# Preface

This work is a synopsis of research work done by me and my fellow co-investigators in the fields of computer arithmetic and computer architecture spanning a period of over 20 years.

During the 1990s, discussion among the computer architects used to be focused on weighing the merits and demerits of control-flow and data-flow models of computation for parallel processing. As a doctoral student of computer engineering at the Florida Institute of Technology (USA) at that time, I became interested in devising a better model of computation which would amalgamate the best features of data-flow model with the content-addressability features of the associative memories. These efforts resulted in formulating the concept of *associative dataflow* and, consequently, the design and implementation of an *associative dataflow processor* by me in 1996.

In 1999, while at the University of Tasmania (Australia), Neville Holmes, a colleague of mine in the School of Computing, showed me a paper written by Donald Knuth, a pioneer in the field of computing, published in the *Communications of the ACM* advocating a binary number system with a base other than 2. This kindled my interest in computer arithmetic and I started doing further research in this avenue of computing. During this investigation, I found out about Walter Penny's proposal for a (-1 + j) base number system which appeared more promising to me and Neville than Donald Knuth's idea. We called (-1 + j) base number system as the *Complex Binary Number System* (*CBNS*) and what followed in the next 12 years of my work on CBNS is now in your hands.

During the past several years, I have worked as principal investigator on several research grants provided by Sultan Qaboos University (Oman) in an effort to establish CBNS as a viable number system. This has resulted in the publication of several conference and journal papers authored by me and my co-investigators and, in this book, I have tried to compile a succinct summary of all these publications for the benefit of anyone interested in continuing research in this area of computer arithmetic. An innovative patent on *complex binary associative dataflow processor* has been granted to me by the Australian Patent Office in 2010 which incorporates CBNS within the associative dataflow processor designed by me earlier.

It is sincerely hoped that this book will give new impetus to research in computer arithmetic and parallel processing and will enable the researchers of tomorrow to improve and implement CBNS within the realm of computing.

Muscat, Oman, 7 July 2012

Tariq Jamil

### Acknowledgments

First of all, I am eternally grateful to Almighty Allah for His countless blessings in completing this task. Without the sacrifices and selflessness of my parents, it would not have been possible for me to be able to get an engineering education, and without the guidance from my teachers, I would not have been able to excel in my search for knowledge. My wife has been a continuous beacon of encouragement to me while my children, Hamiz and Umnia, are the main sources of happiness for me in this life.

I am grateful to two of my high-school mathematics teachers, Mr. Tariq and Mr. Baig, for kindling my interest in mathematics during those years of my life. My Ph.D. supervisor, Dr. Deshmukh, helped me tremendously during my research work on the topic of *associative dataflow* at the Florida Tech (USA) during 1994–1996.

I am thankful to my friend and colleague, Neville Holmes, for introducing me to the realm of computer arithmetic and also for collaborating with me in some of the earlier publications on this topic. David Blest was among the first mathematicians who saw potential of further research in CBNS and wrote papers with me in a few publications.

Australian Research Council was the first agency to support my research on associative dataflow processing during 1997–1998 and I am thankful to them for their financial support. I am grateful to Sultan Qaboos University (Oman) for supporting my research activities on the topic of CBNS through various internal research grants during the period 2000–2012. Dr. Bassel Arafeh, Dr. Amer AlHabsi, Dr. Amir Arshad Abdulghani, Dr. Usman Ali, Mr. Ahmad AlMaashari, Mr. Said AlAbri, and Ms. Sadaf Saeed have worked as co-investigators with me on these research projects and to these researchers, I express my unbridled gratitude for their work. It is due to the efforts of these people that CBNS has matured to become a viable alternative to traditional binary number system.

Finally, I would like to thank Springer for giving me the opportunity to publish this work for the benefit of the computer scientists and engineers worldwide.

# Chapter 1 Introduction

**Abstract** Complex numbers play a truly unique and important role in the realm of modern science and engineering. Using these numbers it is possible to locate a point within two dimensions of a Cartesian co-ordinate system. Therefore, these numbers are used extensively in digital signal processing algorithms and image processing applications. In this chapter we are going to review basic theory about complex numbers and arithmetic operations involving such type of numbers. This will enable us to justify the need for a more efficient representation of these numbers in computer architecture.

#### 1.1 What is a Complex Number?

A complex number represents a point in a two-dimensional system and, in rectangular form, is written in the form (x + jy) where x, called the real part, denotes the position along the horizontal axis and y, called the imaginary part, denotes the position along the vertical axis. "j" is considered equivalent to  $\sqrt{-1}$  and is used to represent the imaginary nature of the variable y. Another way of locating the point in a two-dimensional system is to use polar notation  $r \angle \theta$  where r represents the hypotenuse of length  $\sqrt{x^2 + y^2}$  for a right-angled triangle having x as the base and y as the perpendicular, and  $\theta$  represents the angle made by the hypotenuse with the base of the triangle, given by  $\tan^{-1} \frac{y}{x}$ .

#### **1.2 Arithmetic Operations Involving Complex Numbers**

Arithmetic operations involving two complex numbers (a + jb) and (c + jd) are carried out as follows:

• Addition involves two individual additions, one for the real parts (a + c) and one for the imaginary parts (b + d):

$$(a+jb) + (c+jd) = (a+c) + j(b+d)$$
(1.1)

• Subtraction involves two individual subtractions, one for the real parts (a - c) and one for the imaginary parts (b - d):

$$(a+jb) - (c+jd) = (a-c) + j(b-d)$$
(1.2)

• Multiplication involves four individual multiplications *ac*, *ad*, *bc*, *bd*, one sub-traction *ac* – *bd*, and one addition *ad* + *bc*:

$$(a+jb) \times (c+jd) = ac + j(ad+bc) + j^{2}bd = (ac-bd) + j(ad+bc)$$
 (1.3)

• Division involves six individual multiplications  $ac, ad, bc, bd, c^2, d^2$ , two additions ac + bd and  $c^2 + d^2$ , one subtraction bc - ad, and then two individual divisions  $\frac{ac+bd}{c^2+d^2}$  and  $\frac{bc-ad}{c^2+d^2}$ :

$$\frac{(a+jb)}{(c+jd)} = \frac{(a+jb)}{(c+jd)} \times \frac{(c-jd)}{(c-jd)} = \frac{ac+j(bc-ad)-j^2bd}{c^2-j^2d^2}$$
$$= \frac{(ac+bd)+j(bc-ad)}{c^2+d^2} = \frac{ac+bd}{c^2+d^2} + j\frac{bc-ad}{c^2+d^2}$$
(1.4)

#### **1.3 Justification for Complex Binary Number System**

Let's assume that each individual addition/subtraction, involving complex numbers, takes p ns to complete and each individual multiplication/division takes q ns to execute, such that  $p \ll q$  (multiplication can be assumed to be *repeated-addition* and division can be assumed to be *repeated subtraction*), then each complex addition/subtraction will take 2p ns, each complex multiplication will take 4q + p + p = (2p + 4q) ns, and each complex division will take 6q + 2p + p + 2q = (3p + 8q) ns. Now imagine a number system in which complex arithmetic does not involve any *combination of individual arithmetic operations* as described in Sect. 1.2. That is, addition, subtraction, multiplication, or division of complex numbers is just one *pure* addition, one *pure* subtraction, one *pure* multiplication, or one *pure* division operation respectively and not a combination of various individual operations within a given arithmetic operation as mentioned previously. This will effectively reduce the complex addition/subtraction time to p ns and complex multiplication/division time to q ns. Mathematically, such a complex number system will yield reduction in execution time of addition/subtraction operation roughly by a factor of  $\frac{p}{2p} \times 100 = 50$ %, for multiplication  $\frac{(2p+4q)}{q} \times$  $100 = \frac{4q}{q} \times 100 = 400\%$  (since p is very small compared to q), and for division  $\frac{(3p+8q)}{a} \times 100 = \frac{8q}{a} \times 100 = 800$  %. With the reduction in execution times of complex arithmetic operations roughly by factors of 50-800 % in digital signal and image processing applications, it is possible to achieve tremendous enhancement in the overall performance of systems based on these applications, provided a technique exists which treats a complex number as a *single entity* (rather than two entities comprising of real and imaginary parts) and facilitates a single-unit representation of complex numbers in binary format within a microprocessor environment (rather than two individual representations for real and imaginary parts respectively, as in today's computers). Such a unique number system is referred to as Complex Binary Number System (CBNS).

#### 1.4 What is Complex Binary Number System?

Efforts in defining a binary number system (0 or 1) with bases other than 2, which would facilitate a single-unit representation of complex numbers, date back to 1960 when Donald E. Knuth described a "quater-imaginary" number system with base 2j and analyzed the arithmetic operations of numbers based on this imaginary base [1]. However, he was unsuccessful in providing a division algorithm and considered it as a main obstacle towards hardware implementation of any imaginary-base number system.

Walter Penney, in 1964, attempted to define a complex number system, first by using a negative base of -4 [2], and then by using a complex number (-1 + j) as the base [3]. However, the main problem encountered with using these bases was again the inability to formulate an efficient division process. Stepanenko, in 1996, utilized the base  $j\sqrt{2}$  to generate real parts of complex numbers by taking even powers of the base and imaginary parts of complex numbers by taking odd powers of the base [4]. Although partly successful in resolving the division problem as an "all-in-one" operation, in his algorithm "…everything…reduces to good choice of an initial approximation" in a Newton–Raphson iteration which may or may not converge.

Jamil et al., in 2000, revisited Penney's number system with base (-1+j) and presented a detailed analysis of this number system, now called Complex Binary Number System (CBNS) [5]. During the past several years, Jamil et al. have obtained research grants and published several articles in international conferences and journals describing conversion algorithms, arithmetic operations, and computer hardware circuits involving CBNS. This book is a compilation of the entire

research work carried out on CBNS by the author and his various research teams, and is intended to assist new researcher in the fields of computer arithmetic and computer architecture as well as any student with interest in digital logic towards advancing modern day computing through incorporation of CBNS in both the software and hardware paradigms.

In Chap. 2, algorithms to convert a given complex number into CBNS are presented. This is followed by presentation of techniques in Chap. 3 to carry out the arithmetic and shift operations in the new number system. Chapter 4 describes the hardware implementation, and performance statistics related to arithmetic circuits and, in Chap. 5, incorporation of these circuits within an associative dataflow environment to design a Complex Binary Associative Dataflow Processor (CBADP) has been explained. Conclusion and further research are outlined in Chap. 6.

# Chapter 2 Conversion Algorithms

**Abstract** In this chapter, algorithms for conversion of complex numbers into complex binary number system (CBNS) will be described. We'll start with integers, then explain how fractional numbers can be converted into CBNS, and finally how to represent floating point numbers into the new number system. Along the way, we'll also describe how imaginary numbers can be converted into CBNS. Once the algorithms for conversion of real and imaginary parts of a complex number (whether integer, fraction, or floating point) are known, we'll describe how a given complex number can be represented as single-unit binary string consisting of 0 and 1s.

#### 2.1 Conversion Algorithms for Integers

Let's first begin with the case of a positive integer N (in decimal number system) [1, 2]. To represent N in CBNS, we follow these steps:

(i) Express *N* in terms of powers of 4 using the repeated division process. That is, repeatedly divide *N* by 4 keeping track of the remainders. Examples:
2012<sub>10</sub> = (1,3,3,1,3,0)<sub>Base 4</sub>
2000<sub>10</sub> = (1,3,3,1,0,0)<sub>Base 4</sub>

$$60_{10} = (3,3,0)_{\text{Base 4}}$$

(ii) Now convert the Base 4 number (... n<sub>5</sub>,n<sub>4</sub>,n<sub>3</sub>,n<sub>2</sub>,n<sub>1</sub>,n<sub>0</sub>) to Base -4 by replacing each digit in the odd location (n<sub>1</sub>,n<sub>3</sub>,n<sub>5</sub>,...) with its negative to get (... - n<sub>5</sub>,n<sub>4</sub>, - n<sub>3</sub>,n<sub>2</sub>, - n<sub>1</sub>,n<sub>0</sub>). Examples:
2012<sub>10</sub> = (-1, 3, -3, 1, -3, 0)<sub>Base -4</sub>

<b>Table 2.1</b> Equivalence between normalized base -4	Normalized base -4	CBNS representation base $(-1+j)$
and $(-1+i)$ -base CBNS	0	0000
representation [1]	1	0001
	2	1100
	3	1101

 $2000_{10} = (-1,3,-3,1,0,0)_{\text{Base }-4}$  $60_{10} = (3,-3,0)_{\text{Base }-4}$ 

(iii) Next, we normalize the new number, i.e., get each digit in the range 0–3, by repeatedly adding 4 to the negative digits and adding a 1 to the digit on its left. This operation will get rid of negative numbers but may create some digits with a value of 4 after the addition of a 1. To normalize this, we replace 4 by a 0 and subtract a 1 from the digit on its left. Of course, this subtraction might once again introduce negative digits which will be normalized by the previous method but this process will definitely terminate. What is interesting to note is that, with negative bases, all integers (positive or negative) have a unique positive representation.

Examples:

$$\begin{split} 2012_{10} &= (-1,3,-3,1,-3,0)_{Base \ -4} \\ &= (1,3,4,1,2,1,0) = (1,2,0,1,2,1,0)_{Normalized} \\ 2000_{10} &= (-1,3,-3,1,0,0)_{Base \ -4} \\ &= (1,3,4,1,1,0,0) = (1,2,0,1,1,0,0)_{Normalized} \\ 60_{10} &= (3,-3,0)_{Base \ -4} \\ &= (4,1,0) = (-1,0,1,0) = (1,3,0,1,0)_{Normalized} \end{split}$$

(iv) Lastly, we replace each digit in the normalized representation by its equivalent binary representation in CBNS, as per Table 2.1.

These equivalences can be verified to be correct by calculating the power series for each CBNS representation as follows:

 $\begin{array}{l} 0000 = 0 \times (-1+j)^3 + 0 \times (-1+j)^2 + 0 \times (-1+j)^1 + 0 \times (-1+j)^0 \\ 0001 = 0 \times (-1+j)^3 + 0 \times (-1+j)^2 + 0 \times (-1+j)^1 + 1 \times (-1+j)^0 \\ 1100 = 1 \times (-1+j)^3 + 1 \times (-1+j)^2 + 0 \times (-1+j)^1 + 0 \times (-1+j)^0 \\ 1101 = 1 \times (-1+j)^3 + 1 \times (-1+j)^2 + 0 \times (-1+j)^1 + 1 \times (-1+j)^0 \\ \text{Examples:} \end{array}$ 

$$2012_{10} = (1, 2, 0, 1, 2, 1, 0)_{\text{Normalized}}$$
  
= 0001 1100 0000 0001 1100 0001 0000  
= 1110000000001110000010000\_{Base (-1+j)}

$$2000_{10} = (1, 2, 0, 1, 1, 0, 0)_{\text{Normalized}}$$
  
= 0001 1100 0000 0001 0001 0000 0000  
= 111000000001000100000000\_{Base (-1+j)}  
$$60_{10} = (1, 3, 0, 1, 0)_{\text{Normalized}}$$
  
= 0001 1101 0000 0001 0000  
= 1110100000010000\_{Base (-1+j)}

To convert a negative integer into CBNS format, we simply multiply the representation of the corresponding positive integer with 11101 (equivalent to  $(-1)_{\text{Base }(-1+i)}$ ) according to the multiplication algorithm given in Chap. 3. Thus,

$$\begin{split} -2012_{10} &= 1110000000011100000 \times 11101 \\ &= 11000000000110111010000_{\text{Base}\ (-1+j)} \\ -2000_{10} &= 111000000001000100000000 \times 11101 \\ &= 11000000000110100000000_{\text{Base}\ (-1+j)} \\ -60_{10} &= 11101000000010000 \times 11101 \\ &= 1000111010000_{\text{Base}\ (-1+j)} \end{split}$$

To obtain binary representation of a positive or negative imaginary number in CBNS, we multiply the corresponding CBNS representation of positive or negative integer with 11 (equivalent to  $(+j)_{\text{Base }(-1+j)}$ ) or 111 (equivalent to  $(-j)_{\text{Base }(-1+j)}$ ) according to the multiplication algorithm given in Chap. 3. Thus,

$$-j60_{10} = 1110100000010000 \times 111$$
$$= 11000001110000_{\text{Base }(-1+j)}$$

Having obtained CBNS representations for all types of integers (real and imaginary), it is now possible for us to represent an integer complex number (both real and imaginary parts of the complex number are integers) simply by adding the real and imaginary CBNS representations according to the addition algorithm given in Chap. 3. Thus,

+ 11101000000011101110000000Base (-1+j)= 111010000000001101011010000Base (-1+j)

#### 2.2 Conversion Algorithms for Fractional Numbers

The procedure for finding the binary equivalent in base (-1 + j) for real fraction and imaginary fraction is very similar to the procedure explained for integers in Sect. 2.1. As an example, CBNS representation for  $0.351_{10}$  is obtained as follows [2]:

(i) Repeated multiplication by 4 gives:  $0.351 \times 4 = 1.404;$   $0.404 \times 4 = 1.616;$   $0.616 \times 4 = 2.464;$   $0.464 \times 4 = 1.856;$   $0.856 \times 4 = 3.424;$   $0.424 \times 4 = 1.696;$   $0.696 \times 4 = 2.784;$   $0.784 \times 4 = 3.136;$ and so on. Thus  $0.351_{10} = 0.11213123..._{Base 4}$ 

- (ii) Converting the Base 4 number  $(\dots n_5, n_4, n_3, n_2, n_1, n_0)$  to Base -4 by replacing each digit in the odd location  $(n_1, n_3, n_5, \dots)$  with its negative to get  $(\dots n_5, n_4, -n_3, n_2, -n_1, n_0)$  yields:  $0.351_{10} = 0.(-1)1(-2)1(-3)1(-2)3\dots$ Base -4
- (iii) After normalization, we have:  $0.351_{10} = 1.32221223..._{Base - 4}$

i	$2^{-i}$	CBNS representation base $(-1+j)$
1	$2^{-1}$	1.11
2	$2^{-2}$	1.1101
3	$2^{-3}$	0.000011
4	$2^{-4}$	0.0000001

**Table 2.2** Equivalence between fractional coefficients and (-1 + j)-base CBNS representation [1]

(iv) And, finally replacing each Base -4 digit with its equivalent four-bit binary sequence as given in Table 2.1 gives:

 $0.351_{10} = 1.11011100110011000001..._{Base (-1+j)}$ 

Similarly,

$$j0.351_{10} = (1.11011100110011000001...) \times (11) = 0.0100010000110100001100...Base (-1+i)$$

A more elaborate mathematical algorithm which can be easily programmed in some high-level language for converting fractional numbers into CBNS is described in [1]. According to this algorithm, any fraction *F* can be expressed uniquely in terms of powers of  $1/2 = 2^{-1}$  such that

$$F = r_0 = f_1 \cdot 2^{-1} + f_2 \cdot 2^{-2} + f_3 \cdot 2^{-3} + f_4 \cdot 2^{-4} + \cdots$$
(2.1)

Then the coefficients  $f_i$  and remainders  $r_i$  are given as follows:

Initially, if  $(2r_0 - 1) < 0$  then  $f_1 = 0$  and set  $r_1 = 2r_0$ or if  $(2r_0 - 1) \ge 0$  then  $f_1 = 1$ and set  $r_1 = (2r_0 - 1)$ Then, if  $(2r_i - 1) < 0$  then  $f_{i+1} = 0$  and set  $r_{i+1} = 2r_i$ or if  $(2r_0 - 1) \ge 0$  then  $f_{i+1} = 1$ and set  $r_{i+1} = (2r_i - 1)$ 

This process continues until  $r_i = 0$  or the machine limit has been reached. Then,  $\forall f_i = 1$ , replace its associated  $2^{-i}$  according to Table 2.2 (only the first four values of *i* are listed in the table; for i > 4, refer to Table 2.3).

As an example, let

$$F = r_0 = 0.4375_{10}$$

Initially,

$$(2r_0 - 1) = 2(0.4375 - 1) = -0.125 < 0$$

 $\implies f_1 = 0 \text{ and } r_1 = 2r_0 = 2(0.4375) = 0.875$ Then,

$$(2r_1 - 1) = 2(0.875) - 1 = 0.75 > 0$$

 $\implies$   $f_2 = 1$  and  $r_2 = (2r_1 - 1) = 2(0.875) - 1 = 0.75$ Continuing according to the algorithm, we have

$$(2r_2 - 1) = 2(0.75) - 1 = 0.5 > 0$$
  
 $\implies f_3 = 1 \text{ and } r_3 = (2r_2 - 1) = 2(0.75) - 1 = 0.5$   
 $(2r_3 - 1) = 2(0.5) - 1 = 0(\text{STOP})$ 

 $\implies$   $f_4 = 1$  and  $r_4 = 0$ Thus,

$$\begin{aligned} 0.4375_{10} &= 0.2^{-1} + 1.2^{-2} + 1.2^{-3} + 1.2^{-4} \\ &= 0.(1.11) + 1(1.1101) + 1(0.000011) \\ &+ 1(0.0000001) = 1.11011101_{\text{Base }(-1+j)} \end{aligned}$$

(the addition is according to the algorithm given in Chap. 3)

It is likely that most fractions will not terminate as this example, until the machine limit has been reached, e.g.

$$0.351_{10} = 1.110111001100110000011..._{Base (-1+i)}$$

In that case, it is up to the user to terminate the algorithm when certain degree of accuracy has been achieved.

In general, to find CBNS representation of any  $2^{-i}$ , express *i* as 4s + t where *s* is an integer and  $0 \le t < 4$ . Then, depending upon value of *t*,  $2^{-i}$  can be expressed as given in Table 2.3. All rules for obtaining negative integer and positive/negative imaginary number representations in CBNS, as discussed previously, are equally applicable for obtaining negative fractional and positive/negative imaginary fractional representations in the new base.

A complex number which has only fractional real and imaginary parts can be represented in CBNS simply by adding the CBNS representations of each part according to the addition algorithm described in Chap. 3. Thus,

 $(0.351 + j0.351)_{\text{Base 10}}$ 

$$= 1.1101110011001100000111001100..._{Base (-1+j)}$$

 $+ 0.01000100001101000011001101..._{Base (-1+j)}$ 

 $= 0.0110100011110101111110001001..._{Base (-1+j)}$ 

Table 2.3       Equivalence         between value of "t" and	t	CBNS representation base $(-1+j)$
(-1+i)-base CBNS	0	0.0(8s-1) zeroes followed by 1
representation [1]	1	0.0(8s-1) zeroes followed by 111
1 1 1	2	0.0(8s-1) zeroes followed by 11101
	3	0.0(8s-1) zeroes followed by 11

#### 2.3 Conversion Algorithms for Floating-Point Numbers

To represent a floating-point positive number in CBNS, we add the corresponding integer and fractional representations according to the addition algorithm described in Chap. 3. Once again, all rules for obtaining negative integer and positive/ negative imaginary number representations, as discussed previously, are equally applicable for obtaining negative floating-point and positive/negative imaginary floating-point representations in CBNS. For example,

$$60.4375_{10} = 1110100000010000_{\text{Base }(-1+j)} + 1.11011101_{\text{Base }(-1+j)}$$
  
= 11101000000010001.11011101\_{\text{Base }(-1+j)}  
j60.4375\_{10} = (1110100000010001.11011101\_{\text{Base }(-1+j)}) \times (11)  
= 111000000110000.01000111\_{\text{Base }(-1+j)}

Adding these two CBNS representation using the addition algorithm outlined in Chap. 3 gives:

 $(60.4375 + j60.4375)_{10}$ = 1110100000010001.11011101\_Base (-1+j) +111000000110000.01000111\_Base (-1+j) = 10000011101110.1000011\_Base (-1+j)

In the above example, we have been able to represent a complex number (both real and imaginary parts are floating point numbers) in a single binary string. Thus, following the procedures outlined in this chapter, we can represent any complex number into CBNS format which is characterized by a single-unit string of bits (0 or 1).

# Chapter 3 Arithmetic Algorithms

**Abstract** In this chapter, algorithms for performing arithmetic operations on complex binary numbers, as well as effects of shift operations on this type of numbers, will be described. We will discuss addition, subtraction, multiplication, and division algorithms for complex binary numbers along with some examples. Then, we will describe the results of implementing multiple-bits shift-left and shift-right operations on various types of complex numbers represented in CBNS.

#### 3.1 Addition Algorithm for Complex Binary Numbers

The binary addition of complex binary numbers follows the truth table given in Table 3.1 [1-3].

Table 3.1 is similar to the half-adder truth table of traditional Base 2 binary numbers in the sense that 0 + 0 is still 0 (represented by 0000 in four bits), 0 + 1 is 1 (represented by 0001 in four bits), 1 + 0 is 1 (represented by 0001 in four bits), and  $1 + 1 = 2_{10}$  (represented by 1100<sub>Base (-1+j)</sub> in four bits). The last case can be interpreted as follows.

When two 1s are added, the sum is 0 and (instead of just one carry as in traditional Base 2 binary addition) two carries are generated which propagate towards the two adjoining positions after skipping the immediate neighbor of the sum column.

That is, if two numbers with 1s in position *n* are added, this will result in 1s in positions n + 3 and n + 2 and 0s in positions n + 1 and *n*. Similar to the ordinary computer rule where  $1 + 111 \dots$  (up to machine limit) = 0, we have 11 + 111 = 0, called *zero rule*, for complex binary numbers.

As an example, let us add (1+j) with (2-j2) in CBNS:

Inputs		Outputs		
Augend	Addend	Carries	Sum	
0	0	000	0	
0	1	000	1	
1	0	000	1	
1	1	110	0	

Table 3.1 Truth table for addition of complex binary numbers

(1+j) is equivalent to  $(1110)_{\rm Base\;(-1+j)}$  and (2-j2) is equivalent to  $(111000)_{\rm Base\;(-1+j)}.$  Thus

$$(1+j) + (2-j2)$$
  
= 1110<sub>Base (-1+j)</sub> + 111000<sub>Base (-1+j)</sub>  
= 111010110<sub>Base (-1+j)</sub> = 3 - j

The result can be verified to be correct by calculating the power series of the complex binary number as follows:

$$1 \times (-1+j)^8 + 1 \times (-1+j)^7 + 1 \times (-1+j)^6$$
  
+ 0 × (-1+j)^5 + 1 × (-1+j)^4 + 0 × (-1+j)^3  
+ 1 × (-1+j)^2 + 1 × (-1+j)^1 + 0 × (-1+j)^0  
= 3-j

#### 3.2 Subtraction Algorithm for Complex Binary Numbers

The binary subtraction of complex binary numbers follows the truth table given in Table 3.2 [1-3].

Table 3.2 is similar to the half-subtractor truth table of traditional Base 2 binary numbers in the sense that 0 - 0 is still 0 (represented by 0000 in four bits), 0 - 1 is -1 (represented by  $11101_{\text{Base }(-1+j)}$  in five bits), 1 - 0 is 1 (represented by 0001 in four bits), and 1 - 1 = 0 (represented by 0000 in four bits). The second case of 0 - 1 can be interpreted as a special case and solved by applying the following algorithm:

Assume our minuend is:

$$a_n a_{n-1} a_{n-2} \dots a_{k+4} a_{k+3} a_{k+2} a_{k+1} a_k 0 a_{k-1} \dots a_3 a_2 a_1 a_0$$

and subtrahend is:

$$b_n b_{n-1} b_{n-2} \dots b_{k+4} b_{k+3} b_{k+2} b_{k+1} 1 b_{k-1} \dots b_3 b_2 b_1 b_0$$

Inputs		Outputs		
Minuend	Subtrahend	Borrows	Difference	
0	0	000	0	
0	1	1110	1	
1	0	000	1	
1	1	000	0	

 Table 3.2
 Truth table for subtraction of complex binary numbers

Then the result of subtracting 1 from 0 is obtained by changing:

$$a_k \to a_k + 1 \tag{3.1}$$

$$a_{k+1} \to a_{k+1} (\text{unchanged})$$
 (3.2)

$$a_{k+2} \to a_{k+2} + 1 \tag{3.3}$$

$$a_{k+3} \to a_{k+3} + 1 \tag{3.4}$$

$$a_{k+4} \to a_{k+4} + 1 \tag{3.5}$$

$$b_k \to 0$$
 (3.6)

Note that addition of "1" in the above equations is accomplished by the application of addition algorithm described in Sect. 3.1.

As an example, let us subtract (1 + j3) from 2 in CBNS:

(1+j3) is equivalent to  $(1010)_{Base (-1+j)}$  and 2 is equivalent to  $(1100)_{Base (-1+j)}$ . Thus

$$2 - (1 + j3)$$
  
= 1100<sub>Base (-1+j)</sub> - 1010<sub>Base (-1+j)</sub>

Isolating the special case,

$$= 0100_{\text{Base }(-1+j)} - 0010_{\text{Base }(-1+j)}$$

 $= 111110_{\text{Base }(-1+j)} - 000000_{\text{Base }(-1+j)}$  (by algorithm)

$$= 111110_{\text{Base }(-1+j)} = 1 - j3$$

#### 3.3 Multiplication Algorithm for Complex Binary Numbers

The binary multiplication of two complex binary numbers (multiplicand and multiplier) consists of two operations [1-3]. First, a bit-wise logical AND operation is carried out between each multiplier bit and the whole multiplicand. This will result in intermediate products, just like in the decimal or binary

multiplication process, with each intermediate result shifted one-bit to the left compared to the previous intermediate result. Then, these intermediate products are added according to the CBNS addition algorithm described in Sect. 3.1. The *zero rule* plays an important role in reducing the number of summands resulting from intermediate multiplications.

As an example, let us multiply (1+j2) with (2-j)

(1+j2) is equivalent to  $(1110101)_{\text{Base }(-1+j)}$  and (2-j) is equivalent to  $(111011)_{\text{Base }(-1+j)}$ . Thus

$$(1+j2) \times (2-j)$$
  
=  $(1110101)_{\text{Base }(-1+j)} \times (111011)_{\text{Base }(-1+j)}$ 

First, we obtain the intermediate products by taking each multiplier's bit and ANDing it with the multiplicand as follows:

Then, we are going to add all intermediate products according to the addition algorithm described in Sect. 3.1. To reduce the number of addition operations, we'll also identify the operands which satisfy *zero rule* (111 + 11 = 0) by **boldfacing 1s**.

Thus,

$$(1+j2) \times (2-j) = (1100111)_{\text{Base }(-1+j)} = (4+j3)$$

#### 3.4 Division Algorithm for Complex Binary Numbers

Algorithmically, the division operation can be implemented as a multiplication operation between the reciprocal of the divisor (denominator) and the dividend (numerator) [1-3]. For a more detailed mathematical analysis of the division algorithm in CBNS, the reader is referred to [4, 5].

Thus,

$$\frac{(a+jb)}{(c+jd)} = (a+jb)(c+jd)^{-1} = (a+jb)z$$
(3.7)

where  $z = w^{-1}$  and w = (c + jd).

We start with our initial approximation of z by setting  $z_0 = (-1+j)^{-k}$  where k is obtained from the representation of w such that:

$$w = \sum_{i=-\infty}^{k} a_i (-1+j)^{-i}$$
(3.8)

in which  $a_k \equiv 1$  and  $a_i \equiv 0$  for i > k. The successive approximations are then obtained by  $z_{i+1} = z_i(2 - wz_i)$ . If the values of *z* do not converge, we correct our initial approximation of *z* by setting  $z_0 = j(-1+j)^{-k}$  which will definitely converge [4, 5]. Having calculated the value of *z*, we can multiply it with (a + jb) to obtain the result of the division operation.

In the following examples, for the sake of clarity, we have used decimal number system for the successive values of z to explain the converging process of the division algorithm.

Let us assume that we want to obtain the result of dividing (1 + j2) by (1 + j3). Thus (a + jb) = (1 + j2) and w = (c + jd) = (1 + j3). Our calculations for approximation of  $z = w^{-1}$  begin by first determining the value of k as follows:

$$w = (1+j3) = 1010_{\text{Base }(-1+j)}$$

$$= 1 \times (-1+j)^3 + 0 \times (-1+j)^2 + 1 \times (-1+j)^1 + 0 \times (-1+j)^0 \Rightarrow k = 3$$

Therefore,

$$z_0 = (-1+j)^{-k} = (-1+j)^{-3} = 0.25 - j0.25$$
$$z_1 = z_0(2 - wz_0) = 0.125 - j0.375$$
$$z_2 = z_1(2 - wz_1) = 0.09375 - j0.28125$$
$$z_3 = z_2(2 - wz_2) = 0.099609375 - j0.2988281250$$
$$z_4 = z_3(2 - wz_3) = 0.09999847412 - j0.2999954224$$

$$z_5 = z_4(2 - wz_4) = 0.1 - j0.3$$
$$z_6 = z_5(2 - wz_5) = 0.1 - j0.3$$

Now

$$(0.1 - j0.3) = (0.0011110010111100101111100...)_{\text{Base }(-1+j)}$$

So

$$\begin{aligned} \frac{1+j2}{1+j3} &= (1+j2) \times (1+j3)^{-1} \\ &= (1110101)_{\text{Base }(-1+j)} \\ &\times (0.001111001011110010111100...)_{\text{Base }(-1+j)} \\ &= (1.1111100101111100101111...)_{\text{Base }(-1+j)} \\ &= 0.7-j0.1 \end{aligned}$$

As another example, let w = (-28 - j15)Then

$$(-28 - j15) = (11011010011)_{\text{Base }(-1+j)}$$
  
= 1 × (-1 + j)<sup>10</sup>+1 × (-1 + j)<sup>9</sup>+0  
× (-1 + j)<sup>8</sup>+1 × (-1 + j)<sup>7</sup>+1  
× (-1 + j)<sup>6</sup>+0 × (-1 + j)<sup>5</sup>+1  
× (-1 + j)<sup>4</sup>+0 × (-1 + j)<sup>3</sup>+0  
× (-1 + j)<sup>2</sup>+1 × (-1 + j)<sup>1</sup>+1  
× (-1 + j)<sup>0</sup> ⇒ k = 10

We begin by choosing

$$z_0 = (-1+j)^{-k} = (-1+j)^{-10} = j0.03125$$
  

$$z_1 = z_0(2 - wz_0) = -0.02734375 + j0.0478515625$$
  

$$z_2 = z_1(2 - wz_1) = -0.05861282347 - j0.0007009506465$$
  

$$z_3 = z_2(2 - wz_2) = -0.02227897905 + j0.05242341786$$
  

$$z_4 = z_3(2 - wz_3) = -0.07257188256 + j0.005664255473$$
  

$$z_5 = z_4(2 - wz_4) = 0.01375684714 + j0.06682774792$$
  

$$z_6 = z_5(2 - wz_5) = -0.1198139965 + j0.1209880304$$
  

$$z_7 = z_6(2 - wz_6) = 0.1873379177 - j0.5740439146$$

$$z_8 = z_7(2 - wz_7) = -4.643184188 - j11.58680236$$
$$z_9 = z_8(2 - wz_8) = -4778.731320 + j1299.184773$$

As evident from the above calculations, the value of z is not converging with each successive iteration. Therefore, we correct our initial approximation to:

$$z_{0} = j(-1+j)^{-k} = j(-1+j)^{-10} = -0.03125$$

$$z_{1} = z_{0}(2 - wz_{0}) = -0.03515625 + j0.0146484375$$

$$z_{2} = z_{1}(2 - wz_{1}) = -0.02626419066 + j0.01577854156$$

$$z_{3} = z_{2}(2 - wz_{2}) = -0.02775239316 + j0.01496276824$$

$$z_{4} = z_{3}(2 - wz_{3}) = -0.02775050252 + j0.01486605276$$

$$z_{5} = z_{4}(2 - wz_{4}) = -0.02775024777 + j0.01486620416$$

$$z_{6} = z_{5}(2 - wz_{5}) = -0.02775024777 + j0.01486620416$$

$$z_{7} = z_{6}(2 - wz_{6}) = -0.02775024777 + j0.01486620416$$

$$z_{8} = z_{7}(2 - wz_{7}) = -0.02775024777 + j0.01486620416$$

$$z_{9} = z_{8}(2 - wz_{8}) = -0.02775024777 + j0.01486620416$$

As is clear from the above calculations, the value of z is converging to (-0.0277 + j0.0148). This value of z can be multiplied with any given complex number (numerator) to obtain the result of dividing the complex number by (-28 - j15), as in previous example.

#### 3.5 Effect of Shift-Left Operations on Complex Binary Numbers

To investigate the effects of shift-left (1, 2, 3, and 4-bits) operations on a complex number represented in CBNS format, a computer program was developed in C++ language which allowed (i) variations in magnitude and sign of both real and imaginary components of a complex number to be generated automatically in a linear fashion, and (ii) decomposition of the complex number after the shift-left operation, represented in CBNS format, into its real and imaginary components [6–8]. The length of the original binary bit array was restricted to 800 bits and 0s were padded on the left side of the binary data when the given complex number required less than maximum allowable bits for representation in CBNS format before the shift operation. As an example, consider the following complex number:

Before padding

$$(90 + j90)_{10} = (110100010001000)_{\text{Base }(-1+j)}$$

After padding

$$(90 + j90)_{10} = (0...0110100010001000)_{\text{Base }(-1+j)}$$

such that the total size of the binary array is 800 bits. Shifting this binary array by 1-bit to the left will yield  $(0 \dots 01101000100010000)_{\text{Base}(-1+i)}$  by removing one 0 from the left side and appending it to the right side of the number, ensuring that total array size remains 800 bits. Similarly, shifting of the original binary array by 2, 3, or 4-bits to the left will yield  $(0...01101000100000)_{Base(-1+i)}$  (notice two 0s appended on the right-side of the array),  $(0 \dots 01101000 \ 10001000000)_{\text{Base}(-1+j)}$ (notice three 0s appended on the right-side of the array),  $(0 \dots 0110100010001000000)_{\text{Base}(-1+i)}$  (notice four 0s appended on the right-side of the array), ensuring all the time that total arraysize remains 800 bits by removing two 0s, three 0s, and four 0s, respectively, from the left side of the original array.

Table 3.3 presents characteristic equations describing complex numbers in CBNS format after shift-left operations. We have assumed that initially our complex number is given by  $\pm Real_{old} \pm jImag_{old}$  and, after shift-left operation by 1, 2, 3, or 4-bits is represented by  $\pm Real_{new} \pm jImag_{new}$ .

Type of complex number	Shift-left by 1	-bit	Shift-left by 2	Shift-left by 2-bits	
	Real <sub>new</sub>	Imag <sub>new</sub>	Real <sub>new</sub>	Imag <sub>new</sub>

 Table 3.3 Characteristic equations describing complex numbers in CBNS format after shift-left operations [7, 8]

#### 3.6 Effect of Shift-Right Operations on Complex Binary Numbers

To investigate the effects of shift-right (1, 2, 3, and 4-bits) operations on a complex number represented in CBNS format, a computer program, similar to the one used for shift-left operations, was developed in C++ language which allowed (i) variations in magnitude and sign of both real and imaginary components of a complex number to be generated automatically in a linear fashion, and (ii) decomposition of the complex number after the shift-right operation, represented in CBNS format, into its real and imaginary components [8–10]. The length of the original binary bit array was restricted to 800 bits, as before for shift-left operations, and 0s were padded on the left-side of the binary data when the given complex number required less than maximum allowable bits for representation in CBNS format. Shifting the padded binary string by 1, 2, 3, and 4-bits to the right caused one, two, three, and four 0s to be inserted on the left-side of the string such that the total length of the string remained 800 bits.

Table 3.4 presents characteristic equations describing complex numbers in CBNS format after shift-right operations. Here, again we have assumed that initially our complex number is given by  $\pm Real_{old} \pm jImag_{old}$  and, after shift-right operation by 1, 2, 3, or 4-bits is represented by  $\pm Real_{new} \pm jImag_{new}$ .

Type of complex number	Shift-right by 1-bit		Shift-right by 2-bits		
	Real <sub>new</sub>	Imag <sub>new</sub>	Real <sub>new</sub>	Imag <sub>new</sub>	
Positive Real	$-1/2 \text{ Real}_{old} + 1/4$	-1/2 Real <sub>old</sub> +1/4	0	+1/2 Real <sub>old</sub> -1/4	
Negative Real	-1/2 Real <sub>old</sub> +1/4	-1/2 Real <sub>old</sub> +1/4	0	+1/2 Real <sub>old</sub> -1/4	
Positive Imag	1/2 Imag <sub>old</sub> +1/4	-1/2 Imag <sub>old</sub> + $1/4$	-1/2 Imag <sub>old</sub> + $1/4$	0	
Negative Imag	1/2 Imag <sub>old</sub> +1/4	-1/2 Imag <sub>old</sub> + $1/4$	-1/2 Imag <sub>old</sub> +1/4	0	
+Real +Imag	0	- Imag <sub>old</sub>	-1/2 Real <sub>old</sub> +1/4	1/2 Imag <sub>old</sub> +1/4	
+Real –Imag	-Real <sub>old</sub>	0	1/2 Real <sub>old</sub> +1/4	1/2 Imag <sub>old</sub> +1/4	
-Real +Imag	Real <sub>old</sub>	0	1/2 Real <sub>old</sub> +1/4	-1/2 Imag <sub>old</sub> +1/4	
-Real -Imag	0	-Imag <sub>old</sub>	-1/2 Real <sub>old</sub> +1/4	1/2 Imag <sub>old</sub> +1/4	
Type of complex number	Shift-right by 3	-bits	Shift-right b	y 4-bits	
	Real <sub>new</sub>	Imag <sub>new</sub>	Real <sub>new</sub>	Imag <sub>new</sub>	
Positive Real	1/4 Real <sub>old</sub>	-1/4 Real <sub>old</sub>	-1/4 Real <sub>old</sub>	ı 0

# Chapter 4 Arithmetic Circuits Designs

**Abstract** The algorithms for arithmetic operations in CBNS, described in the previous chapter, have been implemented in computer hardware using Field Programmable Gate Arrays (FPGAs). This chapter includes design information for a nibble-size (four bits) adder, subtractor, multiplier, and divider circuits utilizing CBNS for representation of complex numbers. The implementation and performance statistics related to these circuits are also presented.

#### 4.1 Adder Circuit for Complex Binary Numbers

There have been three known designs for CBNS-based adder circuits published in the scientific literature [1-5]. These circuits have been based on the concepts of minimum-delay, ripple-carry, and state-machine.

#### 4.1.1 Minimum-Delay Adder

The minimum-delay nibble-size CBNS adder has been designed by first writing a truth table with four-bit augend  $(a_3a_2a_1a_0)$  and addend  $(b_3b_2b_1b_0)$  operands as inputs (total of  $2^8 = 256$  minterms), and twelve outputs  $(c_{11}c_{10}c_9c_8c_7c_6c_5c_4s_3s_2s_1s_0)$  which are obtained by adding each pair of nibble-size inputs according to the addition algorithm described in Chap. 3. Each output is then expressed in sum-of-minterms form. The resulting design expressions have been implemented using an  $8 \times 256$  decoder (to generate each minterm) and multiple-input OR gates (to combine relevant minterms for each output).

Tables 4.1, 4.2, 4.3, 4.4, 4.5, 4.6, 4.7, 4.8 present complete truth table for a nibble-size minimum-delay complex binary adder. For the sake of simplicity, the

## 4.1.2 Ripple-Carry Adder

A nibble-size ripple-carry adder consists of typical half-adders, full-adders, and specially designed combinational circuit units. Basically, the adder performs the addition of two 4-bits complex binary numbers (augend:  $a_3a_2a_1a_0$  and addend:  $b_3b_2b_1b_0$ ) and generates a 4-bits Sum and up to 8 Extended-Carries. The block diagram of the ripple-carry adder consists of the Addition Unit, the Zero Detection Unit, the Extended-Carry Generation Unit, and the Output Generation Unit (Fig. 4.2).

The Addition Unit is structured from 4 semi-cascaded stages. Each stage is responsible for generating one of the Sum bits  $(S_0S_1S_2S_3)$ . In CBNS, the addition of two bits at stage *i* produces two carries that propagate to stages i + 2 and i + 3. Since no carry-in(s) to the adder is assumed, stages 0 and 1 are easily implemented using 2 half-adders.

Stage 2 is implemented using a full-adder with a carry-in generated from stage 0. For stage 3, a specially designed 4-input binary variables adding component has been implemented. Stage 3 performs the addition of bits  $a_3$  and  $b_3$  of the Augend and Addend with two possible carries referred to as  $K_{31}$  and  $K_{32}$ , which may be generated from stages 0 and 1, respectively. The stage produces result bit  $S_3$  and two carry bits,  $C_3$  and  $Q_3$ , according to the truth table for addition.  $C_3$  is a normal carry due to adding three ones (1 + 1 + 1), and  $Q_3$  is an extended carry due to adding four ones (1 + 1 + 1 + 1) in complex binary representation.  $C_3$  should propagate to stages 5 and 6, and  $Q_3$  to stages 7, 9,10, and 11. Since the adder performs 4-bit complex binary addition, the carries  $C_2$ ,  $C_3$ , and  $Q_3$  are taken to the inputs of the Extended-Carry Generation Unit in order to generate all the necessary carries. All carries generated by stages 2 and 3 are handled by dummy stages in the Extended-Carry Generation Unit, referred to by stages 4–11. This Unit would generate the extended carries ( $C_4C_5C_6C_7C_8C_9C_{10}C_{11}$ ) as inputs to the Output Generation Unit.

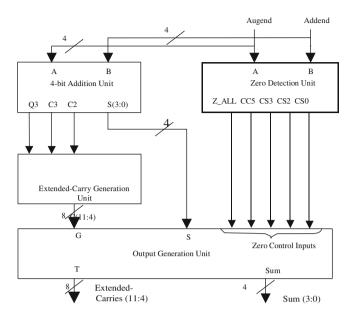

Fig. 4.2 Block diagram of a nibble-size ripple-carry complex binary adder [2, 3]

The Boolean expressions for stages 0, 1, and 2 are obvious from the use of half-adder and full-adder designs. For stage 3, the Boolean expressions for the outputs are found from the minimization of four-variable Karnaugh maps. These are:

$$S_3 = a_3 \oplus b_3 \oplus K_{31} \oplus K_{32} \tag{4.1}$$

$$C_3 = \overline{a_3}K_{31}K_{32} + b_3K_{31}\overline{K_{32}} + a_3\overline{b_3}K_{31} + a_3\overline{K_{31}}K_{32} + a_3b_3\overline{K_{31}} + b_3\overline{K_{31}}K_{32}$$
(4.2)

$$Q_3 = a_3 b_3 K_{31} K_{32} \tag{4.3}$$

The  $S_3$  expression is a four-input odd function which can be implemented using Exclusive-OR gates, the  $Q_3$  expression is a four-input AND function, and the  $C_3$  expression is a sum-of-products expression which can be implemented using AND-OR or NAND-NAND logic gates.

The Zero Detection Unit determines the conditions necessary to generate special output results based on the recognition of specific patterns for the Addend and the Augend. The conditions considered are based on the Zero Rule for the complex binary addition. This Unit receives nibble-size augend and addend inputs and generates five control signals: CS<sub>0</sub>, CS<sub>2</sub>, CS<sub>3</sub>, CS<sub>5</sub>, and Z\_ALL based on the

patterns satisfying the Zero Rule. Table 4.11 lists all the minterms that will generate special output results. The Boolean expressions characterizing each control input are given as follows:

$$CS_0 = \sum(111, 126, 231, 239, 246, 254)$$
(4.4)

$$CS_0 = (a_2 a_1 b_2 b_1) \left( \overline{a_0} b_3 b_0 + a_0 b_3 \overline{b_0} + a_3 b_3 (a_0 \oplus b_0) \right)$$
(4.5)

$$CS_2 = \sum (119, 127, 247, 255) = a_2 a_1 a_0 b_2 b_1 b_0$$
(4.6)

$$CS_3 = \sum(63, 123, 127, 183, 238, 239, 243, 247, 254) \tag{4.7}$$

$$CS_{3} = (a_{1}b_{1})\left(\overline{a_{3}}a_{0}b_{3}b_{2}b_{0} + a_{3}a_{0}\overline{b_{3}}b_{2}b_{0} + a_{3}a_{2}b_{3}b_{2}\overline{b_{0}} + \overline{a_{3}}a_{2}a_{0}b_{3}b_{0} + a_{3}a_{2}\overline{a_{0}}b_{3}b_{2}\right)$$

$$(4.8)$$

$$CS_5 = \sum (191, 251, 255) \tag{4.9}$$

$$CS_5 = (a_3a_2a_1a_0b_3b_1b_0 + a_3a_1a_0b_3b_2b_1b_0)$$
(4.10)

$$Z_{ALL} = \sum (155, 110, 115, 230) \tag{4.11}$$

$$Z_{\text{ALL}} = (a_1b_1) \left( \overline{a_3} a_0 \overline{b_3} b_0 (a_2 \oplus b_2) + a_2 \overline{a_0} b_2 \overline{b_0} (a_3 \oplus b_3) \right)$$
(4.12)

The Output Generation Unit receives the control signals,  $(CS_0, CS_2, CS_3, CS_5,$ and Z\_ALL), from the Zero Detection Unit, the Sum bits  $(S_0S_1S_2S_3)$  from the Addition Unit, and the extended-carries  $(C_4C_5C_6C_7C_8C_9C_{10}C_{11})$  from the Extended Carry-Generation Unit. It, then, determines the actual result of addition (Sum (3:0) and Extended Carries (T11:T4)) according to the control signals described above.

## 4.1.3 State-Machine Adder

The design of this adder is based on using a state machine to store the logic details rather than designing the addition and carry operations with discrete components. This approach results in a very simple circuit implementation and does not impose any limit on the size of the operands. The entire adder consists of a few gates to add single bits from the input numbers, memory to hold the state and output information, and a register to store the current state (in effect, the carry to the next addition). Since the operations are done bit-by-bit, the adder itself imposes no limitations on the sizes of the numbers to be added. The state machine is not aware of the number of bits in the input numbers. The only requirement is to make sure that the inputs are sufficiently padded with high-order zeroes to allow for the carry from the addition of the high-order bits of the input numbers. Depending on the carry-in from the previous addition and the values of the two current bits to be added, a carry of up to 8 bits may result. Consequently, 8 bits of padding of high-order zeroes would be required to correctly complete the addition.

The logic of the adder is stored in a state table. Each entry of the table contains the next state of the state machine and the output from the last addition operation. The table is organized into three sections, one for each state transition. A transition is determined by the result of the addition of the next two input bits. There are three results—(i) 0 + 0, (ii) 0 + 1 or 1 + 0, and (iii) 1 + 1. The result selects the particular section of the state table to use for determining the next state and output. The input to the state machine is the sum of the current two binary bits to be added. The current state is composed of the carry out of the previous operation. The next state (and single bit output for the current addition) is found in the memory location formed by the concatenation of the input and current state bits as described above.

The state table is shown in Tables 4.12, 4.13 and the state diagram is given in Fig. 4.3. The state table was constructed by:

- (i) Starting with a sum of 0 and a carry in (current state) of 0.
- (ii) Adding 0, 1, or 2. (The sum of input bits A and B).
- (iii) Shifting out the low order sum bit (The sum will be a single binary bit, 0 or 1 and a carry. The result of 0 plus 0 is 0 with no carry, 0 plus 1 is 1 with no carry, and 1 plus 1 is 0 with a carry of 110).
- (iv) Repeating the above until all possible results were produced.

(1) Memory location (current state)	(2) Contents (Hex)	(3) Previous carry	(4) Add	(5) Result	(6) After shift	(7) Next state	(8) Output

 Table 4.12
 Adder state table [4]

It can be seen that there are 15 states (representing carries from a previous operation) and 3 inputs per state resulting in 45 state transitions. For each transition the output is 1 or 0. For the purposes of this implementation, an additional redundant state was added simply to fill the 16 memory locations that were

Table 4.13 Adder state table [4]

available. This additional state serves no other purpose and could be deleted with no effect on the operation of the adder.

It should be noted that the adder does not actually add inputs A and B to a previous carry operation. It only changes state based on the current input and current state. The states represent the result of addition operations. The actual result (0 or 1) of the addition of the two current input bits is stored in the state memory and is generated as output as the state changes.

Following is a description of the columns of the adder state table (Tables 4.12, 4.13):

Column Number (1) Memory Location (Current State): Memory is arranged in three banks. Each bank contains 16 locations, 00–15 representing the current state. In a physical implementation various combinations of memory sizes could be used. For example a single 48-location memory or three 16-location memories could be used. Column (1) is the memory location number in decimal. The location is shown only for the first bank of memory. There are three rows of data for each location. Each row corresponds to a bank of memory. For example for location '00', the first row corresponds to location '00' for bank 1, the second row to location '00' for bank 2, and the third row to location '00' for bank 3.

*Column Number (2) Contents (Hex):* The contents of each memory location of each bank are shown in hexadecimal. For example, for memory location '06', bank 1 contains x'04' or binary 00000100. Bank 2 contains x'84' or binary 10000100. These values represent the output and next state. The output bit is in the high order location (leftmost bit). The next state is in the 4 low order bits (4 rightmost bits). For example, memory location 13, bank1 contains x'8F' or binary 10001111. The high order bit is 1 and is the output bit when the current state is 13 and 0000 (see column 3 and 4 explanation) is added via input bits A and B (both A and B are 0). The four low order bits '1111' are the next state. The next state is shown in decimal in column 7. It corresponds to the four low order bits of column 2.

Column Number (3) Previous Carry: This column shows the carry from the result of the addition of the previous two bits. The memory location in column 1 is

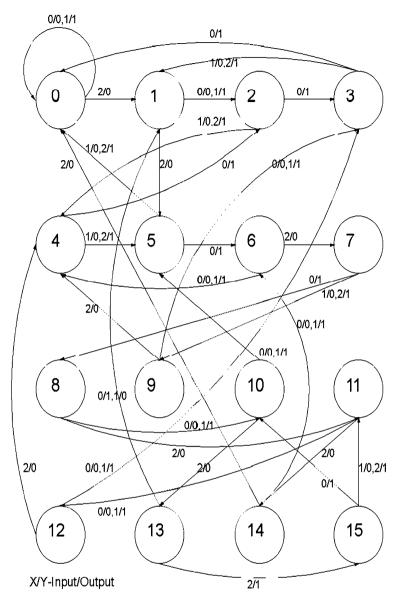

Fig. 4.3 Adder state diagram [4]

the representation of this value. The addition of input numbers A and B and the previous carry is done in the adder by considering the previous carry as the current state and the sum of A and B as selecting the particular state transition from the current state.

*Column Number (4) Add:* This column shows the sum of input bits A and B that is added to the previous carry. The sum actually results in a selection of the memory bank to use for finding the next state. If the sum is 0000 (both A and B are 0), bank 1 is used. If the sum is 0001 (either A or B is one), bank 2 is used. If the sum is 1100 (both A and B are 1), bank 3 is used. The value of the previous state is used to access the memory location of the selected bank to get the next state and output bit.

*Column Number (5) Result:* The result of adding columns (4) and (3) is shown. This addition is not actually performed by the adder. This result after shifting right by one bit is assigned a state number to be used for the next operation. The result after shifting is in column (6). The state number is shown in column (7).

*Column Number (6) After Shift:* This column shows the result of shifting column 5 right by one bit. This is the operation that would be performed to get ready to add the next two values of input bits A and B. The value is assigned a state number (column 7) that is the next state (column 1).

*Column Number (7) Next State:* This number represents the value in column (6). It is the memory location that is used in the next decoding operation. The sum of input bits A and B select the memory bank to use. Column (6) addresses the location within the bank.

*Column Number* (8) *Output:* This is the bit that is output as a result of adding A, B, and the carry operation from the previous addition operation.

Let us add 1 and 1 using the state diagram (Fig. 4.3). Assuming the initial state is 0, the addition of input bit A = 1 and B = 1 results in an input of 2 (in decimal), output of 0, and next state of 1. The next values of A and B are 0, so the next input is 0, output is 0 and next state is 2. Again A and B are 0, the input is 0, the output now is 1, and the next state is 3. Again A and B are 0, the input is 0, the output is again 1, and the next state is 0. (The output to this point is  $1100_{\text{Base }(-1+j)}$  which is  $2_{10}$  as it should be). A and B are 0 for the rest of the 32-bit sequence. The input is 0, the output is 0, and the next state is 0 for all remaining input bits. The same sequence can be followed in the state table.

## 4.1.4 Implementations and Performance Evaluations

Both minimum-delay and ripple-carry adders (nibble-size) have been implemented on Xilinx Virtex FPGA and implementation statistics obtained are given in Table 4.14 [3].

Traditional Base-2 binary adder implementation statistics are also given in Table 4.14. The speed-up comparisons of the four adders' designs are given in Table 4.15.

A functional diagram of the state-machine adder, which can be implemented, is shown in Fig. 4.4 [4]. Data are input by storing two complex binary base numbers in the input memories. The numbers are shifted serially, least significant bit first

	Complex bina	ry adders	Base-2 binary	adders

into the single-bit adder section. As discussed previously the adder merely selects a memory bank to use based on the values of the input bits (00, 01 or 10, or 11). The 'state and output' memory holds the state values and output for a given state transition. The result is shifted into the output shift registers and the carry is saved in a register for addition to the next two input bits. A master clock synchronizes all operations. An implementation (summarized below) allows addition of two 32-bit

numbers. No provision was made for carries beyond 32 bits. In the earlier discussion of the adder state machine it was noted that a carry out value could be up to 8 bits. So, if the input numbers are limited to 24 bits, a maximum size carry could always be handled.

Addition of numbers of any length could be accommodated by expanding the input memory and output shift register length. The adder itself is a single-bit adder. An actual implementation in a digital computing system would use some other form of input and output such as general-purpose registers. Also, provision for carry beyond the maximum register length would be made. In short, there is no limitation to the length of numbers that can be added other than that imposed by the input and output devices. An implementation of the adder was accomplished using System-View, a modeling and simulation tool that provides tokens representing memories, gates, and other devices from which systems may be constructed. The results of output operations can be plotted using 'sink' tokens. For example the display of the results of an addition shifted into the output shift register is shown in Fig. 4.5. On the plot of Token 57 data, the results are read right to left (least significant bit of the sum is on the left). The timescale is arbitrary.

In a physical implementation of the circuit, the main component of delay and thus a limit on performance would typically be the time required to address the memory with the results of the addition operation and store the result in the 'current state' register. Otherwise the addition speed would be limited only by the speed of the logic gates at input and output.

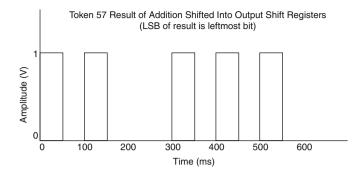

Fig. 4.5 Addition result shifted into output shift registers [4]

In the SystemView implementation numbers to be added (for example 2 and -j) are placed in the input memories. In CBNS, 2 is 1100 or *xC* in hexadecimal. Similarly, in CBNS, -j is 111 or *x*7 in hexadecimal. So, *xC* is entered in one memory and *x*7 is entered in the other. The result can be viewed from the plot of Token 57 (Fig. 4.5). Reading from right to left the result is  $111011_{\text{Base }(-1+j)}$ . An expansion of this number as coefficients of powers of (-1 + j) shows it to be (2 - j).

## 4.2 Subtractor Circuit for Complex Binary Numbers

A minimum-delay nibble-size subtractor for complex binary numbers has been presented in [5, 6].

#### 4.2.1 Minimum-Delay Subtractor

The minimum-delay nibble-size CBNS subtractor has been designed following a procedure similar to what has been described for the adder circuit in Chap. 3. The procedure involves writing a truth table with four-bit minuend  $(a_3a_2a_1a_0)$  and subtrahend  $(b_3b_2b_1b_0)$  operands as inputs (total of  $2^8 = 256$  minterms) and 11 outputs  $(d_{10}d_9d_8d_7d_6d_5d_4d_3d_2d_1d_0)$  which are obtained by subtracting each pair of nibble-size inputs according to the subtraction procedure described in Chap. 3. Each output is then expressed in sum-of-minterms form. The resulting design expressions have been implemented using an  $8 \times 256$  decoder (to generate each minterm) and multiple-input OR gates (to combine relevant minterms for each output).

Tables 4.16, 4.17, 4.18, 4.19, 4.20, 4.21, 4.22, 4.23 present complete truth table for a nibble-size minimum-delay complex binary subtractor. For the sake of simplicity the 11 outputs have been collectively labeled as "Difference" in these tables. The sum-of-minterms expressions for outputs of the subtractor are listed in Tables 4.24, 4.25. Block diagram of the subtractor is given in Fig. 4.6.

# 4.3 Multiplier Circuit for Complex Binary Numbers

A minimum-delay nibble-size multiplier for complex binary numbers has been presented in [5, 7].

#### 4.3.1 Minimum-Delay Multiplier

The minimum-delay nibble-size CBNS multiplier has been designed following a procedure similar to what has been described for the adder and subtractor circuits in Sects. 4.1.1 and 4.2.1 respectively. The procedure involves writing a truth table with four-bit multiplicand ( $a_3a_2a_1a_0$ ) and multiplier ( $b_3b_2b_1b_0$ ) operands as inputs (total of  $2^8 = 256$  minterms) and 12 outputs ( $p_{11}p_{10}p_9p_8p_7p_6p_5p_4p_3p_2p_1p_0$ ) which are obtained by multiplying each pair of nibble-size inputs according to the multiplication procedure described in Chap. 3. Each output is then expressed in sum-of-minterms form. The resulting design expressions have been implemented using an 8 × 256 decoder (to generate each minterm) and multiple-input OR gates (to combine relevant minterms for each output).

Tables 4.27, 4.28, 4.29, 4.30, 4.31, 4.32, 4.33, 4.34 present complete truth table for a nibble-size minimum-delay complex binary multiplier circuit and the sum-of-minterms expressions for outputs of the multiplier circuit are listed in Table 4.35, 4.36. Block diagram of the multiplier circuit is given in Fig. 4.7.

## 4.4 Divider Circuit for Complex Binary Numbers

A minimum-delay nibble-size divider for complex binary numbers has been presented in [5, 8].

## 4.4.1 Minimum-Delay Divider

The minimum-delay nibble-size CBNS divider has been designed following a procedure similar to what has been described for the adder, subtractor, and multiplier circuits in Sects. 4.1.1, 4.2.1, and 4.3.1 respectively. The procedure involves writing a truth table with four-bit dividend or numerator  $(a_3a_2a_1a_0)$  and divisor or denominator  $(b_3b_2b_1b_0)$  operands as inputs (total of  $2^8 = 256$  minterms) and ten outputs  $(R_0R_8R_7R_6R_5R_4R_3R_2R_1R_0)$  which are obtained by dividing each pair of dividend and divisor according to the division procedure described in Chap. 3. Since the result of division operation contains small fractions for some sets of operands, it has been rounded off by converging numbers less than 0.5 to 0 and numbers greater than or equal to 0.5 to 1. This step is taken to avoid representing fractional numbers in CBNS. As a result, some degree of error in the final result has been introduced and, therefore, the resulting circuit can best be described as an "approximate" divider circuit. Each output of the divider circuit has been expressed in sum-of-minterms form and the design is implemented using an  $8 \times 256$  decoder (to generate each minterm) and multiple-input OR gates (to combine relevant minterms for each output).

Tables 4.38, 4.39, 4.40, 4.41, 4.42, 4.43, 4.44, 4.45 present complete truth table for a nibble-size minimum-delay complex binary divider circuit and the sum-ofminterms expressions for outputs of the multiplier circuit are listed in Table 4.46. Block diagram of the divider circuit is given in Fig. 4.8.

# Chapter 5 Complex Binary Associative Dataflow Processor Design

**Abstract** Complex Binary Number System provides an effective method to represent complex numbers in binary notation and, as discussed in the previous chapters, allows basic arithmetic operations to be performed on complex numbers with a better degree of efficiency. Associative dataflow paradigm provides a novel technique to do parallel processing within digital signal and image processing applications. It is, therefore, imperative to study the possibility of amalgamating the unique representation of complex numbers with an efficient parallel processing technique to come up with 'complex binary associative dataflow' processing. In this chapter, we are going to outline the design of a complex binary associative dataflow processor (CBADP) for which an Innovative Patent has been granted by the Australian Patent Office (IP-Australia).

## 5.1 Review of Complex Binary Number System

To completely understand the design of CBADP, let us first review complex binary number system [1]. The value of an *n*-bit complex binary number can be written in the form of a power series as follows:

$$a_{n-1}(-1+j)^{n-1} + a_{n-2}(-1+j)^{n-1} + a_{n-3}(-1+j)^{n-3} + a_{n-4}(-1+j)^{n-4} + \cdots + a_2(-1+j)^2 + a_1(-1+j)^1 + a_0(-1+j)^0$$
(5.1)

where the coefficients  $a_{n-1}, a_{n-2}, a_{n-3}, a_{n-4}, \ldots, a_2a_1a_0$  are binary (0 or 1) and (-1+j) is the base of the CBNS. By applying the conversion algorithms described in Chap. 2, we can represent any given complex number in a unique single-unit binary string, as shown in the following examples:

$$2012_{10} + j2012_{10} = 1110100000001110100011100000_{\text{Base }(-1+j)}$$
$$-60_{10} - j2000_{10} = 111010000000001101011010000_{\text{Base }(-1+j)}$$
$$(0.351 + j0.351)_{\text{Base10}} = 0.0110100011110101111110001001..._{\text{Base}(-1=j)}$$
$$(60.4375 + j60.4375)_{10} = 10000011101110.1000011_{\text{Base }(-1+j)}$$

The arithmetic operations in CBNS, discussed in Chap. 3, follow similar procedure as the traditional Base-2 number system with the exceptions that, in CBNS addition,  $1_{10} + 1_{10} = 2_{10} = (1100)_{\text{Base}(-1+j)}$  and, in CBNS subtraction,  $0_{10} - 1_{10} = -1_{10} = 11101_{\text{Base}(-1+j)}$ . In CBNS multiplication, *zero rule* (111 + 11 = 0) plays an important role in reducing number of intermediate summands and, in CBNS division, we take the reciprocal of the denominator and multiply it with the numerator to get the result of division operation. Finally, in Chap. 4, we have presented individual designs of nibble-size adder, subtractor, multiplier, and divider circuits which can together be incorporated into an arithmetic and logic unit for complex binary numbers (CBALU).

## 5.2 What is Associative Dataflow Concept?

Of the currently prevalent ideas for building computers, the two well known and well developed are the control flow and the dataflow [2]. However, both these models are beset with limitations and weaknesses in exploiting parallelism to the utmost limit. Control-flow model lacks useful mathematical properties for program verification and is inherently sequential. The dataflow model, on the other hand, is based on partial ordering of the execution model and offers many attractive properties for parallel processing, including asynchrony and freedom from side-effects. However, a closer examination of the problems linked with dataflow model of computations. These tokens need to be matched up with their partner token(s) prior to any operation to be carried out. This involves a time-consuming search process which results in degradation of overall performance. Since associative or content-addressable memories (AMs or CAMs) allow for a parallel search at a much faster rate, their use within the dataflow environment has been investigated under the concept of associative dataflow.

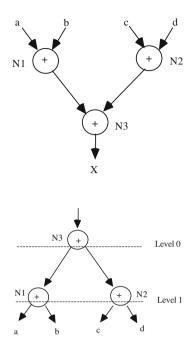

Eliminating the need for generating and handling tokens during the execution of a program, the associative dataflow model of computation processes a dataflow graph (program) in two phases: the search phase and the execution phase. During the search phase, the dataflow graph is conceptually assumed to be upside down and each node at the top of the hierarchy is considered to be the parent of the nodes which are connected to it through the arcs, referred to as children. Taking advantage

Fig. 5.1 Dataflow graph to compute X = a + b + c + d [1]

of the parallel search capabilities rendered by associative memories, the idea behind the search phase is for each parent node to search for its children. Once this search is completed, each node will know what its operands are and where the destination node(s) for the result is. During the execution phase, the operations will be performed as in conventional dataflow paradigm except the fact that now the matching of tokens will no longer be required. Thus, by eliminating tokens from the dataflow environment and using the search capabilities of associative memories, better performance can be achieved in parallel computers.

To better understand the concept of parent and children nodes, let us consider a simple dataflow graph to compute X = a + b + c + d (Fig. 5.1). The search phase of the associative dataflow concept requires that the given dataflow graph be turned upside-down in order for each parent to search for its children. The inverted dataflow graph to allow progress of this search phase is shown in Fig. 5.2, wherein the node at the top (N3) is at level 0, and the nodes N1 and N2 are at level 1. Node at level 0, i.e., N3, is the parent of the nodes at level 1, i.e., N1 and N2, or in other words, the nodes N1 and N2 at level 1 are the children of the nodes N1 and N2, respectively. During the search phase, each parent node will search for its children and, during the execution phase, the operations will be performed as in conventional dataflow paradigm, except the fact that now there will be no delay due to the matching of the tokens.

#### 5.3 Complex Binary Associative Dataflow Processor

Utilizing CBNS to represent complex numbers within associative dataflow processing (ADP) environment will enable us to take the best of both worlds (computer arithmetic and computer architecture) in an effort to achieve better degree of efficiency within digital signal and image processing applications. CBADP, which aims to combine CBNS with ADP, is the hardware realization of these efforts. A schematic block diagram for CBADP is shown in Fig. 5.3.

CBADP consists of following components:

- (i) Associative memory (AM) to collect and store the data needed for carrying out the given parallel computation, to store the dataflow graph in a format so as to permit the implementation of search phase of the associative dataflow concept, and to feed the data to the Processing Unit for computation of the result.
- (ii) Processing unit (PU) containing four complex binary arithmetic and logic units (CBALUs) to compute the results of the operations carried out on the operands (represented in CBNS) and to set appropriate flags in the flags registers (FRs), to forward these results to the appropriate word within the AM (for onward processing at the next dataflow graph level) or to the output registers (ZRs) (for final result).

- (iii) Level incrementer/decrementer unit (LIDU) to increment the current level number by one and to forward the new level number to the AM during the search phase or to decrement the current level number by one and to forward the new level number to the PU during the execution phase.
- (iv) Control unit (CU) is hardwired with the task of generating appropriate control signals for search phase and execution phase.
- (v) Counter-value register (CR) is used to store the counter value at the completion of each successful search phase.
- (vi) Level register (LR) contains information about the maximum level number in the given dataflow graph.
- (vii) Flags registers (FRs), one register corresponding to each CBALU, store the flags as a result of completion of an operation.
- (viii) Output registers (ZRs), one register corresponding to each CBALU, store the result of the operation and make it available to the input/output system (IOS) for reading purposes.

# 5.4 Australian Innovation Patent No. 2010100706

An Australian Innovation Patent No. 2010100706 entitled Complex Binary Associative Dataflow Processor, describing the above design, has been granted in July 2010, details of which can be accessed at the following website address: http://pericles.ipaustralia.gov.au/ols/auspat/applicationDetails.do?applicationNo= 2010100706.

# Chapter 6 Conclusion and Further Research

Abstract Complex Binary Number System (CBNS) with its uniqueness in representing complex numbers as a one-unit binary string holds great potential in the computer systems of tomorrow. With an innovative technique for parallel processing, such as associative dataflow, utilizing CBNS for representation of complex numbers, it is possible to leapfrog the speed of computing within today's signal and image processing applications. Preliminary work, spanning over two decades of research work and presented in this book, has shown good potential in this arena and scientists and engineers are urged to explore this avenue in the years to come. Although simulations of CBADP within digital signal and image processing applications and estimating performance evaluations will be very useful in the theoretical areas of computer architecture research, a complete working implementation of CBADP on a FPGA or an ASIC should be the ultimate goal of any researcher in this area.
