the JavaScript object that holds the data.

Additional calculations take place while the table's elements are being added to the `table` element. Column totals are accumulated during the table assembly (row totals are calculated as the object is generated and preserved as properties of the object). A large `for` loop cycles through each (sorted) row of the `db` array; each row of the `db` array corresponds to a row of the table. Class names are assigned to various rows or cells so that they will pick up the stylesheet rules defined earlier in the document. Another subtlety of this version is that the `region` property of a sales rep is assigned to the `title` property of a row. If the user pauses the mouse pointer anywhere in that row, the name of the region pops up briefly.

```
function drawTextTable() {
    var newRow;
    var accumQ1F = 0, accumQ1A = 0, accumQ2F = 0, accumQ2A = 0;
    var accumQ3F = 0, accumQ3A = 0, accumQ4F = 0, accumQ4A = 0;
    deleteRows(document.getElementById("mainTableBody"));
    for (var i = 0; i < db.length; i++) {
        newRow = document.getElementById("mainTableBody").insertRow(i);
        newRow.className = db[i].region;
        newRow.title = db[i].region + " Region";
        appendCell(newRow, "rep", db[i].firstName + " " + db[i].lastName);
        appendCell(newRow, "Q1", db[i].sales.Q1_2000.forecast + "<br />" +
            db[i].sales.Q1_2000.actual);
        appendCell(newRow, "Q1", db[i].sales.Q1_2000.quotaPct + "%");
        appendCell(newRow, "Q2", db[i].sales.Q2_2000.forecast + "<br />" +
            db[i].sales.Q2_2000.actual);
        appendCell(newRow, "Q2", db[i].sales.Q2_2000.quotaPct + "%");
        appendCell(newRow, "Q3", db[i].sales.Q3_2000.forecast + "<br />" +
            db[i].sales.Q3_2000.actual);
        appendCell(newRow, "Q3", db[i].sales.Q3_2000.quotaPct + "%");
        appendCell(newRow, "Q4", db[i].sales.Q4_2000.forecast + "<br />" +
            db[i].sales.Q4_2000.actual);
        appendCell(newRow, "Q4", db[i].sales.Q4_2000.quotaPct + "%");
        accumQ1F += db[i].sales.Q1_2000.forecast;
        accumQ1A += db[i].sales.Q1_2000.actual;
        accumQ2F += db[i].sales.Q2_2000.forecast;
        accumQ2A += db[i].sales.Q2_2000.actual;
        accumQ3F += db[i].sales.Q3_2000.forecast;
        accumQ3A += db[i].sales.Q3_2000.actual;
        accumQ4F += db[i].sales.Q4_2000.forecast;
        accumQ4A += db[i].sales.Q4_2000.actual;
        appendCell(newRow, "repTotal", db[i].totalForecast + "<br />" +
            db[i].totalActual);
        appendCell(newRow, "repTotal", db[i].totalQuotaPct + "%");
    }
    newRow = document.getElementById("mainTableBody").insertRow(i);
    newRow.className = "QTotal";
    newRow.title = "Totals";
    appendCell(newRow, "grandTotalLabel", "Grand Total");
    appendCell(newRow, "Q1", accumQ1F + "<br />" + accumQ1A);
    appendCell(newRow, "Q1", getPercentage(accumQ1A, accumQ1F) + "%");
    appendCell(newRow, "Q2", accumQ2F + "<br />" + accumQ2A);
    appendCell(newRow, "Q2", getPercentage(accumQ2A, accumQ2F) + "%");
    appendCell(newRow, "Q3", accumQ3F + "<br />" + accumQ3A);
    appendCell(newRow, "Q3", getPercentage(accumQ3A, accumQ3F) + "%");
    appendCell(newRow, "Q4", accumQ4F + "<br />" + accumQ4A);
}
```

```

    appendCell(newRow, "Q4", getPercentage(accumQ4A, accumQ4F) + "%");
    var grandTotalFcst = accumQ1F + accumQ2F + accumQ3F + accumQ4F;
    var grandTotalActual = accumQ1A + accumQ2A + accumQ3A + accumQ4A;
    appendCell(newRow, "grandTotal", grandTotalFcst + "<br />" +
        grandTotalActual);
    appendCell(newRow, "grandTotal", getPercentage(grandTotalActual,
        grandTotalFcst) + "%");
}

function appendCell(Trow, Cclass, txt) {
    var newCell = Trow.insertCell(Trow.cells.length);
    newCell.className = Cclass;
    newCell.innerHTML = txt;
}

function deleteRows(tbl) {
    while (tbl.rows.length > 0) {
        tbl.deleteRow(0);
    }
}

```

Many standalone statements at the end of the `drawTextTable()` function are devoted exclusively to generating the Grand Total row, in which the accumulated column totals are entered. At the same time, the `getPercentage()` function, described earlier, is invoked several times again to derive the quota percentage for the accumulated grand total values in each quarter as well as the complete year.

## select controls

To round out the code listing for this application, the values assigned to the two `select` elements obviously have a lot to do with the execution of numerous functions in this application. Nothing magic takes place here, but you can see the extent of the detail required in assigning script-meaningful hidden values, and human-meaningful text for both `select` elements. For example, dividing lines help organize the long sort key list into three logical blocks.

```

<p>Sort by: <select id="sortChooser" onchange="selectSort(this)">
  <option value="byRep">Representative</option>
  <option value="byRegion">Sales Region</option>
  <option value="">-----</option>
  <option value="byQ1Fcst">Q1 Forecast</option>
  <option value="byQ1Actual">Q1 Actual</option>
  <option value="byQ1Quota">Q1 Performance</option>
  <option value="byQ2Fcst">Q2 Forecast</option>
  <option value="byQ2Actual">Q2 Actual</option>
  <option value="byQ2Quota">Q2 Performance</option>
  <option value="byQ3Fcst">Q3 Forecast</option>
  <option value="byQ3Actual">Q3 Actual</option>
  <option value="byQ3Quota">Q3 Performance</option>
  <option value="byQ4Fcst">Q4 Forecast</option>
  <option value="byQ4Actual">Q4 Actual</option>
  <option value="byQ4Quota">Q4 Performance</option>
  <option value="">-----</option>
  <option value="byTotalFcst">Total Forecast</option>
  <option value="byTotalActual">Total Actual</option>
  <option value="byTotalQuota">Total Performance</option>
</select> &nbsp;&nbsp;&nbsp;Ordered: <select id="orderChooser"
  onchange="selectOrder()">
  <option value="inc">Low to High</option>
  <option value="dec">High to Low</option>
</select></p>

```

## Dreams of Other Views

Confining the example to just one type of view — a table of numbers — should help you grasp the important processes taking place. But with the XML data converted to JavaScript objects, you can build many other views of the same data into the same page. For example, a script could completely hide the numeric table, and generate a different one that draws bar charts for each sales representative or each region (see Chapter 55 for a scripted bar chart example). The horizontal axis would be the four quarters, and the vertical axis would be dollars or quota percentages. Clicking a bar opens a small window or layer to reveal more detail from the sales representative's record, such as the name of the person's manager. More `select` elements can let the user select any combination of subsets of the data in either bar chart or numeric table form to facilitate visual comparisons. You might be even more creative and devise ways of showing the data by way of overlapping positioned elements.

The point is that despite the kinds of rendering opportunities afforded by the XSL Transform mechanism (even if you can get comfortable in the syntax and mental model it presents to authors), JavaScript's detailed access to the DOM offers far more potential. Eventually plenty of content authors will mix the two technologies by embedding JavaScript into XSL stylesheets to supplement XSL features.

## SYMBOLS

`+=` (add-by-value) operator, 112–113  
`+` (addition) operator, 66, 112  
`&` (ampersand), 495  
`&&` (AND) operator, 194  
`@` (at symbol), 27–28  
`{ }` (curly braces), 76  
`/` (division) operator, 66, 494  
`"` (double quotes), 87  
`//` (double slash), 23  
`=` (equal sign), 66  
`==` (equality) operator, 79  
`#` (hash) symbol, 622  
`%` (modulus) operator, 71  
`*` (multiplication) operator, 66  
`\n` (newline) character, 161, 692  
`&nbsp;` (nonbreaking space character), BC22  
`!=` (not equal to) operator, 67  
`()` (parentheses), 24  
`%` (percent character), 1033  
`|` (pipe character), 407  
`+` (plus sign), 24, 66  
`\r` (return character), 692  
`'` (single quotes), 87  
`-` (subtraction) operator, 66  
`_` (underscore), 991

## A

`a` element object properties, 595–599  
`<a>` tag, 137  
`abbr` property, BC57  
`abort` event, 264  
`abort()` method, BC188  
`above` property, BC113  
`absolute` units, 812  
`AbsolutePosition` property, 250  
`accelerator` property, 836  
`acceptCharset` property, 638

## access

access denied warning, 487  
cookies, 522  
errors, BC285  
properties, 43  
server access, reducing, BC386  
`accessKey` property  
  as generic object, 204–206  
  label object, 1033–1034  
`action` attribute, 99, 108, 638  
`activeElement` property, 513  
ActiveX controls  
  ActiveXObject object, 1019–1020  
  plug-ins, 6  
`add()` method, 710  
`addBehavior()` method  
  discussed, 177, BC332  
  generic objects, 261–264  
  return values, 261  
`add-by-value (+=)` operator, 112–113  
`AddDesktopComponent()` method, 378  
`addEventListener()` method  
  discussed, 191  
  generic methods, 264  
`addImport()` method, 804–805  
adding numbers, 64  
addition (+) operator, 66, 112  
add-ons, filters, 226  
`addRange()` method, 1065  
`addReadRequest()` method, BC105–BC106  
`addRow()` function, 259  
`addRule()` method, 805  
`addStyle()` function, 558  
`addTotals()` function, BC369  
`adjustClip()` function, BC150

### prototypes

CGI, 33

objects, 159

properties, 855

prototype inheritance, 1003–1004

prototype property

Array object, 917–918

Boolean object, 890

function object, 987

Math object, 888

RegExp object, BC211

string object, 854–855

pseudo-URLs, 137

public keyword, BC248

## Q

qualifier property, 756

query commands, 569

queryCommandCommandState() method, 569

queryCommandEnabled() method, 569, 1099

queryCommandIndterm() method, 569

queryCommandState() method, 1099

queryCommandSupported() method,  
569, 1099

queryCommandText() method, 569, 1099

queryCommandValue() method,  
569–570, 1099

quoted pairs, strings, 111–112

quotes property, 817

## R

### radio objects

discussed, 103–104

input objects

checked property, 665–666

click() method, 668

defaultChecked property, 666

length property, 667

name property, 667

onclick event, 668–669

overview, 663–664

type property, 667

value property, 667

random access memory (RAM), 36, 60

random() method, 115–116

random number generation, 115–116

RandomDissolve() method, 845

Range object

cloneContents() method, 1046

cloneRange() method, 1046

collapse() method, 1047

collapsed property, 1043

commonAncestorContainer property,  
1043–1044

compareBoundaryPoints() method,  
1047–1048

comparePoint() method, 1051

createContextualFragment() method,  
1051–1052

deleteContents() method, 1052–1053

detach() method, 1053–1054

endContainer property, 1044

endOffset property, 1044

extractContents() method, 1054

insertNode() method, 1054–1055

intersectsNode() method, 1056

isPointInRange() method, 1056

overview, 1039–1040

selectNode() method, 1056

selectNodeContents() method,  
1056–1057

setEnd() method, 1057

setEndAfter() method, 1059

setEndBefore() method, 1059

setStart() method, 1057–1058

setStartAfter() method, 1059

setStartBefore() method, 1059

startContainer property, 1044

startOffset property, 1044–1045

surroundContents() method, 1059–1060

toString() method, 1061

rangeCount property, 1063

### reading

# Wiley Publishing, Inc.

## End-User License Agreement

**READ THIS.** You should carefully read these terms and conditions before opening the software packet(s) included with this book “Book”. This is a license agreement “Agreement” between you and Wiley Publishing, Inc. “WPI”. By opening the accompanying software packet(s), you acknowledge that you have read and accept the following terms and conditions. If you do not agree and do not want to be bound by such terms and conditions, promptly return the Book and the unopened software packet(s) to the place you obtained them for a full refund.

- 1. License Grant.** WPI grants to you (either an individual or entity) a nonexclusive license to use one copy of the enclosed software program(s) (collectively, the “Software”) solely for your own personal or business purposes on a single computer (whether a standard computer or a workstation component of a multi-user network). The Software is in use on a computer when it is loaded into temporary memory (RAM) or installed into permanent memory (hard disk, CD-ROM, or other storage device). WPI reserves all rights not expressly granted herein.
- 2. Ownership.** WPI is the owner of all right, title, and interest, including copyright, in and to the compilation of the Software recorded on the disk(s) or CD-ROM “Software Media”. Copyright to the individual programs recorded on the Software Media is owned by the author or other authorized copyright owner of each program. Ownership of the Software and all proprietary rights relating thereto remain with WPI and its licensors.
- 3. Restrictions on Use and Transfer.**
  - (a)** You may only (i) make one copy of the Software for backup or archival purposes, or (ii) transfer the Software to a single hard disk, provided that you keep the original for backup or archival purposes. You may not (i) rent or lease the Software, (ii) copy or reproduce the Software through a LAN or other network system or through any computer subscriber system or bulletin-board system, or (iii) modify, adapt, or create derivative works based on the Software.
  - (b)** You may not reverse engineer, decompile, or disassemble the Software. You may transfer the Software and user documentation on a permanent basis, provided that the transferee agrees to accept the terms and conditions of this Agreement and you retain no copies. If the Software is an update or has been updated, any transfer must include the most recent update and all prior versions.
- 4. Restrictions on Use of Individual Programs.** You must follow the individual requirements and restrictions detailed for each individual program in the About the CD-ROM appendix of this Book. These limitations are also contained in the individual license agreements recorded on the Software Media. These limitations may include a requirement that after using the program for a specified period of time, the user must pay a registration fee or discontinue use. By opening the Software packet(s), you will be agreeing to abide by the licenses and restrictions for these individual programs that are detailed in the About the CD-ROM appendix and on the Software Media. None of the material on this Software Media or listed in this Book may ever be redistributed, in original or modified form, for commercial purposes.

## 5. Limited Warranty.

- (a) WPI warrants that the Software and Software Media are free from defects in materials and workmanship under normal use for a period of sixty (60) days from the date of purchase of this Book. If WPI receives notification within the warranty period of defects in materials or workmanship, WPI will replace the defective Software Media.
- (b) WPI AND THE AUTHOR(S) OF THE BOOK DISCLAIM ALL OTHER WARRANTIES, EXPRESS OR IMPLIED, INCLUDING WITHOUT LIMITATION IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE, WITH RESPECT TO THE SOFTWARE, THE PROGRAMS, THE SOURCE CODE CONTAINED THEREIN, AND/OR THE TECHNIQUES DESCRIBED IN THIS BOOK. WPI DOES NOT WARRANT THAT THE FUNCTIONS CONTAINED IN THE SOFTWARE WILL MEET YOUR REQUIREMENTS OR THAT THE OPERATION OF THE SOFTWARE WILL BE ERROR FREE.
- (c) This limited warranty gives you specific legal rights, and you may have other rights that vary from jurisdiction to jurisdiction.

## 6. Remedies.

- (a) WPI's entire liability and your exclusive remedy for defects in materials and workmanship shall be limited to replacement of the Software Media, which may be returned to WPI with a copy of your receipt at the following address: Software Media Fulfillment Department, Attn.: *JavaScript Bible, 5th Ed.*, Wiley Publishing, Inc., 10475 Crosspoint Blvd., Indianapolis, IN 46256, or call 1-800-762-2974. Please allow four to six weeks for delivery. This Limited Warranty is void if failure of the Software Media has resulted from accident, abuse, or misapplication. Any replacement Software Media will be warranted for the remainder of the original warranty period or thirty (30) days, whichever is longer.
- (b) In no event shall WPI or the author be liable for any damages whatsoever (including without limitation damages for loss of business profits, business interruption, loss of business information, or any other pecuniary loss) arising from the use of or inability to use the Book or the Software, even if WPI has been advised of the possibility of such damages.
- (c) Because some jurisdictions do not allow the exclusion or limitation of liability for consequential or incidental damages, the above limitation or exclusion may not apply to you.

**7. U.S. Government Restricted Rights.** Use, duplication, or disclosure of the Software for or on behalf of the United States of America, its agencies and/or instrumentalities "U.S. Government" is subject to restrictions as stated in paragraph (c)(1)(ii) of the Rights in Technical Data and Computer Software clause of DFARS 252.227-7013, or subparagraphs (c) (1) and (2) of the Commercial Computer Software - Restricted Rights clause at FAR 52.227-19, and in similar clauses in the NASA FAR supplement, as applicable.

**8. General.** This Agreement constitutes the entire understanding of the parties and revokes and supersedes all prior agreements, oral or written, between them and may not be modified or amended except in a writing signed by both parties hereto that specifically refers to this Agreement. This Agreement shall take precedence over any other documents that may be in conflict herewith. If any one or more provisions contained in this Agreement are held by any court or tribunal to be invalid, illegal, or otherwise unenforceable, each and every other provision shall remain in full force and effect.
