The condition of minimal liberalism, as outlined by Sen (1970, 1976), asserts that some choices between alternative social states may involve differences that are personal to some individual. For example, with everything else the same, Jack sleeps on his back (x) or on his belly (y). Such choices may be taken to be the concern only of the relevant person and to lie in that person's 'protected sphere' (Hayek, 1960).

Let us examine the nature of the conflict a little more closely in terms of two examples introduced into the discussion by Allan Gibbard (1974).

First, suppose that I have a right to choose the color of my bedroom walls. If I prefer white bedroom walls to yellow, then no matter who wants my walls to be yellow, it is preferable for them to be white. Condition L^* (unlike Condition L) claims that everyone has rights in this sense, or in the modest version put forward by Sen (1970) that everyone has at least one such right. Suppose now that I am a perverse non-conformist in that I want my bedroom walls to be a different color from Mrs. Grundy's. Mrs. Grundy, however, is a conformist. She wants her bedroom walls to be the same color as mine.

There are four social states available in this situation, namely a_{ww} , a_{wy} , a_{yw} , and a_{yy} . These social states differ only in the color of our respective bedroom walls. The first index gives the color of my walls and the second that of Mrs. Grundy's. Denoting P₁ for my preferences and P₂ for Mrs. Grundy's preferences, it follows respectively from $a_{yw}P_1a_{ww}$, $a_{ww}P_2a_{wy}$, $a_{wy}P_1a_{yy}$, and $a_{yy}P_2a_{yw}$ that $a_{yw}Pa_{ww}$, $a_{ww}Pa_{wy}$, $a_{wy}P_3a_{yy}$, and $a_{yy}P_2a_{yw}$ that $a_{yw}Pa_{ww}$, $a_{ww}Pa_{wy}$, $a_{wy}Pa_{yy}$, and $a_{yy}Pa_{yw}$. According to Condition L* each of the available alternatives ought not to be chosen. This is an interesting result because it demonstrates that a liberal paradox may arise without reference to the Pareto condition.

Second, suppose that Angelina wants to marry Edwin but will settle for marrying the judge, who wants whatever she wants. Edwin wants to remain single, but would rather marry Angelina than see her marry the judge. There are then three alternative social states:

W_E: Edwin weds Angelina;

 W_J : the judge weds Angelina and Edwin remains single; W_O : both Edwin and Angelina remain single.

Angelina prefers them in the order $W_E W_J W_O$; Edwin prefers them in the order $W_O W_E W_J$. Here Sen's notion of rights and the Pareto principle combine to yield a cycle. First, Angelina has a right to marry the willing judge instead of remaining single, and she prefers W_J to W_O . Hence $W_J P W_O$. Second, Edwin has the right to remain single rather than to wed Angelina, and he prefers W_O to W_E , where the only difference between the two is whether or not he weds her. Hence $W_O P W_E$. Finally, since all three prefer W_E to W_J , by Condition P we have $W_E P W_J$. The cycle is complete: $W_J P W_O$, $W_O P W_E$, and $W_E P W_J$. This outcome is known as *Gibbard's Paradox*.

In 1970, Sen was inclined to infer from the impossibility result that Condition P should be questioned in the context of social choice questions in which there are personal issues for which Condition L* makes sense. While recognizing that unanimity is a powerful reason for a policy to be pursued, Sen warned that it is important "not merely... to know who prefers what, but also *why* he has this preference" (Sen, 1970b, 83).

6. The Perspective of Game Theory

A number of critics of Sen's paradox utilize the social choice framework adopted by Sen (1970) while rejecting

		Lascivious		
		Reads LCL	Does Not Read LCL	
Prude	Reads LCL	a, c	b, c'	
	Does Not Read LCL	a′, d	b', d'	
	Figure 1:			

the particular notion of rights deployed in his analysis (Bernolz, 1974; Sugden, 1985; Buchanan, 1996). In the view of Bernholz (1974) and Buchanan (1996), rights are not to be interpreted to allow individuals to choose among social states. Rather, individuals are assigned rights "to control defined elements which, when combined with the exercise of mutually-compatible rights of others, will generate a social state as an outcome of an interaction process, not of a 'choice' as such, by either one or many persons" (Buchanan, 1996, 124). Nevertheless, rights are assigned through the political process, essentially as part of a constitutional contract. Sugden's (1985) view, which is much closer to our own, will be discussed later in this section.

Let us first focus on the view of Buchanan (1996), using the example of *Lady Chatterley's Lover*. Let us define four states of society as follows:

- I. Prude reads LCL; Lascivious reads LCL.
- II. Prude does not read LCL; Lascivious reads LCL.
- III. Prude reads LCL; Lascivious does not read LCL.
- IV. Prude does not read LCL; Lascivious does not read LCL.

In this depiction, unlike that of Sen (1970) the social state depicted by I is deemed to be possible. Its inclusion does not violate the spirit of his example. Figure 1 sets out these alternatives in matrix form.

According to Sen (1970), the payoffs for Prude are arrayed as follows: b' > b > a' > a. For Lascivious, the payoffs are arrayed as follows: c > c' > d > d'. In each case, these are payoffs over the full set of completed states. Sen's explicit ranking of social states guarantees that the independent adjustment outcome in Cell II is non-optimal in the sense that it is Pareto-dominated by the outcome in Cell III. Since Sen's purpose is limited to that of deriving an ordering over complete social states, there is no issue of assigning or partitioning rights among separate individuals.

However, if individuals are to be allowed to interact, one with another, as Buchanan (1996) suggests, their separate assignments in the interaction process must first be specified. At this stage, the rule of libertarianism comes into play. This rule assigns to each person a protected domain or sphere of private action that he can enforce, if he so desires, as a part of any social outcome. In the post-constitutional situation, once such rights have been assigned, the Pareto criterion offers a means of evaluating potential transfers of rights among individuals. "In the end, the 'meddlesome preferences' may prevail, but only if those who hold them are willing to pay for their exercise" (Buchanan, 1996, 124).

Sugden (1985) strips the starting point right out of the social choice mechanism. He views the notion of the personal sphere — the area of individual action that is protected against social encroachment — as a central idea in the tradition of classical liberal thought. On this he quotes John Stuart Mill (1848):

Whatever theory we adopt respecting the foundation of the social union, and under whatever political institutions we live, there is a circle around every individual human being which no government, be it that of one, of a few, or of the many, ought to be permitted to overstep..... That there is, or ought to be, some space in human existence thus entrenched around, and sacred from authoritative intrusion, no one who professes the smallest regard to freedom or dignity will call in question. (1848, Book 5, Ch. 11, Sec. 2).

Sugden (1985) utilizes this insight to offer a radically different interpretation of Gibbard's paradox to that accepted by Sen. Sugden illustrates this difference with an example more central to classical liberal doctrine than the color of walls. Let x be a social state in which one individual Liz writes a private diary expressing controversial political views. Let y be another social state identical to x in all respects accept that the sentiments Liz records in her diary are nonpolitical. According to Sen (1970) the pair of social states $\{x,y\}$ should be assigned to Liz's personal sphere. If Liz prefers x to y, this implies that she would not choose x if y were available to her. The tie between social preferences and choice is hypothetical.

Suppose now that there is a second person, Ken, who also keeps a personal diary and who also might or might not wish to record controversial political opinions. Then we may distinguish four social states: Let v be the state in which Liz and Ken both keep political diaries; let w be the state in which Liz's diary is nonpolitical and Ken's is political; let x be the state in which Liz's diary is political and Ken's is not; and let y be the state in which both diaries are nonpolitical.

According to Sen the pairs $\{v,x\}$ and $\{w,y\}$ should be assigned both to Liz and to Ken. The paradox is that if the two individuals' preferences happen to take certain forms, this assignment of pairs of social states to personal spheres generates a logical contradiction. Specifically, if Liz's preference ordering, in strict descending order, is x, w, v, y and if Ken's is v, y, w, x, then the assignment of pairs of social states to personal spheres generates a cycle of

Ken's Strategy						
Liz's strategy	Political	NonPolitical				
Political	V	х				
Nonpolitical	W	У				
Figure 2:						

social preference: x is socially preferred to y, y to w, w to v, and v to x.

In reality, however, in even remotely free societies, each individual chooses the content of his own diary. This is not a choice between social states. The content of any one person's diary is a characteristic of a social state and not a social state itself. According to Sugden (1985), the best way to describe this kind of procedure is as a game form (Figure 2).

It is not clear how Liz and Ken would play this game given the preferences outlined above. What strategy is best for Liz depends on what Ken is going to do, and vice versa. If they each choose according to maximin/minimax, then the outcome will be v. Both Liz and Ken will have political diaries. According to Sen, this outcome fails to respect Liz's personal sphere. The pair $\{w,v\}$ belongs to Liz's sphere and she prefers w to v. Therefore, society ought not to choose v if w is available. Her hypothetical choice is not being respected.

Yet, if liberty is understood in terms of noninterference, it is surely Liz's actual choice — to keep a political diary that has the first claim on society's respect. An uncompromising classical liberal would assert that each individual has a right to write whatever he chooses in a private diary, and that the whole purpose of the personal sphere is to protect that individual from other individuals' desires to meddle. This is so, argues Sugden (1985), even if "such a claim cannot be formulated in the language of conventional social choice theory" (Sugden, 1985, 229). In this judgement, Sugden comes close to our own view, though he still appears to allow personal spheres to be determined through the mechanism of social choice itself and he does not distinguish, as we shall, between rights and liberties.

7. The Perspective of Classical Liberal Political Economy

In his book, *On Liberty* (1859), John Stuart Mill set out to identify the nature and limits of the power that can be legitimately exercised by society over the individual. Under conditions of autocracy, the aim of patriots was to set limits to the power which the ruler should be suffered to exercise over the community; and this limitation was what was meant by liberty. As autocracy gave way to representative government, and as the holders of power were made regularly accountable to the community, Mill recognized that the limitation of the power of government over individuals loses none of its importance. The 'tyranny of the majority now must be included among the evils against which society requires to be on its guard (Mill, 1859, 8).

Society can and does execute its own mandates: and if it issues wrong mandates instead of right, or any mandates at all in things with which it ought not to meddle, it practices a social tyranny more formidable than many kinds of political expression, since though not usually upheld by such extreme penalties, it leaves fewer means of escape, penetrating much more deeply into the details of life, and enslaving the soul itself.

and

There is a limit to the legitimate interference of collective opinion with individual independence: and to find that limit, and maintain it against encroachment, is as indispensable to a good condition of human affairs, as protection against political despotism.

In *On Liberty*, Mill asserts one simple principle to govern the dealings of society with the individual in the way of compulsion and control: "the sole end for which mankind are warranted, individually or collectively, in interfering with the liberty or action of any of their number, is selfprotection....[t]he only purpose for which power can be rightfully exercised over any member of a civilized community, against his will, is to prevent harm to others. His own good, physical or moral, is not a sufficient warrant... Over himself, over his own body and mind, the individual is sovereign" (ibid., 13).

For Mill (1859) the freedom of an individual to act upon his own opinions at his own risk and peril, so long as such actions do not harm others, is essential to his development as a human being:

He who lets the world, or his own portion of it, choose his plan of life for him, has no need of any other faculty than the ape-like one of imitation. He who chooses his plan for himself, employs all his faculties. He must use observation t to see, reasoning and judgment to foresee, activity to gather materials for decision, discrimination to decide, and when he has decided, firmness and selfcontrol to hold to a deliberate decision. And these gualities he requires and exercises exactly in proportion as the part of his conduct which he determines according to his own judgment and feelings is a large one. It is possible that he might be guided in some good path, and kept out of harm's way without any of these things. But what will be his comparative worth as a human being? It really is of importance, not only what men do, but also the manner of men they are that do it. (ibid., 59).

Mill was especially energized to protect individuality from societal pressures to conform to so-called public opinion, recognizing that once such conformity has been established it is very difficult to jettison:

The demand that all other people shall resemble ourselves, grows by what it feeds on. If resistance waits till life is reduced *nearly* to one uniform type, all deviations from that type will come to be considered impious, immoral, even monstrous and contrary to nature. Mankind speedily become unable to conceive diversity, when they have been for some time unaccustomed to see it. (ibid., 74).

As many subsequent scholars have emphasized Mill's harm principle provides at best only necessary and not sufficient conditions for the restriction of liberty. It tells us that individual liberty may be limited only to prevent harm to others; it does not indicate which circumstances constitute harms of sufficient magnitude and it does not identify how great an imposition on liberty is justified in order to preclude such harms.

In *Before Resorting to Politics* (1996), Jasay addresses these *lacunae*. He argues that the Kaldor-Hicks potential compensation test, central to modern welfare economics, provides an unsound guide to political action because it cannot resolve the fundamental problem posed by Pareto of making interpersonal comparisons of utility. Where no balance can be struck between the good and the bad consequences of political action, Jasay suggests that the Hippocratic precept applies: "*first, avoid doing harm*" (Jasay, 1996, 5–9).

Making sure to avoid doing harm before trying to do good sets a strong presumption against balancing offsetting interests and determining which should carry a greater weight. Such a precept ensures that the individual should be free to do whatever is not expressly forbidden rather than that he should be allowed to do only what has been expressly approved by the state (Jasay, 1997).

This presumption against using the coercive powers of the state mandates some bounding of the domain of politics and the removal of at least some alternatives from the reach of social choice. From the particular perspective of the paradoxes raised in the Sen literature, the basic rule derived from Jasay's (1996, 1997) analytical framework is that an individual is free to do what is feasible for him to do subject to two compatibility conditions (Jasay, 1996, 5–23).

One condition relates an individual' actions to his own obligations, which in turn, are the rights of other individuals. The other condition relates his actions to harm to other individuals. If neither of these constraints binds, the individual confronts no burden of proof concerning the admissibility of feasible actions. The burden of proof rests with those who would challenge his liberty to undertake them.

Let us define as 'liberties' those feasible actions that an individual is free to execute. Some actions are inadmissible because they would infringe the rights of others. Such rights may be the natural rights of the individual to his life, liberty and property (Locke, 1690). Other rights may arise as a consequence of contractual relationships between individuals. Some actions may also be inadmissible because they would infringe the like liberties of others (Mill, 1859). All other feasible actions by an individual are permissible. In combination, these liberties and rights define the private space of an individual, the domain of his negative freedom that may not be coercively invaded by any other individual or by any government.

8. The Logic of Liberty

In this perspective, an admissible action is the exercise either of a right or of a liberty. Let us henceforth refer to this as Condition L^{**} and use this concept to resolve the various paradoxes that have been posed in the literature induced by the 1970 essay of Amartya Sen.

8.1. Purely Private Choices

Let us first consider the implications of Condition L** for entirely private choices such as: John sleeps on his back or John sleeps on his belly. John may sleep on his back or his belly, irrespective of the preferences of all others. This kind of choice is neither social nor inter-personal in nature. To distinguish this claim from other libertarian claims let us call it the "decisive libertarian claim".

To keep track of these elements of choice a "decisive private sphere set", (DPS_i) is designated for each individual. For entirely private choices the decisive libertarian claim is:

 $\begin{array}{l} \text{Condition } L^{**:} (\forall (i \in N))(\exists (x, y \in DPS_i \subset X, |DPS_i| \geq 2) \\ (x, y \in DPS_i \rightarrow ((xP_i y \rightarrow xPy) \& (yP_i x \rightarrow yPx)))). \end{array}$

Condition L** sends elements of X to the decisive private sphere of each individual in a manner that conforms with the *maximum principle*, the objective of which is to maximize the liberty of any one individual consistent with the like liberty of all other individuals. In the case of private choices, this rule takes the form:

Condition L**

for $j,k \in N, j \neq k, x \in X$: $(\forall j)(f_L: X \to DPS_i | (\forall j,k)(x \in DPS_i \Rightarrow x \notin DPS_k))$

For each individual, the rule sends elements of X to each individual's decisive private sphere. This is done under the qualification that if an element is in the decisive private sphere of individual j, it is not in the decisive private sphere of individual j. Thus, it is entirely appropriate under this rule for John to decide whether he will sleep on his back or on his belly. It is equally appropriate for Karl to decide whether he will sleep on his back or on his belly.

It is entirely inappropriate for John to decide whether Karl will sleep on his back or on his belly or for Karl likewise to make such decisions for John. Neither is socially decisive over the other person's choice. Condition L* as designated by Sen (1970) fails to make this characterization. Condition L** clearly resolves the Sen paradox in the specific case of private choices. The outcomes are mutually compatible across individuals and conform to the like liberty of all others. They are resolved appropriately at the private and not the social level.

8.2. Multiple Purely Private Choices

This result generalizes to the many private choices available to many individuals. The same general rule sends each element of choice to the private sphere of each individual. No individual has the right to dictate the choice of any other individual with respect to any matter of private choice. These mutually exclusive outcomes are compatible across individuals, conform to the like liberty of all others, and are resolved appropriately at the individual level. John, Karl, James and Keith may each sleep as he pleases, each may choose where to live as he pleases, etc., without placing any restrictions on the like liberties of each other. There can be no Paretian epidemic from this libertarian perspective.

This category of choices we designate as *decisive libertarian claims (DLC)*.

8.3. The Indecisive Libertarian Claim

The *decisive libertarian claim* (DLC) applies to a multitude of entirely private choices. Individuals may choose freely without the consent of any other individual. However, the logic of liberty extends far beyond this domain. Interpersonal dependences are pervasive features of any society. We shall argue in this section that many such interdependencies can be handled by the logic of liberty without recourse to social choice in the sense required by Sen (1970). We shall show that the set of interpersonal choices requires mutual consent between individuals defined by reference to prior rights. Let us call this the "indecisive libertarian claim". Such choices are personal, not social choices; yet, they are not entirely private.

Let us now recall the Lady Chatterley's Lover example as outlined by Sen (1970). Mr. Prude (P) and Mr. Lascivious (L), are each endowed with meddlesome preferences. Sen (1970) presents us with the following three subset social states, of U:

x = Prude reads LCL; y = Lascivious reads LCL; and z = no one reads LCL.

Mr. Prude prefers z from {x,z} and {x,y,z} but prefers x from {x,y}. Mr. Lascivious prefers y from {y,z} but prefers x from {x,y,z} and {x,y}. By Condition L*, $zP_px \rightarrow zPx$ and $yP_1z \rightarrow yPz$; but by Condition P, xPy. Hence there is an apparent cycle. Under our formalization, no elements of choice are shared between Mr. Prude and Mr. Lascivious from the perspective of social choice. Sen (1970) has them sharing element z. The choice that no one should read the book is viewed as being in each of their choice domains and yet is ignored by Condition P.

Contrast our fuller characterization of liberty with that implicit in Sen (1970) statement. There is no decisive solution, in terms of the logic of liberty over any of these pairs. The choice is no longer entirely private. When moving from the private realm to the interpersonal realm it is necessary to change the decision-rules. In interpersonal, not private, matters mutual consent is required perhaps constrained by the prior rights of any individual. Of all the commentators on this debate perhaps only Peacock and Rowley (1972), together with Nozick (1974) have recognized the importance of this logic.

Let us now revisit this example from the perspective provided by the logic of liberty. According to Sen (1970) there is only one copy of *Lady Chatterley's Lover* available either to Mr. Prude or to Mr. Lascivious. It is feasible for either Mr. Prude or for Mr. Lascivious to read or not to read the book. Everything now depends on which of the two individuals owns the book.

If Mr. Prude owns the book, he has a liberty to read or not to read it. By a similar line of reasoning, if Mr. Lascivious owns the book he has a liberty to read or not to read the book. Ownership provides either party with a prior right that trumps the liberty of the other party. If the individual who does not possess the right of ownership wants to meddle in the affairs of the person who owns the right he can do so only by contracting with that person. If Mr. Prude owns the book he will not read it and he will not allow Mr. Lascivious to read it unless a contract determines such a transfer of rights. If Mr. Lascivious owns the book, he has a liberty to read the book. He will do so unless Mr. Prude intervenes, via contract, to exchange the right to read the book. All of this falls within the logic of liberty. If there is no prior right, then the logic of liberty implies that he who has access to the book has the liberty to decide.

Suppose now that the choice situation becomes more complex in the sense that individual preferences are even more complex. Even in the "perverse non-conformist case", the logic of liberty also resolves Sen's (1976) dilemma. Let us illustrate with respect to the Mrs. Grundy example, which exemplifies "Gibbard's paradox".

8.4. Gibbard's Paradox

Suppose that I am a perverse non-conformist. It is feasible for me to paint my bedroom walls any color that I choose. My choice is not constrained by any prior contract. Therefore, I have a liberty to choose my color scheme. Mrs. Grundy, likewise, has a liberty to make her own choice. Suppose that I have the right to choose the color scheme; then Mrs. Grundy has no liberty to intervene.

Suppose, alternatively, that Mrs. Grundy holds this right. To realize my preference for non-conformity, I now must contract with Mrs. Grundy, paying her to enter into an obligation not to match my color scheme. If I fail to achieve such a contract, Mrs. Grundy is free to choose the color scheme that maximizes her preferences. The logic of liberty clearly resolves this dispute.

In the "perverse non-conformist case", the logic of liberty resolves the apparent Sen (1970) dilemma. It is feasible for me to paint my bedroom walls any color that I choose as long as my choice does not imply any obligation to Mrs. Grundy. Therefore, I have a liberty to choose my color scheme. Mrs. Grundy, likewise, has a liberty to make her own choice. To realize my preference for non-conformity, I must contract with Mrs. Grundy, paying her to enter into an obligation not to match my color scheme.

From the same perspective, let us now evaluate the case of marital preferences. It is clear that Angelina, Edwin and the judge each has a liberty to remain single. None of the three has a right to marry any of the other participants. If Edwin's preferences are as listed by Sen (1970), he will successfully contract with Angelina to marry him. He has a liberty so to do, but no right. If Angelina declines his offer, then Angelina has a liberty to interact with the judge who has no right to marry her without consent.

9. Conclusions

The logic of liberty and its associated rules enables us to deal with purely private choices, multiple private choices and choices involving interpersonal utilities always assuming that tortious liability is not involved. John may live in New York, read *Lady Chatterley's Lover*, sleep on his back, worship God through Christ, etc. All the while, Karl may live in Massachusetts, read *Das Capital*, and deny the existence of God through Christ. These choices are mutually compatible and respect the like liberty of all others.

This outcome is not compatible, of course, with the *one best choice* viewed as some aggregation of utilities, whether utilitarian or Paretian, refracted upon society by

a benevolent social decision-maker. For those who would allow meddlesome preferences to interfere with strictly private choices, it might appear that society would be better off as a whole if John were constrained to live in Massachusetts, to read *Das Kapital*, and to deny the existence of God through Christ, etc., even though his strictly private preferences are opposed to such a choice.

Sen (1970) would put all this into the melting pot of social choice. Let us not pretend, however, that such a judgment has anything to do with the logic of liberty.

LOGROLLING 1

Vote trading between legislators or committee members is a common phenomenon. The economics and political science literature defines logrolling or vote-trading as follows:

Let (x,y) and (z,w) be pairs of mutually exclusive issues and let voter preferences with respect to each pair be separable. A logrolling situation exists if

xPy and zPw, but ywPxz

where P stands for social preference as defined by the voting rule employed (Bernholz 1974, p. 53). For many logroll theorems it suffices if the first two social relationships are characterized by R (e.g., x and z do not lose to y and w, respectively).

Logrolling is illustrated in Figure 1. Voters 1, 2, and 3 vote on issues A and B using simple majority rule. The payoffs for these three voters on issue A are 5, -1, and -1, and the payoffs for the voters on issue B are -1, 5, and -1. If everyone votes sincerely, issue A and issue B both fail to obtain a majority of votes; neither issue is passed. However, voters 1 and 2 have an incentive to form a vote trade agreement: voter 1 agrees to vote for B and in exchange the second voter agrees to vote for A. Without vote trading no issue passes. In the presence of the vote space and therefore a misrepresentation of preferences — both issues pass. In this example, total utility is increased by 3 units for

ISSUES							
VOTER	А	В					
1	5	-1					
2	-1	5					
3	-1	-1					
	Figure 1:						

each issue and society is better off overall. The trade is welfare enhancing in this case, and logrolling resulted in a positive sum game. However, if the -1's in the table shown in Figure 1 are replaced by -3' a negative sum game will be the result. Voters 1 and 2 still have an incentive to trade votes and while these two voters benefit individually for their vote trade, society is worse off overall, by -1 for each issue.

The normative discussion of logrolling evolves around the issue of logrolling being a positive or negative sum game. It has been argued that vote trading coupled with unanimity rule will result in a positive sum game (Wicksell, 1896). Legislators may deal with public goods issues that could potentially make society better off. In this case logrolling may produce a collective choice that brings society closer to the provision of a socially optimal level of public goods by allowing for an expression of different intensities of preferences through vote trading (Buchanan and Tullock, 1962). Logrolling may result in a negative sum game is if the electoral system does not define jurisdictions according to the spillover of public goods (Tullock, 1959). In Tullock's road example, voters have to decide on the maintenance of access roads to a main highway, with a few farmers served by each access road. Here, each access road is a local public good. The problem here is that voters other than the voters affected by the public good decide on the production of the good. The entire community decides which roads to maintain via simple majority rule. Tullock shows that members of the coalition repair the roads beyond optimal levels because they do not have to bear the full costs of the repair if costs are shared equally among all farmers. Some of the costs are borne by farmers not in the winning coalition. In this case majority rule with trading can lead to too much government spending.

Regardless as to whether logrolling is a positive or negative sum game, vote trading outcomes may not be stable, implying a lack of equilibrium in the vote exchange market (Mueller, 1967; Park, 1967). If trade agreements are broken, instability may arise, and shifting coalitions may lead to a decrease in welfare. The close relationship between vote trading and cyclical majorities can be illustrated by using Figure 1. From this table, four combinations of issue pairs arise: (A,B), (~A,B), (A,~B), and (~A,~B). It is possible to show that a cycle exists over these issue pairs. After voters 1 and 2 have agreed to form a logroll coalition for the passage of both issues (A,B), voter 3 has an incentive to approach voter 2 for the passage of the $(A, \sim B)$ pair. This combination makes voter 2 better off by 3 units and voter 3 better off by 2 units of utility. Next, voter 1 has an incentive to approach voter 3 with the proposal to pass none of the issues (\sim A, \sim B). 3 will abandon the coalition with 2 to

enter a more favorable coalition with 1. From this point, the cycle can start all over again with the combination (A,B). Bernholz (1973) shows formally that preferences that allow for a logroll imply the existence of a voting cycle.

The centralized vote trading model stands in stark contrast to the previous model in its optimism about the vote trading process (Haefele, 1971; Koford, 1982). In the central vote exchange model reneging is not possible as vote trades are organized centrally by party leaders. Votes are prices paid for the passage of legislation. Costs of passing the bill are costs incurred by legislators who are opposed to the legislation but vote for it. These costs are minimized: leaders have incentives to select those legislators to help pass a bill for whom it is cheapest to do so. Further, legislators pass only bills for which benefits exceed costs. Thus vote trades exist within the confines of a positive sum game. Koford (1990) argues that transactions costs, i.e., the costs of informing citizens how their representative voted on a bill, lead to logroll coalitions which are organized along party lines.

One expects the vote trading coalition to be a minimum winning coalition (Riker, 1962). Every unnecessary member included in the winning coalition implies that the net payoff is smaller for the members than needed to secure victory. The largest share for each member is secured when the coalition has the minimum number of members to ensure passage of the bill. However, minimum winning coalitions are potentially unstable (Tullock, 1981). Losers always have an incentive to reformulate the platform, so they are included in the winning coalition. Tullock suggests that stability can be induced by forming a majority that includes nearly every voter in a legislature. Recent work makes this argument using formal models (Groseclose and Snyder, 1996).

Logrolling models give little guidance on how to proceed with identifying vote trades empirically, or how to test implications that are associated with vote-trading models. However, we know that votes that are potentially subject to logrolling are votes where a minority of legislators are intensely in favor (opposed), while the majority of legislators are mildly opposed (in favor) or indifferent. Logrolling gives a specific prediction: xPy and zPw but ywPxz. Vote trades are predicted on issues that would not pass if every legislator votes his or her honest preferences but that are passed if logroll coalitions are formed. Likely candidates are votes where the minority interest has won. Among this set of votes, applying Riker's (1962) size principle, likely candidates are votes in which the outcome has been reasonably close. Using this reasoning and the statistical method outlined above, Stratmann (1992) identifies logrolling statistically among agricultural interests on amendments to the 1985 farm bill. The findings indicate that representatives from tobacco districts traded votes with legislators representing other agricultural commodity interests, specifically sugar and peanut farmers. Fairly equal size on the peanut vote coefficient in the sugar regression and the sugar vote coefficient in the peanut regression provided evidence for reciprocity and coalition formation.

Stratmann's evidence suggests that those legislators who are the cheapest to buy for membership are most likely to be members of the vote trade coalition. For example, on an amendment on peanut subsidies, it was found that 120 legislators switched their vote due to a vote trade agreement. These legislators made up a disproportionate share of those who had a probability between 0.3 and 0.4 and 0.4 and 0.5 of voting for peanut subsidies: 90 percent of legislators who were in the 0.3 and 0.4 range switched and 65 of 134 (48.5 percent) legislators who were in the 0.4-0.5 range switched. This is consistent with the hypothesis that party leaders arrange low cost trades which in turn enhances stability. Recent work by Irwin and Kroszner (1996) shows that final, party-line voting masks a rich vote trading dynamic. They examine logrolling coalitions and show that vote-trading between oil and lumber interests was one of the factors that determined the outcome of tariff-legislation in the 1930s.

If instability were widespread in Congress, evidence for reciprocity in vote trades should be virtually non existent, supporting the view that trading is anarchic. The notion that trading involves instability and shifting coalitions is not supported by Stratmann (1992, 1996). He finds reciprocity among members from agricultural districts voting for their colleague's commodity price supports, quota restrictions, etc. To date, empirical findings appear to point to stable coalitions. For example, the ongoing vote trading coalitions between farm, city, labor and western interests has been documented for over a period spanning from 1947 to 1962 (Mayhew, 1966; Stratmann, 1995). Further, the evidence for reciprocity in vote trades suggests no wide-spread reneging on vote trade agreements.

So far, the evidence on vote trading appears to be consistent with the hypothesis that leaders efficiently organize vote trades: many of the legislators who voted for a bill because of a logroll agreement were legislators marginally opposed to the passage of the bill. Thus, representatives for whom it was cheapest to vote against constituency interests were solicited as members of the logroll coalition. These results suggest that these coalitions are not formed as suggested by the cycling theorems. At one step in a cycle, high demanders form a winning coalition with very low demanders, opposing those with moderate intensity. For example, at some point in the cycle wheat farm representatives are expected trade and form a winning coalition with legislators strongly opposed to peanut subsidies. This implies that legislators with a low probability of voting for peanut subsidies vote for these subsidies due to the vote trade agreement. The evidence is not consistent with this prediction as many of the traders are legislators marginally opposed to subsidies (Stratmann, 1992). More empirical studies are needed to test for logrolling, how coalitions are formed, and whether vote-trading is, on net, a positive or negative sum game.

LOGROLLING 2

Logrolling refers to a political practice of forming majority coalitions to support a potpourri of minority positions. Hence it involves each politician giving up some things to gain some other things of greater value. Typically, it refers to legislative vote trading, but it certainly has broader connotations than that. Indeed, Olson's (1982) argument regarding the decline of empires was predicated on the more general notion that minority interests can logroll successfully to stop efficient growth. As Stein and Bickers (1994) have pointed out even in legislatures its meaning is a bit ambiguous. Some have argued that 'pork-barrel' type legislation (in which a large number of specific projects, each with a very narrow constituency are pulled together to create a majority) is a consummate example of logrolling. Others have pointed to the passage of a number of disparate bills being passed by a narrow legislative committee structure. Still others have claimed that the initial political push for a program may be quite narrow, but to maintain a longterm base of support, the benefits have to broaden, and so a sort of logroll occurs to broaden the impact of the programs.

There have been a number of separate lines of inquiry regarding the subject of logrolling and vote trading. For purposes of this essay I divide them up as: logrolling and the social choice problem; universalism, efficiency, and distributive concerns; empirical studies. I deal with them each in turn.

1. Logrolling and the Social Choice Problem

Binary trades, the mainstays of markets, has long appeared to be the sure ticket to Pareto improvements. In the last decades some of the luster associated with trades has worn off. First came the observation that at the base of all trades seemed to be a less soluble prisoner's dilemma game (each side would like to move second: take the money and run, so to speak). Only the existence of property rights underlying market transactions seem to stabilize the outcomes (see Schwartz, 1981).

This casual observation did not prevent some political observers from conjecturing an amelioratory relationship between social choice paradoxes and the practice of vote trading. The brashest of these claims was by James Coleman (1966) who erroneously argued that vote-trading and other forms of political bargaining implicit in logrolling required a cardinality of the social decision space which would obviate the Arrovian problems of social choice. This, in spite of the early warning by Anthony Downs (1957) that the formation of a "winning coalition" from a coalition of minorities could lead to problems of cyclic outcomes.

The general relationship between creating a victory, when there is no Condorcet Winner and vote cycles was first stipulated by Kadane (1972) and then continued and extended in a number of papers and articles on the trading of votes and general problems of cycles in the 1970's (Bernholz, 1974; Miller, 1975; Oppenheimer, 1975, 1979; Schofield, 1980). Eventually this literature was pulled together into one simple and elegant proof by Thomas Schwartz (1981). Schwartz showed that regardless of the type of institution, any time a trade *had* to take place for an outcome to be reached (i.e., it could not be reached by the mere aggregating of purely individualistic maximizing behavior), there was an implicit cycle going on. This analysis pulled together a number of problems including that of the "Liberal Paradox" (Sen, 1970) which had been shown to be related to cycles (Bernholz, 1976) and the prisoner dilemma (Miller, 1977b).

2. Universalism, Efficiency, and Distributive Concerns

The fact that log-rolling involves cycles doesn't deal with its values and functions. Gordon Tullock (1967) argued that it was an engine for the pernicious growth of majoritarian governmental budgets. In a similar voice, Olson (1982) argued but with a more general voice, that the narrow minorities would form stable blocking coalitions. Of course, this notion flies in the face of the above generalizations, which pointed out that there was no stability in such coalitional structures. Of course, other aspects of the political environment could generate stability to coalitions of minorities, much as Arrow's instabilities can be blocked by violating one or more of his "desiderata" (such as non-dictatorship).

Weingast began to consider one of the fundamental bases for logrolls: that a typical logroll includes many a project where each project's benefits are divisible and concentrated in just a few legislative districts. The funds come from universal taxation. Note that any set of projects would define a winning and a losing set of districts. The concern is why do these sorts of "pork-barrel" projects pass so regularly and easily. The first successful search for an explanation for the creation of stable minorities coalitions came from Weingast (1979). He argued that super-inclusive universal coalitions could form so long as the politicians are left uncertain as to which coalitions might form, and hence fear being left out of the winning coalitions. Indeed, under those conditions, universal coalitions form as the "core" of the cooperative legislative game so as to secure maximum ex ante expected value for the each of the members in a legislature when their inclusion in the winning coalition is at risk.

Weingast et al. (1981) went on to conjecture that strong parties, which could secure membership in winning logrolls for its members, could lead to more efficient, smaller coalitions. This has led to a new argument, that universalism would hold only within majority parties, not across parties whenever the parties are strong enough to keep disciplined coalitions winning (Cox and McCubbins, 1993).

3. Empirical Studies and Conclusions

Recently, the theoretical conjectures outlined above supporting universal log rolling coalitions have been subject to testing (Collie, 1988 presents an overview; Stein and Bickers, 1994 presents interesting and careful tests). In all cases, the results have proven the theoretical conjectures very vulnerable. The results showed that most programs with divisible benefits are passed in bills that benefit very few districts: far fewer than had been conjectured, either by the early universalist conjectures, or by the later partycentric arguments. Indeed, the number of programs and bundles of programs that reward more than a small segment of districts is small. This doesn't mean that there is no vote — swapping and logrolling. But it does mean that the dynamics must be somewhat different than has been conjectured to date. Rather, what is implied is that the premises in the arguments ought to be reassessed.

Some of the premises which are suspect include (1) that the voters track the benefits going to the district; (2) that the legislator can influence benefits by getting a project for her own district; (3) that voters reward legislators for the flow of benefits to their districts. Stein and Bickers note that universalization of benefits was argued for as a strategy to increase reelection chances. There are other strategies which may be more attractive.

But it appears that as long as humans have been around, there has been 'trading' and trading by politicians across programs, often in the currency of votes, is just one form of the activity. It is likely to play a role in the securing of all political outcomes, and perhaps is the reason for the popular notion: "politics makes strange bedfellows."

Μ

MEDDLESOME PREFERENCES AND RENT EXTRACTION: THE TOBACCO SHAKEDOWN

Tobacco has become an arena of civil warfare throughout the Western world over the past half-century or so. This war has been fueled by an ideological rhetoric that speaks of the costs that smokers place on nonsmokers (Office of Technology Assessment, 1985, 1993). The state claims to wage the war to protect innocent nonsmokers from predatory attacks by smokers. This claim has now been thoroughly refuted, starting with Tollison and Wagner (1988), as extended in Tollison and Wagner (1992). Whereas Tollison and Wagner argue that those costs are borne wholly by smokers, such authors as Manning et al. (1989), Gravelle and Zimmerman (1994), and Viscusi (1997) argue that there are some modest costs shifted onto nonsmokers, but that those costs are significantly less than the excise taxes that are currently imposed on cigarettes. As a result, smokers do not impose costs on nonsmokers but rather subsidize nonsmokers. Yet the war on tobacco continues, and in a big way. What the continuation of the war perhaps illustrates is the interaction between meddlesome preferences and rent extraction.

A social democracy with the large government it entails carries within itself tendencies to transform tolerant preferences into meddlesome preferences (Buchanan, 1986). A market economy supports tolerance across different preferences within a society, a collective economy does not. If health care is organized through private property within a market economy, people are responsible for the costs of their health care. People who engage in risky occupations, dangerous leisure time activities, or unhealthy lifestyles would bear the medical costs associated with those personal choices. If people who ride motorcycles incur higher medical costs on average than people who do not, they will bear the higher costs. If people who smoke incur higher medical costs, they will bear those costs. The provision of medical care within the framework offered by the principles of property and contract does nothing to undermine support for the liberal principle of mutual toleration over preferences.

As health care comes increasingly to be financed collectively, however, tolerance over personal choices can give way to intolerance, due to the shifts in political and personal incentives that collectivization creates. The actuarial evidence shows that people who smoke have lower average life expectancies than nonsmokers, though there are many smokers who lead long lives and nonsmokers who die early. Insurance within a market economy charges different prices to people in different risk categories that reflect the different costs of providing service (McCormick et al., 1997).

It is different with collective provision and its replacement of market pricing with tax financing or state-regulated pricing. People who make relatively low use of a service form a natural interest group, whose members have interests that are opposed to those who might make relatively high use. What was a matter of a simple toleration of different choices of lifestyles under market arrangements becomes a matter of political interest and activity. In the presence of collective provision, the costs of activities that entail aboveaverage costs will be shifted partially onto those whose activities entail below-average costs. The transfer of medical care from a market-based to a collective-based mode of organization generates pressures for a similar transfer of control regarding a variety of other personal choices. Activities that have expected costs of health care that are higher than average become of concern to people who dislike those activities, because they now are paying for some of the costs associated with those activities. Toleration recedes as collective provision replaces market provision, as tolerant preferences are transformed into meddlesome preferences.

The state necessarily becomes a battleground for the adjudication of disputes over personal lifestyles. When economic activity is organized according to the principles of property and contract, a society can tolerate peacefully a variety of such lifestyles because those who conduct more costly patterns of life pay for them. But once the market principle of personal responsibility is abridged for some principle of collective responsibility, interest groups are automatically established that will bring personal lifestyles onto the political agenda, which in turn generates opportunities for rent extraction.

A huge literature on rent seeking has been inspired by Gordon Tullock's (1967) seminal articulation. Fred McChesney (1997) advances rent extraction as a closely related cousin to rent seeking. Rent seeking and rent extraction are to politics what bribery and extortion are to ordinary people. For ordinary people, these kinds of activity are wrong. But in politics they are business as usual. Rent seeking describes what people have in mind by lobbying. It refers to the payments people make to secure political favors. A sports magnate would like special tax treatment for a stadium he is building. He lobbies to get this enacted. Or, more likely, hires someone to do this for him. In this regard, it is noteworthy that few defeated or retired legislators return to their home districts. Most of them stay in Washington, where their value as lobbyists is high.

But rent seeking is only part of the story of money and politics, and perhaps only the smaller part. Rent extraction may be even more significant. It refers to the payments people make to avoid being victimized by politically harmful measures. If rent seeking would be called bribery if it occurred between private persons, rent extraction would be called extortion. McChensey (p. 2) uses Citicorp as an example of how corporations react to political rent extraction. "The nation's largest banking company employs eight registered lobbyists in its Washington office. In addition, six law firms represent Citicorp's interests on Capitol Hill. No one should judge this strike force ineffective by how little banking legislation gets through: The lobbyists spend most of their time blocking and blunting changes that could hurt Citicorp's extensive credit-card operations, student-loan business or ever-broadening financial-service offerings."

McChesney notes that rent extraction by politicians is similar to the practice of "mud farming" that William Faulkner described in *The Reivers*. Late at night, farmers would plough up portions of the dirt roads in front of their houses, and then soak the roads. The cars that passed by during the day would get stuck in the mud. The drivers faced a choice. They could abandon their cars. Or they could pay the farmers to hitch up their mules and pull out the stuck cars — for a price, of course.

There is one vital difference between rent seeking and rent extraction that should not be ignored, and which may explain why the former has received more attention than the latter. With rent seeking, politicians are portrayed as relatively passive victims. They are deluged by lobbyists, and on occasion capitulate to them. The politician is caught in a squeeze between the intensity of special interests and the quietude of the public interest.

With rent extraction, however, politicians are in the forefront of the action. They are the active initiators who continually look for targets. Those targets, like the drivers who came across the mud farmers, have a choice. They can ignore the politicians and lose a lot of their wealth. Or they can participate politically, thereby softening their losses.

Not all rent extraction must be produced politically. Rent extraction can be farmed out, much as with the tax farming of old. A practice called tax farming has been traced back at least 4000 years to ancient Mesopotamia (Webber and Wildavsky, 1986). Real farmers raise food from their land. Tax farmers raised revenue from the people who inhabited the lands of some ruler. It is only natural that a practice that has been employed in so many places over 4000 years would show many differences in the particular details by which it operated.

The central idea of tax farming, however, was the same everywhere. A ruler wanted to extract revenue from his subjects, and hired someone to do the extraction. Typically a tax farmer would be awarded a monopoly to harvest taxes from a particular area. In many cases a ruler would assign a revenue quota to the tax farmer. A tax farmer who failed to deliver his quota of revenue would be liable for the shortage.

Tax farmers were generally wealthy men who became even wealthier through tax farming. The ruler's chief concern was to get his desired revenue. If the tax farmer failed to extract sufficient revenue from the people, the ruler could collect the shortage from the tax farmer himself. A ruler would not want to hire a tax farmer who was poor because only a wealthy tax farmer could assure satisfaction of the ruler's appetite for revenue.

While tax farmers were liable for shortages, tax farming was generally a profitable business. Whatever wealth a tax farmer started with, he could generally add to it nicely through tax farming. Tax farmers who extracted revenues beyond their quotas could keep the difference. Such a tax farmer would not invoke a ruler's wrath so long as he raised sufficient revenue for the ruler. From time to time rulers would use such devices as soliciting bids for the right to be a tax farmer, in an effort to increase their share of the tax farmer's harvest.

Tax farming has been widely regarded as a practice of autocracy and not of democracy, for in democracy taxation is the province of the legislature. Despite this common presumption, it would seem as though a form of tax farming has erupted recently in the United States. It takes the form of lawyers filing class action suits, where the results of those suits replace what otherwise would have required legislation to accomplish. The tobacco settlement is a recent case in point (Wagner, 1999). The major tobacco companies settled a suit with all state governments throughout the land for \$246 billion. The revenues are already accruing to the states, and are being used for a wide variety of purposes from A to Z.

The lawyers in this case are modern-day tax farmers. They have used the tobacco companies as a vehicle for collecting taxes on smokers. Instead of state legislatures roughly doubling their tobacco taxes, the lawyers collected the taxes themselves through the tobacco settlement. What makes the analogy with tax farming complete is that the lawyer-tax farmers were able to keep many billions of dollars for themselves. The majority of the revenue collected by the tax farmers of old went to the rulers. It is the same for our new form of tax farming. The tobacco settlement is not the first case of modern tax farming and other cases are now in process. Before tobacco, there was asbestos. Since tobacco, there is gun manufacturing (Levy, in press). What exists in these cases is a form of tax farming, only the farmers wear suits and work mostly in offices. They find people from whom to extract revenue, and typically focus on the easiest and most lucrative targets, which are those targets whose pockets are thought to be the deepest. The new tax farmers keep a good chunk of the revenue they collect for themselves. The remainder goes to politically favored purposes in one form or another. The tobacco litigation involved the state attorneys general in hiring private law firms, and with many of those firms making contributions to political campaigns on behalf of their sponsors.

The recent settlement between the major tobacco companies and the American states illustrates modern tax farming at work. The states could have legislated tax increases on cigarettes, as they have often done. Perhaps influenced by a political calculus that forecast strong opposition to tax increases, they supported suits instead. They farmed out tax collection to law firms rather than resorting to legislation. Meddlesome preferences that were generated in a context of rational ignorance and Paretian non-logical conduct (Pareto, 1935), made this shakedown appear to most people to be not a disguised form of tax but rather justice at work. Most legislators are lawyers, and the growth of democratic tax farming may well strengthen the commingling of law and politics.

THE MEDIAN IN POLITICS

The controversies surrounding democratic institutions can be simplified and brought into clearer focus by considering the properties of the median of a probability density on the line (the "population median") or the median of a sample drawn from that density. Two short contributions by Francis Galton to *Nature* of 1907, in which he demonstrated that one could move from the properties of estimation to the properties of voting, ought to have made it clear to later workers that the median is an appropriate mathematical model of a one-dimensional majoritarian decision-making process, Galton (1907a, b). Any position other than the median, as Galton pointed out, would lose in competition with the median.

Galton's demonstration seems to have been too far advanced for non-statisticians to appreciate, David Levy and Sandra Peart (2002). Most importantly, Duncan Black (1958) from who no predecessor is hidden, described Galton's contribution as an minor forerunner of his own work in which the population of those voting is fixed. Thus Black missed how Galton moves in the context of randomly selected jury from estimation to voting. Once one appreciates that voting and estimation can be represented by the same mathematical structure, the way is clear for the entire apparatus of mathematical statistics to be focused upon the issues of political presentation, Gilbert Bassett and Joseph Persky (1999). Indeed, thinking in terms of political representation as an estimation procedure makes it obvious that democracy procedures are wider than simple voting, encompassing such historically intriguing institutions as the Athenian practice of election by lot in which representatives are selected at random, Levy (1989).

These two ways of thinking about the median in politics help make clear that democratic institutions can be viewed apart from the subjectivist interpretation of voting which rather naturally follows from the neo-classical economic approach to politics adopted by the founders of public choice, by Black (1958), Kenneth J. Arrow (1963), James Buchanan and Gordon Tullock (1962) and those later scholars whose contributions are surveyed by Dennis Mueller (1989). Voting as estimation approach allows an objectivist interpretation of politics. When Galton considered the members of a jury giving numerical votes damages to be awarded he not unnaturally assumed that there was some sense to the proposition that there was in fact some underlying damage to be redressed and so he tested his formalized intuition by studying how the median guess recovered the true weight of a dressed ox!

Using the two-fold interpretation of the median in politics, we consider three contentious issues of political theory: the intensity-blindness of majority rule politics, the possibility of multiple equilibrium in democracy and the problem of lack of influence in an election.

Intensity. The world seems divided between those for whom "one person one vote" resonates and those for whom "one dollar one vote" appeals. This question of intensity occurs at the center of the interpretation we put upon median voter theory because once multiple dimensions are introduced in politics then the possibility of vote trading — "log-rolling" in the American idiom — opens (Buchanan and Tullock, 1962) and there is no reason to believe, save in the symmetrical Plott conditions (Charles Plott, 1967), that the median will prevail issue by issue (Richard McKelvey, 1979).

Violations of median voter desires via log rolling, vote trading, agenda control are positive issues. What interpretation do we put on such results? Those for whom intensity matters will likely approve such institutions as representative democracy where such a political market can be effected. Those for whom interest group politics are distasteful might well prefer such institutions as singleissue direct democracy, as exemplified in citizen initiatives, where the majority's judgment is more likely to be decisive.

Weighting votes by dollars raises throny questions of income distribution. Fortunate that the complication which intensity of preference raises in politics can be considered in the abstract definitions of mean and median. The first property worthy of remark of the population median is that its existence is no more or less problematic than that of probability itself. For whenever there is a probability density, a function f such $f(x) \ge 0$, $\int_{-\infty}^{\infty} f(x)dx = 1$ we can construct the median as that v for which $\int_{-\infty}^{v} f(x)dx = 1/2$. On the contrary the existence of the first moment of the random variable X (the "population mean") $\mu = E(x) = \int_{-\infty}^{\infty} xf(x)dx$ depends upon the delicate question of absolute convergence. Intuitively, if values of X far from center occur with sufficient frequency, the first moment is not defined.

Existence can be guaranteed by making the distribution finite. We may express the sample mean (median) rather neatly as the mean (median) of empirical probability distribution \hat{F} which puts mass 1/n at each point x_1, x_2, \ldots, x_n . This evades rather than solves the problem although the fragility of the sample mean, the textbook estimator, even when there is a symmetric unimodal F underlying the \hat{F} , was perhaps not fully appreciated until the work of the Princeton robustness study (Tukey et al., 1972). Outside the case of a normal distribution in which context it is ideal - which in linear regression form is equivalent to the supposition that the modeler's specification is incapable of improvement! (Levy, 1999/2000) — the mean's performance relative to the median's ranges from mediocre to ghastly. The robustness of the median, and thus the plausibility of issue by issue majority rule, was totally clear to Galton when he pointed out of in a jury setting, the use of the *average* estimate of damage would be hostage to the vote of a single "crank" and that in proportion to his "crankiness." Bassett and Persky (1999) by formulating voting and estimation as equivalents are able to transfer robustness considerations from statistical theory to public choice.

Stability. One aspect of Plato's criticism of democracy in *Republic*, its theoretical instability, has been verified when Arrow and Black demonstrated the phenomenon of cyclical majorities even when the issue is constrained to a single dimension. Constraint to a single dimension is enormously helpful because it tells us that the problem of instability cannot be one of intensities where a vote on one issue is traded for a vote on another. Black's evocative diagnosis of the problem is that the "single peaked" conditions failed; that is to say, some voter in the population has preferences which look like Figure 1 where X is an issue and F(X) is the preference over that issue. Of course, Black takes the population as given and so inquire into the properties of the population median.

Suppose instead of the preferences of an individual voter, Figure 1 represents the population of factionalized voters. There is a smaller faction at A and a larger one at C and nothing much between then. If a small number of votes change (Downs, 1957) the median can be moved rather dramatically. This can be expressed by the fact that in the

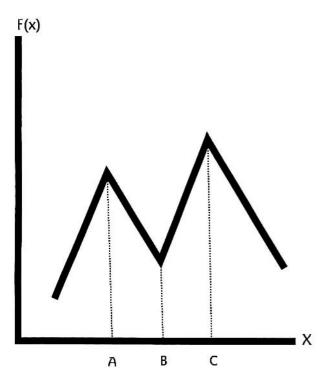

Figure 1: A problem for a median.

context of a bimodal distribution, the influence curve of sample median can be unbounded (Frederick Mosteller and J.W. Tukey, 1977). It is perhaps in this context that worries of factional violence in democracy, as expressed by Plato, make sense. Kill a Cs and the election moves close to A. In this same context, the justification for election by lot becomes clear (Levy, 1989); killing a Cs will only change the probability of the election results slightly.

The advantage of drawing Figure 1 explicitly is that is becomes obvious that, under either interpretation, we are in the presence of a non-convexity. Extremes are preferred to averages; tails are more massive than the center. From standard considerations with non-convexity discontinuous behavior and multiple equilibria can be expected.

Votes without influence. The doctrine of rational ignorance developed at length by Downs (but found in rather earlier in Robert Filmer) supposes that since an individual in a large-number election has no influence to speak out, it is not rational for him to acquire much in the way of information. But this assumes that the voter thinks that being influential is an unmixed blessing. The problem of majority-rule voting in a bimodal distribution suggest that perhaps a rational individual would just as soon not be of much influence. If an individual vote by itself has an important influence then the absence of that vote would also have an influence.

THE MEDIAN VOTER MODEL

1. Introduction

Most analytical work in public choice is based upon relatively simple models of majority decision making. These models are widely used even though the researchers know that real political settings are more complex than the models seem to imply. The use of such simple models can be defended for a variety of reasons: First, simple models allow knowledge to be transmitted more economically from one person to another than possible with more complex models. Second, simple models provide us with engines of analysis that allow a variety of hypotheses about more complex phenomena to be developed, many of which would be impossible (or uninteresting) without the frame of reference provided by models. Third, it is possible that simple models are all that is necessary to understand the main features of the world. The world may be less complex that it appears; in which case simple models that extract the essential from the observed will serve us well.

All of these defenses of simple models apply to the median voter model, which is, perhaps, the simplest possible model of majoritarian decision making. There is no more transparent nor easily communicated explanation of political outcomes in a democracy than that all political outcomes reflect median voter preferences. Moreover, testable implications of the median voter model abound. If the median voter gets more or less what he or she wants, then anything that affects the median voter's assessment of the relative merits of alternative policies or candidates will also affect political outcomes. For example, the median voter's age, sex, income, information, ideology and expectations should all systematically affect public policy. Moreover, to the extent that these predictions are largely borne out by empirical research, the median voter model can be regarded not only as a convenient method of discussing majoritarian politics and a fruitful engine of analysis, but also a fundamental property of democracy.

2. Origins of the Median Voter Theory

For all of its simplicity, the median voter model is by no means obvious. Although majoritarian voting is clearly a very ancient method of group decision making, which doubtless has been used in tribal councils since before the dawn of recorded history, there is no clear statement of the median voter theorem until approximately 1950. For example, there is no mention of the concept of a pivotal or decisive voter in Aristotle's analysis of political decision making written in 330 B. C.. Condorcet, an eminent French mathematician and philosopher, discovered the idea of a pivotal voter and also noted how the accuracy of decisions can be improved by majority decisions in juries, but includes no clear statement of the median voter theorem. Political pundits have noted (and lamented) tendencies for candidate positions to converge in democratic elections, as did the occasional economic theorist, Hotelling (1929), but the median voter theorem awaited Duncan Black's work on majority voting (1948), and Anthony Downs' extension to representative democracy (1957).

That such a simple idea took so many centuries to emerge may seem surprising given the clarity of the result, but both the rational choice framework and statistical basis of median analysis also emerged at surprisingly late dates. In the case of political analysis, analysis of the properties of simple majority rule may have been delayed for historical as well as methodological reasons. The use of national elections to select governments or government policies is a fairly recent innovation for *national* political systems. Even in the United States where elections have used to select representatives to various state and local governmental bodies for many centuries, the members of the U. S. Senate were appointed rather than elected prior to the passage of the 17th amendment in 1913.

3. An Illustration: Direct Democracy and the Median Voter

To appreciate the logic of the median voter model, consider a setting where three individuals: Al, Bob and Charlie are to choose a restaurant to eat lunch at. Al prefers a restaurant where lunch can be had for \$5.00, Bob favors a bit better fare at a restaurant serving \$10.00 lunches, and Charlie wants a gourmet restaurant where lunch will cost around \$20.00. Bob can be said to be the *median voter* because exactly the same number of individuals prefer a more expensive restaurant than Bob as prefer a less expensive restaurant than Bob, here one each. For convenience assume that, given any two options, each member of the lunch group prefers restaurants with prices closer to their preferred restaurant to ones that are farther from it. Now consider some majority decisions over alternative restaurants:

Options	Pattern of votes			Result
\$10 vs. \$20	A: 10	B: 10	C: 20	10
\$5 vs. \$20	A: 5	B: 5	C: 20	5
\$5 vs. \$16	A: 5	B: 5	C: 16	5
\$10 vs. \$5	A: 5	B: 10	C: 10	10

The weak form of the median voter theorem says the median voter always casts his or her vote for the policy that is adopted. Note that Bob always votes in favor of the outcome that wins the election. Note also Bob's preferred \$10 restaurant will defeat any other. If there is a median voter, his (or her) preferred policy will beat any other alternative in a pairwise vote. (The median voter's ideal point is always a Condorcet winner.) Consequently, once the median voter's preferred outcome is reached, it can not be defeated by another in a pairwise majoritarian election. The strong form of the median voter theorem says the median voter always gets her most preferred policy.

4. Illustration: Electoral Competition and the Median Voter

Similar results are associated with representative democracy where voters select policy makers rather than policies. The case of most relevance for the median voter model is that in which there are two major candidates or parties, one of which will be given the power make public policies until the next election. If voters cast their vote for the party or candidate closest to their most preferred feasible policy, it turns out that the candidate who is closest to the median voter always wins the election. This follows because the candidate closest to the median voter is also closest to the ideal points of more than half of the electorate. (This "distance-based" model of voter preferences is sometimes called the spatial voting model.) Consequently, the winning candidate always receives the vote of the median voter, and the *weak form of the median voter theorem holds*.

If candidates can freely choose policy positions to maximize their share of the votes, both candidates will attempt to adopt policy platforms that are closer to the ideal policies of the median voter than the other. Consequently, major party candidates will both tend to select platforms that are relatively close to the median voter's preferred policies. Moreover, as each candidate competes for the favor of the median voter, the positions of both candidates converge toward the policy positions that maximize the median voter's welfare. In the limit, both candidates adopt the same platforms, and both candidates receive essentially the same number of votes. However, it doesn't matter which candidate wins the election in this limiting case. In either case, the strong form of the median voter theorem will hold for national public policies. The median voter gets exactly what he or she wants-to the extent that the elected candidate delivers on his or her campaign promises.

This line of reasoning can be generalized within limits. In electoral contests between two policy alternatives, candidates or parties, if a median voter exists government policy will maximize the welfare of the median voter in equilibrium. Median preferences determine a very wide range of policies if this conclusion can be applied to the broad range of decisions made by majority rule in modern democratic societies.

5. Illustration: The Median Voter's Demand for Public Policy

The strong form of the median voter model allows government policy to modeled as a straightforward application of the rational choice model developed in microeconomics. For example, consider the following model of the median voter's preferred level of environmental regulation. Suppose that environmental quality is a function of regulatory stringency R and national income, E = e(R, Y). Suppose also that the median voter gets a constant fraction "a" of national income, Y^m = aY, which is decreasing in regulatory stringency, Y = y(R). Suppose further that voters care about their own income and environmental quality. The constraints and definitions can be substituted into the median voter's utility function: U = (ay(R), e(R, y(R))), which can be differentiated with respect to R to characterize the median voter's ideal stringency of environmental regulation R*. R* will satisfy $U_Y aY_R + U_E (E_R + E_Y Y_R) = 0$. The first term is the median voter's marginal cost of environmental regulation and the last is his marginal benefit from more stringent environmental regulation.

The median voter will select policies that equate her marginal benefits with her marginal costs $(U_Y \ aY_R = U_E \ (E_R + E_Y Y_R))$. As these marginal costs and benefits change, so will the median voter's preferred environmental regulation. The implicit function theorem can be used to determine the comparative statics of environmental regulation with respect to parameters of the median voter's optimization problem.

6. Policy Implications of the Median Voter Model

Models have been developed for the median voter's demand for other forms of regulation, for public goods and services, for transfers to the poor and elderly, and for national and domestic defense by changing the constraints to fit the policy of interest. This is part of the versatility of the median voter model. It can easily be used to analyze a wide range of public policies. Given the strong form of the median voter theorem, such characterizations of the median voter's preferred policies provide (qualitative) forecasts of public policy in a well functioning democracy.

However, even without a specific characterization of the median voter's preferred policy, the median voter model has a number of clear implications. One implication is that public policies will tend to be moderate middle-of-the-road policies, e.g., drawn from the exact middle of the political spectrum. Such policies can be regarded as "moderate" essentially by definition. Another implication is that many, perhaps most, people will be at least partly displeased with the policies chosen. Voters tend to have different ideal point insofar as their tastes, age, income, tastes, ideology, or information differ. (However, although most people are dissatisfied with government policy, they may still prefer majoritarian decision rules to all the other methods of collective choice that they are aware of). A third implication is that increases in the dispersion of the distribution of voter preferences (increased radicalism) will have little, if any, effect on public policies unless increased dispersion also affects the median of the distribution of voter ideal points. *This implies that median voter policies tend to be relatively more stable than would have been the case if average rather than median voter opinions determined policy*. The properties of median implies that public policies will be relatively stable (robust) through time as voters are subject to life's vicissitudes, technological progress, and political shocks.

To go beyond these general properties of medians, the strong form of the median voter theorem is usually invoked. Given the strong form of the median voter model, any change in circumstance that changes the constraints of the median voter or the identity of the median voter is predicted to have systematic effects on the size and composition of government programs. For example, the median voter's demand for government services tends to increase through time as median income increases and as government services become relatively cheaper than private alternatives. However, as in ordinary microeconomic analysis, not every median voter model yields unambiguous predictions about the effects of changes in the median voter's choice problem on the electoral demand for government services. For example, the median voters demand for government services depends in part on the tax system used to finance them. Government services are generally normal goods in the sense used by economists, however when financed by an income tax the tax price of those services increases as voter income increases. This tax-price effect may partly or totally offsets the normal-goods effect of increases in median voter income.

7. The Normative Properties of Median Voter Policies

The normative properties of median voter outcomes are clearly of considerable interest for political theorists. Insofar as median voter outcomes tend to emerge in open democracies, evaluation of median policy preferences allows the merits of unconstrained democracy to be assessed.

Although the median voter model implies that the median voter gets what "she wants," it does not imply that public policies will be efficient in the usual Paretian sense of welfare economics. There are many reasons for this. First, the median voter model implies that minority interests do not directly affect policies, essentially by definition, and thus every majoritarian policy is likely to impose externalities on the minority. Second, even within the majority, votes rather than the intensity of desire or willingness to pay determine policy in electoral settings. Some voters who feel intensely about an issue may be willing and able to compensate others to adopt policies that differ from those otherwise favored by the median voter. Unrealized gains to trade may exist at the median voter's ideal policy.

A third source of normative difficulty for the median voter model is that the policy information available to the median voter is often fairly limited. It is clear that the task of assessing the relative merits of alternative policies can be a very time consuming and information intense task. Many policy analysts spend a lifetime to master the details of a single policy area such as tax or energy policy. In such areas, voters clearly can not be fully informed about the choices that they confront. In the case where the median voter's expectations are none-the-less unbiased, the median voter will still receive, on average, the package of government services and policies that he or she wants, although mistakes will be made. In cases where informational problems lead to biased expectations about the consequences of policies, the median voter will not get what truly advances his or her interests, but rather what is misperceived as advancing those interests.

Fourth, voter ignorance opens the door to the strategic games of interest groups and the bureaucrats who may manipulate voters by appropriately subsidizing various kinds of information and act counter to median voter interests (agency costs, bribery) in policy areas where the median voter is unlikely to be well informed. (It can be argued that essentially the whole special interest group/rentseeking literature is predicated on informational problems of these kinds in open democratic societies).

8. A Theoretical Problem for the Median Voter Model

There also is a well-known theoretical problem with majority rule that appears to reduce the applicability of the median voter model. A median voter does not always exist. For example, suppose there are three voters, Al, Bob and Cathy who must choose among three policy alternatives, I, II, and III. Suppose that Al prefers option III to II to I, while Bob prefers I to III to II and Cathy prefers II to I to III. Note that the pattern of votes will be, III > II and II >I, but I>III! Majority rule can lead to inconsistent rankings of policy alternatives, and to unstable policy choices. Duncan Black (1948) pointed out that single peaked preferences are sufficient to guarantee the existence of a median voter in one dimensional issue spaces. However, in 2-dimensional cases, a median voter exists only in cases where voter tastes are very symmetrically distributed. In other cases, intransitive cycles are endemic even if voter preferences are single peaked! In such cases, no median voter exists, and every policy has a non-empty win set. (The win set of policy vector z is the set of policy vectors which is preferred to z by a majority of the electorate). The absence of a median voter equilibrium may also arise in models where candidates can manipulate information and voter turnout. Chaos and indecision are predicted features of majority voting in such models.

9. Empirical Support for the Median Voter Model

Although theoretical arguments suggest that the applicability of the median voter model may be very limited, the empirical evidence suggests otherwise. There is a large body of evidence that suggests median voter preferences over policies are (largely) of the sort which can be mapped into a single issue space while retaining "single peakedness" Poole and Daniels (1985) find that 80–90% of all the recorded votes in the US Congress can be explained with a one dimensional policy space. Stratmann (1996) finds little evidence of cycling across Congressional votes over district specific grants.

Moreover, the median voter model has a very good empirical track record in public finance as a model of fiscal policy across states and through time. Recent studies show that the median voter model can explain federal, state, and local spending, as well as international tariff policies. Congleton and Shughart (1990) Congleton and Bennett (1995) suggest that the median voter model provides a better explanation of large scale public programs than comparable interest group models. This is not to suggest that the median voter always exercises the same degree of control over public policy irrespective of political institutions. Holcombe (1980) and Frey (1994) report significant policy difference between representative and direct forms of democracy that would not exist unless significant agency problems exist within representative government. Moreover, statistical tests can never prove that a particular model is correct, only that it is more likely to be correct than false. However, in general, the median voter model appears to be quite robust as a model of public policy formation in areas where the median voter can credibly be thought to understand and care about public policy.

The empirical evidence suggests that the median voter model can serve as a very useful first approximation of governance within democratic polities. As a consequence, the median voter model continues to function as an analytical point of departure for more elaborate models of policy formation within democracies in much the same way that the competitive model serves the micro economics literature.

MEDIEVAL CHURCH

The medieval Roman Catholic Church was an economic entity while at the same time undeniably pursuing social and spiritual goals. Large and powerful enough by the eleventh or twelfth centuries for Europe to be called "Christendom," the Church took on the character of a sophisticated modern corporation. A primary task of the social sciences has been to delineate the role that institutions and technology played in the development of western civilization. Over the past 20 years, the economic role in that development has come to the fore (Ekelund et al., 1996) as part of the overall economics of religion.

Economists are latecomers in the analysis of a number of implicit markets, including that of religion. However the fundamental premise undergirding these new approaches is that economic elements come to play in all markets, implicit as well as explicit. Thus, while it may be the case that economic motives do not necessarily dominate every decision, the "science of choice" may be applied to problems that have heretofore been labeled psychological, sociological, anthropological, political, legal or religious. Increasingly, therefore, the tools of modern microeconomics, public choice (especially as interest group analysis) and property rights are being applied to issues thought to be the exclusive matter of other social sciences. The medieval Roman Catholic Church is one of these issues.

The facts of the medieval church may be stylized and put into the context of an economic model. After the twelfth century, Roman Catholicism (with only insignificant fringe competition from Jews and Moors) came to dominate large parts of Western Europe. The legal system of the Church, canon law, was beginning to supplant and eventually dominate civil law in (then) loosely organized "states" and other political entities. Ecclesiastical officials enacted laws respecting all aspects of the "supply" decision of such goods as "assurances of eternal salvation," political support from the papacy and clergy and social services of all kinds. Marriage, trade and all manner of behavior were regulated in conjunction with the supply of these services. Kings, princes and aristocrats of all kinds owed much of their power to the approbation of the Roman catholic authorities who, with full complements of upstream and downstream agents, helped negotiate trade deals, wage wars and maintain armies. The Roman Church, moreover, was immensely wealthy and was a huge landholder during the medieval period. The retail side of the church offering religious, medical and social services of all kinds was also a primary source of revenues in addition to payments (taxes and other forms of rents) from monarchs, politicians and the local religious establishments (monasteries, parish churches, etc.).

The organization of the church was that of an M-form corporation with the pope as CEO, a financial division called the Papal Camera, upstream directors (the Curia and Cardinals), and a geographically dispersed downstream retail division. The primary role of the upstream church was to provide doctrine and dogma relating to the essential principles of membership (e.g., interpretations of the Holy texts) and to collect downstream rents. It established, with authority centralized in the Pope after the Council of Trent (1545–1563) but formalized only later in the nineteenth century, the often-labyrinthine conditions for eternal salvation and the penalties for violating any of those conditions.

Downstream were the geographically dispersed purveyors of local Roman Catholicism. These included the regional mendicant and contemplative religious orders, monasteries, some of which were as much production units of agricultural and other goods as sellers of religious services, and parish priests and other local clergy. While rents were collected at all levels, primary revenues came from these retail ends of the downstream church. Enforcement policies and assigned agents of the centralized Roman authorities were necessary to prevent opportunistic behavior in distant locales of the church.

Entry control was obviously necessary to maintain the strength of demand for the Roman monopoly. Malfeasors, when caught, were subject to severe punishments. Interdict, whereby the "sinner" could not have contact or truck with other Christians, was one form of punishment. Most severe was excommunication of the wrongdoer — a total separation from the body Catholic and a sentence of eternal damnation if repentance was not made. Heretics of all kinds (those who did not adhere to the main body of Catholic dogma and interpretations) were of course excommunicants, but many were also subject to violent death through the various "holy wars" or crusades of the middle ages. Later, even more virulent punishments were meted out to Protestants and other "heretics" through Inquisitions

in Spain, Rome and elsewhere. These punishments may be seen as attempts to maintain monopoly.

Doctrinal manipulations were also used by the Roman Catholic Church to make its demand curve more inelastic and/or to shift it rightward. The conditions attached to the Church's chief product — assurances of eternal salvation were manipulated throughout the middle ages in order to increase revenues and the number of demanders. Marriage markets, largely of secular and civil concern prior to the Church monopoly, were taken over by the Church with conditions attached to the simple contract respecting endogamy, presence of a priest, posting of bans, and so on. Regulations respecting "divorce" or marriage dissolution were intricate and varied with income and circumstances of petitioners. Such price discrimination manifestly increased the Church's rents over the medieval period. Another doctrine that was almost manipulated out of recognition was that respecting usury and "just price." When the church was a debtor, it seems, usury prohibitions were enforced, but not when it was a creditor. The same manipulations attended church rules respecting monastery thithes and taxes, the granting of indulgences, jubilee attendance, and benefices granted to bishops and cardinals. Such methods and practices of rent collection reached something of a limit in the sixteenth century precipitating the Protestant Reformation (Ekelund et al., 2002).

The economic view of the medieval church featuring the principles of public choice, industrial organization and microanalytic behavior, while still under construction, offers new insights into the development of western institutions. The old Weber-Tawney view of the church, as least as popularized, was that the Roman church and its policies had a negative impact on economic growth and development, a view that contrasts with that of Sombart and Schumpeter. The new microeconomic perspective eschews, to a large extent, these important macroeconomic issues. Rather, a theory of rational behavior permits an understanding of the church as an economic entity - one that benefited from increasing secularization of European society but one that recognized that science, technology and humanism would ultimately weaken the kind and form of "magic" the church was selling. If "belief in Christ and Christian principles" were the main issue, it would be difficult to explain how Roman Christians issued crusades against other "Catholics," the eastern orthodox Christian church or (later) Protestant Christians of all stripes. Moreover, the emergence of fierce censorship of all kinds in the sixteenth and earlier centuries is also difficult to understand (Galileo was a devout Catholic) except in an economic context, that is, the context of monopoly rent seeking by interest groups in the Church. Economists objectively viewing these policies and doctrines

see them as examples of monopoly behavior and all that the model entails. If religious organizations, in this case the Roman church, were acting solely in the public interest, they would behave as a "good government" — one that provides information, spiritual goods and social goods to the faithful at competitive, i.e., marginal cost, rates. An "economic" examination of the behavior of the medieval church does not provide overwhelming support for this view.

MERCANTILISM

Mercantilism, as stylized in standard parlance, is that system of state building and state controls that existed chiefly in European nation states between 1500 and 1776 (sometimes dated 1500-1650 or 1500-1650). Dating at 1776 is apt since the term "mercantilism" was coined by Adam Smith in his Wealth of Nations to describe a loose system of controls epitomized in dispersed writings by an equally dispersed group of pamphleteers of many nationalities (British, French Spanish, Flemish and Scandinavian among others). These writers shared a number of common concerns but no common analytical tools and, as such, the term mercantilism is ambiguous if it refers to some "system" of ideas or theories. There are fundamentally two methods of dealing with mercantilism in the literature of economics. First, mercantilism is characterized as a collection of ideas with a corollary as the history of and ideas leading to controls and state power. A second and newer approach considers mercantilism as a process featuring the declension of economic controls wherein rent-seeking individuals and groups alter constraints establishing a political economy leading to freer trade and the modern world.

There are ideational rationales aplenty for mercantilism and many are of significant historical value. As commentaries on international trade and domestic policies, mercantile writers such as Thomas Mun, Gerard de Malynes, Bernard de Mandeville and many others offered invaluable commentary on the economic history of their time. Mandeville and others in fact espoused variants of what came to be known as "laissez faire" (Chalk, 1951, 1966). Gold or specie acquisition, foreign trade regulation, colonization, or suppression of the poor is served up as objectives in much of this literature and such goals have become the *sine qua non* of ideational mercantilism. But the most famous ideational-historical argument for mercantile controls over trade (e.g. tariffs, quotas, prohibitions, etc.) is that they were the objects of "state power." The origins of this argument are found in the late nineteenth century (Schmoller, 1897) and continue in the magisterial study of Heckscher (1934 [1931]). The modern literature on mercantilism is awash with filigree on these themes but it is far more confused and contradictory than the earlier work of Heckscher (1934) and Viner (1937).

Nowhere does this historical literature consider let alone answer the questions "who is the State" or "why are these policies followed or advocated in place of others?" Only an approach that features rational behavior *as an informant of history* is able to provide satisfactory answers to these questions. That approach combines modern microeconomic theory and the insights of public choice in order to explain how rational economic actors under extant constraints altered (or were unable to alter) political and economic institutions that created (or did not create) the Industrial Revolution. *In Mercantilism as a Rent-Seeking Society* (1981) and later in *Politicized Economies* (1997) Ekelund and Tollison described how public choice and contemporary neoclassical economic theory explain the declension of mercantilism in England and its stubborn persistence in France and Spain.

In England there was a fundamental shift in authority from the monarchy to the British Parliament ---- that is, rent-seeking interest groups altered the source of property rights in the economy. This was accomplished in several ways. First, jurisdictional disputes of the two court systems (royal and common law) shifted the authority to alter property rights from the monarch to nascent democratic institutions. The common law courts often settled these disputes, many over the locus of controls over business and the granting of monopoly, (with Justice Coke often presiding) in favor of Parliament rather than the monarch. Secondly, the decline of internal controls took place due chiefly to the opportunistic behavior of Crown agents and to the self-interested activities of businesses. A prime example of this sort of behavior was the attempted enforcement of the Statute of Artificers (1563). Local guilds after having received monarchical privileges in London and elsewhere to set up regional monopolies were thwarted in their aims by unpaid enforcers of the regulations. Sheriffs, and other unpaid enforcers, were predictably self-interested and made deals that undermined the Statute. The ability of illegal competitors to

escape to the countryside (where any enforcement was more costly) also helped make the regulations ineffective. Thus, the "process view" of mercantilism emphasizes that public choice — wherein manipulations by rent-seeking self-interested groups create property rights changes — is at the center of the explanation of how mercantilism was undermined and freer competition emerged. Naturally, these developments were at first fragile. Commitments to tripartite democratic institutions during the seventeenth century (during the Restoration) had ultimately to be credible (North and Weingast, 1989) and this period of instability carried over into the eighteenth century (Wells and Wills, 1998).

While England had long enjoyed some nature of checks on the authority of the monarchy, especially checks on taxation, France and Spain did not. Colbertism - the name given to mercantilism in France - reigned supreme as monarchical authority established domestic and trading monopolies of many different kinds. As rent-seeking agent for the French Crown, Jean-Baptiste Colbert established a tobacco monopoly in 1681 regulating all aspects of tobacco production, importation, manufacture and sale. This state monopoly, and others like it such as in textiles, generated enormous rents for the Crown with tobacco regulations alone bringing in 500,000 livres in 1681 and 30 million in 1789. In other matters such as the state purchase of inputs, the state acted as a monpsonist. Cartelization or franchising monopoly through competitive bidding also followed a pattern with finished goods the object of rational rent-seeking by the French Crown. Such policies included the retardation of invention, innovation, the arts and academics. French intendents located in the provinces and accountable directly to Crown ministers were the enforcers of all this regulation. Malfeasors and cheating of any kind was dispensed with harshly.

In Spain, mercantilism and centralized control of areas of the economy proceeded with at least as much vigor as in France. Crown and "aristocratic" monopolies were imposed over virtually all domestic and international commerce. Combined with theocratic elements of the Roman Catholic reconquest (persecution of Moors, Jews and Protestants through the Inquisition), Spanish mercantile patterns were more virulent if somewhat less effective due to traditional Spanish "separatism" than in France. These policies often had disastrous effects. The monopolization of sheep farming, for example, into an organization called the Mesta reduced the amount of farming to levels that created periodic famine. Regulatory rents and ever-increasing taxes went to finance the glory of the monarchy and the waging of costly wars. These factors plus strong class differentiation, enormously skewed income distributions, religious persecutions, huge bureaucracy at regional and, later at national levels, and a rent-seeking regulatory death grip on trade all contributed to the later "tragedy" of Spain's lack of economic development.

Mercantilism touched all nations over the period, including colonies. Colonization was indeed the object of European nation states, but rent flows guided the path of colonization. American colonists were asked to conform to trade regulations, production prohibitions and price controls set up by the English monarch and the Parliament. Although they did so imperfectly due to opportunistic behavior on the part of British governors and American agents, customs officials were given extraordinary powers under the Navigation Acts passed between 1660 and 1696. Decrees and Parliamentary legislation of the time, e.g., the Hat Act of 1732, cannot be attributed to "state power" however. Rather it is demonstrably the result of rent-seeking selfinterested behavior on the part of individuals and groups within the polity of England. All such moves towards control of European colonies may be viewed in this light.

Mercantilism then is most fruitfully conceived as a problem in constitutions, interest groups and rational behavior. This view offers, unlike the ideational-historical perspective, a means of analyzing institutions that cause and those that hinder economic growth and development. The tools of public choice and neoclassical economics are essential to that critical undertaking.

MONETARY POLITICS

In many countries monetary policy institutions have been designed to minimize "political" influences on decisionmaking, but given the motivations of politicians, these protections will always be imperfect. This entry describes the most important political influences on monetary policy. We first consider monetary policy cycles related to the timing of elections, then those involving partisan change. Next considered are political models of inflationary biases, including applications of the time inconsistency problem and models of bureaucratic behavior. Finally, monetary policy choices are briefly described in the context of public choice models of committee decision-making.

1. Electorally Motivated Political Monetary Cycles

In Nordhaus's (1975) model of the political business cycle, vote-seeking politicians opportunistically manipulate the economy to gain the support of myopic voters who are concerned with current macroeconomic conditions. Incumbent politicians engineer pre-elections booms to gain votes; these booms are then followed by post-election contractions. Political business cycles could be produced with either fiscal or monetary policies, but monetary policy changes can be implemented quickly and without special enabling legislation.

The Nordhaus model was probably inspired by the 1972 U.S. presidential election. In that year, incumbent Richard Nixon was the beneficiary of a healthy pre-election boom, a boom that many suspected was engineered with the cooperation of Chairman Arthur Burns at the Federal Reserve (Fed). Woolley (1984) carefully reviewed Fed decisionmaking in that year, and concluded that the Fed's Federal Open Market Committee (FOMC) was not directly motivated by a desire to insure Nixon's reelection. However, price controls imposed by the Nixon administration transferred intense political pressure to the Fed — any move by he Federal Reserve to raise interest rates in a regime of controlled price and wages would surely have drawn ire from politicians and the public. Thus, while the Fed's accommodative stance probably reflected bureaucratic self-protection, the effect nevertheless advanced the reelection prospects of the incumbent.

Systematic quantitative evidence of political monetary cycles also exists. Grier (1987) estimated a monetary policy reaction function for the U.S. that was augmented with dummy variables to account for electoral timing. He found that the electoral dummies were statistically significant, supporting the hypothesis of cycles. These results were questioned by Beck (1987), who suggested that the electoral pattern primarily reflected accommodation of fiscal policy pressures, but Grier (1989), using more flexible empirical specifications, later found evidence of electoral cycles even when the stance of fiscal policy was accounted for. Subsequent evidence has been mixed, but the hypothesis of a monetary political business cycle clearly cannot be dismissed.

2. Partisan Political Business Cycles

In a pioneering cross-country study, Hibbs (1977) found that unemployment rates were lower under left-leaning than right-leaning political regimes, reflecting the underlying concerns of the parties' core constituencies. Supporting this theme in the monetary policy arena, Beck (1984) concluded that U.S. monetary policy is easier under Democratic presidents than Republicans; Cowart (1978) and Minford and Peel (1982) provided similar evidence for left- and right-leaning governments in Europe and the U.K. Grier (1991, 1996) provided striking evidence that the partisan composition of Congressional oversight committees affects the stance of monetary policy in the U.S.

With the advent of the rational expectations revolution, political business cycle models of both partisan and electoral varieties were questioned, and ultimately reformulated. A rational model of electoral cycles was presented by Rogoff and Sibert (1988) and rational partisan models were formulated by Alesina (1987), Alesina and Sachs (1988), and Chappell and Keech (1986, 1988). In the rational partisan models, election uncertainty causes partisan-related policy surprises and fluctuations in real economic outcomes. Chappell and Keech (1988) empirically linked election-related surprises in monetary policy to changes in unemployment in the U.S., finding modestlysized partisan impacts. Alesina, et al. (1997) found broad supportive evidence for rational partisan cycles and related patterns in monetary policy across a panel of 18 OECD countries.

3. Channels of Influence

Partisan and political business cycle models require that politicians control, or at least influence, fiscal or monetary policies. How do they do so? Building on the arguments of Kane (1980), Havrilesky (1995) suggests that, in the U.S., presidential influence over monetary policy derives in part from the Fed's need to deflect Congressional threats to its independence — i.e., the Fed accommodates presidential wishes; in return, it is understood that the president will protect the Fed from threatening legislative

intrusions. The Congress implicitly gains from this standoff as well: it can publicly "bash" the Fed for its bad performance, while escaping direct responsibility for economic outcomes. Havrilesky's (1988, 1995) statistical evidence showed that the Fed was responsive to direct executive branch "signals" of monetary policy preferences reported in the press.

Politicians also influence monetary policy through the power of appointment. Havrilesky and Gildea (1992) have argued that economists are particularly reliable ideologues and that presidents, recognizing this, choose economists for their early-term appointments. Waller (1992) also investigates the appointments process, developing a model of bargaining between an appointing executive and a confirming legislature. Both Waller (1989) and Keech and Morris (1997) have noted that if influence over policy comes primarily through the power of appointment, policy shifts associated with regime changes in the executive branch may be gradual and delayed; it takes time for a president to "pack the Board" with loyal supporters. Chappell et al. (1993) have used dissent voting data to infer that U.S. presidents' partisan influences over monetary policy come primarily via the power appointment rather than direct pressure. This poses a particular challenge for rational partisan models described earlier: rational partisan models require that elections produce policy surprises, but election-related surprises will be minimal if policy change must await a packed Board.

4. The Political Origins of Inflation

In most economies the price level rises over time. In the absence of a strong case for the desirability of inflation, one is led to suspect a political bias toward inflationary policies. The time inconsistency problem, described by Kydland and Prescott (1977) and applied to monetary policy by Barro and Gordon (1983), provides a possible explanation for such a bias. According to this theory, policymakers value both low inflation and output in excess of its natural rate. If the public expected zero inflation, policymakers would have an incentive to increase output with a positive money supply surprise. But if the public had rational expectations, this incentive would be anticipated, rendering a zero inflation equilibrium untenable. Rather, inflation will be positive in equilibrium, and will persist at a level where the marginal costs of inflation and the associated marginal (short-run) gains in output are balanced. Although it is not widely appreciated, a similar result was described by Nordhaus (1975) in a setting where expectations were adaptive rather than rational.

MONETARY POLITICS

To avoid a suboptimal inflationary equilibrium, some have proposed that politicians might wish to appoint "conservative" central bankers (i.e., those who are less concerned with output gains than their political principals) and grant them independence in day-to-day policymaking (Rogoff, 1985). Such a solution is problematic: it is not clear how conservatives are to be identified and selected. nor is it clear how their independence is to be protected given the incentives of political principals (Toma, 1997). These issues aside, a substantial empirical literature has developed on the relationship between central bank independence and inflationary performance across countries. After exhaustive study, Cukierman (1992) concluded that the preponderance of the evidence supports the view that independence and low inflation are connected, but that evidence is not overwhelming.

Inflation may also arise from the desire of governments to directly extract revenue via money creation - it is widely recognized that hyperinflations have political origins in the need to raise revenue without levying explicit taxes. Using a model that employs the logic of the time inconsistency problem, Cukierman (1992) has shown that the revenue motive can produce an inflation rate exceeding the steady-state seigniorage-maximizing rate. He also provides some empirical support for the seigniorage motive from cross country evidence — seigniorage is a more important source of revenue when tax institutions are less efficient and political systems less stable. For the U.S., Toma (1997) has described how institutional changes affecting the Federal Reserve's revenue generating capacities have mirrored changes in the government's need for seigniorage revenue.

Although most theories focus on the political "demand" for inflation, the political "supply" is also an important public choice issue. In the U.S., the operating budget of the Federal Reserve bureaucracy is funded by interest earnings on government bonds that it holds. When the Fed exchanges money for bonds, it trades an asset that bears no interest for one that does, providing a bureauratic incentive for monetary expansion (Toma, 1982). Tollison and Shughart (1983) have provided empirical support for Toma's model by demonstrating that expansions in Federal Reserve employment have been related to expansions of the monetary base.

5. Committee Decisions

Monetary policy decisions are usually made by committees, and committee decision-making is a topic of intrinsic interest in public choice. In the U.S., monetary policymaking provides an excellent opportunity to study committee decisions because the FOMC meets repeatedly to consider a single issue (the degree of ease or tightness in the policy stance) and because there are extensive records describing both the preferences of individual members and FOMC decisions. Formally, monetary policy directives require majority approval by the FOMC. Members must cast assenting or dissenting votes; these votes are recorded and later made available to the public.

Investigations of dissent voting patterns have shown that there are systematic differences in policy preferences across members. For example, district Reserve bank presidents tend to favor tighter policy than Federal Reserve Board governors (Belden, 1989), and Democratic appointees favor ease relative to Republicans (Havrilesky and Gildea, 1991). Policy preferences of FOMC members are also related to educational background, profession, and other career characteristics (Havrilesky and Schweitzer, 1990; Chappell et al., 1995). Econometric analysis of FOMC voting patterns also reveals that the Fed Chairman has disproportionate weight in committee decisions, undermining the simple median voter hypothesis (Chappell et al., 1993).

The availability of information on policy preferences of individual committee members suggests a fruitful direction for research on politics and monetary policy. Political influences, whatever their source, must operate through the decisions of individual policymakers. This in turn suggests that political influences may be more clearly detectable when individuals provide the unit of analysis, rather than a governmental entity that has already aggregated those preferences. A nice illustration of this is provided by McGregor's (1996) investigation of political monetary cycles using data describing individual FOMC members' votes. McGregor found that FOMC members who were appointed by the party of the incumbent president tend to favor pre-election ease, while members appointed by the opposition favored pre-election tightness. At the individual level political influences were abundantly clear; at the level of committee outcomes these influences were obscured.

Ν

THE NEW DEAL

I pledge you, I pledge myself, to a new deal for the American people. (Franklin Delano Roosevelt) The Great Depression is to economics what the Big Bang is to physics. (Margo, 1993)

Whatever else might be said about the New Deal — and scholars and polemicists alike have said much — the fact of the matter is that it did not work. Despite unprecedented federal government spending over the period 1933 to 1939, recovery from history's worst depression, in the United States at least, ultimately awaited Pearl Harbor: GNP in 1958 prices remained below that of 1929 for more than a decade (Couch and Shughart, 1998: 26). By contrast, 'recovery occurred in 1932 for New Zealand; 1933 for Japan, Greece, and Romania; 1934 for Chile, Denmark, Finland, and Sweden; 1935 for Estonia, Hungary, Norway, and the United Kingdom; 1936 for Germany; and 1937 for Canada, Austria, and Italy' (Romer, 1993: 23–24).

There are a number of reasons why the policies and programs set in motion by FDR failed to achieve at least the first two of his stated goals of 'relief, recovery and reform'. One is the First New Deal's (1933-35) wrong-headed strategy of responding to a colossal decline in real output by implementing programs that had the effect of reducing production even further (Higgs, 1987: 174). Confusing effect with cause, the operation of salutary market forces was shortcircuited by the administration's efforts to prop up farm prices by drastically reducing the number of acres under cultivation and by actually destroying crops and livestock; to prop up wages by fostering unionization and by enacting minimum wage and 'prevailing wage' laws; and to prop up industrial prices by exempting from the antitrust laws codes of 'fair competition' negotiated under the National Industrial Recovery Act. Another reason for failure is a series of disastrous monetary policy initiatives, beginning with a sharp contraction in the money supply at the depression's onset, and ending with a doubling of the banking system's required reserve ratios at a time (1936–37) when recovery seemed finally to be underway (Friedman and Schwartz, 1963: 299-545). Yet another reason is the uncertainty created by the administration's anti-capitalist rhetoric, which turned especially virulent during the Second New Deal (1935–39). FDR's notorious plan to 'pack' the Supreme Court and his nomination of ultraliberal Senator Hugo Black to that suddenly complaisant body combined with the administration's attacks on business to chill investment incentives by outwardly threatening the separation of powers and constitutional protections for private property (Higgs, 1997).

When FDR began his first term of office on March 4, 1933, the US economy was in shambles: 'net national product in current prices fell by more than one-half from 1929 to 1933 and net national product in constant prices by more than one-third' (Friedman and Schwartz, 1963: 299). Real incomes dropped by 11 percent between 1929 and 1930, 9 percent between 1930 and 1931, 18 percent between 1931 and 1932, and 3 percent the next year. 'These are extraordinary declines for individual years, let alone for four years in succession. All told, money income fell 53 percent and real income 36 percent' (ibid.: 301). American workers were losing their jobs in unprecedented numbers. Beginning in the last half of 1929, unemployment rates rose steadily until fully 25 percent of the US labor force had been idled (Stein, 1984: 30). Indeed, the annual rate of unemployment has reached double-digit levels in the United States in only 17 of the last 100 years for which data are available. Ten of these milestones occurred during the Great Depression (Vedder and Gallaway, 1993: 75).

Facing 'an emergency more serious than war' (Higgs, 1987: 159), the Roosevelt administration's response was both swift and massive. FDR's legendary First One Hundred Days were legislatively the most active of any US chief executive before or since. Many of the alphabet agencies of the New Deal, addressing 'virtually all basic economic activity of the nation, such as banking, employment, unemployment, housing, agriculture, transportation, salaries and wages, credit, insurance, and regional economic development' (Hosen, 1992: 8), were hastily put in place. As Arthur Schlesinger describes it,

on adjournment on June 15, 1933, the President and the exhausted 73rd Congress left the following record: March 9 — the Emergency Banking Act, March 20 — the Economy Act, March 31 — the establishment of the Civilian Conservation Corps, April 19 — abandonment of the gold standard, May 12 — the Federal Emergency Relief Act, setting up a national relief system, May 12 — the Agricultural Adjustment Act, establishing a national agricultural policy, with the Thomas amendment conferring on the President powers of monetary expansion, May 12 — the Emergency Farm Mortgage Act, providing for the refinancing of farm mortgages, May 18 — the Tennessee Valley Authority Act, providing for the unified development of the Tennessee Valley, May 27 — the Truth-in-Securities Act, requiring full disclosure in the issue of new securities, June 5 — the abrogation of the gold clause in public and private contracts, June 13 the Home Owners' Loan Act, providing for the refinancing of home mortgages, June 16 — the National Industrial Recovery Act, providing both for a system of industrial self-government under federal supervision and for a \$3.3 billion public works program, June 16 — the Glass-Steagall Banking Act, divorcing commercial and investment banking and guaranteeing bank deposits, June 16 — the Farm Credit Act, providing for the reorganization of agricultural credit activities, and June 16 — the Railroad Coordination Act, setting up a federal Coordinator of Transportation. (Schlesinger, 1958: 20–21)

That was only the beginning, however. Over the next six years, the New Dealers spent prodigally in an attempt to jump-start the economy. The most famous of the New Deal agencies, the Works Progress Administration (WPA), was launched in early April 1935 with an appropriation of \$5 billion, at the time the single largest budget request in American history (Conkin, 1975: 56). Headed by Harry Hopkins, the WPA financed tens of thousands of public works projects, including paving and repairing 240,000 miles of roads, constructing 153 air fields and laying 280 miles of runway, erecting 4,383 new school buildings and repairing 30,000 others, and building or refurbishing more than 2,000 sports stadiums (Couch and Shughart, 1998: 113-14). Ostensibly believing that the work provided should match the skills of the jobless as closely as possible, Hopkins financed thousands of projects that employed out-of-work painters, sculptors, actors, and other artists (ibid.: 114). The common perception that the WPA is synonymous with the New Deal has some basis in fact: it and other public works programs accounted for 34 percent of total federal emergency spending during the depression years (Couch and Shughart, 2000: 108).

Charges of fraud and waste were quite common and, in fact, the WPA, dubbed 'We Piddle Around' by its many critics, is credited with adding the word 'boondoggle' to the English language. The conventional wisdom about the WPA in particular and the New Deal in general, however, is that it saved American capitalism from its own excesses. Were it not for the federal government's active intervention at a time when markets seemed incapable of selfcorrection, the demands of a beaten people would have forced far more drastic policy changes, perhaps propelling the nation into the waiting arms of the socialists. As one contemporary admirer put it,

federal policy providing work for the jobless ... has been of inestimable value to millions of workers who otherwise would have been idle and, in many instances, without means of subsistence. Furthermore, the demonstration that a democracy could assure to a substantial fraction of its jobless workers an opportunity to work as well as the actual work that was accomplished represented priceless gains to the American people as a whole. (Howard, 1943: 841)

With billions of dollars available for distribution in the form of direct relief, work relief, subsidized loans and insurance, it should come as no surprise that the competition for federal dollars was intense, or that complaints by some state and local politicians of constituents being shortchanged frequently were strident. Congressional delegations from the South, a region that FDR often referred to as the 'nation's number one economic problem', were especially vocal in charging that the New Dealers responsible for allocating funds had their eyes on more than simple economic need. It was not until much later, however, that serious empirical study of the New Deal's spending priorities became possible.

The modern literature on the New Deal was launched by Leonard Arrington's (1969) announcement of his discovery of a set of documents prepared by the Roosevelt administration in 1939 to showcase its economic policy accomplishments, and by his own descriptive statistical analyses of the data showing wide disparities in the cross-state distribution of funds (also see Arrington, 1970). Don Reading (1973) was the first economist to exploit Arrington's dataset econometrically. He found modest support for a 'relief' hypothesis of New Deal spending. In particular, states experiencing the most severe declines in per capita incomes between 1929 and 1933 received more federal aid per person (summed over the entire 1933-39 period) than did less hard-hit states. Nevertheless, most of the crossstate variation in the distribution of New Deal funds was explained, not by other indicators of economic distress (the level of income per capita in 1933, the unemployment rate in 1937, and the percentages of the population that were either black or engaged in tenant farming in 1930), but by variables controlling for the presence of national assets in a state (the fraction of state lands owned by the federal government and the number of highway miles per capita).

Reading's most enduring contribution to the literature, however, was to speculate that his failure to find empirical support for the New Deal's stated goals of promoting economic recovery and fostering institutional reform left room for political explanations of the administration's spending priorities. Perhaps, Reading (1973: 803) suggested, states were rewarded or punished according to the roles they played in electing FDR in 1932. A variant of that hypothesis was subsequently tested by Gavin Wright (1974), who found that a measure of 'closeness' of presidential vote shares in a state, along with the standard deviation of that variable, explained nearly 59 percent of the variation in the interstate distribution of New Deal funds. Other things being the same, states where presidential races historically were tight and party vote shares were more volatile received more New Deal largesse. FDR would have anticipated higher political returns per dollar spent in such states, compared with others where the Democratic Party's vote share traditionally had been both either very large or very small and stable (reflecting entrenched voter positioning).

Wright's presidential vote-buying model of New Deal spending thus supplies a public choice explanation for why the solidly Democratic South received proportionately less federal aid than other regions of the country. Importantly, variables controlling for economic need (the decline in income per capita between 1929 and 1932, the fraction of the population on relief in 1935, and the unemployment rate in 1937) were not statistically significant when Wright estimated a more general model of the determinants of the cross-state distribution of New Deal funds. Other than the two political variables, only the percentage of state land owned by the federal government and the fraction of the population living on farms (which Wright included as a proxy for the political effectiveness of the farm lobby) contributed significant explanatory power. Similar findings emerged when Wright investigated the allocation of WPA jobs across states.

In sum, Wright's empirical evidence pointed to presidential politics as the chief determinant of New Deal spending. These results were later confirmed and extended by Anderson and Tollison (1991), who also found evidence of congressional influence on New Deal priorities, and by Couch and Shughart (1998), who exploited annual state employment indices developed by Wallis (1987) for the depression period to disaggregate the data by year and by expenditure category.

In a series of papers, John Joseph Wallis (1984, 1987, 1989, 1991) offered an alternative explanation for the failure of prior studies to find a significant relationship between New Deal spending and economic conditions in the states. In particular, Wallis argued that implicit and explicit matching requirements, whereby the states were required to share the cost of financing many of the New Deal's programs, are decisive in explaining the cross-state distribution of federal funds. Indeed, when a two-equation model designed to capture the interrelationships between federal spending and state spending during the New Deal was estimated (Wallis, 1984) or, alternatively, lagged federal grants were included in a single-equation model of federal spending across states (Wallis, 1987), economic conditions in the states became statistically significant. Moreover, the estimated signs on these variables were consistent with the hypothesis that the New Dealers responded to economic need, thereby helping 'restore a measure of credibility to the traditional view of the New Deal' (ibid.: 519). One interpretation of Wallis's matching hypothesis is that ideological opposition to the New Deal on the part of the region's political elites explains the South's comparative relative neglect: southerners simply balked at contributing the money necessary to attract significant federal aid.

Exploiting data on the matching requirements actually used by the Works Progress Administration, Couch and Shughart (2000) find, however, that the funding formula was itself perverse. They report a negative relationship between state matching contributions and state income. States hit harder by the Great Depression, in other words, were required to bear larger shares of the cost of financing WPA projects. They also find that, holding income per capita and other variables constant, states making smaller matching contributions tended to receive larger federal grants. (Consistent with regional differences in the marginal vote-buying power of New Deal spending, significantly less WPA money was allocated to the southern states than predicted by their cost shares.) With respect to the WPA at least, it does not appear to be the case that states with healthier economies benefited disproportionately from the New Deal merely because they had more resources available for matching purposes. (If that were true, why would such a formula have been adopted for distributing emergency relief funds in the first place?) What does appear to be the case is that Harry Hopkins rewarded his agency's supporters: funding for work relief projects was more generous in states represented by US Senators who voted to pass the Emergency Relief Appropriation Act of 1935, the legislation authorizing the creation of the WPA.

Public choice interpretations of the New Deal have yielded significant insights into the political forces that shaped the US government's responses to the unprecedented economic events of the 1930s. Many questions remain unanswered, of course, but we can now be reasonably confident that a vote motive belongs on the list of reasons why the New Deal failed to achieve its stated goals. Although he denied saying it, the New Dealers were for the most part motivated, not by public spirit, but by Harry Hopkins's celebrated call to political arms: 'we shall tax and tax, and spend and spend, and elect and elect'.

NONPROFIT ORGANIZATIONS

Although public choice theorists and other researchers typically dichotomize the economy into the private and public sectors, a large and growing segment of the U.S. economy does not appropriately belong in either category: nonprofit entities. The terms "third sector" and "independent sector" are used to refer collectively to nonprofit organizations and to emphasize how they differ from for-profits firms and governmental bodies.

Nonprofits are artificial creations of the federal tax code under section 501(c) and can be further divided into notfor-profits and charities. Not-for-profits operate exclusively to serve a specific membership or client group, e.g., the American Automobile Association which aids member motorists. Charities or nonprofits, at least in theory, benefit society as a whole and are far more important in the size and scope of their activities than not-for-profits. Thus, my discussion is limited to charitable organizations which are classified by the Internal Revenue Service (IRS) as having 501(c)(3) or 501(c)(4) status and religious organizations. Such entities engage in a myriad activities including, but not limited to, health (hospitals, clinics, nursing homes, and physical fitness facilities), museums, education (college, university, and other institutions), disease research, public policy, and addressing society's ills disaster relief, illness, homelessness, unemployment, abuse of humans and animals, and hunger, for example.

Conventional wisdom holds that most charities help the unfortunate in society who cannot help themselves, "but only about 10 percent of charities do that. Many organizations, declared to be charities by the IRS, serve the wealthy and middle class. ..." (Johnston, 1987). A survey by the Urban Institute "of 3,400 human service organizations revealed that the poor comprised the majority of the clients of only about 30 percent of the agencies, and that for half of the agencies, the poor constituted less than 10 percent of the clientele" (Salamon, 1985, p. 44).

Some nonprofits are national in scope, collect and spend hundreds of millions of dollars each year, and employ thousands of staff members, e.g., the American Red Cross, while others may serve only a small local constituency through volunteer effort with a small budget, e.g., a local soup kitchen aiding the hungry or a shelter for the homeless. There is no "typical" nonprofit in terms of size of staff, scope of activities, budget, functions, or any other operating dimension.

The term "nonprofit" is rather misleading in that most of these entities do, indeed, earn profits, in the sense that their revenues exceed costs. There are two primary characteristics of every charity: (1) there are no residual NONPROFIT ORGANIZATIONS

claimants, i.e., the "profits" — the excess of revenues over costs — cannot be distributed to any person or group and (2) society as a whole must, at least in theory, benefit from the organization's operations.

Nonprofit entities have "been a feature of Anglo-American law for nearly a millenium," (Hansmann, 1980, p. 884), and in his classic work, Democracy in America, Alexis de Toqueville (p. 198) praised the extensive voluntary activity that he observed and asserted that "Nothing ... is more deserving of our attention than this sector." Charitable activity is a significant and growing fraction of economic activity in the United States. As shown in the Table 1, there were 1.23 million charitable organizations in 1998 (including social welfare and religious congregations) with 10.9 million full-time and part-time employees who account for approximately 7.1 percent of total employment. These entities received \$664.8 billion in revenues in 1997 from private contributions, dues, fees, and charges, and government grants and other sources. Moreover, the nonprofit sector is growing rapidly: Between 1982 and 1998, the number of nonprofits rose by 437,000 (55.1 percent); their revenues soared by \$453 billion (213.7 percent); paid staff increased by 4.4 million; and the number of volunteers in full-time equivalents climbed by 1.2 million (26.7 percent).

Nonprofits are unique from all other organizations in society in that only they can call forth the energies of volunteers and donations of money and goods from private households. Independent Sector, a trade association for nonprofits, estimates that in 1998, 55.5 percent of Americans volunteered, some 109.4 million persons, who contributed 19.9 million hours of their time which was valued at \$225.9 billion. Some 70.1 percent of households on average contributed \$1,075 to charitable activities in 1998. (Independent Sector, 2001)

Table 1: Size and scope of the nonprofit, tax-exempt sector^a in the U.S., selected years, 1982–1998

Attribute	1998	1992	1987	1982
Number of organizations (millions) Total revenues (\$ billion)	1.23 665 ^b	1.03 509	.907 317	.793 212
Paid staff (full- and part-time) (millions)	10.9	9.1	7.4	6.5
Full-time equivalent volunteers (millions)	5.7	5.5	5.1	4.5

Notes

^a Includes 501(c)(3), 501(c)(4), and religious organizations.

^b This figure is for 1997.

Source: Independent Sector (2001).

Although the rationale for nonprofit status has never been explicitly stated by Congress, three economic justifications have been offered: "thin markets," "market failure," and "public goods." A university press, for instance, publishes books that most commercial publishers would disdain because the market for the books is so limited that their production would not be profitable, but society is better off with the book, despite its small readership. "Market failure" is used to justify nonprofit hospitals; e.g., the market failure occurs because consumers are supposedly incapable of judging the quality of their medical care. Removing the profit motive by having nonprofit provision in theory helps overcome the principal-agent problem in such cases, a rather questionable notion given that both forprofit and nonprofit hospitals and other medical facilities exist. The public goods argument applies to museums; volunteer labor and private contributions efficiently produce a cultural and artistic heritage that is highly desirable to society at little cost to the state.

To encourage charitable activity, nonprofits are heavily subsidized to reduce their operating costs. Nonprofits are exempt from local, state, and federal income, sales, and property taxes; they receive special treatment from the federal government regarding unemployment insurance, minimum wages, securities regulation, bankruptcy, antitrust restrictions, and copyright; charities enjoy a host of exemptions from onerous state and local laws and regulations regarding franchises, inspections, bonds, and so forth. Employees of nonprofits are even treated differently under the law; an employee of a charity can contribute more to a retirement fund than can an employee of a forprofit. Nonprofit postage is subsidized, and these organizations can mail literature and catalogs at much lower costs than their for-profit counterparts. Finally, contributors to a charity with 501(c)(3) status obtain a deduction from federal, state, and local income taxes. (Bennett and DiLorenzo, 1989, pp. 9–11.)

From an economic perspective, the most critical characteristic of charities is that they are virtually insulated from both marketplace competition that disciplines managers of private firms and electoral constraints faced by politicians in the public sector. Nonprofits are run by self-perpetuating boards of directors, so there is never an election contest to oust incumbents, and there are no shareholders demanding accountability — after all, the *sine qua non* of the nonprofit form is that profits may not be distributed. The directors are volunteers who serve part time, so professional, full-time staffs have wide discretion in controlling the organization and its agenda and are able to divert resources to perquisites that benefit the staff. Research has shown that although charities describe themselves as

"volunteer" organizations, a large portion (half or more) of the budget typically goes for staff salaries, benefits, and perquisities; substantial wealth is held in reserve at the same time that fund raising is relentless. Indeed, fund raising and organizational survival and growth become the primary objectives of long-established charities after professional staffs gain control (Bennett and DiLorenzo, 1994). X-inefficiency is a characteristic of nonprofit institutions (Duizendstraal and Nentjes, 1994). In large, bureaucratic nonprofits directed by professionals, charitable activity is undertaken primarily as an adjunct to the fund raising function. Many programs are not intended to benefit the public but rather to give publicity to the organization to aid fund raising (Bennett and DiLorenzo, 1999). Small, local charitable organizations serving a specific clientele and operated mainly by volunteers and religious institutions tend to be more charitable in the traditional sense.

Three trends are emerging which have major implications for nonprofits in the long run. First, spurred on by the success of AIDS activists in obtaining ten millions of dollars from local, state, and federal governments, many charities are increasingly seeking funding from the public sector to support their programs (Smith and Lipsky, 1993). The taxpayer is viewed as a much more reliable source of funding than contributions from corporations or individuals. Although this approach may increase revenues in the short run, the inherent problems is that with government funds come bureaucratic restrictions about how nonprofits must operate, who must be served, and so forth. Second, and relatedly, nonprofits are becoming much more active in the political arena as advocates of various public policies, some of which stray far from the realm of traditional charity. (Bennett and DiLorenzo, 1998, 2000). Taken together, these two trends imply that nonprofits are diminishing their separate identities as "independent" organizations and inevitably becoming more like adjuncts of government.

The third trend involves ties between nonprofits and forprofits, i.e., the commercialization of the nonprofit sector through endorsements and "seals of approval" on products of commercial firms and through nonprofits' own commercial activities (Bennett and DiLorenzo, 1989, 2001). Weisbrod (1998, pp. 287–288) has observed that "Nonprofit organizations' are bringing revolutionary changes in traditional behavior, and in the process they are blurring the distinction between nonprofits and private firms." The issue with commercialization of charity is that charity, in a sense, is the antithesis of commercialism. In the world of commerce, consumers expect goods and services in return for payments to producers. In the world of charity, donors expect nothing in return for their contributions, and society benefits from the benevolence of the giver. As commercialism of charities becomes more widespread again driven by the search for revenue — different individuals assume importance in the organization. Marketing and production experts gain power at the expense of those dispensing charity. Goal displacement is inevitable in the long run.

Taken together, three trends imply that nonprofits are becoming more closely tied to government and more like commercial enterprises. Thus, their unique role and functions in society are being steadily diminished. If donors perceive that nonprofits are adjuncts of government or commercial in nature, private contributions and other support may wane for these institutions that have important roles to play in contemporary society.

THE ORIGINS OF SOCIAL CHOICE THEORY

The term "social choice" originated with Arrow's (1951) theoretical analysis of the problem of aggregating the transitive preferences of individuals into a transitive collective preference outcome. The concept of social choice is also associated with "collective choice" analysis rooted in an economic analysis of the logic of democratic consent found in the work of Buchanan and Tullock (1962).

Both of these analytical approaches are related to earlier, relatively unknown studies of the properties of voting methods. From the Roman Republic until today, voting analysts have identified methodological properties and dilemmas. But it was not until late in the 18th century that this knowledge began to be developed cumulatively within a common theoretical framework. Instead, the insights of one analyst in defining and approaching a problem were often lost. So later analysts had to start from scratch, often with very different analytical tools, concepts, and objectives.

The history of voting ideas has an ambivalent status in social choice and collective choice theory. On the one hand, pursuing the goal of a deductive science of voting seems to reduce historical developments to purely antiquarian significance. For in principle, the generality of theories makes it unnecessary to know historical background in order to learn how to apply modern concepts. Consequently traditional or historical definitions of problems are often redefined within the frameworks of contemporary mathematical models. On the other hand, the history of voting provides a rich source of theories, experiences, and problems that challenge us to rethink our interpretation of voting processes. These challenges are not purely analytic; they direct our attention to applications outside the traditional sphere of elections. In addition, by examining voting arguments from the past, we can learn about the underlying metaphysics of contemporary normative debates such as the choice of the "best" voting system.

Voting theory and its contemporary social and collective choice derivatives can be seen as pathways in the development of a deductive, experimental science of voting. In Kuhnian terms, there still is no "normal" paradigm for voting science. Theoretical ideas about voting lack a common framework of concepts, models, and predictions that are essential for defining the science as paradigmatic. Instead there are divergent arguments about the goals of voting as well as the interpretation of standards for measuring consensus. Some see this diversity as an obstacle to intellectual progress; others see divergent intellectual directions as a creative force that enriches problem solving.

Pliny the Younger (1995), who confronted a dilemma associated with casting a vote when the agenda consists of more than two choices, did the earliest known analysis of a social choice phenomenon. Before Pliny, voters in traditional cultures typically faced binary choices, so these dilemmas did not occur.

The institutional context for Pliny's analysis was a Senate tribunal rendering a verdict in a murder trial of former slaves of a Roman consul, who had been found dead. Instead of conducting separate votes for each verdict alternative — banishment, death, and acquittal, Pliny arranged an agenda of binary choices among the three verdict alternatives and attempted to manipulate the collective outcome by controlling the agenda of binary choices. Writing retrospectively to a colleague in A.D. 105, Pliny describes his attempted manipulation and asks if what he did was a mistake.

Pliny's discomfort about strategic manipulation of the agenda highlights the complexity of voting analysis. This complexity can make it difficult for others to answer and discuss questions such as Pliny's. We do not know if Pliny received a response from his correspondent, but subsequent voting theorists also struggled with developing a dialogue about empirical and normative issues. In fact, an underlying current in early voting analyses is the tension between two criteria for evaluating collective outcomes: preference aggregation and making the "right" choice.

This tension became institutionalized in the social contexts of theorists from Pliny until the 18th century. Whether the norms were secular or religious, the tension was a characteristic of pre-modern legislatures, which not only voted to produce new laws, but also served as juries to render verdicts in criminal and civil cases. These dual functions sustained a concern with producing the right choice, a concern that continues in contemporary political decision making.

Between Pliny and the 18th century, Ramon Lull and Nicolas Cusanus explored social choice ideas in religious institutions. Lull's (1914) novel, *Blanquerna*, written in 1285, addresses voting procedures as part of a story about a hermit who becomes a monk, abbot, bishop, and the pop. Lull outlines a voting system based on pairwise comparisons of ranked choices. His didactic exposition makes it clear that not following the "art" can produce dire consequences. For when electors choose *Blanquerna* as bishop without following the "art," they generate an indecisive

outcome and the decision must be appealed to the Pope to produce a winner.

Lull's more scholarly work such as *De Arte Eleccionis* (1937), written in 1299, outlines a pairwise election method that clearly resembles a Condorcet procedure. Lull's use of matrix notation and his recommendation that the number of voters be odd (to prevent ties) distinguish him as an imaginative precursor of ideas that did not emerge until for nearly 500 years. But Lull never found an audience in which his analytical ideas could grow.

Nicolas Cusanus developed in an intellectual environment in which Lull's works were part of the curriculum even though Lull was reputed to be a dangerous thinker. Although Lull and Cusanus were both intellectuals in a Catholic culture, Cusanus (Häegele and Pukelsheim, 2000) was more focused on the problem of ending a long schism in the papacy by designing a voting procedure for the election of a Holy Roman Emperor — rather than a Pope. Approximately 130 years after Lull had outlined an "honest" method of elections for the Church, Cusanus proposes a Borda system and criticizes attempts to control the collective outcome by manipulating electors. Cusanus also applies the Borda method to votes on propositions with more than two possibilities, contrasting it with the binary procedure in use in Venice for propositions and elections. The Venetian method, similar to approval voting (Lines, 1986), simplified the process of selecting 41 electors from an initial assembly of 1500 members.

In the Church, unanimous collective outcomes were valued as a sign of divine inspiration. But when voting outcomes were not unanimous, the custom of distinguishing between the *sanior et major pars* (sounder — as in "more correct" — and greater part) was adopted (Moulin, 1958). In some cases, the authority of an individual or subset of voters was used to overrule a plurality coalition. Gradually, however, divisiveness caused by defining the *sanior* voters led to reliance on the *greater* part as a criterion for defining a consensus.

The tension between selecting the right choice and the most popular choice continued in the analyses of voting in the 18th century French Academy of Sciences (FAS). Members of the FAS were generalists, scientists who shared a concern with managing problems associated with electing and promoting members of the Academy. LaPlace, Poisson, and Lavoisier all developed mathematical models to support their arguments about how to elect or promote the "right" or most meritorious candidates (Rapaport, 1967). But it was Borda who first raised the issue in a 1770 FAS paper, "On Elections by Ballot," (Borda, 1784) in which he showed that the conventional plurality method would not select what is now known as the Condorcet

winner. To remedy this problem, Borda recommended a method in which each candidate would receive points according to his ranking in voter preference orderings. Although FAS papers were normally published within three years, Borda's paper did not appear until 1784, when it was published with an introductory note by Condorcet, the Secretary of the FAS. Condorcet was responsible for setting the publication schedule and may have delayed publication for political reasons.

One year after the publication of Borda's paper, Condorcet (1785) presented his analysis of voting, 13 "hypotheses" about the effects of voting procedures on the group probability of making a correct collective choice. The 1785 Essai includes the first statement of the inconsistency between individual and collective transitivity in voting. Condorcet viewed this inconsistency as an "effect" not a "paradox" — that was significant because it effected the performance of the group in selecting a correct choice.

There is no evidence that Condorcet and Borda — or surrogates — actually debated voting methods. To some extent, the issue of voting methods was overshadowed by political animosity between Condorcet — who wanted to modernize the French state by introducing popular representation — and Borda — an ardent supporter of absolute monarchy. And although Condorcet explored the properties of different voting methods, he seemed to recognize that plurality voting was easier to manipulate than Borda voting. For Condorcet's election as FAS secretary was a manipulation that was facilitated by plurality voting (Urken, 1991).

After the 1789 Revolution, Condorcet supported the Republican cause and wrote a constitutional plan that included a practical voting method that had nothing to do with his 1785 Essai. However when the design of a jury for the trial of King Louis XVI was debated, Condorcet proposed a jury size and voting method based on a mathematical argument extracted from his 1785 Essai (Urken, 1991).

Condorcet's 1785 Essai and practical proposal were read by Lhuilier, 1794), who showed that the practical method could not select the Condorcet winner. Later theorists like Nanson (1882) were influenced by Condorcet's analysis. But there is no evidence that Jefferson, Madison, or Carroll ever read the 1785 Essai (Urken, 1991; McLean and Urken, 1992).

After the Revolution, when the FAS was reconstituted into the Institute of France (IOF), internal political conflicts once again prevented French scientists from clarifying their ideas and developing their arguments experimentally (McLean and Urken, 1996). Napoleon, an IOF leader before ascending to political power, appointed a special commission to study voting methods for the IOF. The commission included Borda and Daunou, an expert in literature who had worked on voting problems with Condorcet before the Revolution. The IOF adopted a Borda method. Daunou wrote a scathing critique of IOF problems created by strategic manipulation of Borda voting. But when Napoleon, as political leader, unilaterally changed the method back to plurality voting, there is no evidence that he was influenced by Daunou's analysis. It seems that Napoleon, like Condorcet, appreciated the ease of manipulating collective outcomes under plurality voting.

None of these pre- or post-Revolutionary French works on social choice were studied at all in France for approximately 65 years, when a French economist rediscovered, but did not revive, the classical tradition. Duncan Black's (1958) path-breaking FAS archival work and economic analysis resuscitated awareness of the classical tradition in the middle of the 20th century. However his interpretation of the dualism in social choice theory was to relegate Condorcet's analysis of the probability of making a correct choice in voting processes to jury decision making. And the name that Black coined, the "jury theorem," has become a conventional reference for Condorcet's 1785 Essai even though Condorcet's primary objective was to design social choice procedures to maximize the group probability of making a correct choice in all collective choices, which in his view, did not theoretically or practically differentiate between legislative, electoral, or jury environments.

Condorcet viewed his 1785 Essai as a starting point for developing experimental knowledge about voting processes. But preference aggregation is still the dominant framework in social choice theory following Arrow's "impossibility" results and "paradox of voting." In some respects, we have not advanced much in balancing the analyses of preferences aggregation and making the right choice. For example, the current-sometimes metaphysicaldebate between advocates of Borda and Approval voting about the "best" voting method are reminiscent of the adversarial debates that occurred in the 18th century FAS (Mackenzie, 2000). However contemporary appreciation of the "jury theorem" has extended Condorcet's analysis of competence in social choice and begun a tradition of rigorous experimental analysis of social choice problems in juries (Guarnaschelli et al., 2000) that takes account of aggregating preferences and making a correct choice.

P

THE PARADOX OF REBELLION

In the mythology of revolution, the people rising to throw off a tyrannical ruler is the dominant theme... Most of the mythology concerns a people driven beyond endurance by the vicious oppression of their masters rising up and establishing a noble and just republic. I regret to say that this myth is mainly myth. Gordon Tullock, *Autocracy* (Tullock, 1987: 53)

Rebellious activities are illegal activities directed at a change in the policies or leadership of a political regime or in the nature of the regime itself. They are usually, but not always, instances of collective action, i.e. they require the participation of two or more individuals and — if successful — produce an outcome that may be enjoyed by everyone sympathizing with the rebellion, irrespective of participation. But in that respect rebellion is, even when bad, a collective good and hence open to the problems of free-riding so familiar to economists. The problem has perhaps been most eloquently summarized by the late philosopher, Gregory Kavka:

Imagine a country in which a small elite rules over and exploits the vast majority of the citizens. All the members of the exploited group know that if they acted together, they could easily overthrow the present regime and set up a new and just government that would better serve their interests. Furthermore, the elite regime has not rendered the exploited so fearful that they fail to communicate their dissatisfaction to one another. Initially, it seems obvious that, if the members of the exploited group are rational, they will pursue their common interests by revolting against the regime, toppling it, and establishing a new government in its place. But now consider the question of participation in the revolution from the point of view of an individual member of the exploited group. It would appear that, for him, the substantial costs of participation — the risk of being punished by the regime for participating or of dying in the fighting — will greatly exceed the expected benefits. For, in the first place, it is highly unlikely that his participation would significantly increase the chances of the revolution succeeding. And, in the second place, the benefits of better government that would follow a revolution are essentially public goods, i.e. the average individual would receive them even without being an active participant in the revolution. Hence, if he maximizes expected utility, our potential revolutionary will not join in the revolt. Nor, for like reasons, will his fellows; and as a result, there would not be a revolution. (Kavka, 1982: 455)

The basic reasoning has been known at least since the writings of the English 17th century 'Leveller' political activist John Lilburne, and Vladimir I. Lenin may be seen to have drawn attention to the neglect of the problem in the thought of Karl Marx. However, the first to explicitly identify the collective good nature of rebellious activities and submit it to public choice analysis were Mancur Olson (Olson [1965] 1971: 105-109, 161-162) and Thomas Ireland (Ireland, 1967), and it was Gordon Tullock who first devoted considerable attention to the problem and who coined the phrase 'the paradox of revolution' (Tullock, 1971, 1974, 1987). The problem identified is, however, much more general than revolution alone and may logically be extended to rebellion in general, so it is no doubt more fitting to speak of a 'paradox of rebellion' (Kurrild-Klitgaard 1997) and a resulting 'rebel's dilemma' (Lichbach, 1995), and this line of analysis has influenced the treatment of rebellious activities in a long list of publications (e.g., Silver, 1974; Salert, 1976; Buchanan, 1979; Kirk, 1983; Finney, 1987; Taylor, 1988; Coleman, 1990; Sandler, 1992).

The basic logic of the paradox may be expressed by a modified version of Olson's logic of collective action, i.e. by an inequality which must be satisfied if it is to be rational for a potential rebel to contribute to collective rebellious action:

$V_{\rm i}\Delta R_{\rm i}+B-C>0,$

where V_i is the potential rebel's 'share' of the collective good produced by a successful rebellious act, ΔR_i is the change in the probability of success of the rebellious act given the individual's contribution, B are the benefits he may derive from the process itself, while C represents all the costs he may incur from participating. Tullock's point is that rebellious activities usually are large-scale phenomena where the typical individual's contribution is insignificant, and where the expected value of the collective good accordingly goes to zero. The individual's problem then is that if we for the moment disregard the private benefits, then all that is left are the costs. In other words, in the absence of private, participation-related benefits, it will never be rational for an individual to participate; he will rather choose to free-ride on the risks taken by his fellow comrades. But if they all are similarly rational, the potential rebels will find themselves in a situation resembling a *n*-person Prisoners' Dilemma, and there will never be any collective rebellious action at all.

To many such conclusions seems completely at odds with a reality, where after all there are many examples of revolutions, rebellions, riots, not to mention coups and instances of terrorism. On the other hand, the analysis highlights an important, but neglected fact, namely that the occurrence of large-scale collective rebellious action may be a highly overestimated phenomenon: While some rebellious activities, e.g., coups, occur frequently in some societies, empirical examples of large-scale collective activities is in fact quite rare, and when they do occur, it is rare to find more than five percent of the relevant sympathizers participating (Lichbach, 1995: 11f, 17f; Kurrild-Klitgaard, 1997: 124ff).

Unless one adopts the view that real-world rebels are irrational or completely rejects public choice analysis as such, the reasoning indirectly gives rise to two central and related questions: (1) Given the public goods problem, why do some collective rebellious action occur at all? (2) Why do some rebellious activities end up as large-scale revolutions, while others become rebellions, riots, or simply just coups or terrorism?

The answer given by Tullock to the question of why rebellious activities occur at all is basically a by-product explanation that may be called the Tullock Model: Events such as a revolutions do not occur because of the collective good that is officially sought or that is sometimes produced, but rather, first and foremost, because of the private benefits to be reaped by the participants, or they may occur in those rare situations, where there are no costs associated with the rebellious actions. As such Tullock himself has found the model useful for explaining the student rebellions of the late 1960s and the frequently occurring coups in societies with large rents to be reaped by a political class as well as the general absence of large-scale rebellions (Tullock, 1971, 1974, 1987).

Tullock's analysis has been submitted to fierce criticism from a number of sides. Observers have often felt that it was simply absurd to think that, e.g., ideology and the policies of a regime should be unimportant for the level of rebellious activities. Even among rational choice theorists the view has often been that the analysis is too simplistic (DeNardo, 1985), less than fruitful (Buchanan, 1987: 14; Mueller, 1989: 175), or partly misapplied (Kurrild-Klitgaard, 1997). Against this it must, however, be kept in mind that Tullock's claim is not that no individuals ever act altruistically; it is only the more modest (if only slightly less cynical) that most of the time people do not act predominantly altruistically, and that when personal costs are high and the expected utility of contributing to the collective good is small, large-scale collective action is unlikely. And whereas the critics usually point out that some forms of rebellious action, obviously do occur, the Tullockian answer would probably be: Yes, but very rarely, and usually only when some Olsonian selective benefits are applied.

Other analysts working within the rational choice paradigm have put the emphasis elsewhere, and there is by now a very wide range of types of 'solutions' that have been proposed to the paradox of rebellion (cf. Lichbach, 1994; Lichbach, 1995; Kurrild-Klitgaard, 1997). In particular, many studies have focused on the possibility of including some 'softer' values in the calculations of individual rebels, thereby changing the payoff so as to be positive. Many such suggestions have focused on, e.g., Kantian moral reasoning, notions of group solidarity, class consciousness, etc. (Muller and Opp, 1986, 1987; Elster, 1988; Finkel et al., 1989; Opp, 1989; Motyl, 1990; Opp, 1994). But what is less obvious is how that alone necessarily will do the trick; it seems that either such a type of reasoning simply represents an increase in the collective good value, or it is a question of acting in the interest of the group, but where the individual action still remains insignificant for the outcome. Either way this alone seems logically insufficient to solve the collective action problem (Buchanan, 1979; Kurrild-Klitgaard, 1998). If anything, it must be the case that the values included in the calculus refer to benefits connected directly with the process itself, e.g., a sense of doing one's duty, a 'moral satisfaction', etc.

A different line of research has been to focus on the importance of the size of the relevant group of rebels. If relatively few individuals are required in order to achieve the desired outcome, the efficacy of the typical individual rebel may be much bigger than in settings requiring thousands of participants, just as the transaction costs associated with coordinating plans and utilizing common resources effectively are smaller for small groups. Together these aspects are seen as playing a part in the explanation of the frequency of coups relative to grand revolutions (e.g., Kurrild-Klitgaard, 2000). They also suggest an explanation of the relative success of terrorist acts and guerilla warfare (cf. Tullock, 1975; Sandler and Scott, 1987; Popkin, 1988; Tong, 1988). On the other hand, there is a certain safety in numbers, i.e. the risks of being caught or injured are often relatively smaller in the case of thousands of rioters than in the case of small groups of conspirators or individual demonstrations of civil disobedience (DeNardo, 1985).

Yet another line of research has focused on the dynamics of rebellious action and the role of expectations (Gunning, 1972; Chalmers and Shelton, 1975; Roeder, 1982; Mason, 1984; DeNardo, 1985; Oberschall, 1993, 1994; Kuran, 1989, 1991, 1995; Kurrild-Klitgaard, 1997, 1998). The point of such studies have often been that it may be misleading to portray the decision of a potential rebel as either joining or not joining an already ongoing collective act; the decision will rather be influenced by certain expectations as to how many others will be participating, how many will be needed, how much the individual can contribute, etc. Incorporating such elements into the calculus of the potential rebel makes it much more likely that the situation will resemble a coordination game than a Prisoners' Dilemma. Finally, the analysis of the Tullock Model may be too stylized to be descriptive of real world situations, where there may often be considerable differences in the talents and the intensity of the preferences of the potential rebels, and where organizations exist. What rebellious movements need in order to be successful at overthrowing a regime is, first and foremost, political entrepreneurship (cf. Wagner, 1966; Frohlich et al., 1971; Frohlich and Oppenheimer, 1974). This has been argued both theoretically and in connection with a number of case studies, where it has been shown how the presence of radicals acting as political entrepreneurs may help rebels overcome the initial collective action problems and thereby change the dynamics of the situation (Popkin, 1979; Popkin, 1988; Taylor, 1988; Kurrild-Klitgaard, 1997; Parikh and Cameron, 2000).

What seems to be lacking in the public choice analysis of rebellious activities are two things. First, at the theoretical level there is a lack of explanations for why collective rebellious action sometimes become 'big' (revolutions and rebellions), other times 'small' (riots), and sometimes do not get off the ground at all. Second, there is a lack of detailed public choice based analyses of specific events, e.g., in the form of analytical narratives. What could seem to be a fruitful line of research would be studies trying to incorporate public choice analysis into grander historical case studies (cf. Goldstone, 1994).

PARCHMENT VERSUS GUNS

It is widely thought that just as a market economy is an expression of economic freedom, so is a democratic polity an expression of political freedom. A market economy and a political democracy would thus seem to combine to form a constitution of liberty for a free society. In this respect, the renowned constitutional scholar Charles McIlwain once noted that "constitutional government is by definition limited government" (McIlwain, 1947, p. 21). Without some explanation as to how it is possible truly to limit government, however, this common formulation is perhaps more sentimental than realistic. The task of giving that sentiment some grounding in reality is a difficult one that raises some knotty issues regarding the institutional framework of a free society.

The very idea of limited government implies that government is not the source of personal rights, for government itself is limited by the prior and superior rights of the people who form it. People form government, government doesn't form people, a theme that is developed crisply in an economic context in James Buchanan and Gordon Tullock (1962). One use that people make of their rights is to create governments to preserve and protect those rights. Without government, people would be subject to predatory attack, both from each other and from outsiders. Rights are of little value if they cannot be preserved and protected. For government to pursue this protective task, it must be sufficiently powerful to subdue potential predators, both domestic and foreign. Government thus must be the locus of predominant force within a society, for otherwise it could not fulfill its protective role.

The eternal question that won't go away is how, or whether, it is possible to design a government that will use its power to preserve and protect without using that same power as an instrument of predation (Scott Gordon (1999) presents several historical episodes where different societies have taken different approaches to limiting government). It is easy to illustrate the problem of limiting government. If two people acting privately cannot rightfully take the property of a third person, neither should they be able to do so simply because they comprise a political majority. Suppose Primo, Secundo, and Terzo comprise a town. Primo's property contains some marshland which he plans to drain and fill to create a shopping center. Secundo and Terzo each prefer to see the land remain as marshland, even if it means they must go elsewhere to do their shopping.

The institutional framework of the market economy provides an easy way for Secundo and Terzo to secure their desired marshland. All they have to do is to get Primo's permission to keep the land as a marshland rather than turn it into a shopping center. There are many particular ways they could accomplish this. A simple way would be for them to buy the relevant portion of Primo's land. Alternatively, Secundo and Terzo could lease the land from Primo, say for 99 years. They could act on their own behalf in doing this, or they could act in the name of a conservation trust which they established. In any case, the basic principles of property and contract that provide the legal framework for a market economy provide a set of simple rules within which market participants can create quite complex patterns of governance to carry out their desired transactions (Epstein, 1995). Regardless of the particular form that a transaction might take, the market framework provides a consensual method for resolving this divergence of opinion among Primo, Secundo, and Terzo. If Secundo and Terzo place a higher value on using the land as a bird sanctuary than Primo places on building a shopping center, Secundo and Terzo will be able to convince Primo to give up on the shopping center and let the marshland serve as a bird sanctuary instead.

For Secundo and Terzo, the problem with this method of resolving this difference of opinion is that they have to pay full price to get their way. Yet they comprise a majority in the town. So long as political decisions can be made by majority vote and do not require unanimity, Secundo and Terzo can do better for themselves by adopting a motion to treat the construction of a bird sanctuary on Primo's land as a town project. The cost of securing the land would now come from town funds. Public financing of the bird sanctuary thus allows the winning majority to transfer some of the cost onto the losing minority. The extent to which such a transfer occurs depends on the type of tax system the town uses. A very simple tax system would be one that imposes equal cost sharing across residents. In this case, Secundo and Terzo would each pay but one-third of the cost, whereas under the market-based method of creating the bird sanctuary they would each pay one-half the cost.

To be sure, Primo would not voluntarily sell the land to the town under these circumstances because refusing to sell the land would prevent the tax from being imposed. Secundo and Terzo would have to use the name of the town to invoke eminent domain to get the land. Doing this allows the majority to take Primo's land against his will, and to force him to accept only two-thirds of the compensation the town offers, because his taxes also cover one-third of that compensation.

The Fifth Amendment to the American constitution allows governments to take private property through eminent domain, but also places tight restrictions on the use of this power. One such restriction is that any such taking must be to advance some legitimate public (as distinct from private) purpose. Another restriction is that the owners of property be justly compensated for any such taking. As Richard Epstein (1985) explains, the history of eminent domain over the past century or so has increasingly run in the direction of governments taking property for what are private uses and paying only partial or token compensation in the process. Despite its clear wording about public use and just compensation, the Fifth Amendment does not seem to be a strong bar against governments taking private property for private use while failing to pay just compensation. The Fifth Amendment, along with any constitutional document, is just a piece of parchment. While parchment paper is stronger than ordinary writing paper, apparently it is not sufficiently strong to deter rapacious governments and interest groups from using government as an instrument of predation.

In Federalist No. 48, James Madison noted that legislatures in Virginia and Pennsylvania had repeatedly violated their state constitutions, acting thereby as an instrument of predation on behalf of some people at the expense of others, in sharp contrast to acting as an instrument of protection and preservation. Madison concluded his examination by noting "that a mere demarcation on parchment is not a sufficient guard against those encroachments which lead to a tyrannical concentration of all the powers of government in the same hands." The articulation on parchment of a declaration of limited government to protect and preserve is not by itself sufficient to generate protection and preservation as the core activity of government.

There is a tenuous balance between liberalism or capitalism on the one hand and democracy on the other, as the American Founders recognized. A system of economic organization based on private property will require some measure of government activity, if to do nothing else than protect people's rights of person and property. Liberalism is grounded in individual freedom and private property. In this scheme, government itself is simply a reflection of people's use of their rights of person and property, and is not a source of those rights. Governmental authority is limited to securing individual rights.

Even though there may be general agreement about the proper principles of governmental activity, that agreement often dissolves in the specifics of particular practice. Primo, Secundo, and Terzo might all affirm the principle of limited government, and yet Secundo and Terzo will participate willingly and even eagerly in taking Primo's property when doing so allows them to promote a favored project at lower cost to themselves. To be sure, Secundo and Terzo may have some moral qualms about their use of politics to circumvent the market in building their bird sanctuary. To subdue such qualms, they might invoke such doctrines as strategic holdouts and free riders as a kind of therapy to ease their minds. This would allow Secundo and Terzo to deceive themselves into believing that Primo really valued the bird sanctuary, only refused to say so because he was holding out to get a higher price.

As Vincent Ostrom (1984) explains with particular cogency, government involves a Faustian bargain: instruments

of evil — power over other people — are to be employed because of the good they might do, recognizing that evil will also result. This raises the issue of the terms of that bargain. There are two principle approaches to securing more favorable terms. One approach looks primarily to education and related processes for cultivating virtue and wisdom within a population (Walker, 1990). The claim here is that the wiser people are about the dangers of the Faustian bargain, the less eagerly they will embrace it. Parchment will serve as a stronger barrier to predatory uses of government as people become wiser in their understanding about such predatory uses of government.

The other approach looks primarily to a kind of opposition of interests to limit government predation. Metaphorically speaking, this alternative approach looks to guns more than to parchment (Wagner, 1987, 1993). The basic principle behind this approach is for governmental action to require some concurrence among different participants with opposed interests. Such concurrence, it should be noted is exactly what market exchange promotes. Within the frameworks of property and contract, Primo, Secundo, and Terzo will all concur in the market-generated outcome concerning the use of Primo's marshland. If that land becomes a bird sanctuary, this will be because Primo concurs with Secundo's and Terzo's desire to exercise dominion over the marshland. The testimony about Primo's concurrence lies in his willingness to cede control over the land to Secundo and Terzo. If that land becomes a shopping center, this will be because Secundo and Terzo concur with Primo's desire to build a shopping center. The testimony about Secundo's and Terzo's concurrence lies in their unwillingness to make an offer that would be sufficient to convince Primo to cede control over the land.

Both approaches reflect a presumption that self-interest is predominant in all human activity, in government as well as in commerce. The justification for government resides in the need to control the darker side of self-interest. With self-interest being ineradicable, the problem of constitutional control becomes one of how to control the operation of self-interest within government while allowing government the ability to perform those governing tasks that its justification requires. Ultimately, the task would seem to require both parchment and guns, that is, both knowledge pertinent to the task and rightly aligned incentives to act consistently with that knowledge. Knowledge and incentive, moreover, do not act in separable fashion, for knowledge is generated through practice and practice is shaped by incentive, as Richard Wagner (2002) explains. For instance, Charles Warren (1932) describes how the general welfare clause of the American constitution underwent a transformation from a strong limit on the ability of Congress to appropriate money to a situation where Congress could appropriate for whatever it chooses, so long as it pronounces that it has some good civic reason for doing so. The process Warren describes is clearly one of a continuing spiral involving both belief or knowledge and incentive or interest. One of the central themes of the classical approach to moral education was that morality was simply good conduct that was reduced to habit through practice. The ability successfully to take property through politics instead of relying upon market transactions is to engage in a contrary form of practice. This alternative form of practice, where legislative takings replace market transactions, may, if repeated sufficiently, become sufficiently habitual to promote alternative beliefs as to what comprises just conduct. Knowledge and incentive, parchment and guns, would seem to be nonseparable ingredients of constitutional order in the final analysis. This interaction between knowledge and incentive was clearly recognized in the Germanic branch of constitutional economics that is known as ordnungstheorie, a founding statement of which is Eucken (1950), whose subsequent literature is represented nicely in Stützel, Watrin, Wilgerodt, and Hohmann (1981), and which is given a nice textual presentation in English in Kaspar and Streit (1998).

POLITICAL AND CULTURAL NATIONALISM

Nationalism is an emotional identification with fellow subjects of a state on the basis of shared language, customs, values, religion or culture. Nationalism is not a sense of loyalty to international organizations such as the United Nations, or to non-governmental bodies such as Amnesty International. There is no such thing as "Prozac Nation," even if that term is an arresting metaphor. However, it would be a mistake to insist too strongly upon a bond to a de jure state. It was meaningful to speak of nineteenthcentury German nationalism before the unification of that country, even as it is meaningful to speak of Quebec nationalism today. On the other hand, one may distinguish between nationalism and a purely local attachment to one's city or region. There is no such thing as Virginia nationalism today, although it might have been different in 1861 when Robert E. Lee followed his "country" into secession.

The definition of nationalism also excludes a bond to a diverse state whose subjects cannot be said to share core set of values or a common culture. Before World War I, there was no such thing as Austro-Hungarian nationalism. In such cases, one should distinguish between nationalism and patriotism, for the first but not the second term seems to require a common set of values.

Nationalism is also a normative political theory under which a geographically compact distinct people has a right to self-determination (Ignatieff, 1993: 145). Since an "ought" cannot be derived from an "is," one might admit the existence of a Serbian nation prior to World War I, while denying that the break-up of the Austro-Hungarian Empire was benign.

The opposite of normative nationalism is a normative universalism, which asserts that (1) norms must be universalizable if they are to count as norms; and (2) purely national norms which cannot be universalized are necessarily suspect. Modern political theory is almost always universalist, and based upon an abstract deliberation of the rights and duties common to all men without regard to their nationality. The universalist may point to such extreme cases as Serbia as an object lesson of the vices to which nationalism might be prey (Gomberg, 1990; Nussbaum, 1996).

Nationalism is often identified with a conservative perspective, particularly when employed to justify barriers to immigration, or (in the case of English conservatives) opposition to European integration. However, anti-globalists who reject free trade also appeal to a sense of nationalism.

1. A Curious Omission

Marxism was faulted for lacking a theory of nationalism, and the same charge may fairly be leveled at public choice theory and political theory scholarship. Recently Robert Goodin and Philip Pettit excluded a section on nationalism in their recent book of essays because it "hardly counts as a principled way of thinking about things" (Goodin and Pettit, 1993: 3). But since nationalism is one of the most potent sentiments in the political arena, this argues for more, not less, scholarly attention.

Forty years ago it was easier to imagine that nationalism had been all but dissolved in the acid baths of rationalism and modernism. In its place, scholars on the left proposed an internationalism based on more encompassing structures such as the United Nations or broader ideologies such as socialism; meanwhile, scholars on the right, who saw political choice through the prism of narrow economic calculation, or who espoused libertarian principles, typically regarded nationalism as an atavistic sentiment that had lost its appeal. Moreover, those on the right who supported less encompassing structures, such as the states rights movement in the United States, usually asserted that the strongest attachments were local and never national. The nationalism of Charles de Gaulle was thought faintly ridiculous, and the few academics who responded to such appeals believed themselves on the losing side of history. When George Grant (1978) wrote his account of Canadian Prime Minister John Diefenbaker's 1963 defeat at the hands of a continentalist Liberal party, he called it Lament for a Nation: The Defeat of Canadian Nationalism.

It is no longer possible to dismiss the appeal of national sentiment. Communism did not bury nationalism; instead, communism lies buried, to an important extent by the nationalism it had dismissed. In the first world, the rise of nationalist movements in Quebec, Scotland and Corsica have led to a devolution of powers from central governments. In the United States, the terrorist attack of September 11, 2001 awoke powerful nationalist sentiments. Finally, the darker varieties of nationalism that emerged in the Balkans remind us that the progressive defense of universalism cannot entirely be dismissed.

2. Theories of Nationalism

Nationalism's continuing importance invites one to consider its benefits and costs. The simplest explanation for nationalism's appeal is that it is one of the particularistic emotions, like love of family and friends, that bind us to others, and that constitute the sense of *solidarity* or community that is one of the most basic human goods (Weil, 1955). Ignoring such bonds drains the life and ideals out of the particular content that alone gives it substance.

The second benefit of nationalism is related to the first. Nationalism fosters a homogenous culture, high and low, and what a common culture may offer, to those who were formerly Bretons or Lorrainois, is the ability to deal with each other across increased distances with lower *transaction costs*. Dialects disappear and a single language emerges, with all of the gestures and facial clues that are the common currency of exchange in a conversation. "To 'do business with each other'," notes Charles Taylor, or to "operate a system of courts, run a bureaucratic state apparatus and the like, we need millions who can communicate without difficulty in a context-free fashion" (Taylor, 1998: 192).

Such theories have been thought to explain the rise of European nationalism in the nineteenth century. Prior to then, the impulse to solidarity found its expression through membership in more encompassing religions, such as Christendom prior to the Reformation, or through more local attachments. For Ernest Gellner (1997), nationalism was a response to the anomie of modernity that followed on the shift from an agricultural to an industrial economy. Nationalism united an alienated society, with "Gessellschaft using the idiom of Gemeinschaft." The deserted village was reinvented in the nation-state, and a "mobile anonymous society simulate[d] a closed cosy community" (Gellner, 1997: 74; see also Berlin, 1999).

Purely local bonds, to town or region rather than state, were also stronger prior to the expansion of transportation that followed the Industrial Revolution. As commerce became national, so too did the need for national sentiments as a means of reducing the transaction costs across a country. Extrapolating further, one might predict the decline of national sentiments in an era of transnational free trade agreements such as the North American Free Trade Agreement and intergovernmental structures such as the European Union.

German history might seem broadly consistent with this view of nationalism. There was relatively little national

sentiment prior to the nineteenth century, but the flow of people and commerce across the Germanic states that followed the customs union contributed to the sense of nationalism. A similar story may be told of nineteenth century Italian nationalism. In addition, the decline in international trade during the 1930s might plausibly be linked to the subsequent rise of perverse nationalistic political parties during that decade.

The difficulty with such explanations is that, resting on a naive Whig view of history, they make nationalism seem over-determined. Religious sentiments did not weaken during the nineteenth century. If anything, they were strengthened during the Victorian period, even among the elites. And while the decline in free trade produced pathological brands of nationalism in some European states, in others they produced wholly marginal figures such as Sir Oswald Mosely. Indeed, one should not underestimate the extent to which fascism was an international antidemocratic movement, linking national parties in states such as Spain, Italy and Germany.

The third benefit of nationalism is that, by bonding us more closely to our fellows, nationalism increases altruistic impulses and reduces *free riding*. We are more willing to perform acts for the general good — serving in the military, contributing to charity — when we feel a kinship to others. This promotes the trust that is the cement of our society.

In this way, nationalism might actually reduce the possibility of war. While some wars are fought on nationalist grounds, patriotism plausibly decreases the likelihood of conflict by increasing the costs of aggressive war. The patriot can be readily enlisted to defend his homeland, but persuading him to invade another country may be a harder sell. Non-patriots might fight for private ends, for glory or material gain, but not so effectively as the patriot who defends his country. So viewed, patriotism increases the costs of imperialist or aggressive wars by reducing the probability of success. When the war requires mass armies (or mass support through taxation), securing patriotic backing is critical in the war effort, and the bias towards defensive wars will reduce the overall likelihood of war. The success of the Russian forces in the "Great Patriotic War" is consistent with this thesis, and so too is English resistance to Hitler. "What has kept England on its feet during the past year?," asked George Orwell in 1941. It was not the desiccated liberalism of an H.G. Wells or George Bernard Shaw. Rather, it was "the atavistic emotion of patriotism, the ingrained feeling of English-speaking peoples that they are superior to foreigners" (Orwell, 1984: 196).

A fourth explanation of the emergence of nationalism sees it as shaped by elite opinion-makers who *rent seek*.

For example, Jean-Luc Migué (1979) attributes the remarkable degree of support for separatism among francophone intellectuals in Québec to the political plums that would be available in a sovereign Quebec. In particular cases, such theories might have much to commend them; but as a general explanation of nationalism they resemble the reductionist accounts of religion associated with vulgar Marxism.

3. Varieties of Nationalism

The intensity of nationalist sentiment varies among nations. In addition, nationalist sentiments may be distinguished on the basis of their membership rules. A very thick criterion of inclusion might have its members share a common language, religion, culture, and even ancestry. At the other extreme, liberal nationalism emphasizes core political values while downplaying other aspects of national identity. While the United States remains relatively unilingual, cultural and religious bonds are weak. What increasingly takes the place of a cultural heritage is a common adherence to liberal legal traditions, as seen by the prominent role played by the Bill of Rights in American society. If gessellschaft used the idiom of gemeinschaft in Gellner's (1997) analysis of nineteenth-century nationalism, with the state emerging from shared cultural norms, the cultural norms must arise from the state in liberal nationalism and gemeinschaft builds upon gessellschaft.

Early forms of English nationalism were intertwined with the philosophical emphasis on individual rights and the humanitarian enthusiasm for liberty, and this was inherited in America. Even during the American Revolution, those of the Patriot side appealed to the "common rights of Englishmen." The absence of ethnic uniformity, even in colonial times, shifted the nexus of nationalism from culture to the libertarian ideals of the Founders.

French nationalism also has an important ideological component that dates from the Revolution. However, these ideals were univeralized so as to provide a justification for Napoleonic wars of "liberation." After the fall of the First Empire, nationalism became closely identified with the anti-Dreyfusard right, including antiliberals such as Charles Maurras.

German writers and intellectuals were quite critical of the universalistic ambitions of French nationalism. Instead, German nationalism was based on the cultural identity of the German people and their traditions. The German historic school stressed the priority of customary acceptance of rules and institutions over reason. According to this school, there is no absolute notion of just social and legal order. To the contrary, the different historical heritage of the various nations may justify differences between their national aspirations. The German premises were thus more respectful of the historical differences among the various national traditions and skeptical of any attempt at formulating universal principles that could govern the process of unification of the German people.

POLITICAL BUSINESS CYCLES

Few concepts in political economy are more widely known than the political business cycle (PBC). Nor have many given rise to such heated debate among scholars. The extent of debate reflects the highly mixed empirical evidence that has been found, but the heat of the debate has come largely from the challenge to the economists' favorite assumption — rationality — posed by traditional formulations of the political business cycle theory. This in turn follows from the roles of macroeconomists and political scientists in the early contributions to political business cycle analysis. (For discussions of these see Drazen, 2000; Keech, 1995; Paldam, 1997.)

The expositions that focused widespread attention on the topic were by Keynesian oriented economists (William Nordhaus, 1975; Duncan MacRae, 1977) and a political scientist (Edward Tufte, 1978). The basic idea rested on the political assumption that favorable economic conditions before elections help incumbent office seekers and the then common macroeconomic assumption that inflation ---unemployment tradeoffs are much flatter in the short run than in the long run. As a result a well-timed expansion before an election could result primarily in an expansion of output and decline in unemployment before election day with most of the concomitant increase in inflation being delayed until safely after the election. This opportunistic or office-seeking motivated version of political business cycle theory, sometimes referred to as 'election cycles,' implied similar behavior by governments of both the left and the right before elections and quickly became an important challenger to the more traditional "partisan" view in political science of the politics of macroeconomic policy. Here cycles were generated by the different priorities of left and right wing governments as each came to power (see Hibbs, 1987). There are other examples of how government action can generate fluctuations based on a radical economics view (Kalecki, 1943; Feiwel, 1974; Boddy and Crotty, 1975; Sherman, 1979) or on the monetarist view of long and variable outside lags in monetary policy (Friedman, 1970). We will not focus on these here.

The opportunistic version assumed candidates were only interested in reelection. Although the original formulation by Nordhaus assumed that incumbents would always manipulate the economy to win elections and hence produce regular macroeconomic cycles, systematic policies of this type cannot be expected to occur at every election in part because of the rational expectations critique (see below). Not surprisingly, the empirical evidence clearly rejects such systematic cycles for the industrial countries in economic target aggregates such as unemployment and output. Moreover, Nordhaus's model was developed using a voting function approach. If instead governments observe approval ("popularity") ratings to monitor their likelihood of reelection, then incumbents with partisan objectives would only be expected to manipulate the economy to win elections when a significant 'popularity deficit' exists. During other times they would pursue policies based on ideologies and the interest of their support groups ('partisan view'). Hence both considerations are likely to be of relevance and were neatly combined in the 'contingent partisanship' formulation of Frey and Schneider (1978).

Along with the emerging literature on the politics of monetary policy (which entry see) and mounting evidence of government policy actions that tended to destabilize economies and generate high inflation, such contributions dealt a powerful blow to the traditional assumption of Keynesian economists that macro economic policies were set on public interest criteria free of political pressures (see Buchanan and Wagner, 1977). This helped stimulate growing interest in institutional arrangements to lessen political influences on monetary and fiscal polices (see Willett, 1988).

The basic proposition that good economic conditions enhance the popularity of incumbents enjoys massive empirical support. There is a large body of literature on voting and approval functions (see Lewis-Beck, 1998; Nannestad and Paldam, 1994). Fair regularly updates his specifications before U.S. elections (see, e.g., Fair, 1996, 2000). The specific trade offs among economic variables, the relative influence of levels versus rates of change, and the extent of retrospective versus prospective voting based on consumer-voter expectations (MacKuen et al., 1992; Norpoth, 1996) are nod clearly understood and some of these relations clearly vary over time. For example, during the 1990s electorates in Europe were tolerant of much higher average levels of unemployment than in the 1970s, and even in the U.S., incumbents could not have received relatively high approval ratings in the face of very high inflation and unemployment levels in the '70s and early '80s. There is also evidence that voters give as much or more weight to aggregate economic conditions as to their own circumstances. (On such sociotropic voting see Lewis-Beck, 1988.) Thus while precise relationships are still the subject of dispute, the general proposition that economic conditions have a strong influence on vote and popularity functions is a safe one.

More controversial is the idea of inflation unemployment trade offs — the Phillips curve. The 1970s saw the rise to prominence of new classical macroeconomics with its twin emphases on rational expectations and flexible wages and prices. Along with the earlier contributions by monetarists such as Milton Friedman (1968). this approach stressed the distinction between anticipated and unanticipated policies. It was only unanticipated changes in macroeconomic policies that would face fairly flat short run inflation unemployment trade offs. But if the opportunistic political business cycle game were played before every election, then regular pre election expansions could hardly be a surprise so continued electoral success would seem to require irrationality on the part of voter expectations. While Nordhaus (1989) indicated his comfort with the assumption of irrational expectations formation, to many economists this was quite unappealing. Thus more than a few economists felt an obligation to discredit opportunist PBC theory; and in some cases, to undertake reformulations consistent with rational expectations (Minford and Peel, 1982; Alesina, 1988). The Alesina version has been labeled a rational partisan cycle and results not from opportunistic pre-election behavior by governments but from the responses of private sector behavior to the outcomes of uncertain elections. This "surprise" element should be greater, the higher the level of uncertainty pre-election about the outcome. The effect would give rise to post election shocks rather than cycles per se, but the literature has loosely interpreted the term political business cycle to include almost any type of political influence on the economy or economic policy variables. The concern with rational expectations has led to the development of ingenious models with imperfect information under which the surprise elements of election outcomes generate rational partisan cycles after elections (Alesina, 1988) or signal an incumbent's competence (Rogoff and Siebert, 1988) and even PBC elements in a real business cycle model (Blomberg and Hess, 2002). There has been extensive empirical testing only of the rational partisan model where the results are mixed with Alesina and his coauthors generally interpreting their studies as being supportive (e.g., Alesina et al., 1997) and most other authors being less impressed (see Drazen, 1990).

Had the initial disputants been more familiar with public choice theory, these early debates could have been more productive. In its early stage of development macroeconomic rational expectations analysis tended to assume that actors had high levels of information. These have proved to be overly optimistic for many economic actors with strong interest at stake and are even more so for many voters who have little direct incentive to be informed about macroeconomic policies. The public choice concept of rational ignorance in the face of information costs is tremendously important in this context (see Willett, 1988).

Of course if played regularly information on PBCs would spread and limit their effectiveness, but in political markets informed voters do not cancel out uninformed voters the way they tend to in financial markets (see Willett, 1988) so the spread of disincentives for PBCs could be slow, especially when the PBC is not played at every election. And the evidence is clear that it is not. It is widely conceded that President Richard Nixon did practice the Nordhaus-Tufte model, in part because President Eisenhower was unwilling to do so when then Vice President Nixon first ran for the presidency (and in his view lost as a result). And Jimmy Carter played the opportunistic-PBC backwards, following expansionary policies when he first came in office (on the frequency of this type of partisan PBC behavior see the discussion and references in Paldam, 1997). President Carter was forced by accelerating inflation to tighten before the next election. While this episode conflicts with the opportunistic PBC, Carter's subsequent loss of his re election bid could be interpreted as support for the belief that incentives to play the PBC game still exist — in part because it has not been played at every election. One way to make sense of the mass of often contradictory or inclusive findings of empirical studies on PBCs is that no one version is played with consistent regularity, but that both opportunistic and partisan versions have some explanatory power. For the OECD countries partisan patterns tend to show up more regularly in the data (see the discussion and references in Drazen, 2000), but we cannot safely conclude that well-informed rational voters have eliminated all incentives for opportunistic PBC behavior. And anecdotal evidence suggests the possibility that opportunistic PBC behavior is much more common in the so far seldom studied developing countries than in the industrial world. Shi and Svensson (2000), in a study of 123 industrial and developing countries, find that on average budget deficits are larger in pre-election years by an average of one percent of GDP, but that for the developing countries the average was two percent. Remmer (1993) also finds considerable evidence of electoral patterns in Latin American economics, but these do not conform to the traditional PBC. They suggest that this reflects both greater incentives for politicians to stay in office due to corruption, and a less informed electorate as a result of lower press freedom.

For the OECD countries the evidence of election cycles is much stronger for policy instruments (monetary and fiscal policy) than for real outcomes (output and unemployment). One possible interpretation would be that voters are better informed than policy makers so that continued efforts by politicians are offset by the public à la the rational expectations critique. Also consistent with this interpretation is the tendency to find some evidence of cycles in inflation rates. While such a scenario could be plausible with respect to a set of key private sector decision makers, it doesn't seem plausible for the public at large.

A more likely explanation in our judgment starts with focus on the incentives for micro oriented PBCs that have macro consequences. It is hardly a surprise that politicians tend to give out favors prior to elections to improve the likelihood of success at the polls. One of the strongest regularities in the OECD data is that fiscal transfers tend to rise before elections, while tax cuts are much more likely then tax increases. These actions of course result in a cycle in the fiscal deficit, but this needn't have had any connection with desires to exploit the inflation-output trade offs emphasized in the traditional opportunistic PBC models. Pissarides (1980) is the only study we are aware of, where a policy instrument, tax rates in this case, enters a popularity function directly. Perhaps because the literature on PBCs has been dominated so heavily by macroeconomists, the micro incentives for political cycles have received insufficient attention. (Important exceptions include Drazen, 2000; Rogoff and Siebert, 1988; Shughart and Tollison, 1985; Tufte, 1978.)

Such cycles in fiscal policy can also explain nonopportunistically motivated cycles in monetary policy. This also helps explain another apparent anomaly. Nordhaus's model focuses on monetary policy as the government's policy instrument. However, in the United States and an increasing number of other countries the government does not directly set monetary policy. This is done by central banks with some degree of political independence. Why would independent central banks generate political business cycles? Laney and Willett (1983) suggest that even nonpartisan independent central banks may be political in the sense that they are concerned with criticisms of high interest rates and are especially sensitive to this in pre-election periods. (For evidence on the latter for the US see Willett, 1990). Where the central bank has a desire to avoid interest rate fluctuations then a cycle in the fiscal deficit would generate a corresponding cycle in the monetary aggregates. (For discussion and references to further literature on such "passive" monetary cycles see Drazen, 2000; pp. 236-237, 242-243; interesting examples for recent episodes of political pressure on monetary policy in the U.S. can be found in Woodward, 2000.)

Note also that such micro motivated cycles in policy instruments would likely occur much closer to elections than would macro oriented ones since the micro benefits would come immediately with the expenditure increases and tax cuts while the macro effects would occur only with (possibly substantial) lags. Indeed the post election lagged macro effects of pre election micro oriented pre election polices could be part of the explanation for why the standard opportunistic PBC model appears to explain only a quite limited amount of the OECD data.

Of course micro focused PBC analysis would lead us to look for cycles in non-budgetary items such as trade protectionism (which see). Also under explored are the international dimensions of PBC behavior. While the effects of alternative exchange rate regimes on the incentives for opportunistic PBCs was addressed relatively early on (see Willett and Mullen, 1982), there has been relatively little empirical research, but many anecdotes about political cycles in payments deficits and exchange rates especially in the developing countries. For example, Rudiger Dornbusch (2001: 241) points out that for Mexico "with surprising regularity, the currency collapsed every six years, shortly after each new president took office." (For recent evidence on the effects of elections on exchange rate policies in Latin America see Blomberg et al., 2002; Frieden and Stein, 2001 and on industrial countries see Bachman, 1992; Bernhard and Leblang, 2002; Blomberg and Hess, 1997; Lobo and Tufte, 1998.)

There has of course also been interest in the effects of the incentives for PBCs generated by alternative political institutions such as parliamentary versus presidential systems and fixed versus variable election dates (see Drazen, 2000) for institutional mechanisms such as balanced budget requirements, independent central banks, and fixed exchange rates to limit PBC behavior. One interesting theoretical conclusion is that while a regime of high capital mobility and fixed exchange rates would effectively limit the ability of a government to manipulate mandatory policy directly to generate an opportunistic PBC, under these conditions an increase in the fiscal deficit would force a PBC in the money supply even if there were an independent central bank (see Willett, 2001). This illustrates the need to carefully examine the full range of possibilities when proposing institutional solutions.

POLITICAL ECONOMICS AND PUBLIC CHOICE

Political economics is a strand of literature that emerged in the mid-1980s and mostly deals with the same topics as public choice. A quick look at the indexes of two of the most widely read reviews of the literature (Persson and Tabellini, 2001; Drazen, 2000) gives a sufficient idea of how much the interests of political economics overlap with those of public choice. We read "economic models for political analysis," "electoral competition," "median voter equilibria," "laws, institutions and delegated authority," "rent seeking and predation," "lobbying" "legislative bargains," "electoral cycles"... and the list could be longer.

This overlap in topics is in striking contrast with the limited interaction between the two research communities. Very few political economics scholars participate to meetings of the public choice societies publish in journals such as *Public Choice* and quite seldom refer to contributions of the public choice school (short of the *Calculus of Consent* and with the exception of the two above mentioned literature reviews).

If we take the textbooks as an indicator of the attitude of one discipline towards the other, we keep the impression that the dialogue does not flow exactly seamlessly. On the one hand, public choice handbooks like Mueller (1997) and Shughart and Razzolini (2001), do not consider political economics as a separate discipline. They do cite and examine single contributions, like the theory of the strategic use of the debt (Tabellini and Alesina, 1990) or the innovations to the theory of the political business cycle (Alesina, 1987; Rogoff, 1990). The same applies to the forthcoming Public Choice III. On the other hand, political economists look at the relation between their discipline and public choice in two different and contradictory ways. Persson and Tabellini (2001) basically state that political economics analyses the same subject matter as public choice but with superior theoretical rigor. In their words "... Researchers in [public choice] tradition were reluctant, however, to use formal game-theoretic tools or to impose strong notions of individual rationality. As a result, the initial work sometimes relied on weaker theoretical or microeconomic foundations" (Persson and Tabellini, 2001, p. 3, italics added). Political economics, instead, borrows the methodology of the new classical macroeconomics and of the rational choice theory. It can thus be defined as a discipline that "... adopts the equilibrium approach of macroeconomic theory of policy and exploits the tools of rational choice in analysing some of the classic problems in public choice" (Persson and Tabellini, 2001, p. 4).

Drazen (2000) acknowledges that the differences between public choice and political economics are blurred. "Many treatments of the new political economy would not make a distinction between the fields, arguing that public choice is an integral part of the new political economy" (Drazen, 2000, p. 9). Drazen, however, argues that a distinction can be made in terms of topics: in his view public choice is interested in politics *per se*, while political economy focuses on the effect of politics on economic outcomes. Never he points out to a difference in methodology or analytical rigour, as Persson and Tabellini do.

In this entry we try to represent the Venn diagram of these two sets, public choice and political economics. We will focus, however, exclusively on the areas where they do not intersect and therefore may learn from each other. In science, however, two disciplines may dialogue and corroborate each other provided that they share the paradigm. We must therefore assess first whether the two disciplines are methodologically incompatible, as Persson and Tabellini state, or not.

Public choice theory is founded on the axiom that human behaviour, as described by the rational choice paradigm, is invariant with respect to the environments where the individual makes its choices; the outcome depends on the constraints that characterize these environments, be they monetary, legal, institutional, or related to the information available, but the process remains the same. Indeed, public choice owes its success to the first application of the paradigm of rational choice to the political process. This application was, from the beginning, so rigorous as to interpret the lack of participation of most individuals in politics as a form of rational ignorance (Downs, 1957), i.e., as the result of a rational calculus that evaluates the individual's opportunity cost of being informed about political matters higher than the expected rates of return. These rigorous behavioural postulates forced political scientists to a paradigm shift that yielded the rational political science of the Rochester school and economists to abandon the Keynesian presupposition that political economy was chosen by a benevolent despot aiming to maximize a social welfare functional.

In particular, the public choice critique of Keynesian political economy represents the first crossroads between public choice and political economics. Political economics develops from the New Classical Macroeconomics and especially Kydland and Prescott's (1977) conclusion that not all policies are equally plausible; only those that the policymaker has no incentive to abandon become credible or "time consistent." A technology is needed to make it impossible for policymakers to use their discretionary power and thus make time consistent choices; rules, the constitution, the institutional framework in which and by which policies are decided supply that technology. By that, around the early 1980s political economics arrives to the long-standing public choice tenet that "institutions matter."

It seems thus fair to conclude that both disciplines adopt a positive approach where economic policies and outcomes are the result of rational agents that maximize their private interests subject to institutional constraints. The two literature strands are based on the same paradigmatic plank. The critique of insufficient rigour that Persson and Tabellini move to public choice seems therefore misplaced. It is true that a few public choice models deflect from rational choice paradigm: for instance, the explanation of high public deficit in terms of fiscal illusion (Buchanan and Wagner, 1977), as a critique to the Ricardian equivalence theorem; the theory of expressive voting (Brennan and Buchanan, 1984); and, obviously, the philosophical explorations of the foundations of society (Buchanan, 1975; Brennan and Buchanan, 1985). But besides these offshoots, it seems unjustified to accuse the Chicago school and the Rochester school of public choice of adopting "weaker theoretical and microeconomic foundations," not to mention the Virginia school whose theoretical restrictions receive strong empirical support both from econometric and experimental analyses.

A difference between the two strands of literature may appear not in terms of methodologies, but of analytical devices used in the models. Political economics seems to have exploited to a greater extent than the Virginia and the Chicago schools of public choice the non-cooperative game theory, as Persson and Tabellini also affirm. These models are apt to represent the interrelations between agents within a specific institutional set-up. The rules (extensive forms) of the games may represent the institutional frameworks under scrutiny, the sequence of the moves the relative agenda setting power of the players, and the solution to the game is the economic and/or political outcome. This analytical approach has allowed political economics to produce significant processes in the analysis of comparative economic systems and of general equilibrium models of government. A case in point is the analysis of electoral accountability and the separation of powers among the different branches of government (Persson et al., 1997). Public choice scholars had already dealt with the issue, which is central to the analysis of modern democracies (Breton, 1996). Yet only within the precise specification of the institutional set-up allowed by the extensive form of the game is it possible to derive under what conditions the government system (parliamentary, congressional or presidential) will converge towards a competitive equilibrium, with fully functioning systems of checks and balances, or towards a collusive, oligarchic equilibrium. Furthermore, the insistence on non-cooperative game theory has moved the interests of political economics from policies to political process; witness the proliferation of research on electoral accountability and on budget processes. The distinction proposed by Drazen, that tends to confine public choice to political processes and political economics to policy outcomes, seems thus less and less appropriate, if it has ever been so.

On the other hand, the analytical device that public choice theory has exploited most often is the principalagent model, both because of its original interest in government failures and for its focus on the behaviour of agents within a single institution: the legislative, the bureaucracy, or regulatory agencies. By isolating one relationship between, say, voters and legislators, public choice models cast the other influences on the behaviour of legislators under a *ceteris paribus* conditions. Hence, another distinction that can be traced between public choice and political economics is in their perspectives. Public choice tends to adopt a Marshallian, partial equilibrium approach, whereas political economics models are more often (but not always) couched in a Walrasian, general equilibrium perspective.

This difference in perspectives creates excellent opportunities for gains from trade between the two disciplines. While a Walrasian perspective is certainly broader and more complete than a Marshallian one, the partial equilibrium approach adopted in public choice allows a greater precision in the description of the institutional details where political and economic decisions are taken. In a more and more integrated world for what it concerns economic processes, political differences are increasingly the most important source of variation among countries and of asymmetries in economic performances: the lesson of the literature on budget rules as the determinant of cross country difference in fiscal performance is clear in this respect. This literature, among others, confirms that one must pay attention to the details in order to understand how different institutional frameworks yield different economic outcomes. In this field, a Marshallian perspective is often the sole possible approach.

Furthermore, this approach is generally more amenable for empirical testing. The level of abstraction needed to keep a general equilibrium political model tractable often opens a wide gap between the theory's predictions and empirical reality. This distance is not only due to lack of institutional detail, but also to the need to choose variables in the econometric models that are loose and often disconnected proxies of their theoretical counterparts. Many political economics models, even relatively simple ones, are often quite problematic to test: for instance the war of attrition explanations of fiscal outcomes tend to confound notions of institutional ex post stability with political, ex ante stability, which is a relevant problem in cross section tests (Padovano and Venturi, 2001). The risk to produce mixed results is ceteris paribus lower from a partial equilibrium, public choice perspective, than from a general equilibrium approach. These tests, however, provide firmer grounds for further theoretical developments. Hence the existence of gains from trade.

Finally, there are topics that the two disciplines have so far left completely one to the other. For instance, political economics has developed an interesting theory of the optimal size and number of countries (Alesina and Spolaore, 1997; Bolton and Roland, 1997). These theories explain the forces, such as income redistribution, preferences over policies, risk sharing with respect to exogenous shocks, which lead to a breakdown and formation of countries and political unions. New insights can thus be drawn on the causes of the breakdowns of countries, like many that formerly belonged to the socialist bloc, as well as on the dynamics of political unions, such as the process of European integration. On the other hand, public choice is expanding its analysis of political system from democracies to autocracies or dictatorships. To witness the importance of this development, one must bear in mind that most countries of today's world (not to mention historical times) are ruled by dictatorships. Moreover, the most delicate issues in international affairs revolve around the relationship between democratic systems and dictatorial countries.

In conclusion, one can be assured that political economics and public choice share the same rational choice paradigm and areas of interest. The main difference, and not a great one, is a prevalence of partial equilibrium models in one strand of literature and of general equilibrium ones in the other. But once these differences are presuppositions for scientific progress, trying separate the two research fields or to assess the superiority of one over the other is a futile enterprise.

THE POLITICAL ECONOMY OF FEMA DISASTER PAYMENTS

A central contribution of public choice theory to the analysis of government activity is in viewing the activities of government, not as determined by some single altruistic dictator, but rather as the result of a process involving individual political agents who react to the incentives they face. Federal disaster relief, administered by the Federal Emergency Management Agency (FEMA), is one activity that is ripe for political influence due to the process of disaster declaration and relief. After a disaster strikes a particular state, the governor makes a request to the president for disaster assistance. Following a governor's request, the president then decides whether to declare the state or region a disaster area. Only after a disaster has been declared by the president can disaster relief be given. FEMA is in charge of determining the level of relief funding for the area, but additional appropriations are determined by congress in cases requiring large amounts of funding beyond FEMA's allocated budget. The Act which governs the rules of federal disaster declaration and expenditures gives the president the authority to declare a disaster without the approval of congress. Furthermore, the Act prohibits the use of any arithmetic formula to determine levels of disaster relief to any area. The potential thus exists for political influence to affect the disaster relief process at two distinct stages; whether or not a disaster is declared by the president, and how much money is allocated through

FEMA and congress for disaster relief after a disaster has been declared by the president.

FEMA was created by an executive order of President Carter in 1979 that essentially merged many separate disaster relief agencies that had already been in existence. The vast majority of FEMA operations and expenditures are undertaken under the rules and processes established by the Robert T. Stafford Disaster Relief and Emergency Assistance Act (Public Law 93-288), hereafter called the Stafford Act. This act establishes the process for requesting a presidential disaster declaration, defines the types of relief that are available for relief expenditures, and the conditions for obtaining assistance. From a budgetary standpoint, expenditures under the Stafford Act come from the portion of FEMA's budget known as the President's Disaster Relief Fund. Besides FEMA's activities under the Stafford Act, there are several additional, smaller programs undertaken outside the Stafford Act such as the flood insurance program and the U.S. Fire Administration. The activities of FEMA are subject to congressional oversight by several committees. In the House of Representatives, for example, there are four committees partially responsible for the oversight of FEMA. Two of these committees oversee the activities of FEMA under the Stafford Act. while the other two oversee the smaller, non-Stafford Act activities. A similar process is present on the Senate side of congressional oversight of FEMA.

The process for FEMA disaster relief suggests there are two potential sources by which political influence may enter into the FEMA disaster relief process. The first avenue of political influence is the process of disaster declaration. Because this is a decision left entirely up to the president, and because there is such a wide range of possible weather phenomenon (such as thunderstorms and snowstorms) for which disasters may be declared, it is possible that he may be more likely to declare a disaster in a state that is politically important. Also, because the Stafford Act allows the president to unilaterally declare a disaster without the approval of congress, it is possible that the president may use this power to punish or reward legislators who support or oppose his policies, or just simply tarnish the image of opposing party legislators in hopes of reducing their probability of reelection.

The second avenue through which political influence may affect FEMA expenditures is through congressional oversight. It is important for the agency to be in good standing with the oversight committees, as these committees can have considerable influence over the agency. In public choice theory, this relationship between congress and a bureau such as FEMA is traditionally examined within a framework known as the congressional dominance model, which postulates that bureaus are very responsive to the wishes of congress and the president [see Moe (1987, 1997); Weingast and Moran (1983); Weingast (1984); Anderson and Tollison (1991); Couch and Shughart (1997); Young et al. (2001)]. Specifically, the model suggests that congressional committees having both budget and oversight responsibilities see that bureaucrats carry out the policy preferences of the legislators. In 1992, for example, the House Appropriations Committee found evidence of excessive and wasteful spending by several senior executives at FEMA, such as chauffeur-driven cars. The Appropriations Committee readily cut several executive positions and reduced the budgets of others. Given the power of oversight committees, it is thus possible that states who are represented on these committees overseeing FEMA receive a disproportionally larger amount of money for disaster relief to remain in the good graces of the oversight committees. This possibility is augmented by the fact that the Stafford Act explicitly prohibits the use of any formula to determine levels of disaster payments.

Using FEMA disaster expenditure and disaster declaration data for all 50 states over the period 1991 to 1999, Garrett and Sobel (2001) measure the impact presidential and congressional influences have on disaster relief. To assess the impact of presidential influence, they hypothesize that the decision of presidential disaster declaration in a state is a function of several state socioeconomic characteristics, the electoral importance of a state [Willet (1989) and Tabellini and Alesina (1990)], whether or not the state governor is of the same political party as the president, and the percent of congressional representation from the state that is of the same political party as the president. Given that a disaster has been declared in a state, Garrett and Sobel hypothesize that the level of FEMA disaster relief to a state in a given year depends upon the size of the natural disaster (which they proxy with private insurance disaster payments and Red Cross disaster assistance), and the number of legislators from the state that are on one each the FEMA disaster payment oversight committees. In addition, they test for differences in disaster declaration and expenditures during election years versus non-election years.

Their results support the predictions of the public choice model. They find that political incentives facing the president do significantly affect the decision of disaster declaration. Those state having greater electoral importance have a higher rate of presidential disaster declaration. They also find evidence that the mean rate of presidential disaster declaration is higher during election years compared to a non-election year, and for all years in the sample the mean rate of disaster declaration was highest in the year of Bill Clinton's reelection campaign in 1996.

Garrett and Sobel also find strong evidence that political incentives in congressional oversight are significant determinants of FEMA disaster relief payments. They find that those states having greater representation on FEMA oversight subcommittees received higher FEMA disaster relief payments. On average, each additional member on a FEMA oversight committee results in \$20 million in additional FEMA disaster payments to the committee member's state. Focusing on differences in Senate and House representation, they find that House representation on either a Stafford Act or non-Stafford Act committee significantly impacts the level of disaster relief (roughly \$30 million in additional FEMA disaster payments, on average), but Senate representation does not. This is possibly because House members have a higher percentage of their constituency impacted by a disaster than a corresponding Senator. This finding also supports Goff and Grier (1993) who suggest that Senators will be less politically effective and less likely to apply influence relative to House members.

Garrett and Sobel use their empirical estimates to determine how much of FEMA disaster relief is due to political influence. They find that, on average, 44.5 percent of total FEMA disaster payments over the sample period were a result of congressional representation on FEMA oversight committees. Thus, their calculations reveal that nearly half of all FEMA disaster relief is explained by political influence rather than actual need based on disaster severity and frequency.

Although FEMA is often promoted as a savior for individuals and communities hit by a disaster, Garrett and Sobel find evidence that disaster declaration and the level of FEMA disaster expenditures are both politically motivated. Their results lend further support to the congressional dominance model, and the public choice model of government more generally. Their findings cast doubt on FEMA's altruistic goal of financial assistance to those most in need, and questions the role of government versus private agencies in providing disaster relief.

THE POLITICAL ECONOMY OF ITALIAN ELECTORAL REFORM

1. Introduction

In the public choice tradition, politics is seen as a market activity in which individual preferences are revealed and translated into public policies through a 'production' process. In this framework, a sequence of elections may be considered as a repeated game in which the preferences of society are expressed and find representation (Ordeshook, 1997). The expression and implementation of societal preferences and the production of implied policies are guaranteed by the repeated nature of the game. The market where this game is played is the electoral market.

To apply this perspective to the understanding of elections we require a model of a typical market whose basic elements are the demand side, i.e., the behavior of buyers, the supply side, i.e., the behavior of sellers, and a set of rules that constrain buyers' and sellers' market activities (Navarra and Mudambi, 2001). The supply side of the electoral market is composed of political parties that mainly produce policies. The demand side is made up of voters who select their preferred policies through the electoral process — the expression and representation of societal preferences. The set of rules governing the way elections are implemented is the electoral system that represents the mechanism through which electoral choices are translated into implemented policies through the selection of elected representatives. In this framework, electoral systems are the rules that regulate the electoral game in which democracy is practiced (Grofman and Reynolds, 2001).

The actions of political agents in the electoral game are linked with one another by a complex system of incentives. Since this system of incentives is affected by the election rules, any alteration of the rules alters the incentives of the different agents in the game (Myerson, 1999). Thus, we are obliged to consider changes in rules as well as particular choice options available within the set of rules that exist.

In this essay we review the literature on the change of the electoral rules in Italy during the 1990s. The extant proportional representation system was changed to a system with strong elements of plurality at both the national and local level. Following Mudambi et al. (2001a,b), we strive to unify constitutional political economy with public choice analyzing both choices between rules and choices subject to rules (Rowley, 1997). When we deal with choices subject to rules we are concerned with the behavior of political agents under a given electoral system, whereas when we consider choices between rules we focus on behavior when the electoral system itself is in the process of being changed. The change of the electoral system in Italy was a process of choice between different electoral rules that, once taken, affected decision-making on both the demandand the supply-side of the electoral market.

2. Choices between Rules

Alternative electoral rules have several consequences for a political system. Mudambi et al. (1996, 1997, 1999) compare the two systems of representation regulating Italian local elections before and after the implementation of the electoral reform. The electoral systems whose peculiarities they investigate are proportional representation (PR) and a system incorporating many elements of plurality (PL). They compare empirically the two systems of representation with respect to the following variables: the information engendered to voters, their commitment in participating in the electoral process, the dilution of the power of elected representatives and the degree of proportionality in translating votes into seats.

As argued by Stigler (1971) indirect democracy naturally results in elected representatives with considerable latitude in interpreting the wishes of their constituents. This suggests two important measuring rods that may be used to compare electoral systems. The first is the amount of information that the system engenders amongst the voters. The second is the level of interest that they elicit from the voters. Mudambi et al. (1996, 1997) use Olson's (1965) theory of groups as the basis upon which to construct a *proxy* for the information level and electoral turnout as the *proxy* for voter commitment. Comparing local elections in Italy before and after the electoral reforms, Mudambi et al. (1996) find strong evidence for higher levels of information and voter commitment under the old PR system than under the new system incorporating significant elements of plurality.

In a different paper Mudambi et al. (1999) compare the effects of two variables on the power wielded by elected representatives electoral systems before and after the reform: the information level engendered amongst the eligible voters and the effectiveness of the electoral process in translating votes into seats (i.e., the degree of proportionality). Again the proxy for the information level is based on Olson's theory of groups. The measure of power dilution is constructed using the index of control developed by Cubbin and Leech (1983). Finally, the effectiveness of the electoral system in translating votes into seats is measured an index proposed by Mudambi (1997). They find that both information level and the degree of proportionality had a negative effect on power dilution in the 1985 and 1990 PR elections. However, these two effects disappear in the results of an identical model run for the 1994 PL elections

3. Choices Subject to Rules

Once the electoral properties of alternative electoral systems have been compared and the choice amongst them has been made, the selected rules constrain political behavior on both the demand and the supply side of the electoral market. Most of the literature analyzing the effects of the new Italian electoral rules on the choices of voters and political parties has focused on their impact on representation at national level. In particular, researchers have analyzed the election of representatives to the Chamber of Deputies (CD), i.e., the Lower House of the Italian Parliament. The new system of representation adopted at for the elections to the CD is a mixed-member (MM) system. These systems incorporate elements from both PR and PL electoral rules. The Italian case is characterized by a 75%/25% PL/PR split, i.e., 75% of the members of the CD are elected in single-member constituencies (SMCs) using a PL system, while 25% are elected on the basis of a list PR system from multi-member constituencies.

3.1. The Supply-side of the Electoral Market

Countries that have adopted MM systems have generally witnessed the generation of political competition between two broad political coalitions. This is one of the most important features of MM systems. Italy is no exception. Electoral competition under the new Italian rules is characterized by two sets of incentives created by the PL and PR components of the MM system. Competing in small singlemember PL constituencies requires the creation of broad coalitions capable of winning majorities in geographically cohesive but politically diverse districts. However, political parties must maintain their unique identities in order to maintain their appeal to their core supporters in the large multi-member PR districts (i.e., plurality maximization *vs.* vote maximization; Navarra and Lignana, 1997).

Mudambi and Navarra (2002) analyze party electoral strategies that emerge from the incentive structure generated by the Italian MM system. Parties craft their strategies on the basis of two-ordered objectives. The primary objective is a coalition-focused objective of achieving a coalition victory in each SMC. The secondary objective is a party-focused objective aimed at minimizing the margin of victory of candidates from other coalition parties, while attempting to maximize the margin of victory of the party's own candidates. They show how party strategies in a given electoral coalition are sensitive to the nature of the coalition as well as the nature of the individual SMC electoral contest in which the parties are engaged. Finally, they estimate the impact of intra-coalition behavior on the probability of victory in SMC races.

The analysis of electoral competition by Mudambi and Navarra (2002) has two main implications, both of which derive directly from the game theoretic nature of the contest. First, parties in coalitions face two sets of rivals parties in other coalitions and parties within their own coalition. In the pursuit of their electoral objectives, there are circumstances in which intra-coalition rivals are considered more serious threats than extra-coalition rivals. Second, coalitions are often composed of heterogeneous parties that have joined for purely electoral purposes with significant differences in their political platforms. Such purely electoral coalitions are likely to be extremely unstable (Mudambi et al., 2001a,b).

The distinction between electoral and political coalitions is fundamental to understanding the dynamics of the formation and collapse of Italian governments in the years following electoral reform. Giannetti and Laver (2001), drawing from Laver and Kato (2001), suggest that the inherent features of the new system of representation produce two interacting party systems: one for the

'electoral politics' and the other for the 'legislative politics'. The *electoral* party system is viewed as responding to the centripetal logic of PL races in SMCs producing the formation of large electoral coalitions. On the other hand, in the parliamentary party system, the PR component that supports the centrifugal logic of parties to maintaining their separate identities by breaking away from electoral coalitions and bargaining as smaller units over government formation. The interaction between electoral and legislative party systems creates forces that have destabilizing effects on the incumbent government.

Italian Government instability in the post-reform period has been also analyzed by Mudambi et al. (2002). In this paper, as in Giannetti and Laver (2001), the decisive structure of the legislature is an endogenous and dynamic product of the government formation process (Laver and Shepsle, 1996). The formation of government with heterogeneous parties is modeled as a two-stage game. In the first stage, parties form electoral coalitions to fight the elections. In the second stage the parties in the winning coalition bargain over the division of net benefits from office. Extreme elements in each of the coalitions have the least in common with each other, but also have the least to gain from the continuation of the government in office. Therefore they have a shared interest in undermining the stability of the government. Finally, they show the conditions under which rational parties play the two-stage game as a dynamic game in which electoral victory is subsidiary to government stability in the formation of the electoral coalitions.

The most important objective of the Italian reformers was the generation of a bipolar party system (Duverger, 1954) that in turn would lead to effective governance and alternation in power. The introduction of an MM system with a significant PL component was seen as the means to achieve this goal. Katz (1996) suggests that Italian electoral reform did not produce the two-party politics it was supposed to provide according to Duverger's predictions. However, Reed (2001) demonstrates that Duverger's law not only works in Italy, but it does so rapidly and powerfully. Following Wildasky (1959) and Riker (1986), he points out that the electoral system effects operate at the district level and it is by agglomerating these district level effects that politics at the national level affected. He uses three indicators of party competition and shows that the MM system not only reduced the number of candidates per district but also produced a movement towards twocandidate competition. In Reed's view, bipolar candidate competition at the district level should be understood as the first stage of a process that is likely to be lead to two-party competition at the national level.

3.2. The Demand-side of the Electoral Market

MM systems are operationalized allowing each voter to cast two ballots. The first ballot is a PL ballot cast for the selection of a candidate in the SMC; the second vote is a PR ballot for the most preferred political party list in a larger multi-member district. This mechanism implies that voters may vote for a candidate of one party (or coalition) in the SMC and for the list of a different party at the PR level. As argued by Cox (1997), different voting systems confront voters with different problems of strategic electoral choice. The introduction of a significant PL component in the electoral formula for transforming votes into seats (75% of the total seats in the Lower House) implies that casting a vote for the most preferred candidate, i.e., voting 'sincerely', is not always the best way to have an impact on the outcome of the election. Did the Italians vote strategically in the elections governed by the new rules?

Benoit et al. (2002) estimate the level of strategic voting in the 1994 and 1996 Italian national elections. They group Italian voters into three categories. The first category comprises 'loyalist' voters. These voters vote for their most preferred party in the PR ballot, find a candidate from that party in the PL ballot and vote for him. The second and third categories comprise 'strategic' and 'non-strategic' voters. They vote for their most preferred party in the PR ballot, but find a candidate from a different party in the PL ballot. Strategic and non-strategic voters differ in their behavior in SMC races. The former vote for a candidate from a party within the same coalition as their most preferred party, whereas the latter vote for a candidate of a party that is *not* in the same coalition of their most preferred party. Benoit et al. (2002) apply King's (1997) technique of 'ecological inference', to estimate the relative number of strategic and non-strategic voters in each SMC. They find that a higher proportion of supporters of the Center-left coalition (Ulivo) are strategic as compared to supporters of the Center-right (Polo). Center-left voters, therefore, voted more strategically since they did not split their PR and PL votes between the two competing coalitions to extent that Center-right supporters did. Analyzing a risk-bearing model to capture the extent of strategic voting emerging from the implementation of the MM system in the 1994 Italian national elections, Navarra (1997) reaches similar conclusions.

Majoritarian electoral formulae provide strong incentives for abstention due to the 'wasted votes' phenomenon (Cox, 1997). Given the strong elements of PL in the Italian MM system, one would have expected high abstention rates. However, the change in the electoral rules had no effect on the abstention rate, which continued to grow following to a long-established trend. The abstention level maintained its classic geographical and social pattern and further, there was no significant difference between the rate for PL and PR races. In sum, in the PL ballot, where voters have a direct influence on the outcome in terms of candidates and majority voting, turnout (a) was no higher than before; (b) was no higher than in the PR races, and (c) was not affected by the degree of uncertainty in the particular electoral contest.

POLITICAL TRANSACTION-COST MANIPULATION

"Political transaction-cost manipulation" is a general theory of the growth of government that integrates diverse analyses in the public choice literature. Its core idea is that federal officials have both the incentive and the opportunity to manipulate private citizens' (and other government officials') transaction costs of taking political action on measures that alter the national government's authority. The theory provides an explanation of how government often grows even when the public does not want it to grow, and why government usually doesn't shrink even if the public would prefer it to shrink.

Political transaction costs by definition here denote costs of reaching and enforcing agreements regarding the role and scope of government. If federal officials are able to raise the transaction costs of opposing governmentexpanding measures, they can block public resistance and thereby enable the national government's authority to grow (and remain) beyond the level that otherwise would be tolerated (Twight, 1983, 1988, 1992). Treating political transaction costs as endogenous, this model analyzes in detail government officials' incentives to engage in transaction-cost manipulation, the specific forms the behavior takes, and its implications for the growth of government. Political transaction-cost manipulation thus provides a unifying framework that integrates and extends important aspects of prior scholarly work on fiscal illusion, cost concealment, strategic use of information, government autonomy-enhancing strategies, agenda control, credit claiming, blame avoidance, and related forms of congressional and bureaucratic behavior (Twight, 1994).

1. Natural versus Contrived Political Transaction Costs

Political transaction-cost manipulation theory distinguishes "natural" from "contrived" transaction costs, focussing primarily on the latter. Natural transaction costs are those that would exist even if all political actors tried to minimize transaction-cost impediments to political exchange. They are what most people think of when they consider the transaction costs of political action. For example, in the absence of other incentives, the high transaction costs of organizing large groups whose members naturally have small individual stakes in the outcome may preclude their formation into viable interest groups (Olson, 1965). Such political transaction costs inhere in the nature of reality: they are not created by federal officials.

"Contrived" political transaction costs, on the other hand, are created by federal officials, a product of their self-interested use of the mechanisms of government. The key insight is that political transaction costs often are increased intentionally: political actors manipulate them strategically to achieve personal political objectives. Such contrived political transaction costs alter either people's perceptions of the costs and benefits of government authority in a given sphere, or the costs of taking political action based upon those perceptions. For example, politicians long have understood that by disguising the outcome of governmental policies or by purposely concentrating a policy's benefits and dispersing its costs, public resistance can be curtailed. In these and myriad other ways, government officials thus often manipulate the costs of collective action encountered by the public or by others in government (Twight, 2002).

2. Rent-seeking through Political Transaction-cost Manipulation

Clearly, political transaction-cost manipulation is a form of rent-seeking. Consistent with Tullock's (1967) rent-seeking insight, the creation of contrived political transaction costs enables lawmakers, bureaucrats, executive branch officials, and others in government to obtain more of what they — and any interest groups they serve — personally value, at the expense of the general public.

3. Determinants of Political Transaction-cost Manipulation

The question is, what circumstances make support for a transaction-cost-increasing measure more feasible and attractive to a government official? The theory of political transaction-cost manipulation identifies variables that shape a federal official's decision to support or oppose such a measure. Variables that encourage support for a transaction-cost-increasing measure include: an appealing rationale; complexity (which reduces the likelihood that the measure will be understood, while allowing informed sponsors later to feign mistake); executive support for the measure; political job security and perquisites associated with it; third-party payoffs; party support; and high perceived importance of the measure to the official's constituents. Ideology is another key determinant: the theory predicts that government officeholders will favor laws, regulations, and policies that increase transaction costs associated with disapproval of programs that they personally favor on ideological grounds. Media attention to the transaction-cost-increasing features of a measure is predicted to negatively influence support for the measure. Time plays a more ambiguous role: it may increase support for a transaction-cost-increasing measure by facilitating

formation of interest groups likely to benefit from it, yet it may decrease support for the measure by providing greater opportunity for those harmed to discover the measure's likely effects (Twight, 1988, 2002).

4. Transaction-cost Manipulation in the Private Sector

Of course, transaction-cost-increasing behavior also occurs in the private sector. Although firms in perfectly competitive markets have no leeway to increase transaction costs, most businesses operate in imperfectly competitive markets that allow possible benefits to firms that engage in such behavior. Fraud is one example of these market strategies (Darby and Karni, 1973); firms' attempts to raise their rivals' costs provide another (Salop and Scheffman, 1983). Nonetheless, although transaction-cost augmentation by private firms sometimes does occur in the short run, associated direct costs as well as long-run competition and potential legal prosecution reduce its viability and appeal.

Constraints on transaction-cost manipulation are weaker in the public sector. In the private sector, consumers' desire not to be misled operates as a significant constraint on private actors' ability to effect contrived transaction costs. In political markets, the incentive of private individuals to acquire and act upon information relating to governmental officeholders' performance is minuscule by contrast. Higher natural transaction costs create greater slack in the political process, which in turn allows greater scope for transaction-cost manipulation. Reduced private incentives to acquire information also dampen incentives of potential "competitors" in political, bureaucratic, and judicial markets to reach citizens with information regarding changes in political transaction costs. Moreover, government officials who raise transaction costs to voters by lying about the nature of a government program or by mislabeling a statute face no legal penalty for their behavior that is comparable to punishment for private sector fraud.

Costs generated by adopting measures that increase relevant transaction costs thus do not impinge upon government decision makers as direct costs to the same extent that they do upon private decision makers engaged in analogous behavior. As a result, the government sector provides more fertile ground for such activity (Twight, 1988, pp. 140–145).

5. Intra-governmental Manipulation of Political Transaction Costs

In addition to changing private citizens' transaction costs, government officials also have incentives and ability to manipulate each other's transaction costs. Just as changes in political transaction costs facing the public may result from legislative, executive, judicial, or administrative action, so too the transaction costs facing government functionaries in each branch may be altered by actions of their government counterparts both within and outside their particular branch of government. For example, those serving on key congressional committees are in prime positions to manipulate information flowing to the rest of Congress. Bureaucratic cost concealment directed at other government officials supplies another well-documented example (Niskanen, 1971, 1975). Spiller and Tiller (1997) have described other examples that illustrate transaction-cost manipulation between Congress and government agencies and between Congress and the courts. The result of all such behavior is intragovernmental alteration of targeted government officeholders' transaction costs of perceiving and reacting to the costs and benefits of actual or proposed government authority in a given sphere. Intragovernmental manipulation of political transaction costs is expected to be responsive to the variables discussed above, though the relative importance of specific variables will vary with the particular governmental context.

6. Types of Political Transaction-cost Manipulation

The actions that fall under the rubric of political transactioncost manipulation are varied, united by their common ability to alter the transaction costs of resistance to government authority-expanding measures. The main forms of political transaction-cost manipulation are those involving "information costs" on the one hand and "agreement and enforcement costs" on the other. Alternatively, these two categories might be termed "perception costs" and "action costs." However diverse the practices involved, they are cut from the same cloth.

The common ground shared by the superficially dissimilar forms of behavior identified below has not been widely understood. It has not been intuitively obvious that behavior as diverse as, for example, labeling statutes euphemistically, dispersing programmatic costs, unilaterally reinterpreting statutory law, and inserting parochial riders in politically safe omnibus bills might be reflections of the same impetus to manipulate political transaction costs. The transaction-cost-manipulation approach strives to systematically identify these linkages, developing a taxonomy of the different forms of this behavior.

On the information-cost manipulation side, the behavior includes such things as semantic efforts to alter public perception of the costs and benefits of government activities; distortion of information, or restriction of access to information, about the nature and consequences of government activities; forms of taxation that change people's perception of the tax burden imposed on them; forms of subsidy that alter public perception of the benefits and costs implied; forms of regulation that obscure its cost to the individual; off-budget techniques; and incrementalism in expanding government authority. Prohibiting legitimate private contracts so as to increase the information costs of evaluating private alternatives to government control also falls under this heading.

On the agreement- and enforcement-cost side, the behavior encompasses all transaction-cost manipulation strategies that restructure costs of political action rather than costs of political information. One such category is "unilaterally changing the locus or scope of government decision-making authority in ways that shift the transactioncost burden entailed in effectuating or forestalling change in the role of government" (Twight, 2002, p. 54). An example here is changing the meaning of the Constitution by means of the U.S. Supreme Court rather than through the formal amendment process established by Article V. When the Supreme Court expanded the meaning of the Constitution's interstate commerce clause, for instance, it turned the formal amendment process upside down. Instead of requiring those who wanted to expand the government's role to amend the Constitution as specified by Article V — a process designed to protect the original Constitution by making it costly to change the document — the Supreme Court made the change by judicial fiat. As a result, any subsequent effort to restore the Constitution's prior meaning required defenders of the original Constitution to incur the high transaction costs of amendment that had been intended for those who wanted to alter the original document, a complete reversal of the transaction-cost burdens of constitutional change. Whenever the Supreme Court has reinterpreted various provisions of the Constitution so as to expand the reach of federal authority, the court has shifted transaction cost burdens in this way.

Other subcategories of agreement- and enforcementcost manipulation include: deliberately concentrating the benefits and dispersing the harm born of government action; changing the cost to private individuals of effecting administrative or judicial challenge to the government's interpretation of its existing powers; directly changing the cost to private citizens of achieving political agreement to revise the scope of government authority; interaction between government agencies that alters the cost to individuals of revising the scope of government authority; and adopting procedural strategies that alter costs to congressmen of implementing their decision-making authority (e.g., tying different legislative proposals together into a single bill to make it a package deal). These and other subcategories are identified, with examples of each, as part of the model's taxonomy of transaction-cost manipulating strategies (Twight, 1994, p. 203).

Empirical Evidence

Evidence consistent with this theory is now abundant. Research has shown that political transaction-cost manipulation was pivotal in developing and implementing key federal programs and policies that touch the lives of all Americans. Creation and expansion of Social Security, income tax withholding, federal education controls, Medicare and related health care regulation, and federal database mandates and surveillance measures, for instance, all entailed such manipulation.

The Social Security Act was passed in 1935 through a variety of transaction-cost manipulating techniques. People at the time did not want compulsory old-age insurance for everyone; rather, they wanted means-tested public assistance for the aged poor. As Carolyn Weaver (1983) has shown, Franklin Roosevelt secured Social Security's passage only by tying it to other more popular measures, controlling information flowing to Congress and the public, dominating the agenda with the FDR-backed bill, and refusing to sign individual sections of the bill if separated from the other sections. All of these strategies increased the political transaction costs of opposing the Social Security Act.

Today, because of deliberate increases in political transaction costs, resisting this program is virtually impossible. Employers are required by law to extract payroll taxes from wages without employees' consent, making the cost of the tax less apparent than it would be if wage-earners had to write a check for the same amount. Government officials continue to tell Americans that they have a contractual right to Social Security benefits, despite the U.S. Supreme Court's 1960 ruling that people who have paid Social Security taxes for their entire working lives have no contractual right to anything as a result. The payroll tax itself is said to be "split" between employers and employees, with the employer shouldering half of the 12.4% Social Security tax.

In truth, economists and government officials have known for decades that employees bear almost the entire 12.4% tax — both halves — the "employee's" half through payroll tax deductions noted on their pay stubs, and the "employer's" half in the form of reduced contractual wages. As Edgar Browning (1975, p. 381) stated, "the dual nature of the levy does not influence the incidence of the tax," so that "its only impact" is on "voter awareness of the costs." Nonetheless, government officials continue to misrepresent the extent of the tax burden borne by employees, deliberately raising the transaction costs to voters of perceiving the full impact of the Social Security tax — and thus reducing public resistance to it.

Similarly, federal income tax withholding was mandated in 1943 by means of a variety of transaction-costmanipulating techniques. For example, legislators told the public that withholding was for the benefit of taxpayers and would lower their tax burdens. Yet in congressional hearings at the time they discussed the revenue that needed to be "fried out" of taxpayers, how they could not "get those fellows" without withholding, and how withholding would increase future federal tax revenues (Twight, 2002). From 1943 to the present, mandatory withholding has dramatically increased the political transaction costs of resisting federal income taxes and thus the expanded power of government.

Laws establishing federal controls over education likewise were passed and implemented by means of transaction-cost manipulation. For example, legislators secured passage of a 1958 law by calling it the "National Defense Education Act," although they acknowledged among themselves that the tie to national defense was a "gimmick," a "sales argument," a way of providing federal revenues even to students studying "social welfare work, automobile driving or...flower arranging" (Twight, 2002, pp. 147, 153). Similar techniques were used to pass the 1965 Elementary and Secondary Education Act. For example, although the bill was said to be part of President Lyndon Johnson's "war on poverty," congressional hearings show that the Act's antipoverty rationale was a sham, with the bill's benefits in fact designed to disproportionately benefit the affluent, not the poor. Legislators also claimed that these laws would not result in federal "control" over education, yet deliberately established such control by requiring states and localities to comply with federal educational goals in order to obtain federal funding.

Passage of the 1965 Medicare law as well as more recent federal health care controls hinged on similar strategies. Incrementalism, lying, and tying were used repeatedly. After decades of failed political efforts to mandate compulsory health insurance for all Americans, advocates deliberately narrowed the proposal to compulsory national health insurance for the aged. This incremental strategy proved crucial to passage of the 1965 Medicare law. In addition, the Medicare bill was made part of the Social Security Amendments of 1965, which contained a 7% increase in cash benefits for Social Security recipients. Tying these measures together meant that a legislator could not vote against Medicare without voting against the Social Security benefit increase, thus increasing the political transaction costs to legislators and to private citizens of opposing the Medicare bill. In addition government officials deliberately misrepresented Medicare, claiming that it provided coverage for catastrophic illness when they knew it contained no such provision. Moreover, once in place it was implemented with the familiar transaction-cost-increasing strategies of withholding and ostensible "splitting" the Medicare tax. Today, government officials tell us that if we decline Medicare hospital insurance benefits, having paid Medicare and Social Security taxes our entire working lives, we will forfeit all Social Security benefits. It would be difficult to devise a more powerful strategy for forcing people not to resist Medicare.

Similar strategies were used in passage and implementation of the 1996 Health Insurance Portability and Accountability Act (HIPAA). Though legislators represented the bill as a benign measure aimed at assuring that workers could retain health insurance upon changing jobs, the bill also contained privacy-endangering features of the previously rejected Clinton Health Security Act of 1993. A provision labeled "Administrative Simplification" contained requirements for "unique health identifiers" for all Americans, uniform electronic databases of personal medical information, and standardized data formats nationwide. By obscuring these provisions and tying them to more appealing measures, government officials increased the political transaction costs of resisting HIPAA and facilitated its passage. Misrepresentation continued at the implementation stage when government officials assured Americans that the new electronic databases would not be harmful because of HIPAA-mandated privacy regulations adopted by the Clinton and Bush administrations. Again, it was a transaction-cost-manipulating untruth: the so-called "privacy" regulations in fact dramatically reduced Americans' medical privacy.

Detailed empirical studies of these and other policy measures document the ubiquity and deliberateness of political transaction-cost manipulation, showing the linkage between the variables discussed above and federal officials' decisions to use transaction-cost-increasing strategies. Evidence consistent with the model's predictions is found in congressional hearings, the *Congressional Record*, and other official federal documents.

Impact on the Growth of Government

Manipulating costs of political decision making in order to achieve results initially inconsistent with actual public preferences has been a recurrent strategy in capturing and maintaining increased government authority over U.S. citizens. In contrast to some economists' visions of a transactioncost-minimizing state, this model and associated empirical work have documented government officials' characteristic willingness and ability to increase the political transaction costs facing others on issues that influence the scope of government authority. The result has been steady expansion of the role and scope of government, buttressed by resistanceblocking mechanisms deliberately embedded in our institutional structure. Political transaction-cost manipulation thus has allowed government to grow beyond the level that otherwise would be tolerated, making a vastly expanded central government now largely self-perpetuating.

PRESSURE GROUPS AND UNINFORMED VOTERS

During the last quarter of the twentieth century, economic and political science journals were filled with models of interest group politics. Their details differed, but, with certain exceptions (most of which are noted below), the message was the same: politicians tradeoff good policy in return for campaign contributions from special interests. The appeal of these models was the plausibility of their assumptions and the apparent realism of their conclusions. Since voters are often persuaded by political advertising, it makes sense that candidates would move their policies away from the median voter in order to gain the pressure group contributions that pay for such advertising. In this essay, I take a closer look at how uninformed, but rational voters, respond to such advertising. In the process, I show that pressure groups play a much more beneficial role in elections then generally believed.

1. The Standard Model and its Critics

Uri Ben Zion and Eytan (1974) and Welch (1974) published the first formal models showing the relationship between campaign funding by pressure groups and the behavior of the uninformed voters. In these models, a candidate maximizes vote share, which is a positive function of the candidate's position and campaign expenditures on advertising. An interest group donates money to the candidate in turn for the politician choosing a policy closer to the pressure group's preferred policy. The politician will agree to this quid pro quo if the politician gains more votes from advertising than are lost from choosing an inferior policy position. For want of a better term, I will refer to this and similar models as the standard model.

A large body of research incorporated the basic insights of this argument [see Mitchell and Munger (1991) and Morton and Cameron (1992) for surveys of the early literature]. This argument was also an important justification behind a whole host of articles even when the articles did not explicitly deal with voters. Consider Becker (1983, 1985) who assumes an interest group influence function other things being equal, the greater the expenditure by the group, the more that the group will get its way in the political sector. How this money is turned into political pressure is not specified — it may be used for bribes or for informing legislators. But certainly an important motivating force for acceptance of Becker's model is that the money could be used for campaign advertising.

In the late 1980s and early 1990s several authors attacked the standard modeling of pressure group influence. Wittman (1989, 1995) argued that these models suffer from a meta-theoretical inconsistency — if voters believe that the standard model is correct, then voters would not act in the way posited. In particular, if the median voter knew that advertising comes at the cost of the candidate moving away from the median, then the median voter would vote for the candidate doing less advertising. Thus the standard model makes no sense when the voters understand the model. In the words of Lohmann (1998), the standard model requires "voter illusion."

Now in the standard model, the behavior of the voters is treated as a functional form — the more advertising, the more votes for the candidate. But as Austen-Smith (1991), in his critical review of *Black-Hole Tariffs and Endogenous Policy Theory* pointed out, voters should be modeled as utility maximizers rather than as mere automatons. While Austen-Smith did not provide any model in his review, he did list the requirements for a rational model of voter behavior — that voters will include in their calculations the knowledge that parties seek to win office and lobbies seek to influence policy.

For the most part, these arguments seemed to fall on deaf ears during the 1990s. Prominent examples include Baron (1994) and Grossman and Helpman (1997). In their models, a pressure group again provides money for advertising in exchange for a policy move by the candidate. They divided voters into two groups — informed voters who vote purely on policy grounds and uninformed voters whose vote for a candidate depends only on the candidates' advertising expenditures. So the uninformed voters are again just automatons. And once again, a candidate moves away from the median voter toward the preferred position of the pressure group whenever the candidate gains more votes from the uninformed through advertising than the candidate loses from the informed by taking a less desirable position.

If the uninformed voters had an ounce of wisdom in their heads, they would abstain and let the informed make the decision for them (see Fedderson and Pesendorfer (1998) for the argument); and, as already noted, if the median uninformed voter had two ounces of wisdom in his head, he would realize that the candidate doing more advertising is farther away from the median and, consequently, would vote for the candidate doing less advertising.

The question for the most of the remainder of this essay is: under what circumstances would uninformed but rational utility maximizing voters be more likely to vote for a candidate when the candidate spends more money on advertising.

The short answer is rational voters only respond positively to more advertising if the voters are on average better off by doing so. But how can the voter be better off? There are two ways this question has been answered. (1) There is some benefit that the rational uninformed voter gains in return for the candidate choosing an inferior position. And (2) advertising moves the outcome toward the preferred position of the median uninformed voter. We start with the first answer.

2. Uniformed Voters Gain some Benefit in Exchange for an Inferior Policy

Maybe voters gain enjoyment from political advertising and rationally vote for the candidate doing more advertising. Frankly, I am skeptical that the entertainment value of political advertising is very high.

A more convincing approach is that voters may tradeoff reduced risk for an inferior policy. Congleton (1986) argued that advertising increases information about the candidate's policies, thereby reducing policy risk. Austen-Smith (1987) developed this insight about risk-reduction into a model of political campaigns. In his model, the median voter is willing to vote for a candidate whose expected policy is worse than the other candidate's expected policy if the risk (variance) is lower for the first candidate. At the same time, the pressure group is willing to provide money for advertising if the candidate moves away from the median voter toward the pressure group's most preferred position. So the median voter rationally votes for the candidate doing more advertising whenever the reduction in risk compensates for the loss in expected policy position. Extensions of the Austen-Smith model were made by Ingberman (1992) and Gersbach (1999). Ingberman assumed that more is known about the incumbent, while Gersbach considered the case where candidates have policy preferences.

Several authors have assumed that the pressure group has inside information regarding the relative quality (e.g., honesty or leadership skills) of the candidates. Voters know the positions of the candidates, but not their quality (or, in some models, voters have only a weak signal of quality). All of the voters prefer higher quality to lower quality. The pressure group provides information about the quality of the high-quality candidate in return for the high-quality candidate moving toward the position of the pressure group and away from the median. Voters are willing to tradeoff the inferior policy for a higher-quality candidate.

Prat (1999, 2000) and Gerber (2001) model the process as one of costly signaling. In these signaling models, there is no content to the advertising; rather voters infer quality from the amount of advertising. The models are similar. I concentrate on Gerber's model, which is somewhat easier to understand but employs stronger assumptions. In his basic model, the candidates' positions are given. The voters, but not the pressure group, value quality per se. The pressure group and challenger observe a signal (high or low) regarding the quality of the challenger. The pressure group then enters into a contract with the challenger to exchange money for favors (since voters dislike favors, this can be interpreted as policy along a different dimension). During the campaign, the voters get their own signal of quality and are also able to observe the amount of campaign expenditures, thereby inferring the pressure group's signal, as well. High campaign expenditures indicate a high-quality challenger. Under plausible assumptions this means that the median voter is better off voting for the candidate that is doing more advertising even though he has sold more favors. Like most signaling models, this one has many equilibria.

Wittman (2001a) employs a model of cheap talk endorsements where content is important. Again, voters know the positions of the candidates, but not their relative quality. Here, the pressure group also values quality. In his model, both candidates' positions are endogenous. Although the pressure group can lie and endorse the lowquality candidate as the high-quality candidate, in equilibrium the pressure group tells the truth. Therefore, the uninformed voters become fully informed after observing the endorsement. Although competition for endorsement by the pressure group means that the high-quality candidate moves away from the median voter, the median voter gains more by having the high-quality candidate elected than she loses in policy. If there are pressure groups on both sides of the median, the equilibrium outcome is that all of the pressure groups endorse the high-quality candidate who is at the median voter's most preferred position.

3. Advertising Provides Information about Position to the Uninformed

The second approach assumes that some of the voters are uninformed about the true position of the candidates. Political advertising and/or endorsements provide the requisite information. As a result, the candidates move away from the median informed voter toward the median of the uninformed voters, making the median uninformed voter better off. Clearly, the pressure group provides such information only in the case where it is made better off by such a move.

Seminal work by McKelvey and Ordeshook (1984, 1985) showed how uninformed voters could make use of poll data and endorsements to make rational inferences about the positions of the candidates. In their model, uninformed voters do not know the position of the pressure group. An endorsement by the pressure group tells the uninformed voter which candidate is to the left and which is to the right. The uninformed voter also knows where he stands on the distribution of voters (informed and uninformed), all of whom have linear symmetric loss functions. Suppose that the particular uninformed voter is considerably to the left. If the poll data says that more than 50% of the voters prefer the left candidate, then that indicates that this particular uninformed voter should prefer the left candidate, as well. In a sequence of polls, the uninformed voters become more informed, and they have a greater say in the election.

Wittman (2001b) also assumes that that there are two types of voters, informed and uninformed, and that candidates are only interested in winning. In contrast to McKelvey and Ordeshook, the uninformed do not have access to poll data. Uninformed voters may have preferences that differ from the informed voters. If the median uninformed voter is closer to the pressure group than the median informed voter is to the pressure group, then it may pay the pressure group to contribute to a candidate's advertising campaign. In a series of models, Wittman shows how the uninformed, combining their understanding of the political process with bits of information derived from advertising and/or endorsements, can become fully informed. The outcome is at the median of all voters. In the absence of advertising, the outcome would be at the median of the informed voters. So pressure group contributions move the outcome toward the median voter, overall.

Schultz (2001) and Wittman (2000) consider the case where truthful advertising about the relative positions of both candidates can be directed to a subset of voters. In both papers, those who do not receive advertising can make intelligent inferences. For example, not receiving information from a candidate informs the voter that she is not being favored by that candidate. Schultz assumes that there are two candidates with policy preferences and a certain amount of money to be given to n groups. He shows that information and subsidies will go to those who are marginally uninformed and unbiased toward either candidate. Wittman considers office-motivated candidates within the context of a single-dimensional policy framework. In equilibrium, all voters are informed and the winning candidate is at the median voter's most preferred position.

Coate (2002) assumes that political parties represent perfectly opposing ideological preferences. Each party's candidate is either ideological or office oriented, the latter taking a less extreme position vis a vis the median voter. The positions of the ideological and office oriented candidates are exogenous in the model. Ordinary voters cannot distinguish between the ideological and office motivated candidate, but the pressure group can. Other things being equal, the members of the political party prefer the ideological candidate. In contrast, the pressure group is more interested in getting its policy implemented. Here advertising is always truthful. Only moderate candidates will be supported by pressure groups since only moderate ideologies will gain voters. The net result from pressure group contributions is that parties tend to choose candidates closer to the median.

To sum up the micro-foundations literature: rational voters vote for the candidate doing more advertising only if the voters are on average better off by voting for that candidate than the other. Stated in this way, this is not a surprising result. It just contradicts a very large literature.

4. Do Pressure Group Contributions Aid or Hinder the Political Process?

A more subtle question is whether pressure group contributions aid the political process, and if so, by how much. Generally, the results depend on the degree of competition, on who makes the offers, the distribution of preferences, the response function of the voters, the nature of the information provided, and, in the signaling models, on equilibrium selection and whether there is a pooling equilibrium. If there is more than one pressure group, then competition is likely to shift the surplus from the pressure group to the candidates, which ultimately means the median voter (when the candidates maximize votes). If the pressure group makes an all or nothing offer, this gives more power to the pressure group; if it is the candidates who make offers to the pressure group, then the superior candidate captures some of the surplus. Again this surplus will accrue to the median voter if the candidates are maximizing votes. The effect of the distribution of preferences on the equilibrium outcome is more complicated (see Wittman (2001a) for a discussion). Generally, when uninformed voters are rational, pressure group contributions for advertising are more likely to aid the political process than do it harm. That is, the median voter's welfare is likely to be improved in comparison to the situation where there are no pressure

groups and no advertising. But with sufficient ingenuity, one can still construct models where the competition for endorsements makes the voters worse off.

5. Future Research

The question of how uninformed but rational voters make use of information that comes from sources who have their own agenda is an extremely interesting one. The answers provided here are only the beginning. Undoubtedly, this question will inspire a large body of research in the coming years.

PRINCIPAL-AGENT RELATIONSHIPS IN THE THEORY OF BUREAUCRACY

The theory of the firm has many applications to political markets, and principal-agent theory in particular has been used to describe the relationship between Congress and the bureaucracy. The principal-agent model of the bureaucracy addresses the importance of property rights and contracts in political markets. In this regard, the development of this model parallels the evolution of the theory of the firm that has stressed the significance of transactions costs associated with using the price mechanism. Coase (1937) describes how firms emerge within a market to minimize transactions costs, and Alchian and Demsetz (1972) describe how institutions emerge within a firm to minimize transaction costs. Similar developments have occurred in the theory of bureaucracy and representative government.

The application of principal-agent theory to bureaucratic outcomes finds its roots in the theory of regulation developed by Stigler (1971), who maintained that, as a rule, regulation is acquired by an industry and designed and operated primarily for its benefit. The basic resource of the state, the power to coerce, is a commodity freely traded in the political market place and moved to its most efficient margins by competing pressures. Stigler's theory was extended and formalized by Peltzman (1976). Like Stigler, Peltzman assumed that transfers of wealth were at stake in the regulatory process, not usually in cash form, but rather indirectly in the form of regulated prices, entry restrictions and the like. The legislator is viewed as vote maximizing by allocating transfers in response to the competing bids of political coalitions. Generally, the legislator (as broker) has incentives to provide welfare transfers as long as the gain in political support from the winners outweighs the loss of support from the losers. From this generating assumption, Peltzman formulated a theory of the optimum size of effective political coalitions within a framework of a general model of the political process. Becker (1983) presented a theory of competition among pressure groups for political influence that built on Peltzman's analysis. Political equilibrium was shown to depend on the efficiency of each group in producing pressure, the effect of additional pressure on the influence of the group, the number of persons in different groups, and the deadweight cost of taxes and subsidies.

Building upon this concept of political equilibrium, Weingast and Marshall (1988) used the theory of the firm to show how the institution of the committee system developed in the legislature to minimize the transactions costs of delivering services to constituents once the political equilibrium was reached. Following Williamson (1985), three conditions determine a contractual breakdown; (1) bounded rationality, (2) opportunism, and (3) asset specificity. Each of these conditions are present in the legislative market for votes. The legislators operate under the constraints of bounded rationality because the nature and benefits of all future bills cannot be known at the time of the vote trade. The problems of noncontemporaneous benefit flows and nonsimultaneous exchange in vote trading result in opportunistic behavior, and legislators invest their time and staff resources into issues that are specific to their constituency. Weingast and Marshall argue that reputational effects of repeat play alone cannot overcome these contractual failure conditions; therefore the congressional committee system emerged and gained power in order to facilitate efficient trading and enforcement between legislators. Legislators, acting alone, cannot ensure the provision of services to their districts; therefore, gains from trade exist in the legislature. Instead of trading explicitly in votes to capture the gains from exchange, legislators sacrifice the property right of agenda power over some policy areas in exchange for a committee assignment in which they have near monopoly rights over a subset of policy areas.

Congressional committees, then, reflect the specialization of legislators in order to provide their constituents with services. While the committee system helps legislators to serve their constituents, the committee cannot directly provide all of the appropriate services. Instead, the legislators delegate the provision of some of these services to bureaus that trade a total budget for a total output of these services. As in the team production case of Alchian and Demsetz (1972), marginal productivity is costly to observe; so bureau shirking may occur. Weingast (1984) argues that the delegation will only occur if bureau production (complete with shirking) provides greater net benefits than any other method of providing the service.

In summary, the simple principal-agent model of the relationship between Congress and the bureaucracy described above incorporates many facets of the theory of the firm. The congressional committee system is seen as a governance structure that emerged to solve contractual problems in the market for votes so legislators could capture gains from trade. Legislators sacrifice control over some policy areas in exchange for near monopoly rights over policies that benefit their constituencies. The committees delegate the provision of some services to bureaus; hence, a principal-agent relationship develops. The principal-agent problems can be alleviated if the committees develop efficient incentive structures to discipline the bureaus.

This simple principal-agent theory is appropriate for analyzing a two-tiered organization. Recent work in the theory of the firm has recognized the need to explore more complex hierarchical structures. Specifically, the principalagent model has been extended to incorporate a third tier, that of an intermediate supervisor who monitors the agent for the principal. Tirole's (1986) formal presentation of the three-tier principal-supervisor-agent (P-S-A) model illustrated how this lengthening of the hierarchy introduces the possibility of collusion between the supervisor and the agent, which could decrease the efficiency of the organization. Further work by Laffont (1990), Tirole (1992), and McAfee and McMillan (1995) show that adding a supervisor increases the extent of the principalagent costs of operating the hierarchy, and thus, decreases the efficiency of the organization.

In this respect, the P-S-A model finds its roots in von Hayek (1945) who argued that organizational costs develop because knowledge is dispersed among individuals within the hierarchy who have incentives to exploit their informational advantage. This loss of information control was formally modeled by Williamson (1967) who showed that there exist diminishing returns to scale which serve to limit the optimal firm size. In the McAfee and McMillan (1995) version of the P-S-A model, each layer added to the hierarchy is predicted to double amount of rent. As the source of the information (the agent) becomes further removed from the decision-making unit (the principal), this distortion of information increases exponentially, resulting in organizational diseconomies of scale. Much of the literature that applies principal-agent theory to bureaucratic oversight focuses on the relationship between one congressional oversight committee and one bureau; however, the pattern of congressional oversight in practice is much more complicated, indicating that use of the principal-supervisor-agent model may be more appropriate.

At the supervisory level of the hierarchy there are, in fact, many supervisors of the bureaucracy agents. First, there is legislative oversight. There exist jurisdictional overlaps in the legislature, that is, the legislative committee jurisdictions are not always aligned with the jurisdictions of the bureaucracy, and most bureaus are actually overseen by two or more standing legislative committees.

Even if one of the oversight committees can be shown to dominate, the multiplicity introduced by bicameralism cannot be ignored. Oversight activities occur through both House and Senate committees. If both chambers pass measures in different forms and if these differences cannot be resolved via amendments, a compromise bill must be forged in a conference committee before the bill can be sent forth for Presidential review.

Another legislative supervisor of the bureaucracy is revealed by the budgetary process. In addition to responding to multiple oversight committees, each bureau's budget must be approved by a subcommittee of the Appropriations committee of the relevant chamber. Appropriations committee proposals can then be amended by the full chamber before being passed. Often there can be a conflict of goals between the appropriations and oversight committees.

The jurisdictional overlaps in the legislative oversight system, then, offer a challenge to one of the major assumptions in the simple principal-agent model: that the near monopoly power of committees solves the contractual problems of vote trading in the legislature. The simple principal-agent theory concludes that for a policy change to occur, there must be a substantial change on the oversight committee. The weakening of the agenda power of committees through jurisdictional overlaps within and between chambers means that entities other than oversight committee members have an influence on bureau policy. Any change in policy, in all likelihood, may not be traced back to one particular committee.

In addition to legislative oversight, the President is another supervisor within the hierarchy. The power struggle that may occur between the President and the legislature would seem to have a great influence on bureau policy, whether the agency is independent or part of the President's cabinet. Budgets of bureaus are submitted to the Office of Management and Budget (OMB) for approval who then prepares a total federal budget for Presidential review. It is the President, then, who presents the total budget to Congress, a budget that reflects his goals for the nation. Finally, another supervisor with influence over federal policy is the judiciary that interprets legislation. Supreme Court decisions often lead to reforms in the body of legislation, and the precedents set in the courts have an impact on federal policy.

The existence of multiple supervisors overseeing the bureaucracy may result in a greater role for bureaucratic preferences in the political market. If the interaction among supervisors leaves room for the bureaucracy to assert power, the model must be amended to include incentives for the bureaus to monitor themselves. Indeed, these incentives were incorporated into the theory of the firm in the literature on the separation of ownership and control (Jensen and Meckling, 1976; Fama, 1980). In this literature, monitoring of agents is accomplished by the presence of efficient capital markets and the outside managerial labor market. These devices, however, are not available to cure the monitoring problems inherent in the bureaucratic model.

In the political market, there does not exist a tool like the capital market to signal the performance of a bureau. Indeed, the outputs of most bureaus are extremely difficult to measure. Unlike stockholders, legislators cannot shift costlessly among investments, because the rank (and thus, power) of a legislator on a committee depends on his seniority on that committee; a move to another committee would entail a loss of such seniority. A committee assignment is seen as a long-term investment by the legislator rather than as a portfolio diversification (Rowley and Elgin, 1988).

The monitoring of bureaucrats also does not seem to come from the outside managerial labor market. Public sector managers do not have incentives to monitor themselves in order to improve their promotion chances within or outside the bureau because salaries and promotions are strongly linked to seniority. The difficulty of measuring bureau performance extends to the evaluation of managers. The performance qualification that can be measured and is most likely to be rewarded is that of obtaining budget increases for one's bureau rather than that of operating more efficiently.

Thus, it seems that the property rights that are available in the private sector to mitigate principal-agent problems, are severely attenuated in the bureaucratic version of the model. Rowley and Vachris (1993) explain how nonexistent or poorly defined property rights cause inefficiencies in political markets. Unlike economic markets, which are proprietary in nature and in which individuals bear the full consequences of their choices, political markets are largely non-proprietary, and individuals do not necessarily bear the full consequences of their choices. Moe (1990) discusses how the uncertainty of property rights in political markets distorts the choices made by political actors. Delegation of authority to federal bureaus is not the result of legislators putting their property to the most efficient use. Rather, those in power today are most concerned with setting up a governance scheme for the bureaucracy that cannot in turn be amended or reversed by those who may be in power tomorrow. To ensure that opponents do not control the bureaucracy in the future, then, the legislature purposely gives up control over it in the present. The same can be true of the industry special interest groups that demand the services provided by the bureau in the first place. Bureaus are given great discretion in order to insulate policy outcomes from future changes in the balance of political power. The bureaus, themselves, also favor insulation from political uncertainty; and once agencies are set up, bureaucrats predictably take steps to increase their autonomy. They can accomplish this independence partly by gaining expertise, or asset specificity, in their field.

The ultimate principal in the political market is the "demander" of the bureaucratic services. Just as there are multiple agents and supervisors in this hierarchy, it can be argued that there are also multiple principals or demanders. Voters are one source of demand. As a principal in the hierarchy, voters could exert control over supervisors (that is, legislators and Presidents) who did not provide appropriate levels of service. According to the median voter theorem, legislators and Presidents cater to the median voter's demands instead of attempting to appease the preferences of all voters in the country because median voter preferences determine a political market equilibrium (Downs, 1957). Rowley (1984) has shown that the outcome predicted by the median voter theorem is dependent upon a set of very stringent and unrealistic assumptions about the election process. If, for example, more than two political parties contest an election, or if voters refrain from voting, then the median voter theorem does not hold. Therefore, we cannot generally assume that the median voter's preferences dominate in the political market.

Without the equilibrium solution of the median voter, the extent of control that voters have over legislators and Presidents is necessarily diminished. Rowley and Vachris (1995) discuss other reasons why the vote motive cannot serve as an efficient control mechanism in political markets. First, unlike private markets, voting processes do not guarantee that the highest bidder wins the right to office; instead, the distribution of bids from politicians to voters also matters (McCormick and Tollison, 1981). Second, voters cannot transfer their property rights predictably and cannot abandon them without high transactions costs such as emigration or revolution. Third, political choices are bundled, so voters lose control over specific issues. Finally, the problems of voter memory decay and rational ignorance prevent voters from effectively punishing politicians for deviating from voter preferences.

If voters are incapable of effective oversight over the supervisors in the political hierarchy, special interest groups may be able to capitalize upon this market failure and exert control over policy outcomes. Stigler's (1971) capture theory of regulation points to industry special interest groups as demanders or principals in this sense. The interactions of these special interest groups play a role in determining the policy outcome. Yes, politicians predictably will cater to successful interest groups, but such an outcome can hardly be described as politically efficient. Rowley and Vachris (1995) argue that special interest groups achieve their redistributive goals through wealth dissipating rent-seeking. These groups exacerbate the informational asymmetries in political markets because opaque policies are more likely to be enacted than transparent ones; therefore, they achieve their goals with a high degree of technical inefficiency.

In summary, then, the institutional description provided above of the many agents, supervisors and principals involved in the oversight of the bureaucracy indicates that the simple principal-agent model is not a reflection of institutional reality. In the case of federal antitrust enforcement, at the bottom of the hierarchy, the Antitrust Division and the Federal Trade Commission serve as multiple agents. The separation of powers and the jurisdictional overlaps in the legislature serve to widen the hierarchy at the supervisory level in that the President, the judiciary, and several legislative committees influence antitrust policy. At the top of the hierarchy, multiplicity of principals result from the failure of the median voter theorem and the logic of collective action. Voters and various special interest groups all demand antitrust services and thus influence the pattern of enforcement. In reality, then the hierarchy is widened at all three levels, making an efficient outcome difficult to obtain.

PROHIBITION

The policy of prohibition is an extreme measure directed at the production, distribution, and consumption of a good or service. Whereas policies such as regulation, taxation, price controls and licensing seek to control and limit a market, prohibition is intended to completely eliminate the market. Historically, prohibition has been applied to markets that have been deemed to be morally repugnant to society and in conflict with state religion or ideology. Therefore we find that prohibition has been applied to such activities as usury, prostitution, insider trading of corporate securities, and nudity and to goods such as alcohol, tobacco, narcotic drugs, marijuana, firearms and freon. Because prohibition has generally been limited to highly dangerous products and activities of a questionable moral character they can be viewed as serving the public interest. Additionally, the production and consumption of these goods and services are typically associated with selfdestructive behavior, harm to the social and civic order, increases in crime, accidents, and the spread of disease and the degradation of the environment.

The primary problem with the public interest view of prohibition is that the policy cannot in fact achieve the result of prohibiting the targeted good or service. A strictly enforced prohibition will eliminate the legal market, but will also result in the establishment of a black market. As market suppliers leave the market, price of the product rises in the black market; tighter enforcement increases cost, especially risk of capture, increase price further and result in a smaller quantity demanded. Becker and Stigler (1974) argue that the trouble with prohibition is that suppliers enter the black market in response to higher prices, so that increased enforcement only serves to increase potential earnings. However, the more vexing problem of prohibition is that it changes the entire nature of the market. For example, Paul and Wilhite (1994) note that prohibition removes government from the role of enforcing property rights and that the alternative regime of violence and coercion not only sets up opportunities for the collection of monopoly profits, but also results in the production of significant negative externalities.

In total, the economics of prohibition shows that the policy cannot in fact remove the good from society, that prohibited products are more dangerous and are consumed under conditions of greater risk and ignorance, and that black markets increase the amount of violence and crime in society (Thornton, 1991a). As applied to the market for illegal drugs and alcohol, prohibition results in products of a higher level and variability of potency. This effect combines with increased ignorance concerning product quality and adulterates and results in a product that is much more dangerous than its counterpart in the legal marketplace (Thornton, 1998a). Prohibition-related crime includes the production, distribution, and consumption of the illegal product, all the acts of violence committed to enforce contracts and sales territories, acts of violence inflicted on innocent bystanders, corruption of politicians, public officials, and law enforcement officers, and the criminal acts committed by consumers in order to pay black market prices. Prohibition can even increase crime by reducing the number of legal market job opportunities available in the workforce (Beil and Thornton, 2000). The full economic cost of prohibition also includes the direct enforcement costs, civil liberties and privacy rights lost in the attempt to improve the effectiveness of enforcement and all the expenditures by the public to insulate itself from the ravages of prohibition.

Although economists generally supported prohibitions such as alcohol prohibition based on the 18th Amendment to the U.S. Constitution, long periods of experience and evidence with these prohibitions have made economists increasingly skeptical of prohibition and increasingly supportive of alternative policy regimes (Thornton, 1991b; Miron and Zwiebel, 1995). Public choice economists have recently turned their attention to prohibitions such as the "Noble Experiment" with alcohol prohibition (1920–1933) and the prohibition of narcotics (1917-present) and marijuana (1938-present) known as the "War on Drugs." These investigations have provided great insight into the public choice nature of these policy regimes, additional evidence on the public choice nature of governmental institutions, and provided useful insights into the workings of black markets.

In retrospect, alcohol prohibition in the United States during the 1920s was a highly unusual policy that would seem to lend support to Arrow's impossibility theorem; imposed as it was by Constitutional Amendment and ended with the only repeal of an Amendment in history. Thornton (1991, 1996, 1997) however shows that this policy was proceeded by a long history of government intervention into alcohol markets including colonial prohibitions, heavy taxes, licensing, local option, state prohibitions and that these policies were ineffective and tended to cycle as a result. These interventions, in turn created criminal and social externalities and helped turn temperance organizations into the first public interest groups such as the Anti-Saloon League and the Prohibition Party. With the demand-side bolstered by rent-seeking commercial interests and the 17th Amendment that gave women the right to vote and the supply-side weakened by conditions created by World War I, national prohibition became a reality.

Boudreaux and Pritchard (1994) adopted an explicit public choice perspective to analyze the 18th and 21st Amendments. They argue that representatives ignored their constituents' desire for alcohol prohibition because the Federal government received approximately 1/3 of its total revenue from taxes on alcohol. The passage of the 16th Amendment, which permitted the Federal government to tax income, created a new and significant source of revenue. The Income Tax quickly dwarfed alcohol as a source of revenue and therefore greatly lowered the cost of voting for prohibition and thus nicely explains both the adoption and timing of prohibition. They go on to show that the Great Depression resulted in falling income tax revenues in 1931 and that this reduced the cost of Congress voting for the 21st Amendment repeal prohibition in 1933 and restarting the flow of alcohol tax revenue.

Goff and Anderson (1994) also examined the votes in the U.S. Senate for the Prohibition and Repeal amendments from a public choice perspective. They modeled support or opposition to the amendments as a function of constituent preferences, interest group activity, political party activity, and legislator ideology and they found support for the idea that economic interests played in an important role in the passage of both Amendments. Munger and Schaller (1997) examined the Amendments using a cross-section of state-level voting. They also found that the preferences of citizens and economic interests played important roles in both votes. In addition, they found that that economic interests in the alcohol industry were insignificant in opposing the passage of prohibition while Goff and Anderson measure of the alcohol industry was significant. Thornton and Weise (2001) add that tax revolts against local governments during the early years of the Great Depression were an important component in the political push for Repeal and the returning flow of alcohol tax revenues.

The public choice approach has been extremely useful in dissecting the modern war on drugs. One important conclusion in the public choice literature on prohibition runs counter to the argument that increased enforcement leads to decreased crime (Benson et al., 1994). This literature (Benson and Rasmussen, 1991; Benson et al., 1992; Rasmussen et al., 1993; Sollars et al., 1994; Benson et al., 1995; Bumgarner and Sjoquist, 1998) stresses that the incentives and strategies to increase drug law enforcement actually result in more violence and criminal activity and bigger budgets for law enforcement. Of course, prohibitions are also a major cause of corruption (Benson, 1981; Benson, 1984; Benson and Baden, 1985; Thornton, 1991a).

Rasmussen and Benson (1994) provide a book-length examination of the war on drugs from a public choice and property rights perspective that explains why drug policies have produced results that are far different than policy makers and citizens expect. For example they show that increased drug law enforcement encourages crime by reducing the probability of arrest and that increased enforcement efforts knock drug dealers out of spatial equilibrium resulting in large increases in violence on the part of drug dealers in order to restore equilibrium. They also demonstrate that laws permitting the confiscation of drug dealer property create incentives for law enforcement that reduces the probability of apprehension for non-drug crimes and increases crime rates. In conclusion, they argue that the criminal justice system is a common property resource and drug laws only encourage the exploitation of this resource, resulting in a tragedy of the commons.

The public choice literature indicates that prohibition, once established is generally stable, or that it cycles between prohibition and "sin taxes" because prohibition is supported strongly by ideology, special interests, and bureaucracy. However, the public choice literature on the war on drugs has greatly supplemented the economic literature and further depicts prohibition as an unworkable, self-defeating, or ineffective policy and this knowledge could contribute to a counter-ideology to prohibitionism, which along with a victims-of-prohibition interest groups, might serve to undermine that stability (Thornton, 1995, 1998a).

PUBLIC CHOICE AND SOCIALISM

The idea of constructing a rational economic order through state control dominated 20th century public policy. The theory of socialism swept the intellectual world by grabbing the higher moral ground, and in the policy realm, socialism exerted its influence by creating political revolutions in Russia, China, and throughout the underdeveloped world. Less obvious, but no less important, was socialism's influence on the policies of non-socialist countries. The great "liberal" democracies all moved in the socialist direction in terms of public policy throughout the 20th century. The rise of the democratic welfare state in the UK and US and the explosion of the government's regulatory role in these economies are all manifestations of the socialist victory in the world of ideas.

The socialist experiment proved to be a failure. It proved not only an isolated failure, but also a global one — every political and economic system influenced by socialism suffered from a severe crisis in the last decades of the 20th century. The soft socialism of the democratic welfare states suffered from fiscal crises in the 1970s and 1980s and led to dramatic policy transformations in the UK (Thatcher), and US (Reagan). Other highly regulated and egalitarian societies followed the Thatcher/Reagan path in the 1980s and 1990s - New Zealand, Ireland, and even the Scandinavian welfare states had to adjust their fiscal houses. Of course, perhaps the most dramatic political-economic event of the 20th century was the collapse of real-existing socialist states throughout East and Central Europe in 1989 and the dissolution of the former Soviet Union in 1991 (the only other contender for most dramatic event this century is the Great Depression of the 1930s). A century that began with increasing demands for the regulation of business and economic planning by government to achieve more efficient production and a more egalitarian distribution of income, ended with a worldwide privatization revolution and a generalized recognition of the innovative benefits that accrue from entrepreneurship. The intellectual demand for state control of economic life was replaced by a "gains from trade" understanding of how the world works. Public choice theory played no small role in this dramatic shift in the intellectual climate of opinion. More pertinent for our purposes here, public choice theory provided the intellectual apparatus needed to pierce the Romantic veil of socialist ideology and lay bear the ugly reality of the political economy of socialism.

1. The Austrian Contribution

Before detailing the public choice contribution to our understanding of real-existing socialist economies, we will discuss the economic debate over socialism that took place in the 1930s and 1940s that set the stage for the development of public choice theory in the 1950s and 1960s. The Austrian economist Ludwig von Mises (1920, 1922, 1949) challenged advocates of socialism to provide an answer to the problem of rational economic calculation in the socialist society. Mises, building on the earlier work of Barone, Pareto and Wieser, pointed out that if socialism was to operate efficiently and rationalize the process of production as was claimed, it would have to replicate the marginalist principles that had been detailed in the neoclassical analysis of the market economy. In other words, there was a formal similarity in the efficiency propositions of capitalism and socialism. The crucial difference was that socialism promised to achieve efficiency through an alternative institutional regime. Mises asked the advocates of socialism to detail exactly how the institutions of collective ownership and centralized economic planning would replicate the functional roles played by private property, free pricing and profit and loss accounting within the coordination of economic activities (also see Hayek, 1948). Mises pointed out that no such argument could in fact be made. Without private ownership in the means of production, there would not be a market for the means of production. Without a market in the means of production, there would not be any exchange ratios established for the means of production. Without exchange ratios reflecting relative scarcities of the means of production, economic planners would not be able to rationally calculate alternative uses of scarce capital resources in production. This constituted Mises' famous argument that rational economic calculation under socialism is impossible.

It is important for our purposes, however, to point out that Mises' analysis of socialism raised at least four objections to the economic practicality of socialism: (1) private property rights and economic incentives; (2) prices as economizers of information within a complex system of exchange and production; (3) profit and loss accounting and the problem of economic calculation; and (4) politics and the problem of the abuse of power and tyranny (see Boettke, 2000a, 2001). Mises (and later Hayek, 1948) tended to emphasize the problems of economic calculation and knowledge precisely because during the debate over socialism questions of incentives and complexity were eliminated by hypothesis by their opponents. Lange, for example, argued that questions of incentives lie outside the bounds of economic discourse (Lange, 1936–37a and 1936–37b: 127). Such questions are best left to sociology, and to introduce them would violate the maxims of value-free economic analysis, at least that is what Lange and other pro-socialist

economists contended. Moreover, Lange also maintained that developments in computational technology would solve the complexity problems associated with the coordination of economic activities (Lange, 1969). So it makes sense that Mises and Hayek would emphasize the issues of calculation and dispersed knowledge in the debate with the market socialists. The calculation argument was the decisive intellectual argument because it could not be answered by assumption in the way that incentives and computational complexity could. The reason for this inability to assume away the problem was that the calculation argument was grounded in an institutional context. Outside of the institutional context of private property economic calculation was not just difficult; it could not take place. Of course, in the examination of real existing socialist economies, the problems of incentives and computational complexity were damaging enough from the point of view of successful economic coordination. Socialist economies were characterized by inefficient production, and pervasive shortages of poor quality consumer goods (see Boettke, 1993: 12-45).

A useful way to view the Austrian "calculation" argument is that it serves the same function within the analysis of socialism that Ronald Coase's argument that in a zero transaction cost world firms would not exist serves within the development of the theory of the firm. The Austrian argument served to establish what real-existing socialism could not be, and thus enabled scholars to look inside the "black-box" of Soviet-type economy (see Boettke, 1998). Unfortunately, much of the 1950s-1960s literature in comparative economic systems was diverted into two unproductive research paths - mathematical models of optimal planning, and macroeconomic econometric examinations of comparative economic growth rates. Both of these research programs, at best, added little to our understanding of Soviet-type economies, and at worst, significantly distorted that understanding (e.g., see Besancon, 1980). This distortion was most evident in the claims made by leading economists, such as Paul Samuelson, that Soviet planning techniques rationalized production, and that the Soviet economy would catch-up and outperform the market-oriented economies of the west in the near future.

On the other hand, the Austrian "impossibility" theorem, interpreted as we have suggested, sets the stage for a microeconomic analysis of how economic life within the politicized environment of the Soviet-type system actually operated. It strips the 'Romance' from socialist ideology and instead demands "realism" in political-economic analyses of socialism. As we have suggested by analogy to Coase's work on the firm, the Austrian argument opened the "black box" of real-existing socialism. And once

opened, a public choice analysis allowed us to look inside and understand the incentive structures in operation internal to real-existing socialist economies.

2. From Romance to Realism in the Economic Analysis of Socialism

The Soviet system could not operate as the socialists of the late 19th and early 20th century had promised it would. It is important to remember the outlandish promises made on behalf of socialism. The socialists claimed that their system would out-perform capitalism by abolishing private property and rationalizing production. In substituting production for direct use for production for exchange by way of a settled economic plan, the socialist system would achieve unprecedented levels of material progress and do so in a manner that ensured harmonious social relations. The exploitation of man by other men would be abolished, and our state of alienation would be transcended. Mankind would move from the Kingdom of Necessity to the Kingdom of Freedom (see, Roberts, 1971; Boettke, 1990). Even the more informed arguments by economists, such as Lange, retained aspects of this earlier utopianism. Lange argued that while in theory socialism merely performed as well as capitalism, in reality it would outstrip capitalism's productive capacity and ensure an egalitarian distribution of income (Lange, 1936-37b: 127).

Such socialist promises for enhanced economic performance and greater social justice proved chimerical on all levels. First, socialism in practice could not abolish private property rights completely because real collective property is conceptually incoherent — someone must retain control rights (Barzel, 1989). The Soviet system had an attenuated private property rights system in which decision makers retained control rights, but not cash-flow rights (see Boyko, Shleifer, and Vishny, 1995: 33–38).

The Soviet industrial sector was characterized by the literal monopolization of production. However, these monopoly firms were inefficient and required continuous subsidization from the central government. This created the problem that economic enterprises confronted a "soft-budget" constraint (Kornai, 1986).

Furthermore, bureaucratization of economic production was pervasive. The original advocates of planning did not believe this would be a problem (e.g., Bukharin and Preobrazhensky, 1919). According to socialism's advocates, in abolishing private property socialism would overcome the division of labor. This being the case, individuals would be constantly shifting in and out of the different bureaus. The organizational reality of socialism, however, revealed just the opposite. In order to operate in a non-chaotic manner, a standing bureaucracy had to be formed. Thus, behavior in the Soviet bureaucracy, just as in its counter-part in the Western democracies, could be rendered intelligible through an economic analysis of bureaucratic incentives (Tullock, 1965).

Finally, the glue that held the Soviet economic system together was the "rents" to be had both internal and external to the plan. The Soviet economy was one of pervasive shortages where administrative prices were not allowed to adjust upwards to clear the market. The shortage situation created costs to buyers, (e.g., queuing), that were not simultaneously benefits to sellers. In such a situation, sellers have a strong incentive to transform these costs to buyers into benefits for themselves — either in monetary rewards or non-monetary compensation (e.g., the exercising of a preference). Building on Tullock's (1967) basic model, several scholars have attempted to depict the Soviet system as a rent-seeking society. David Levy (1990), for example, argued that the bias in Soviet pricing was to set prices below market clearing levels because this generated "rents" to those in control of the distribution of goods. Shleifer and Vishny (1992) developed a similar model to explain the pervasive shortages under socialism. Anderson and Boettke (1997) apply the "rent-seeking" model further to explain the entire mature Soviet industrial structure, and through an argument by analogy relate the Soviet system to earlier mercantilist domestic arrangements for fiscal issues. In the absence of a well-ordered tax system, both the monopolistic industrial structure and the elaborate mechanisms in place to ensure that structure are designed to raise state revenue via the means of monopoly privilege and venality.

3. Public Choice and Transition Strategy

James Buchanan has stressed that work in political economy, if we desire to retain some level of realism and relevance, must begin with the "here and now" and not just postulate whatever start-state of analysis might be desired to make the model tractable (see, e.g., Buchanan 1975: 78). Unfortunately, most models of socialist transition that have been developed fail to appreciate the *de facto* organizing principles that governed life in the Soviet-type system. Concentration has instead been focused on the *de jure* statements of what constituted the system.

The Soviet system was made up of a series of interlocking "contracts" and "vested interests," and any attempt to change the system must begin with this institutional inheritance. *If* the Soviet system was actually a land without any ownership claims, then post-communist reforms would be immeasurably simpler than they are - even given the cultural conditioning often invoked to explain the resistance to reform. But the social fact is that many limited — though tacitly legitimated — ownership claims had been established throughout the economic system. The implication of this fact for the transition is that what is required is the divesture of some interests, the legitimation of others, and the creation of conditions so that others can be determined in the new social arena of politics and law. As Boycko, Shleifer and Vishny (1995: 36) put it: "The structure of ownership under Soviet socialism was thus both different from the textbook model and highly inefficient. The politicians had almost all the control rights, and no cash flow rights either. The managers had some of the control rights, but no cash flow rights either. The objectives of the politicians who possessed the control rights were very far removed from the public interest. The virtually complete political control without countervailing cash flow rights to moderate political temptations did not constitute an inefficient ownership structure." Given the reality of this ownership structure, the reformer's primary goal is to depolitize economic life. Thus, Boycko, Shleifer and Vishny argue that "controlling managers is not nearly as important as controlling politicians, since managers' interests are generally much closer to economic efficiency than those of the politicians. Once depoliticization is accomplished, the secondary goal of establishing effective corporate governance can be addressed" (1995: 65).

The socialist regime did not abolish the market anymore than the prohibition on alcohol in the 1920s stamped out the buying and selling of liquor. We know from historical examination of the War Communism period (1918–1921) that even during the height of the campaign against all forms of capitalist relationships (and the threat of death) some individuals still found it advantageous to enter the "black market." Of course, in both the attempt to eliminate commodity production in the Soviet Union and the attempt at prohibition in the United States, the nature of the market was transformed by the *de jure* structure. But if we want to understand how the market actually operated, the *de facto* rules must be the focus of our attention (see, Hewett, 1988; Boettke, 1993).

At the time of the introduction of radical market reforms in Russia (January, 1992) there existed an array of ownership claims. The right of ownership constitutes a claim to (1) the right to use the asset, (2) the right to appropriate the returns from the asset, and (3) the right to change the asset's form and substance (see Furubotn and Pejovich, 1974). Institutions are the formal and informal rules governing the social intercourse under discussion. In this regard, when discussing the institution of ownership we are attempting to specify those formal and informal rules that govern the use, transfer and capitalization of an asset. In a world where formal rules are absent or defined in an incoherent manner, informal rules emerge to provide a governance structure within which economic decisions will be made. How effective or ineffective this system of governance will be is an empirical matter. Both formal and informal rules can imperfectly define rights and lead to social conflict. In pre-Yeltsin Russia, private property was not abolished despite the formal rules that said this was so. As Yoram Barzel put it: "The claim that private property has been abolished in communist states and that all property there belongs to the state seems to me to be an attempt to divert attention from who the true owners of the property are. It seems that these owners also own the rights to terminology" (1989: 104, fn. 8).

Markets are embedded within (and operate on the basis of) a governance structure, the formal component of which has in contemporary history been the domain of the Nation-State. But the Nation-State is itself embedded within a set of underlying cultural beliefs. Governance is required for the market to operate in a manner conducive to modern industrialization, but governance is also a function of market forces. Rules of the game engender patterns of exchange and production, and the emerging pattern of exchange and production aid in the selection between different regime rules. The political center is rarely, if ever, truly uninhibited — even in a totalitarian system. Pockets of civil society (perhaps sub rosa) emerge to challenge the legitimacy and power of the center. The center is inhibited, not only by formal rules of limited government, but also by the legitimating authority of civil society. Successful political and economic transformation, however, requires the development of transparent formal rules to subordinate the center to the rule of law. The key issue for this transformation is how to work through the indigenous institutions of informal inhibition to legitimate formal rules of subordination. The contrast is not really between the state and the market. It is between the state and civil society, within which market activity and non-market voluntary association co-exist. In an ironic twist, the public space required by civil society for political voice might only be possible when the private space of market competition is guaranteed. Looking at the issue this way leads to widely different implications for the manner in which privatization (and transition policy in general) should be pursued. Constraints on actions come not only from formal rules of governance, but from the informal rules rooted in "culture" as well. Hayek (and others) has stressed the tacit presumption that undergirds the formal adoption of law

(1973). In this sense, law is seen as a codification of rules of the social game that already attained a level of legitimacy through *de facto* observance, rather than as the creation of new rules. Attempts to impose rules unconnected to pre-existing social practices then are severely limited (see Boettke, 1996).

The path from "here to there" in former socialist countries then requires not only an idea of the "there" intended, but also the "here" from which one is starting, before an appropriate strategy for the path can be determined. With regard to the question under examination (i.e., the transfer of ownership) the steps required for the divesture of property from some owners, the legitimization of property held by others, and the establishment of conditions for the attainment, use, transformation, capitalization, and transfer of assets for new owners should be the focus of our attention. The appropriate policy path is necessarily multidimensional and grounded in the previous historical pattern of ownership. As David Stark (1996) has pointed out, postcommunist developments are following a path-dependent trajectory. Therefore, it is more appropriate to view post-communism as a process of transforming existing institutions, than it is to view post-communism as a transition to a new economic order lying outside of history.

4. Conclusion

Building upon the Austrian argument against the possibility of a rational socialist economy, public choice economics offers crucial insight into the actual workings of realexisting socialist societies. Demonstration of the perverted incentive structure necessarily confronted under central planning, and the disastrous effects such an incentive structure generates under real-existing socialism is a great credit to the theory of public choice. Furthermore, in bringing to bear much-needed emphasis on the true nature of realexisting socialist societies as societies characterized by de facto property rights operating against the distorting backdrop of *de jure* property prohibition, public choice offers an invaluable insight into the way successful postcommunist reform in Eastern and Central Europe must be undertaken. Public choice sheds light on the fact that a realistic reform strategy must be predicated on a realistic model of political economy that recognizes that the transition from real-existing socialism to the market cannot be achieved costlessly. Entrenched bureaucrats in the central planning system face strong incentives to resist reform, and however illegitimately, these bureaucrats must be viewed as 'property holders' who need to be dealt with accordingly if real reform is to take place at all. Without the crucial analysis offered by public choice theory, both our understanding

of the true nature of real-existing socialism, the functioning of this system and appropriate method of dealing with the transition process would be seriously compromised.

PUBLIC CHOICE AND THE CHICAGO SCHOOL OF ANTITRUST

Be true to your school. (The Beach Boys, 1963)

1. Economists and Antitrust: Background

Antitrust — meaning statutory prohibition of contracts and practices deemed anticompetitive — is essentially an American invention. English common law included jurisprudence concerning restraints of trade, and the civil law sometimes outlawed certain commercial practices. But until Congress passed the Sherman Act of 1890, there was no general legislation against contracts "in restraint of trade" or practices in pursuit of "monopolization," to use the language of the statute's operative sections. (Some American states had previously enacted their own antitrust laws.)

The statute did not define these terms, leaving courts to pour content into them. Leaving controversial and (as discussed below) politicized issues for judges to decide did not produce felicitous outcomes. Vertical contracts explicable only in terms of greater efficiency, mergers involving two firms in industries with thousands of competitors, or singlefirm actions that explicitly increased output, nonetheless were condemned because the results (such as increased price competition) reduced the number or significance of rival firms. Especially once the second important antitrust statute (the Clayton Act of 1914) established private rights of action for alleged antitrust violations, courts found it hard to separate firms' actions that anticompetitively reduce social welfare from socially-beneficial competition that just harms competitor-plaintiffs, who can use antitrust to raise rivals' costs in court. Economists studying antitrust's important cases have concluded that a majority were decided wrongly as a matter of welfare-maximizing economics (Rubin, 1995).

Many of the practices subject to antitrust scrutiny after 1890 were ones that economists had analyzed very little. Things like mergers (horizontal and vertical), tying, information sharing, and resale price maintenance were not matters of general familiarity, nor were their welfare implications well understood. As antitrust cases stimulated economists' interest in such contracts and practices, however, economists typically condemned practices they could not explain using models of perfect competition. All of that began to change with the rise of the Chicago school.

2. Chicago's Welfare Analysis of Antitrust

The fame of the Chicago school approach to antitrust rests on its normative, social-welfare analysis of practices theretofore subject to judges' and economists' condemnation. Chicago influence dates from the 1950s, the seminal work beginning with Aaron Director and the Antitrust Project at the University of Chicago Law School (Kitch, 1983). Chicagoans perceived the logical fallacy of condemning practices just because they are absent in the perfect competition model, which assumes away transaction costs, information costs, contractual opportunism and free-rider problems. In the real world, businessmen cannot assume away such things. The Chicago school explained how many practices condemned under antitrust actually are welfare-enhancing.

The contributions made along these lines by pioneers like Robert Bork, Yale Brozen, John McGee and Lester Telser have been summarized elsewhere (e.g., McChesney, 1993; Kitch, 1983). The impact of the Chicago school revolution in antitrust has been remarkable, both in the courts and in the academy. By the 1980s, it had become the dominant mode of antitrust analysis, acknowledged as the reigning paradigm even outside Chicago (e.g., Joskow, 1991).

3. Positive Analysis of Antitrust

Increasing realization that much of antitrust had been wrong-headed from the start, treating as competitively malign things that in fact are quite benign, prompts questions of a positive rather than normative sort. Why does antitrust exist at all? How does it function? Has it increased social welfare? Such questions were downplayed during the more normative debates over Chicago-school welfare analysis. But with the normative issues for the most part resolved in Chicago's favor, economists' focus has increasingly shifted to the positive issues.

Several points are useful in addressing the positive issues. First, antitrust is a political creature. In the United States, Congress created and sustains it, and political appointees enforce it. Second, antitrust is a form of economic regulation, punishing certain types of economic behavior while allowing others. Antitrust lends itself, therefore, to positive analysis under the general economic theory of regulation.

Under the economic theory of regulation, the stated goals of the particular regulatory regime are of little help in deciding whether that regime is economically beneficial. One must look at actual performance — the demonstrated costs and benefits of the regulation — to reach a defensible positive conclusion. But, finally, an analyst must be mindful that much regulation exists for political, not social-welfare, reasons.

So, a positive analysis of antitrust must begin with appraisal of its benefits and costs. In considering the benefits, however, one should realize that cartels and monopolies, the twin evils identified in antitrust law, are usually transient phenomena. Cartels set up a prisoner's dilemma wherein the dominant strategy for all participants is to defect, thus ending the collusion. (Courts themselves early recognized that price fixers soon start chiseling on price.) Monopoly, on the other hand, can only be sustained if there are barriers to entry into markets, and even potential entry restrains the prices a firm with market power can charge.

The benefits of laws against cartels and monopolies thus depend on the relative costs of legal intervention relative to natural dissolution of cartels and natural erosion of monopoly by new entry. Whether antitrust has benefits is an empirical question. There has been no systematic showing of any antitrust benefits. Quite the contrary. All existing evidence, notably the sophisticated statistical analyses performed by George Bittlingmayer, indicates that antitrust has imposed net costs on American economic performance. Antitrust enforcement (including the uncertainty caused by constantly shifting amounts and patterns of enforcement) decreases output (Bittlingmayer, 1996) and business investment (Bittlingmayer, 2001). With the suspension of antitrust enforcement under the National Industrial Recovery Act (NIRA) in the 1930s came increases in output (Bittlingmayer, 1995). These results, noteworthy in their own right, help explain Sproul's (1993) finding that in markets undergoing antitrust prosecution prices actually rise when cases are filed. The results are also corroborated by other work: antitrust case activity leads to increases in unemployment, for example (Shughart and Tollison, 1991).

The effects of antitrust enforcement on stock returns parallel antitrust's negative effects on real activity (output, investment and employment). Antitrust case filings are associated with large and significant declines in overall stock prices (Bittlingmayer, 1992; see also Bittlingmayer and Hazlett (2000) concerning the stock-return effects of the *Microsoft* case). Not surprisingly, then, with the suspension of antitrust altogether under the NIRA came an increase in stock prices as well as a jump in industry output (Bittlingmayer, 1995).

In short, no economic case has been made that antitrust has any net benefits. At the same time, antitrust clearly is costly. More important than the sheer administrative costs of operating many (two federal plus 50 state antitrust regimes), wrongfully decided cases deter efficient business practices. Questions necessarily arise: why were antitrust laws passed and, since they are on net more costly than beneficial, why do they survive?

4. Antitrust: The Public Choice Perspective

Deleterious economic regulation ordinarily owes its origin and survival to politics. Antitrust, researchers find, is no different. DiLorenzo (1990) shows empirically that there was no economic rationale for the Sherman Act. The trusts against which the Sherman Act supposedly was directed were expanding output many times faster than overall production was increasing nationally; their prices were falling faster than overall prices nationally. But the Sherman Act was a politically useful smokescreen, allowing the Republican Congress in an election year to pose as anti-business populists while passing the legislation of true political value to them, new tariffs. Several subsequent analyses provide additional evidence that trace the origins of antitrust to interest-group pressures (e.g., Libecap, 1992; see also McChesney, 1995: 331).

The origins of antitrust legislation other than the Sherman Act have likewise been traced to politics. The Clayton Act in 1914 was passed after a presidential campaign in which the perceived need for stronger antitrust laws was a principal plank of the Republican, Democratic and Bullmoose parties. Not surprisingly, then, the Act itself is explained by the politics of wealth transfers, including transfers to small firms engaged solely in intrastate commerce and so immune from the Clayton Act (Ekelund et al., 1995). State antitrust laws that preceded passage of the Sherman Act also passed for political, not economic reasons. Midwestern farm interests in particular found antitrust useful in combating more efficient, centralized meat processing firms in cities like Chicago (Boudreaux et al., 1995).

Subsequent enforcement of antitrust laws has likewise been a function of politicians' self-interest, including response to political pressure. Bittlingmayer (2001: 297) notes that, historically, "its [antitrust's] enforcement has often had a substantial political component," starting with Teddy Roosevelt's celebrated trust-busting. Elsewhere, he notes several more recent examples, including the Microsoft case (Bittlingmayer, 1996: 372–73; see also Bittlingmayer and Hazlett, 2000).

Statistical analyses of particular enforcement areas find that politics rather than economics explain antitrust activity. In theory, antitrust is a useful form of political rent extraction; and in fact, political influence helps explain why the government brings but then dismisses cases (Faith et al., 1982). Merger enforcement policy cannot be explained in efficiency terms; the statistical evidence indicates that efficient mergers are the ones challenged (Eckbo and Wier, 1985). But a model of political pressure to stop mergers can explain patterns of merger enforcement (Coate et al., 1990).

The foregoing leaves much of the public choice literature concerning antitrust unmentioned. The point, however, is to indicate that public choice scholars have produced a body of theoretically based and empirically validated work on antitrust which finds that politics explain the origins and survival of a regulatory system that overall has proven costly to social welfare.

5. Chicago Positive Opinions on Antitrust

If antitrust is just economic regulation, a political system with no discernible net benefits, one would think that Chicago — one of the earliest hubs of economists working within the economic theory of regulation — would view antitrust with at least suspicion. Instead, Chicagoans have viewed antitrust with respect, even enthusiasm. The first notable "Chicago school" scholar of antitrust, Henry Simons, in the 1930s saw monopoly as the source of the Depression, which he feared would destroy American democracy. Vigorous antitrust enforcement was the solution, Simons wrote. "The Federal Trade Commission must become perhaps the most powerful of our government agencies" (1948 reprint: 58).

Subsequent Chicago analysts of antitrust, while perhaps not as exuberant as Simons, still have had nothing but praise for it. George Stigler, the best known Chicago scholar of industrial organization during his time, was a member of the National Committee to Study the Antitrust Laws, which in 1955 issued a report advocating aggressive enforcement of the law. Earlier, he had called for "dissolution of a few score of our giant companies." Thirty years later, he still believed that antitrust was "a sort of public-interest law" (Hazlett, 1984: 46).

One could add any number of other Chicagoans to the list of antitrust fans. Ignoring any costs of antitrust, Posner writes (2001a: 2) that the value of efficiency "establishes a prima facie case of having an antitrust policy." Robert Bork, part of the original Antitrust Project at Chicago, likewise claims that efficiency explains the Sherman Act (1978). That claims rests on his reading of the statute's legislative history, that is, what politicians said as they legislated.

It is difficult to imagine a mode of analysis further from public choice than evaluating government policy in terms of putative benefits (without costs), or in terms of what politicians say about those claimed benefits. Indeed, that perspective would be anathema in Chicago itself, were the subject not antitrust. Stigler himself (1975: 140) wrote, "The announced goals of a policy are sometimes unrelated or perversely related to its actual effects, and the *truly intended effects should be deduced from the actual effects.*"

Antitrust causes Chicagoans to transgress their general mode of positive economic analysis (summarized, e.g., in Reder (1982)) in other ways. For instance, there is the general Chicago stance (Reder, 1982: 31) that "objectives that cannot be achieved except through the state are to be scrutinized carefully and sceptically.... [Chicago takes] a generally adverse view of government intervention. Any reformer must either refute it or minimize its importance." The burden therefore is on those who think a particular government regulation or policy works to demonstrate that fact.

But not when it comes to antitrust. How to deal with all the evidence (some of it mentioned above) concerning antitrust's net costs? Posner (2001a: 2) dismisses the bad case law as dated, though little of it has been overruled, and ignores the statistical showings of antitrust's other costs. How, next, to deal with the public-choice explanations for antitrust's birth and growth — much of it appearing in journals published by the University of Chicago? Posner (2001b: 942, citations omitted) again dismisses the evidence without explanation: "There is a history of efforts to explain antitrust enforcement as just another example of interest-group politics, an approach that has worked for a number of government agencies and programs. But the efforts have not been successful." How then does Posner explain antitrust? "Looking over the entire history of U.S. antitrust law, I conclude that the most powerful explanatory variable is simply the state of economic opinion" (Id.). Antitrust regulation is due to some economic Zeitgeist, not the ordinary political reasons that explain most other forms of economic regulation.

One exception to the general approval of antitrust in Chicago should be noted. Coase (1988) complained that antitrust, nominally a subset of industrial organization, had in fact swallowed up the entire subject. Economists' fascination with 'the monopoly problem,' as he called it, had distracted their attention from the true object of industrial organization, the behavior of firms. In addition, Coase continued, economists too quickly ascribe unfamiliar business practices to monopoly power. Coase may well be right in both respects, but his points have nothing to do with public choice, an area about which he has shown only scepticism (Coase, 1994: 42–46). The questions noted above remain: why was antitrust created and why has it survived?

One other Chicagoan belatedly reached the same stage in evaluating antitrust. Shortly before his death, Stigler (1993: 401) recanted his previous approbation of antitrust: "at the risk of being called fickle, many economists (I among them) have lost ... our enthusiasm for antitrust ... The declining support for antitrust policy has been due to the often objectionable uses to which that policy has been put." Like Coase, though, Stigler suggested no reasons to explain antitrust's century of "objectionable uses," nor any for its survival (indeed, robust growth) during that time. His disavowal therefore stopped well short of embracing the alternative public-interest model of antitrust.

In Hyde Park, Stigler's recantation is perhaps viewed as apostasy. No other Chicagoan has come forward to join the growing group of economists noted by Stigler who have lost their antitrust enthusiasm, much less to join the growing public-choice group that has begun to answer the questions that Chicago does not ask.

PUBLIC CHOICE IN ITALY

Italian scholars are at the forefront of research in public choice if we accept the view that the strand of literature generally termed "political economics" (Persson and Tabellini, 2001) is germane in methodology and subject matters to traditional public choice. Outstanding researchers in this fields are Italians, Guido Tabellini, Alberto Alesina, Roberto Perotti to name a few, publish regularly in first class journals, such as AER JPE, QJE, *Econometrica* and are enrolled in Economics departments of top American Universities.

But even if we prefer to keep political economics and public choice as two separate strands of literature, there are more Italian researchers active in this field and, consequently, the country's contribution to the progress of public choice is more significant today than at the times when Buchanan won the Nobel prize. A few facts support such claim. During the entire decade of the 1980s, only two articles by an Italian scholar was published in the journal Public Choice (Fratianni and Spinelli, 1982; Forte, 1987); during only the year 2001 no less than 8 Italians published in the same journal and 3 in Constitutional Political Economy. Between 1990 and 2002 three meetings of the European Public Choice Society have been organized by Italian Universities (Torino, Siena and Piemonte Orientale) while only one in the 1980s (Reggio Calabria, 1986). Quantity wise, since 1995 Italian scholars are steadily the more numerous national group within the EPCS; quality wise, in 2002 an Italian won (*ex aequo*) the Wicksell Prize for the best paper by a scholar under 30 years of age presented to the EPCS meeting.

However, similar remarks might have been stated about public choice in other countries. What makes Italy special for public choice?

The answer requires a bit of history of public choice ideas. Italian scholars of public finance of the XIXth century, such as De Viti de Marco, Mazzola, Puviani, Pantaleoni, have been precursors and a source of inspiration for the development of the public choice paradigm (da Empoli, 1993; Buchanan, 1960). In 1861, Italy was created as a state from the unification of several smaller states, most of them with a long history of bad government (Mack Smith, 1996). Some of the unwelcome legacies of the pre-unitary states for the new kingdom were a very high public debt, budget unbalances and unequal levels of development across regions. The link between types of government and fiscal and economic outcomes was clear under the eyes of the Italian public finance scholars and became an underlying theme of their research. By and large they published in Italian, and knowledge of their contributions was mostly confined to Italians and to scholars such as Buchanan who learned the language of Dante. Da Empoli (1993) points out that many of Buchanan's contributions to public choice and public finance have been inspired by the Italian school. If Buchanan derived from Wicksell the emphasis on decision-making rules, he absorbed from the Italians the ideas of contractarianism and of government failure.

However, this school did not last long as the cultural background of the Italian economic profession. The onset of the Keynesian revolution, the influence within the country of economists such as Franco Modigliani and Paolo Sylos Labini in favor of state manipulation of the economy, the economic prosperity of the postwar years persuaded the Italian economists of the desirability of an increasingly active role of the state into the economy. From the 1960s to the early 1980s the Italian climate was not favorable for public choice. Few scholars, like Domenico da Empoli, Emilio Giardina and Francesco Forte, were pursuing a public choice research agenda then.

Until the late 1970s, these scholars, as well as some others affiliated to them, tried to diffuse the new paradigm into the country's economic culture mainly by translating works of Buchanan, Tullock and Olson¹ and by trying to re-tie the knot between modern public choice and the Italian school of public finance. The goal was twofold. First, pointing out the relevance of these theories to explain structural problems of the Italian economy, the rising public debt to name one, and institutional setup. Second to show that public choice had deep roots into our cultural heritage. These efforts were, however, insufficient to displace the country's prevailing the-state-should-intervene attitude. What lacked was a robust and wide-ranging research program that applied public choice theories to Italian cases.

In the early 1980, four events created the preconditions for such a program to emerge. First, in 1983 Da Empoli Journal of Public Choice and Public Finance. The journal aimed to establish a connection between researches in public choice conducted on the American and European side of the Atlantic (as well as on the Italian shores of the Mediterranean). To this end the journal was published increasingly in English; most of all, in several issues, articles by very well known economists (Buchanan, Tullock, Stigler, Duncan Black, Lejonhufvud, Allais among others) were side by side with articles by (much) lesser known scholars (such as myself). The Editor's strategy was to attract Italian scholars to the field of public choice, as well as trying to raise new researchers. Secondly, in 1986 Giorgio Brosio published Economia e Finanza Pubblica, the first Italian textbook of public finance that paid considerable attention to public choice. The innovation of the book was not to treat public choice theories as a topic per se, but as perspective from which to explain public finance topics. The (still) wide circulation of this textbook within Italian universities contributed to the diffusion of public choice ideas among undergraduate students. Third, in the 1980s some Italian professors began to send their graduate students to American Universities specialized in public choice. George Mason University, the University of Maryland as well as other larger though less specialized Departments received a string of Italian students. This is also the period when people like Tabellini, Alesina, and Perotti studied in American Universities that subsequently hired them. A new generation of Italian scholars was created that not only received a systematic training in the field, but also learned to do research from people who regularly published in high level scientific journals.

To an extent all these events were endogenous results of the deterioration of Italy's economic and political situation in the 1970s to the 1980s. The worsening situation of the public finances, the spreading of corruption within the political elite and the public sector, ultimately due to the lack of alternation in government, pointed out, within the economic profession, that Keynesian macroeconomics lacked explanations and solutions that public choice instead could offer. Although, as Keynes himself pointed out, ideas change with generations, and still the majority of Italian economists (and people) tend to see the government as the solution, rather than the problem, from the early 1990s on the Italian climate became more pleasant for the public choice paradigm.

Today, several academic groups pursue a public choice research agenda, often publish in international journals, develop theories inspired by Italian experiences and apply public choice models to Italian cases. A first group (in a strict geographical order from North to South) holds its intellectual center in Turin; among the various topics, this group is active in the study of political business cycle, fiscal federalism and comparative economic systems. Rome has three research groups. One, centered around Political Sciences at La Sapienza (da Empoli) and the Center for Economics of Institutions at Roma Tre, studies the relation between political institutions and economic performance in terms of output growth, budget outcomes and tax structure at the national and local level; the public choice of international organizations; and, as a new research agenda, how the internal structure of government affects legislative production. The branch of this group at La Sapienza publishes the Journal of Public Choice and Public Finance. A second research group is located at the Law School of La Sapienza, studies checks and balances and law and economics. Within this group Gianluigi Galeotti is, with Albert Breton and Pierre Salmon, one of the founders of the Villa Colombella Group, which promotes a series of international research seminaries. The Department of Economics of La Sapienza is the base of the newly founded European Center for the Study of Public Choice, which invites international scholars and pursues a research agenda chiefly interested in constitutional political economy. Other members of the Department work on government coalitions and bureaucracy. Sicily has no less than three groups: the University of Messina focuses on electoral rules and outcomes, both at the local and at the national levels; the University of Palermo is active in social choice; the University of Catania studies rent seeking, devolution of government powers and public expenditures in support of the arts.

Two further research groups deserve attention. A first is in Milan, between the IGIER (at the Bocconi University) and the Cattolica University. Led by Guido Tabellini, this group is one of the most important and active springs of research in political economics. Several of their working papers, after having been published in top journals and widely circulated collected works, are cited very often. Another, more recent group is composed by young Italian scholars who work abroad and share the London School of Economics as their *Alma Mater*. This group is composed by political economists, political scientists, public choice scholars and cover fields such as interest groups, economics of corruption, media, information and politics, as well as others.

Italy's economic and political situation tends to mold the research culture in favor of applied work over basic theorizing. Hence the evolution of public choice research within the country and the attention to such ideas appears related to the economic and political situation of the country. The worse the economic situation, especially in the area of the public finances, and the more significant the evolution of the institutional framework, the greater was the interest in public choice. It is no accident that the peaks were in the XIXth century, after the unification of the state, and today, after the crisis of the so-called First Republic, the federalist reorganization of the state and the acceleration of the process of European integration. With respect to the scholars of the XIXth century, however, the diffusion of contemporaneous Italian works in public choice is no longer limited by the language; the future of public choice research in Italy will be more closely correlated with the paradigm's fortune worldwide. Similarly, public choice research in general, which so far has suffered of excessive Americanism, will take advantage of the contribution of a country that has proved to be inspiring as well as, unfortunately, a particularly interesting case study.

PUBLIC ENTERPRISE

A public or political enterprise is a government-owned business firm. To understand the nature of these firms, it is useful to examine why they exist and how they behave.

Hypotheses why *private* firms exist hinge on transaction costs, the firm being a nexus of contracts formed to solve the shirking-information problem of joint production (Coase, 1937, 1988; Alchian and Demsetz, 1972; Williamson, 1975, 2000; Grossman and Hart, 1986; Furubotn and Richter, 1997; Holmstrom, 1999; Demsetz, 2002). Hypotheses why *public* firms exist span a broader spectrum, including a taste for government ownership, patronage, failure to understand how markets work, and limitations of the market system, whether inherent or imposed (Pashigian, 1976; De Alessi 1982, 2001; Eggertsson, 1990; Levy and Spiller, 1994; Troesken, 1997). These hypotheses, which are not mutually exclusive, are examined next.

Public enterprises may arise if individuals have a taste for them, that is, are willing to give up other commodities in order to have more of them. Individuals, however, presumably choose one kind of firm over another because they believe that the consequences benefit them. The evidence bears this out; taste is not a significant explanatory variable (Pashigian, 1976).

Public enterprises may arise to facilitate patronage. Individuals with a comparative advantage in the exercise of political power have incentive to use the state to benefit themselves and groups they favor; concurrently, politicians have incentive to provide such benefits to gain political support (McChesney, 1997). Accordingly, public enterprise may be established to mask or ease wealth transfers. For example, exempting state enterprises from property and other taxes lowers their production outlays, encouraging their existence and benefiting their clients at the expense of taxpayers. A related hypothesis is behavior modification. Thus, individuals can be encouraged to behave in certain ways by having public enterprises produce and sell appropriate commodities at subsidized prices.

Public enterprises may arise because individuals misunderstand how markets work. For example, a sharp

increase in price caused by a sharp increase in demand or decrease in supply provides information and incentive for producers to increase output or consumers to reduce consumption. Such events, however, offer special interest groups an opportunity to argue that the market has failed and seek patronage through production by public firms.

Public enterprises may arise from limitations of the market, whether inherent or imposed. If the costs of establishing, enforcing, and exchanging private property rights are too high or the market is too small, private firms may not arise, thereby offering scope for public firms. Such conditions may exist in an open market or may result from government actions that make private property rights insecure and otherwise increase transaction costs.

Public enterprises, like private enterprises, may also arise to solve the shirking-information problem of team production. The higher are the costs of monitoring whether a commodity meets the specifications provided in a procurement contract, the greater is the opportunity for all parties to shirk, reducing the gains from specialization (contracting out) and encouraging vertical integration. This incentive is particularly acute in government when terms such as "for the public good" and "in the public interest" appear. These terms are not specific enough to define the rights and duties of the parties involved, expanding the opportunity to shirk.

Other explanations, such as the desire to provide a check on the performance of private enterprises, are variants of the hypotheses already discussed or mere rhetorical noise. The actual or fancied reasons for the existence of public enterprises, however, affect behavior only to the degree that they are reflected in binding constraints on the enterprises' decision makers. To predict a firm's behavior, it is necessary to focus on the cost-reward structures embedded in its organizational form and examine their economic consequences.

A distinguishing characteristic of public enterprises is that ownership shares in their specialized assets are not transferable. Taxpayers who wish to change their portfolio of shares in public enterprises must change the political jurisdictions in which they work and live or the way in which the political enterprises operate. This lack of transferability implies that individuals cannot specialize in the ownership of public enterprises and risk bearing and that the future consequences of managers' decisions are not reflected (capitalized) in the shares' current transfer prices. The results include a loss of information on economic performance and a reduced incentive by owners to monitor managers. Thus, managers of political enterprises may be expected to have weaker constraints on their choices than managers of comparable private enterprises. The latter are subject to the discipline of the market and must respond to market signals if their firms are to survive. Managers of public firms, on the other hand, are less constrained by market considerations, finding it easier to obtain subsidies and mask discretionary behavior under the guise of fulfilling various social goals. Public enterprises, especially those with politically influential clients, can survive for long periods, and their managers prosper, in the presence of persistent losses and mismanagement.

Managers of political enterprises have greater opportunity for discretionary behavior than managers of comparable private firms. In particular, they have more opportunity to increase the resources (e.g., staff and assets) under their supervision and to allocate these resources in ways designed to enhance their own welfare. Their salaries and other contractual pecuniary rewards, however, often are subject to ceilings, whereas those paid to managers of private enterprises are not. This difference implies that managers of public firms have greater incentive to allocate resources to enhance their job security, thereby increasing the present value of all future job-related benefits. Such benefits, however, cannot be capitalized and human life is finite. Moreover, it is costlier for owners to monitor the acquisition of non pecuniary than pecuniary benefits. Thus, the cost of non pecuniary benefits is lower and managers of political enterprises acquire more of them.

The analysis implies that managers of public enterprises are more likely to adopt policies that enhance their position, ease their work load, and generally make their jobs more rewarding as they see it. For example, they are more likely to choose pricing policies that are easier to administer. This strategy includes changing output prices less frequently, tailoring them less closely to existing demand and supply conditions, favoring influential special interest groups, and giving subordinates across-the-board wage increases. Similarly, they are more likely to hire subordinates with characteristics they prefer, discriminating on the basis of race, sex, education, and congeniality, and giving such subordinates benefits designed to reduce friction. They also have incentive to reduce risk and enhance their survival by engaging in anti competitive behavior, including predatory activities. In general, public enterprises may be expected to be less responsive to consumer wants, less efficient by market standards, and more aggressive in inhibiting competition.

These implications are supported by the evidence (De Alessi, 1982; Borcherding et al., 1982; Millward and

Parker, 1983; Boardman and Vining, 1989), including evidence from the current world-wide privatization movement (Villalonga, 2000). Compared to regulated private firms, for example, municipal electric utilities generally charge lower prices, apply fewer peak-related tariffs, favor business relative to residential users and voters to non voters, change prices less frequently and in response to larger changes in economic determinants, relate prices less closely to the costs of serving particular user groups, sell wholesale electric power at lower prices and buy it at higher prices, spend more on plant construction, have greater capacity and higher operating costs, adopt costreducing innovations less readily, offer a smaller variety of output, maintain managers in office longer, and exhibit greater variation in rates of return.

Evidence from other industries provides additional support for these and other implications. Relative to regulated private enterprises, municipal water utilities have lower tariffs with fewer service categories and fewer blocks within each category, have rate structures that favor more politically active groups, use more capital-intensive production techniques, and are less efficient by market standards. Relative to both regulated and unregulated private enterprises, public enterprises are less successful in satisfying consumer wants for urban transit, are less efficient by market standards in providing bank and airline service, and incur higher costs in providing fire prevention and refuse collection services. Evidence from the U.S. hospital industry suggests that public enterprises have more binding and explicit internal monitoring rules, make less use of market information, are more likely to give across-the-board rather than selective wage increases, are less likely to use cost-minimizing input combinations, are more likely to respond to an increase in occupancy by increasing the proportion of administrative personnel at the expense of medical and other services, are less efficient by market standards, and emphasize the production of those services more easily monitored by trustees and legislators.

Managers of public enterprises are also more likely than managers of comparable private firms to engage in anti competitive behavior (Lott, 1999; Sappington and Sidak, 1999). That is, they are more likely to seek to raise competitors' costs, block entry of prospective competitors, evade regulations intended to encourage competition, and sell below cost to drive competitors out of business.

In summary, theory and evidence indicate that, relative to private enterprises, public enterprises are less responsive to consumer wants, less efficient by market standards, and more likely to engage in discretionary and anti competitive behavior.

PUBLIC FINANCE AND THE MEDIAN VOTER MODEL

The median voter model is a model of demand aggregation under majority rule. Economists find the market demand for private goods by horizontally summing the demand curves of all individuals in that market; similarly, when individual demands are aggregated through majority rule voting, the demand of the entire group is the demand of the median voter. The idea can be traced back at least to Hotelling (1929), who suggested it in an article on spatial competition. Black (1948a, 1948b, 1948c) developed the median voter model in detail, discussed the cyclical majority problem, and used the median voter model to lay the foundation for the development of modern public choice theory.

The median voter model is really not a single model, but a conclusion that is generated through a family of similar models. The median voter conclusion is that when collective decisions are made by majority rule, the demand of the median voter is the demand of the group. Bowen (1943) demonstrates this in a model of referendum voting, and Black (1948a, 1958) analyzes democratic decision-making in a committee setting in detail, and arrives at the same conclusion. Black also explains the cyclical majority and discusses conditions under which the median voter result will not hold. Downs (1957) extends the formulation of Hotelling (1929), and presents the median voter result in a model of representative democracy. Downs goes well beyond discussing voting to give an insightful analysis of many aspects of representative democracy, and both Downs (1957) and Black (1958) are among the classic works in public choice that enabled it to emerge as a separate subdiscipline. Taking formulations of Bowen (1943), Black (1958), and Downs (1957) together, the median voter model suggests that in many different institutional settings referenda, committee decision-making, or representative democracy — when decisions are made by majority rule, the median voter's demand is the group's demand.

By the early 1970s the median voter model was being used as a description of both the supply and demand sides of public sector resource allocation. Articles in prominent journals, such as Barlow (1970), Borcherding and Deacon (1972), and Bergstrom and Goodman (1973) developed empirical results based on the assumption that the output produced by the public sector is the output most preferred by the median voter. At this point, the median voter model was generally accepted not just as a model of demand aggregation, but as a more general model of public sector resource allocation. The median voter model was one of the most substantial and long-standing models in the young discipline of public choice, and by the early 1970s was often depicted as concluding that the public sector produces what the median voter wants.

The median voter model fell out of favor during the 1970s, as Holcombe (1989) describes. Niskanen's (1971) model of bureaucratic resource allocation argued that public sector output is much larger than the median voter would prefer, immediately calling into question the model's broad interpretation. Still, Niskanen used the median voter model for the demand side of his model, and his innovation was the modeling of the supply side of the public sector, which up to that time had mostly been neglected. A more substantial blow to the median voter model came from a theoretical literature, led by McKelvey (1976), which argued that in general, majority rule voting would not produce a unique and stable outcome, and the median voter result would hold only in the most narrow of special cases. The possibility of cyclical majorities had been well-known by public choice scholars. Black (1948a) illustrated the possibility clearly, and Arrow (1951) began his book with a discussion of cyclical majorities. Black (1948a, 1958) showed that they would arise only if individual preferences were not single-peaked, and for decades public choice scholars assumed that preferences were likely to be singlepeaked, so cyclical majorities would be rare occurrences. McKelvey (1976) argued that once a framework like Black's is extended from one to many dimensions, cycles would be expected even when all preferences are singlepeaked. This created quite a debate in the literature.

Some, such as Riker (1980), argued that this inherent tendency for cycles meant that political markets were fundamentally different from economic markets, and that there could be no political equilibrium as such. Others, such as Tullock (1982) argued that political outcomes were, in fact, more stable than market outcomes, and challenged public choice scholars to explain why. One outcome of this debate was a closer integration of voting models with political institutions, log-rolling, and interest group politics (Weingast, Shepsle, and Johnsen, 1981; Holcombe, 1986). This emphasis on institutions pushed pure voting models like the median voter model into the background and brought aspects of the political bargaining process into more prominence.

In addition to being used as a theoretical foundation for public choice models, the median voter model has also been subject to direct empirical tests, almost always using cross-sectional data on local governments in the United States. Barr and Davis (1966) showed that public sector expenditures were correlated with median incomes across jurisdictions, and McEachern (1978) looked at local debt levels across states and found results consistent with the median voter model. Holcombe (1980) calculated the median voter's preferences from school finance referendum data, and found that referenda tended to produce the outcome most preferred by the median voter. Inman (1978) examined whether the median income voter explained local expenditure levels better than average income or other variables, and his results supported the median voter model. While most empirical tests of the median voter model tend to support it, Romer and Rosenthal (1979, 1982) find inconclusive results that do not support the median voter model. The median voter model does seem to hold up well to empirical testing, but it is worth noting that it has been tested almost exclusively with state and local government data because crosssectional data are readily available, and because of institutional differences, the results may not extrapolate to national data.

While theorists as far back as Downs (1957) have tried to incorporate factors affecting voter turnout into the median voter model, it has never been done in a convincing way, and the model does not account for the impact of political campaigning and interest groups on voter preferences. Rather, the model assumes that voter preferences are fixed and that candidates and parties adjust to them. Furthermore, the model assumes that voters always vote their true interests, which has been insightfully questioned by Brennan and Lomasky (1993). These omissions could be viewed as shortcomings of the model, or as simplifying assumptions. As simple and unrealistic as the model is in some regards, it still goes a long way toward explaining how voter demands are aggregated through democratic decision-making.

The median voter model is best viewed as a model of demand aggregation which concludes that under majority rule, the aggregate demand of a group of voters will be the demand of the median voter. Interpreted in this way, the model offers substantial insights into the democratic decisionmaking process, and empirical evidence suggests that it is descriptive of actual collective decision-making outcomes.

PUBLIC FINANCE IN DEMOCRATIC PROCESS

The origins of public finance, as a field of study though most certainly not as an object of practice, can be traced to the emergence of the cameralists after 1500 in central Europe (Backhaus and Wagner, 1987). The focal point of cameralist concern was on survival of the regime, which in turn, required a military capacity and economic development. This concern about development took place within absolutist regimes that existed in a highly competitive, Tiebout-style (1956) environment. The Peace of Westphalia in 1648, for instance, recognized more than 300 independent units of governance within the cameralist lands. Joseph Schumpeter (1954: 143-208) described the cameralists well when he referred to them as "Consultant Administrators." They were both consultants and administrators. They were consultants to the various kings, princes, and other royal personages who ruled throughout those lands. The cameralists were not, however, anything like contemporary academic consultants. They were real-world administrators as well. They were engaged in such activities as managing mines or glass works. Many of the cameralists also held academic posts (as noted in Albion Small's (1909) thorough but more descriptive than analytical examination).

If one were to construct a model of the cameralist vision of the state, it would look like a model of a business firm. The state's lands were potential sources of revenue. Forests could be harvested, game could be caught, and mines could be worked. The ruler would also sponsor an assortment of commercial enterprises, as in operating a glassworks or a brewery. Taxes occupied a secondary position as a source of revenue. They were a last resort option for public finance, and not the first source of revenue.

The cameralist absolutisms have long given way to democracies throughout the Western world. In many respects, however, public finance has not kept pace with this change in political regime. Cameralistic public finance was a choice-theoretic approach to public finance. The phenomena of public finance, state revenues and expenditures, arose out of some ruler's optimizing choices. It is quite different in modern democratic regimes. The phenomena of public finance do not arise from someone's optimizing choice, but rather arise through interaction among the many participants within the fiscal process. This interactive or catallactic approach to public finance leads often to quite different implications for public finance than does the choice-theoretic approach (Wagner, 1997). A good deal of contemporary public finance has maintained the choice-theoretic orientation toward public finance, as if fiscal phenomena are still generated through the same processes that were in place in mercantalistic and cameralistic times. This astonishing situation was noted in 1896 by Knut Wicksell (1958: 82), when he observed that the theory of public finance "seems to have retained the assumptions of its infancy, in the seventeenth and eighteenth centuries, when absolute power ruled almost all Europe."

The distinction between a choice-theoretic and a catallactic orientation toward fiscal phenomena is a central fault line that runs throughout contemporary public finance. The seminal articulation of the choice-theoretic orientation can be attributed to the British economist Francis Edgeworth (1897). The seminal articulation of the catallactic orientation can be attributed to the Swedish economist Knut Wicksell (1896). While both of these authors are now more than a century behind us, their central orientations toward public finance are readily visible in contemporary fiscal scholarship.

The Edgeworthian, choice-theoretic orientation treats public finance as the study of government intervention into the economy, typically expressed as maximizing some form of social welfare function. In particular, Edgeworth raised the question of how a government would impose taxes within a nation if it wanted to raise those taxes with a minimum amount of sacrifice to taxpayers. For a given amount of revenue to be raised, Edgeworth's ideal state would be one that imposed the least amount of sacrifice upon taxpayers in raising its revenue. This Edgeworthian, choice-theoretic approach to public finance treats the phenomena of public finance as arising from the maximizing choices of a benevolent entity, the state. The state stands outside the market economy and its participants. The people who participate in the market economy may write the first draft, so to speak, but it is the state that revises and perfects the manuscript.

The Wicksellian, catallactical orientation treats public finance as the study of how people participate through government to achieve their various ends (Wagner, 1988). This orientation, with its emphasis on fiscal institutions in place of the Edgeworthian emphasis on resource allocations, is illustrated with striking lucidity in James Buchanan (1967). The state does not stand above the market economy and its participants. The same people who participate in the market economy participate in state governance as well. Fiscal phenomena are not the product of some ruler's maximizing choices, but rather emerge through interaction among people. This interaction might be beneficial for everyone or nearly everyone, or it might be beneficial for only a few, and costly for many others. The state is treated as a nexus of contractual and exploitive relationships. The extent to which those relationships are contractual or exploitive depends on the constitutive structure of governance that is in place.

As a matter of general principle, political relationships are both contractual and exploitive. It is fine to say that taxes are the prices we pay for civilization, to recall the inscription attributed to Oliver Wendell Holmes that is chiseled above the main entrance to the headquarters of the Internal Revenue Service in Washington, D.C. This doesn't mean, however, that the relationship between citizens and state is the same as the relationship between customers and the retail outlets they frequent. A customer can refuse to buy and, moreover, generally can return merchandise that turns out to be defective or otherwise unsatisfactory. There is no option to do this in politics. To say that civilization is being priced too highly and to withhold payment will only land the protester in prison. And there is certainly no point in asking for a refund by claiming that the state's offerings weren't as good as its advertisements claimed them to be.

To speak of a catallactical approach to public finance is not to claim that the phenomena of public finance arise through voluntary interaction among people. It is only to say that those phenomena arise through interaction among people, the very same people as who interact with one another within the market economy. Much of the phenomena of public finance surely arise through duress and not through genuine agreement. This aspect of duress was given particular stress in a good deal of the Italian scholarship on public finance, and which is surveyed in James Buchanan (1960).

Within the Wicksellian, catallactical tradition, primacy of analytical attention is placed upon the institutions of governance, both market governance and, especially, political governance. This contrasts sharply with the Edgeworthian, choice-theoretic tradition where the primary analytical attention is placed upon prices and resource allocations. The state is not treated as some exogenous force that perfects and corrects the outcomes of the market economy. The actual fiscal conduct of the state emerges through complex interactions among fiscal and political participants, and the precise character of those interactions is constrained and shaped by a governing institutional and constitutional framework.

A choice-theoretic approach to public finance was suitable in cameralist and mercantilist times. A cameralist

ruler could reasonably be described as seeking to use his fiscal means to promote his dynastic ends. For the cameralists it was historically accurate to ascribe the phenomena of public finance to the choices of the rulers. The state's revenues depended on the ruler's choices about how to operate his mines and how to farm his lands. The extent to which state expenditures were directed to projects that might increase future productivity were likewise objects of choice for the ruler. Suppose two kingdoms were observed to undertake different expenditure programs. In Primo's kingdom, expenditures were heavily oriented toward such investments as draining swamps and building roads that would be likely to increase future production. The budget in Secundo's kingdom, however, did little about swamps and roads, and instead spent lavishly on amusements for Secundo and his court. It would be reasonable in this case to compare the budgetary choice of the two kingdoms, and to say that Primo had a lower time preference, or was otherwise more far-sighted than Secundo. To the extent it is possible to make inferences about preferences from the observation of choices with respect to private choices, it would be possible to do the same thing with respect to state choices within the cameralist setting. To be sure, the conduct of cameralist rulers was relatively civilized, and nothing like the experience with dictators in the 20th century. The conceptual construction of a benevolent despot perhaps finds historical validation in the cameralist period. That does not, however, validate the use of constructions based on benevolent despots in public finance today.

Whether budgets are tilted toward amusements or capital projects would not be directly a source of information about some ruler's preferences in a democratic regime. Budgets emerge out of interactions among participants, and those interactions are governed and shaped by a variety of procedural and constitutive rules. The people who participate in a market make their various choices, but it makes no sense to speak of the market itself as making choices. The market simply registers and reflects the choices and interactions among the participants. It is the same with budgetary outcomes within a democracy. Furthermore, the same set of people can generate quite different budgetary outcomes, depending on the institutional framework within which the budgetary process proceeds. In this respect, there are an indefinitely large number of particular budgetary processes that can be imagined, and it is conceivable that a wide variety of budgetary outcomes could be generated, if the experiment were performed of having the same people engage in successive interactions across differing institutional frameworks. This consideration suggests immediately that a post-cameralist public finance would place particular importance and significance

on the institutional framework within which fiscal outcomes emerge.

Taxation is most surely a Faustian bargain, as Vincent Ostrom (1984) explains. Excess burden is one of the primary tools that is employed in public finance. The claim on behalf of excess burden is that taxes have burdens beyond the burden associated with the revenues that taxes collect, due to the changes in market choices that people make in response to taxation. Despite the widespread use that is made of excess burden analytics, the concept suffers from some deep institutional problematics within a democratic political system, as Richard Wagner (forthcoming) explains. In a pure Wicksellian framework, public projects are approved to the extent that political participants value the resulting public programs more highly than they value the private alternative they had to sacrifice. It simply makes no sense to speak of excess burden in a Wicksellianlike institututional setting. In non-Wicksellian settings, the democratic fiscal process involves significant elements of domination and subordination. Those who are subordinated may well bear costs beyond the gains that are attained by the dominating classes, but this is simply to say that any process by which some people are taxed for the benefit of others will involve costs beyond the directly observed budgetary magnitudes. There is nothing surprising about this. Taxation transforms private property governance into common property governance (Wagner, 1992), and the balanced budget multiplier that results from this transformation is generally negative. Taxation does truly represent a Faustian bargain, particularly outside the framework of Wicksellian or consensual governance.

PUBLIC GOODS

Public goods are goods with benefits that extend to a group of individuals. The interest in public goods can be traced back to classical economics. David Hume and Adam Smith agreed that government intervention is needed to supply goods and services characterized by collective benefits. If left to the spontaneous action of individuals or organizations, these goods would not be adequately provided.

A theory of public goods was first developed with the publication in 1954 of Paul Samuelson's seminal paper "The Pure Theory of Public Expenditure." Since then, research interest in the topic has grown rapidly. Economists have studied systematically pure public goods and distinguished them from the opposite case of pure private goods. Pure private goods do not involve collective benefits, are rival in consumption and can be efficiently allocated by the private market. On the other hand, pure public goods are characterized by non-rivalry of benefits and non-excludability. For these reasons, collective provision is considered a necessity for these goods.

1. Characteristics of Public Goods

Two characteristics mostly distinguish public goods from private goods. Pure public goods are non-rival in consumption and non-excludable. Consumption of a good is *non-rival* if a person can increase her consumption without reducing the quantity of the good available for anyone else's consumption — the principle as stated by Samuelson in 1954 "one man's consumption does not reduce some other man's consumption." This contrasts with pure private goods, in that consumption by a person reduces availability to others. A fireworks display or a television broadcast are examples of non-rival goods, as long as the view is unobstructed or one has access to a TV set; and so are vaccination programs and national defense. A public good may also create disutility or negative benefits. Consider air pollution: the disutility suffered by one person does not reduce the disutility suffered by anybody else in the community.

Non-rivalry in consumption means that public goods can be consumed by more than one person at a time, and the marginal cost of extending the service to an additional individual user is zero. In this sense, non-rivalry creates market inefficiencies regarding the allocation of these goods.

The second characteristic is non-exclusion. Public goods are *non-excludable* whenever the benefits from the good are available to all once the good is provided and nobody can be excluded from consumption. Fireworks displays, street lighting and national defense are nonexcludable public goods, since it is impossible or very costly to exclude individuals from consumption once they have been provided. Once a good is excludable, private property rights can be created and a price can be charged in order to access consumption. Non-exclusion creates additional market inefficiencies.

2. Public Goods and Market Inefficiencies

The main problem caused by non-rivalry is that consumers are not motivated to reveal their preferences. Once the good is provided, there is no incentive for individuals to disclose their willingness to pay for the good, since everybody can consume it without decreasing the amount available to others. Individuals become "free riders" and thus enjoying the benefit from a good that others are providing, without having to pay for their consumption. Furthermore, since everyone can free ride, no one has an incentive to produce the public good. Everyone tends to wait for others to produce it. As a result, the public good will be underproduced, if produced at all. Experimental evidence suggests, however, that this outcome is not as prevalent as the theory indicates and individuals tend to contribute to the provision of public goods even if not at the efficient level.

Non-rivalry also implies that the marginal cost of adding any additional consumer is zero. For this, society's welfare would be maximized when the good is available for consumption at no cost to everyone who places a positive value on it: that is, no individual should be excluded from consumption. However, even if it is inefficient to exclude individuals from consumption, the market does not have a good way of allocating the public good to all individuals who place a positive value on it. In fact, a private firm would be able to provide these goods and sustain the production costs only if it could raise a revenue by charging user fees to consumers. Such charges would obviously cause some potential user to forego consumption, thus causing a loss in efficiency.

The main obstacle to charging user fees resides in the non-excludability property of public goods. If potential users cannot be excluded from consumption, then private sellers are unable to use prices to finance production. The only alternative available is to rely on voluntary contributions by users, and this will be unlikely to provide the efficient amount of public goods. Free riding, in fact, will always be an option: to enjoy the good no matter whether or not a person contributed to it.

3. Efficient Provision of Public Goods

With private goods consumers decide what quantity to buy for any given market price. Individual demand curves show the willingness to pay for any quantity of the good and the market demand is found by horizontally adding the individual demand curves, determining for each price level the total quantity requested by the market.

With public goods, on the other hand, there is only one level of output and consumers are willing to pay different prices for each level. Therefore, the market demand for a public good is found by vertically adding all the individual demand curves. For each potential level of public good output, the market demand reveals the total amount that consumers are willing to pay. An efficient allocation would then require producing the public good as long as society's total willingness to pay for it is greater than the marginal cost of producing the good. This is the so-called Samuelsonian condition, stating that an allocation will be efficient if the sum of marginal benefits from the public good equals the marginal cost of providing it. The intuition behind this condition is straightforward: since the benefits from a public good are not exclusive to any individual, the marginal benefit is obtained by summing each person's willingness to pay, or marginal valuation, over all individuals.

4. Lindahl Prices

The Lindahl pricing system (after the Swedish economist who first proposed it) suggests a pricing system according to which "prices" for a public good are set so that each individual pays a price equal to the marginal benefit he/she derives from the public good. Lindahl "prices" are personalized prices. Even though consumers are all consuming the same quantity of a public good, they all enjoy the good differently and are willing to pay different amounts. With private goods, individuals all face the same price for the good, and choose the quantity they wish to consume, and these quantities differ among individuals. With a pure public good the opposite situation arises: everyone consumes the same quantity of the public good, but individuals' "prices" are different. While the price of a private good is the price that people actually face in the market, Lindahl prices are hypothetical prices and this explains the quotation marks. They are the prices that individuals would be willing to pay for an additional unit of the public good. The main advantage of Lindahl prices is that when they are charged, every individual prefers and demands the same level of output for the public good, and such a level of output is the efficient one.

The Lindahl pricing system, however, has a number of drawbacks. The main one is the lack of relevant information to actually calculate the prices. To implement Lindahl prices, in fact, one must know the individual's demand curves for the public good. As we have argued above, individuals in general lack the proper incentives to reveal their preferences toward public goods, and this makes the calculation of Lindahl prices a difficult undertaking.

5. Government Provision of Public Goods

All societies face the problem of providing public goods. Individuals are better off if all participate in to the provision of public goods rather than if all choose not to do so, but each individual at the same time is better off if she alone does not pay for the public good. For these reasons, public goods are of particular interest to public policy makers because they tend to be inefficiently provided by the market or by private arrangements.

Government production of a public good has a main advantage, because a government can impose taxes and fees to pay for the public good. Still, the main problem of deciding the optimal level of public good production remains. To determine it, the government would need to know its citizens' preferences. However, as we have previously argued, since exclusion is not possible, nothing forces citizens to reveal their true preferences. Furthermore, citizens are not willing to reveal their willingness to pay for the public good if the actual payment they will be assessed depends in some way on their reported willingness to pay. Mechanisms have been designed to induce true preference revelation under specified conditions and to attain an efficient provision of public goods. For instance, the Clarke (1971) demand revealing mechanism is one of such mechanisms. It has been defined by Tideman and Tullock as "a new and superior process for making collective choices" (Tideman and Tullock, 1976). These mechanisms, however, are subject

to the same criticisms as the Lindahl prices, particularly concerning their practicality.

Societies have dealt with government provision of public goods in different ways: a dictator may choose for the people, a representative political body may represent people's preference, or citizens may vote directly. Voting is a common way to decide the allocation problem, whether people vote directly on local public goods issues or vote to elect representatives who will in turn decide about the public goods. Most voting contests are decided according to majority rule voting. Under majority rule, the level of spending chosen will be the one preferred by the median voter, though not necessarily the efficient level.

Often, when economists think about the market failure caused by public goods they concentrate on the fairness issue of some individuals having to pay for the consumption of others. The far more serious issue regarding public goods, however, is not that few individuals have to pay for somebody else's consumption, but that not enough individuals pay and the public goods are not provided at all, even though it would be socially beneficial to do so. Hence, societies often must rely on governments to provide public goods, if not by producing them, then at least by paying for their production with tax revenues.

PUBLIC SCHOOLS

State and local governments spend more on the primary and secondary public school system than on any other government function. Its critical role in the development of skills is noted in numerous state supreme court rulings on the constitutionality of public school finance systems. Public school systems also have provided an important laboratory for testing various theories that have been developed in public choice. PUBLIC SCHOOLS

One of the first major contributions of public choice was the recognition of the key role played by the median voter. Pioneering empirical studies of the demand for government services replaced the mean income measure used in earlier public finance studies with median income. Subsequently others have realized that the median voter need not have the jurisdiction's median income. To take an important example, the distribution of preferred spending levels for public schools depends on how many families send their children to private school. Some of the community's richest families utilize a private school to obtain the school quality they prefer, which is higher than the school quality chosen by the median voter. Having chosen private school, these parents are best off minimizing their tax burden, and consequently voting for low public school spending. A coalition of poor parents and private school parents thus favor low spending, implying that the median voter has an income that is less than median income. Romer and Rosenthal (1982) searched over the income distribution to see which decile best explained school spending. They got the best fits using the fourth decile income and the fifth decile income (i.e., median income), with the fourth decile income providing a slightly better fit than the median income. This suggests that the median voter has an income that is a little lower than median income, perhaps due to private school parents aligning themselves with poorer families.

We have concluded that relatively rich parents turn to private schools when public schools do not provide the quality these parents desire. Thus the demand for private school is expected to be greater when the typical school district has a larger fraction of families making much more than median voter. This hypothesis receives empirical support in studies by Hamilton and Macauley (1991), and by Schmidt (1992). To provide a more equitable education, some state governments have made it harder for rich school districts to provide the quality of schooling their voters demand. As expected, Husted and Kenny (2002) find that private school enrollment has risen in the relatively affluent metropolitan areas in states that have limited the variation in school spending across school districts.

The price facing the median voter depends on the distribution of income in the community. Lovell (1975, 1978) showed that if taxes are proportional to income then the price facing the median voter is proportional to the ratio of the median voter's income to mean income in the jurisdiction. In a Tiebout (1956) world, where households sort into communities providing their preferred spending levels, communities are homogeneous and thus the ratio of median to mean income equals one. In a more typical setting with imperfect sorting and the distribution of income skewed toward the

rich, the ratio of median to mean income is less than one. This ratio is smaller in communities with more *relatively* rich households to tax to help pay for the median voter's government services. That is, the price of government services facing the median voter is lower if there is a greater subsidy resulting from the higher taxes levied on richer households. Lovell (1978) explains spending in Connecticut school districts. He finds support for the prediction that a fall in the price of schooling, measured by ratio of median income to mean income, leads to higher spending.

The median voter theory implies that the pivotal median voter's preferences will be reflected in spending decisions. But there has been concern that the institutional structure of spending referenda may allow budget maximizing bureaucrats to induce the median voter to spend more than that voter would prefer. Romer and Rosenthal (1978, 1979, 1982) hypothesize that these bureaucrats take advantage of a low reversion budget to obtain approval for a budget that is slightly more preferred than the reversion budget and is higher than the median voter's preferred budget. Utilizing the larger K-12 school districts in Oregon that approved a school budget in 1971-72, Romer and Rosenthal (1982) find that minimum-spending reversion levels result in higher spending levels, which is consistent with their theory. On the other hand, increases in the reversion level above this minimum level are associated with higher spending, contrary to their prediction. Holcombe (1980) utilized school referenda results from Michigan to compare the level of school expenditures chosen in school spending elections with that preferred by the median voter. Utilizing a referendum's proposed and reversion spending levels, the fraction of voters supporting the proposed spending level, and estimates of the dispersion of preferred spending levels, he is able to estimate the median preferred spending level under the assumption that the distribution is normal. On average, actual spending is 2.4 percent less than that preferred by the median voter. Munley (1984) gets very similar results using school spending referenda in New York. This research suggests that the median voter is getting the budget that he prefers and is not being induced to approve a higher level of spending, which would appeal to budget maximizing school bureaucrats.

On the other hand, there is some evidence that school boards often select a date for a school spending referendum that favors higher spending. In general elections, federal and state races are being decided. Turnout is much lower in special school elections, in which little else is decided. Special school elections tend to be dominated by parents and teachers, who have more at stake in the outcome. Not surprisingly, Pecquet et al. (1996) find that there is more support for higher spending in special elections. School boards

appear to recognize the benefit from getting a favorable mix of voters. Dunne et al. (1997) report that only 5 percent of school spending referenda in Oklahoma are scheduled for the same date as the general election, and only 3 percent take place in the summer, when it is harder to reach parents. Dunne et al. also examine the selection of school bond election dates in twenty states in which school boards can set the election date. The timing of school board elections plays a crucial role in this decision. School boards elected in general elections tend to set school bond elections for general elections, and school boards elected in special elections tend to choose special elections for bond elections. In each case, the school board is picking an electoral setting that would be preferred by the voters who selected the school board. Thus scheduling school board elections as special elections results in excessive school spending.

The incentives that voters have to vote and to gather information about elected officials and the performance of government agencies are quite limited. But this monitoring of elected officials and of government agencies is crucial to the development of strong incentives for elected officials to do what voters wish and for government agencies to be efficient. A number of state supreme courts have ruled that the state system of education finance was unconstitutional because it was inequitable. The Serrano ruling in California, for example, permitted very little variation in spending across school districts. Furthermore, some state legislatures, perhaps anticipating an adverse ruling from the court, restructured the education finance system to reduce the inequality in school spending across school districts. These changes give school districts less latitude in determining educational spending. As a result, voters have less at stake in school board elections and in school spending referenda and are expected to devote less effort to monitoring school district performance, resulting in less efficient schools. Consistent with this reasoning, Husted and Kenny (2000) find that a representative drop in spending inequality caused average SAT scores to fall by 4 to 21 points, holding various school and parental inputs constant. Reducing voter autonomy in school decisions thus appears to make schools less efficient.

Comparison across jurisdictions helps voters monitor governmental performance, and competition among jurisdictions may force governments to be more efficient. Zanzig (1997) found that public school efficiency increased as the number of school districts per county rose from 1 to approximately 4. Further increases in the number of school districts had no effect on school efficiency, implying that only 4 districts are needed to reap the full benefits of competition among school districts. A lack of competition raises the cost of education, which should lead to higher spending. Kenny and Schmidt (1994) conclude that spending is 12 percent higher, other things equal, in states with little competition among school districts. The effects of reduced efficiency and excessive spending are especially pronounced in Hawaii, with a state-wide school district, and in states with countywide school districts (Florida, Louisiana, Maryland, Nevada, Virginia, West Virginia).

These studies of public schools have provided valuable evidence on public choice theories. Families with slightly less than median income appear to be decisive voters in the determination of school spending, perhaps because private school parents are joining with poor families in voting for lower spending levels. Rich parents choose private schooling when the public schooling districts are not sufficiently homogeneous or when rich districts are constrained in raising school quality. Public school spending is higher when the median voter can tax richer families to help pay for better schools. Although the evidence suggests that the median voter is getting his preferred school spending, school boards sometimes manipulate the identity of the median voter; utilizing special school elections instead of general elections results in a median voter who views higher school spending more favorably. Schools become more efficient when school districts have more autonomy, giving families a greater benefit from political participation, and when there is competition between school districts, which facilitates comparison of district performance.

PUBLIC UTILITY REGULATION

Public utility regulation originates from the problem of natural monopoly. Where there are overwhelming scale economies as in the case of public utilities, traditionally, electric, gas, water and telephone, the cost to society is arguably minimized by having one supplier. The problem with one supplier is that it allows for monopoly exploitation with the resulting efficiency losses from monopoly. The Marshallian Triangle ABC in Figure 1 is the efficiency loss and the rectangle EAB"F is the monopoly exploitation. The latter is also the monopoly profits and constitutes a transfer from consumers to the monopolist. As such it is not an efficiency loss. However, following Tullock's (1967) insight on rent seeking, this rectangle is much more important to the process of natural monopoly regulation. It consists of the rents from monopoly and, indeed, will normally be much larger than the triangle. Indeed, it becomes the principal bone of contention in the regulatory process and the quest for these monopoly rents is the main driver of the process and is critical to understanding the process.

The first problem of regulation is an old one involving second-best issues. If regulation set price at C where the allocative efficiency losses ABC were totally eliminated the firm would not cover its fixed costs and would either have to go out of business or recover them by some form of lump-sum subsidy. Here is the source of the rent-seeking dilemma. Regulation has to find a way of covering the firm's costs. It would traditionally do this by moving to the second best optimum of C', which provides an efficiency gain of AB'C' and the monopoly rents are all taken by consumers. This second-best optimum effectively recognizes that the maximum gain of ABC is not attainable.

For many years this simple view of the regulation of natural monopoly was rather generally accepted with few exceptions (Averch and Johnson, 1961; Posner, 1969, 1974). This is evidenced by the fact that prior to the 1980s there were two dominant forms of natural monopoly regulation, viz. public enterprise (PE), and cost-of-service or rate-of-return regulation (ROR). PE was the predominant form of regulation in most of Europe and ROR predominated in North America. During the 1970s and 80s a change took place in the views of economists with the result that increasingly these regulatory institutions were the subject of greater criticism and in the 80s a new form of regulation, incentive regulation or price-cap regulation (PCR) became increasingly important. This was spawned by political changes in United Kingdom with the election of Margaret Thatcher in 1979 and her program of privatization of public enterprise. Along with privatization, changes in regulation were required. Stephen Littlechild (1983), a long time critic of ROR, proposed PCR for British Telecom, the former Post Office Telephones and PCR spread to other public utilities in the United Kingdom Meanwhile, theorists - most notable being Jean-Jacques

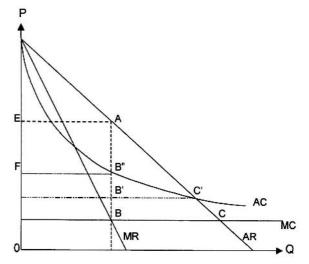

Figure 1: The welfare cost of monopoly.

Laffont and Jean Tirole (1993) — developed elegant mechanism design theories of incentive regulation. In the 80s incentive regulation came alive. However, by the mid 90s the façade of incentive regulation started to crack and hybrid systems known as performance-based regulation (PBR) appeared on the scene. What was it that Littlechild and most economists found so problematical about ROR and why did regulatory practice partially turn against PCR?

The feature of ROR that most offended economists was that it coupled revenue and cost together. The firm earned revenue by demonstrating that its costs were at a particular level and its regulators then allowed revenues based on the proof of these costs. Thus, revenue directly depended on costs. The greater its costs the greater the revenue allowed. Given the asymmetry of information about the firm's costs it was very difficult for a regulator to determine whether the firm's costs were minimized. The firm was able to take some of the monopoly rents in the form of higher costs entirely consistent with the much earlier notion of J.R. Hicks (1935) that the "quiet life" was the "best of all monopoly profits." It was this internal inefficiency or X-inefficiency that was at the root of most economists' distaste for ROR and PCR was an attempt to overcome these inefficiencies.

PCR, by setting price, broke the link with costs and provided incentives for internal efficiency absent under ROR. In terms of the Figure 1 it created a discontinuity in the firm's marginal revenue curve. Unfortunately, PCR offered no free lunch as readily became apparent in theory and practice. Laffont and Tirole's exploration of information asymmetries provides a very clear basis for understanding why PCR might be extremely problematical in practice. This can be seen from examining their assumptions and realizing that they are extremely unlikely to be met in practice. They assumed that the firm's costs were known accurately only to the firm but that both the firm and the regulator had common knowledge of the probability distribution of costs, i.e., of the likelihood that the regulated firm's actual costs were at various levels. Under these circumstances they were able to show that the firm would operate in a least-cost manner provided it was able to appropriate the rents attributable to its information advantage and (emphasis added) provided the regulator allowed it to continue to retain these rents. They showed that if a regulator later changed his mind and attempted to appropriate these information rents that the firm would lose its incentives to operate at least cost. They dubbed this a failure of commitment. But, as history has demonstrated, regulators simply cannot promise to leave rents on the table, whether or not this might be theoretically justified. Thus, in practice, under PCR, regulatory commitment and

reneging was a significant problem. When the firm made significant profits, regulators adjusted PCR parameters to appropriate them. When the firm showed signs of approach financial distress, regulators relaxed the PCR regime. The required theoretical commitment of the regulator to a stable regime was not in evidence in practice, with the end result that PCR has been difficult to implement in practice. Thus, Laffont and Tirole's contribution has been to indicate the importance of information rents in regulation and their framework has turned out to provide effectively an impossibility theorem for the direct application of PCR, since real regulators are not able to comply with the commitment requirements theoretically required for PCR to work.

In the United States PCR was rarely embraced so enthusiastically as it was in Europe. Could it be that years of regulatory practice had bred a concern about the regulator's congenital inability to commit? Put more gently, there was a long established practice in regulation of pragmatism or "working things" out as you go along. Goldberg (1976) argued that regulation should be seen as a complicated form of contract for which all eventualities could not be specified and saw the regulator as the intermediary between consumers and the firm to address problems as unforeseen eventualities arose. An alternative argument developed from Tullock (1967) would see the regulator as a broker distributing the rents dependent on changes in the political equilibrium, as developed in Crew and Rowley (1988). Either interpretation is consistent with the way practice developed in the United States PBR is a hybrid of PCR and ROR. The firm's ability to make profits is attenuated by a sharing rule, whereby above or below an upper and lower limit respectively the firm shares profits or losses respectively. This provides a process for attenuating the regulator's ability to take away what are perceived as excess profits by agreeing up front on a process for limiting the scope for excess profits on the upside and limiting the exposure faced by the firm for losses on the downside. Clearly, incentives for X-efficiency are weakened in the process but this may be the best that it is achievable now given the state of technology in regulatory economics today.

This brief sketch notes the two predominant forms of regulation in the past: rule-based and regulator-based. Rule-based regulation, like pure PCR, is intended to bind the hands of the regulatory agency to a formula, on which the regulated firm can rely in its future planning. Regulator-based regulation may have some overriding principles, typically set in place by authorizing statutes, but it is intended to leave considerable judgment to the regulator(s) in determining policies and outcomes going forward. Where is the future of regulation of network industries, the traditional public utilities, likely to lie? The steady progress of new technologies may erode economies of scale and scope sufficiently so that regulation will just fade away, the Posnerian vision. A major hurdle to this, of course, are rent-seeking strategies of incumbents and their supporters. At present, it seems likely that regulated utilities will be with us for at least a few more years. Given the rents at stake, the most likely form of regulation will likely continue to be regulator-based, building on some forum, like state and federal commissions, that provides a semiopaque process for dividing these rents, while providing a modicum of protection for small consumers with no other options against monopoly exploitation. This sort of regulation may seem a lame approach to the problem, and the regulator in this approach may be subject to capture by one or another of the contending protagonists to the regulation game, as in Stigler (1971) and Peltzman (1976). However, it does at least provide for a managed resolution of the continuing contingencies that arise when society attempts to control or influence economic organizations through regulation. Notwithstanding a number of promising experiments over the past century, and some progress in understanding the incentives engendered by regulation, such regulator-based governance structures seem likely to remain the vehicle of choice for "public utility" regulation.

R

RATIONAL CHOICE APPROACHES TO ECONOMIC AND POLITICAL HISTORY

Douglass North, Mancur Olson and William Riker have each, in their various ways, attempted to develop "rational choice" approaches to the evolution of society.

North's approach is perhaps the most wide-ranging. Work with Thomas (North and Thomas, 1973, 1977) attempted an economic explanation of the transition from hunter/gatherer societies to agriculture. Later, he proposed a "neoclassical theory of the state", wherein "Leviathan" contracts to set up a system of property rights and taxes (North, 1981). His later work has focused on institutions, and how they change as a result of incentives, knowledge and beliefs (North, 1990, 1994). One of his most persuasive pieces is his work with Weingast (North and Weingast, 1989) on the Glorious Revolution in 1688 in Britain, and how this transformed Britain's ability to manage debt, fight wars (particularly with France), and develop an empire.

Riker's earliest work was on American Federalism, particularly the logic underlying the need for Union in 1787 (Riker, 1953, 1964) and the stability of parties as coalitions (Riker, 1962). After working for a number of years on rational choice theory (Riker and Ordeshook, 1973), Riker returned to American political history, to interpret key events in terms of heresthetics (see "Heresthetics and the Evolution of the U.S. Constitution": this Encyclopedia).

Much of Olson's work has attempted to grapple with understanding how some societies are successful and others much less so. In his early book, Olson (1965) used the idea of the prisoner's dilemma to suggest that cooperation may fail, as individuals pursue their selfish ends (by strikes, revolutions, etc.) and indirectly constrain economic growth. Later, Olson (1982) used this argument to provide a "declinist" explanation of why stable democracies such as Britain and the U.S. appeared less vital (in the 1980s) than the newer democracies of the post World War II era (such as France, Germany, Japan, etc.). Olson's argument at that time had some similarities with an historical one put forward by Paul Kennedy (1987). Based on the evidence from the "decline" of Spain after 1600, of France after 1815, and of Britain after 1945, Kennedy suggested that empires tended to engage in military adventures, at great cost, eventually

weakening their own economic structure. The U.S., in 1987, appeared, to Kennedy, to be just such a declining military power. In fact, in 1990, U.S. military expenditure accounted for about 5% of GNP and 20% of government expenditure, while the parallel shares for the Soviet Union were 10% and 43% respectively. Olson's last book published posthumously (Olson, 2000) attempted an account of how the predatory state apparatus of the Soviet Union could induce relatively rapid industrial growth in its initial phase, and then collapse as abruptly as it did in the 1990s.

One way to attempt an integration of these various analyses of economic history is to use the idea of factor coalitions. Rogowski (1989) has used the notion, from economic theory, that there can be assumed to be three factors of production: land, labor and capital. External and internal features may grant advantages to particular coalitions of these factor "interests." For example, the U.S. in the late 1700s could be characterized as abundant in land, with both labor and capital relatively scarce. Principal imports were manufacturers, intensive in capital and skilled labor. Thus protection in the form of tariffs would necessarily benefit capital and "industrial labor." In contrast, since land was abundant, this economic interest, together with agricultural labor, would benefit from free trade. Consequentially, the political conflict between the commercial Federalist Party and the agrarian Jeffersonian Republicans, at the election of 1800, can be interpreted in factor terms. However, some of the elements of this controversy can only be understood with respect to earlier factor conflicts in Britain, from 1688 on.

North and Weingast (1989) had argued that the creation of the Bank of England in 1693 provided a method of imposing credible commitment on Parliament. The dilemma facing any government of that time was that war had become more expensive than government revenue could cover. Consequently, governments, or monarchs, became increasingly indebted. Risk-preferring, or warloving, monarchs, such as Philip II of Spain or Louis XIV of France, were obliged to borrow. As their debt increased, they were forced into repudiation, thus making it more difficult in the future to borrow. Since the Bank of England "managed" the debt in Britain after 1693, there was an incentive for Parliament to accept the necessary taxation, and also to avoid repudiation. However, it was clear in 1688 that William would pursue the war with France with great vigor and cost. Contrary to the argument of North and Weingast, this escalating debt could, in fact, force Parliament to repudiation. Until 1720, it was not obvious how Parliament could be forced to commit to fiscal responsibility. How this was done was through the brilliant strategy of Robert Walpole, first "prime" minister.

The fundamental problem was that the majority of members of both Commons and Lords were of the landed interest. The obvious method of funding government debt (which had risen to 36 million pounds sterling by 1713) was by a land tax. Indeed the land tax raised approximately 50% of revenue. War weariness had brought in a Tory government in 1710, and the obvious disinclination of the Tory landed gentry to pay increasing land taxes forced up the interest rate on long term government debt from 6% to 10% (Stasavage, 2002). In some desperation the government created the South Sea Company in 1711. After Queen Anne died in 1714, and the Hanoverian, George I, became sovereign, increasing speculation in South Sea Company stock and then the collapse of the "bubble" in September 1720, almost bankrupted the government. Walpole stabilized confidence in the Company by a swap arrangement with the Bank of England. In April 1721, Walpole, now Chancellor of the Exchequer and First Lord of the Treasury, began his scheme to stabilize government debt by instituting a complex system of customs and excise. By restricting imports, mostly foodstuffs and land intensive commodities, this system had the effect of supporting the price of the scarce commodity, land. From 1721 to 1740, these excise taxes and customs raised an increasing share of government revenue. As Brewer (1988) has described, the system required a sophisticated and skilled bureaucracy. The Walpole device had many effects. Firstly, it ushered in a long period of Whig dominance (at least until the 1800s). Protection of land remained in place until the Repeal of the Corn Laws in May 1846. As McLean (2001) has described, the Repeal was effected by Robert Peel, leader of the Tories (or conservatives), together with Wellington in the Lords, against the interests of the majority of their party. Famine in Ireland made it obvious to Peel and Wellington that unless food prices were lowered then social unrest could lead to civil strife. The Walpole "bargain" of 1721 essentially created a compact between the "commercial" Whig interests and both Whig and Tory "landed" interests. By supporting land prices, the bargain led to increased investment in agriculture, and (possibly counter-intuitively) the decline of the agricultural labor force. Increased food prices may have reduced the real wage of industrial labor (Floud and McClosky, 1994).

Although agricultural output increased in Britain, the population grew even more rapidly, and Britain became increasingly defendant on food imports, particularly from the U.S.

Jefferson was well aware of the implications of the Walpole bargain. His reading of the works of Henry St. John, Viscount Bolingbroke, led him to believe that the land–capital bargain led to corruption, and the filling of Parliament by placemen. In fact, Bolingbroke's arguments against Walpole were, to some degree, invalid, since the compact did make it possible for Britain to manage its debt, fight its wars, and create an empire. Bolinbroke's logic was, however, valid for the U.S. Hamilton's attempt in 1793 to recreate a Walpole system would have necessitated both a land tax and a tariff system. Since U.S. imports were primarily manufactures, a tariff would protect the scarce factor, capital, associated with these imports. In Jefferson's view, this would have disadvantaged the landed interest. By creating an agrarian coalition, essentially of the southern slave-owning landed interest, and western free farmers, Jefferson created a long-lasting compact under which the U.S. became the food supplier for Britain. Just as the Walpole compact persisted until 1846, so did Jefferson's agrarian coalition survive until 1860. At that point, the southern demand for expansion to the Pacific destroyed the Jeffersonian-Jacksonian Democracy.

The aftermath of the Civil War created a new coalition, of commercial interests and industrial labor, as represented by the presidential victory of the Republican, McKinley, over the populist Democrat, William Jennings Bryan in 1896.

From this perspective, U.S. politics in the period 1896–1956 can be interpreted in terms of a single factor dimension, capital, since we can regard the interest of land to be generally, in opposition to capital. Thus in the 1930s, the inclination of Republicans for the preservation of a hard money or gold standard rule was in opposition to the need for available credit in the agricultural sector.

In the 1960s, agitation for greater civil rights brought the labor axis into prominence. L.B. Johnson's positioning on this axis contributed to his great electoral victory in 1964, but also opened the way for the Republican Party to adopt an increasingly conservative social position and gain political control in the southern states (Miller and Schofield, 2002).

In Britain, since 1846, all these factors have played a role at various times. For example, McLean (2002) has observed that the success of the Reform Bill, under the Conservative, Disraeli, in 1867, depended on beliefs about Empire. For industrial labor, "Empire" meant the opportunities for emigration and a better life in the Dominions of America, Canada and South Africa. By using the rhetoric of "Empire", the conservatives could hope to appeal to working class voters. In fact, such rhetoric was an important aspect of Thatcher's electoral success in the 1980s. Indeed, recent empirical analysis of electoral beliefs in Britain (Martin et al., 2002) make it clear that in addition to the usual economic (or "capital") axis, it is necessary to employ a second "social" axis. This axis incorporates "civil rights," but is also characterized by attitudes to European Union. Conservative MPs' responses to a questionairre on this topic suggests that they are strongly opposed to the incorporation of Britain within the European Union. In other words, political beliefs, that were founded on an economic rationale dating back over a hundred years, are still relevant, in a somewhat different form, today.

This narrative suggests that preferences, or interests, on economic factors or dimensions, play an important role in political decisions. However, the manner in which these interests are transformed into beliefs is, to a considerable degree, still a matter of conjecture. Indeed, how these beliefs take political expression seemingly depends on the perception and strategies of political leaders such as Walpole, Peele, Disraeli, Jefferson, Lincoln or Johnson.

It has been a long standing controversy in rational choice theory whether political economy is best described by the concepts of "equilibrium" or "chaos" (Austen-Smith and Banks, 1998). In his later work, after 1980, Riker opted for chaos, and focused on key "contingent" events like the Ratification of the U.S. Constitution in 1788, or the onset of the Civil War in 1860–61.

The brief description of British and U.S. political history offered here suggests that there can be long periods during which political economic equilibrium is quite stable. However, equilibria can be destroyed and dramatically transformed at key historical periods, as described above. Denzau and North (1994) have adopted ideas from evolutionary theory in biology (Eldredge and Gould, 1972) and from the notion of "informational cascades" (Birhchandani et al., 1992) and proposed the concept of "punctuated social equilibrium." As they suggest, this idea is an analogue in the social realm of Kuhn's notion of scientific revolution (Kuhn, 1962). At least intuitively, the notion of "punctuated social equilibrium" would seem entirely relevant to the puzzle of the collapse of the Soviet Union that so intrigued Olson. Indeed, it is entirely possible that the apparent relative decline of the U.S. and Britain (which seemed so obvious to Olson in 1982 and Kennedy in 1987) has been reversed, as the underlying political economic equilibrium has been transformed in these two countries since 1980. Constructing a historically based theory of social, political and economic evolution to explain these phenomena is the task facing the next generation of scholars.

RATIONAL IGNORANCE

1. Theory

Information is a good like any other. The primary benefit of information is that it reduces the probability of acting on false beliefs; the primary cost is that acquiring information requires time. Basic microeconomics predicts that (ignoring risk-aversion) individuals acquire information up to the point where the expected marginal benefits equal the expected marginal costs (Stigler, 1961). Beyond that point, acquiring information becomes selfishly counterproductive; while you will avoid more mistakes, it is on balance cheaper to commit them.

A corollary is that if the marginal benefits of information are always zero, the rational economic decision is to be ignorant. If the market pays nothing for knowledge of ancient Egypt, there is no reason to spend time learning about it. In general terms, then, "rational ignorance" refers to any situation where individuals know little or nothing because the expected benefits of knowledge are negligible.

However, it has long been recognized that rational ignorance has far more empirical relevance in public choice than in other branches of economics. Why? Suppose that spending one more hour learning about politicians' voting records allows you to shift your vote to a candidate whose policies, if adopted, would be \$100 better for you. The *expected* marginal benefit of an hour of study is emphatically not \$100, but \$100 multiplied by the probability that you cast the decisive vote, tipping an otherwise deadlocked outcome. In virtually any real-world election, that probability will be essentially zero, implying an expected marginal benefit of zero as well (Olson, 1965; Downs, 1957).

The upshot is that imperfect information matters far more in politics than in markets. Consumers are not omniscient, but they have clear incentives to roughly figure out whether a piece of merchandise is worth the asking price. They are ignorant of details of the marketplace, not its basics. In contrast, voters' have no more incentive to study the *basics* of politics than they have to study the minutiae! Even if a person voted in a completely random manner, he could still enjoy personal comfort and security. A person who consumed in a completely random manner could not.

2. Evidence

At any rate, this is what the economics of information tells us. But do these predictions hold up empirically? Obviously they are not literally true. Everyone knows something about politics. Nevertheless, the empirical evidence on political knowledge reveals that citizens are ignorant to a shocking degree. Consider the following table showing the percentage of adult Americans aware of various elementary political facts.

Item	%
Know President's term is 4 years	94
Can name governor of home state	89
Can name vice president	78
Know which party has U.S. House majority	69
Know there are two U.S. senators per state	52
Can name their Congress member	46
Aware Bill of Rights is first ten amendments to	
U.S. Constitution	41
Can name both of their U.S. senators	39
Can name current U.S. secretary of state	34
Know term of U.S. House members is 2 years	30
Can name one of their state senators	28

Source: Dye and Zeigler, The Irony of Democracy (1996, p.132).

More comprehensive works (e.g. Delli Carpini and Keeter, 1996) are quite consistent with this outline; in fact, they show that knowledge of foreign affairs is even more limited. It is particularly striking that such a small percentage knows unchanging characteristics of the U.S. Constitutional structure like the number of senators each state has or the length of House members' terms. Without this knowledge, it is hard to see how voters could hold the politicians who represent them accountable for anything. Politicians' low level of name recognition is less surprising, but similarly disheartening: if voters are unable even to name their representatives, it is wishful thinking to imagine that they keep track of their voting records and reward or punish them accordingly in the next election. Politicians' party affiliations obviously simplifies this problem to some degree, but voter knowledge of the party to which secondtier politicians belong is also quite limited.

3. Consequences

One of the main themes of public choice is that democracy is paradoxically run for the benefit of "rent-seeking" special interests rather than the general public. Rational ignorance is at the root of most efforts to model this outcome. If voters have no idea what politicians are doing, then politicians can safely cater to the special interests who make it their business to closely follow whatever aspects of policy they depend on. This pattern often goes by the name of "concentrated benefits, diffuse costs." Each piece of special interest legislation takes only a few cents from the average voter, but provides millions for the special interests who back it. No voter, therefore, will bother to even learn of the existence of the legislation, but its beneficiaries may well employ a full-time staff of lobbyists to protect their livelihood (Olson, 1965; Weingast et al., 1981; Rowley et al., 1988; Magee et al., 1989).

A more complex account of the connection between rational ignorance and the predominance of special interests focuses on campaign contributions. Special interests can use their money to buy politicians' support. These politicians then use donations to pay for misleading political advertising. Precisely because voters are so uninformed, this misleading advertising is generally an effective way to get votes. In equilibrium, of course, politicians have to strike a balance between special interests and voter interests, but the less informed the voters are, the less their interests count (Grossman and Helpman, 1994).

4. Responses

The empirical evidence on voter ignorance is widely, though not universally, accepted. A minority of scholars maintain that "political IQ" tests understate the true competence of the individual voter (Popkin, 1991; Lupia and McCubbins, 1998). The most effective critiques of the standard analysis, however, concede voters' severe ignorance, but maintain that even so, democracy works remarkably well.

The leading version of this argument is sometimes called "the miracle of aggregation" (Page and Shapiro, 1992; Wittman, 1995; Hoffman, 1998). Suppose that only 10% of voters are well-informed; they vote for the candidate who puts more weight on voter welfare. The remaining 90% are completely uninformed and vote by flipping a coin. Common sense says that this situation is hopeless. Basic statistics, however, implies that as the size of the electorate increases, the randomness of individual voters matters less and less. In percentage terms, errors tend to cancel each other out. In fact, for a reasonably large electorate, we can practically guarantee that in a two-party race, each candidate gets half of the uninformed vote. No matter what a candidate does, he gets at least 45% of the votes. To win, though, a candidate needs more; and the only way to get more is to court the informed voters. What fraction of the well-informed does a politician need to win? 51%. In other words, whichever candidate *the majority of well-informed voters prefers* wins the election, even though by assumption the well-informed are out-numbered 9:1.

A parallel argument holds for ignorance about policy. Suppose that most voters are ignorant about international economics. As long as this ignorance leads equal fractions of voters to over- or under-estimate the benefits of free trade, the equilibrium policy remains the same. Voter ignorance by itself therefore does not imply that protectionism prevails. As long as errors are random rather than systematic, and the electorate is large, an ignorant electorate acts "as if" it were fully informed.

This sort of reasoning is especially persuasive to economists because it is an obvious extension of the familiar rational expectations assumption. Most formal economic models routinely represent imperfect information as measurement error; they assume that individuals observe the "true value plus noise." In Akerlof's (1970) famous article on asymmetric information, for example, ignorant car buyers know the *average* value of used cars, but nothing about any particular car. From a rational expectations standpoint, systematic errors are by definition "irrational," a condition that most economists are unwilling to invoke.

Aside from the miracle of aggregation, another source of optimism in the face of voter ignorance emerges from the economics of crime (Becker, 1968). This literature suggests that politicians can be kept in check even if voter ignorance occasionally rises up to 100%. All that is necessary is that politicians have a strictly positive *probability* of being caught if they abuse the public trust. If so, voters have a simple way to deter abuses: over-punish whoever they catch. If a politician has a 1% chance of being caught taking a \$1 bribe, bribery has to be punished with far more than a \$1 fine. Voters could penalize wayward politicians for even minor infractions by throwing them out of office, demonizing them, or putting them in jail. This is not idle theorizing, either; a number of politicians have ruined their careers by saying the wrong word at the wrong time, or by misusing a trivial amount of official resources.

The "concentrated benefits, diffuse costs" story has also been specifically challenged. Perhaps if there were only a single program in the federal budget that fit this description, that program would survive indefinitely. But most economists concerned about programs with concentrated benefits and diffuse costs believe that they number in the thousands. If so, there is a simple way to get rid of them: set up some sort of omnibus repeal bill (Wittman, 1995). Bundle thousands of tiny affronts against the average taxpayer into one bill that pulls the plug on all of them. In this way, politicians could overcome the dilemma that no one program is big enough to attract voters' attention. Interestingly, after economists raised this theoretical possibility, U.S. politics provided a clear empirical illustration with the post-Cold War base closings bill.

Finally, even if one believes that voter ignorance remains a serious problem for democracy, it is important to carefully work through the direction of the effect. Rational ignorance has generally been thought to make government inefficiently large. But standard asymmetric information models actually predict the opposite (Breton and Wintrobe, 1982). In the Akerlof lemons model, to take the canonical example, informed sellers and uninformed buyers leads the used car market to shrink. The reason is that buyers realize that they are unable to judge product quality, and therefore become more reluctant to buy. In a parallel manner, if political insiders know more about program quality than voters, voters' rational response is, in effect, to say "When in doubt, vote no." In equilibrium, then, asymmetric political information tends to make government smaller, not bigger.

RATIONAL IRRATIONALITY

1. Puzzles for Rational Ignorance

Economists have long been aware of voters' rational ignorance. But the beliefs of many voters seem anomalous even taking their severe ignorance into account. Voters frequently have systematic biases rather than random errors. They underestimate the economic benefits of free trade, overestimate the percentage of the budget spent on welfare, and misinterpret low economic growth as absolute economic decline (Caplan, 2002; National Survey of Public Knowledge of Welfare Reform and the Federal Budget, 1995; Survey of Americans and Economists on the Economy, 1996). From a rational expectations standpoint, such systematic errors are by definition a sign of "irrationality" rather than ignorance. Even on less restrictive cognitive assumptions, the further beliefs diverge from the truth, the harder it becomes to interpret them as honest mistakes.

Another puzzle is that people are often *emotionally committed* to their political beliefs (Hoffer, 1951). They look at new evidence and empirical tests more as a threat than an opportunity to learn. The modern history of socialism provides a standard example: as evidence of its failures mounted, a large fraction of socialists refused to acknowledge not only its inadequacies, but true disasters such as the collectivization famines under Lenin, Stalin, Mao, and others. Similar mindsets are easy to find across the political spectrum. A new study finding that the Laffer curve peaks at a marginal rate of 90% would probably antagonize or even enrage conservative proponents of tax cuts, but is unlikely to make many conservatives rethink their views.

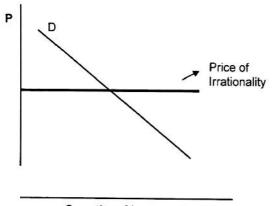

A related oddity about voters' beliefs is the extreme certainty with which many voters hold them. The basic economics of information predicts that the poorly informed will be open-minded. The less you know, the more you must recognize how many possible ways you could have gone wrong. In politics, though, extreme ignorance often co-exists with dogmatism. Passionate protectionists are rarely able to correctly explain the principle of comparative advantage, few fierce opponents of government spending are aware of the composition of the budget, and so on. As the saying goes, "Don't confuse me with the facts."

2. A Simple Model of Rational Irrationality

These are some of the reasons that led Caplan (2000, 2001c) to introduce the concept of *rational irrationality* as a rival to the better-known concept of rational ignorance. The standard analysis of rational ignorance indicates that when there are weak incentives to reach correct answers, individuals realize this fact and accordingly choose to gather little information. Caplan proposes that agents optimize along a second margin as well: their *degree of rationality* itself (Akerlof and Dickens, 1982). When there are weak incentives to reach correct answers, an otherwise intelligent person may opt to turn off his critical faculties and believe whatever makes him feel best.

If comforting beliefs are false, there is a obviously tradeoff between your beliefs' psychological benefits and your material well-being. The key assumption of rational irrationality is that agents on some level have rational expectations about this trade-off. Suppose for convenience that the trade-off is linear. Then like any other product, we can draw a demand curve showing the "quantity" of irrationality a consumer selects at any given "price" (Figure 1).

For example, a doctor may want to believe that he can perform surgery while drunk without additional risk, but

Quantity of Irrationality

Figure 1: The demand for irrationality.

this belief would have high expected material costs from law suits and loss of business. The same doctor could however vote on the basis of lame economic sophisms without fear of negative consequences. Since his vote is almost certain to have no effect on the outcome anyway, he could safely indulge irrational political beliefs at the ballot box even though he refrains from such cognitive excesses on the operating table.

In terms of Figure 1, the standard neoclassical assumption is that demand for irrationality is vertical at q = 0; that is, that individuals are fully rational regardless of the practical relevance of the question. Voters are as rational as consumers. But if we relax this polar assumption, there is a strong reason to expect people to become markedly *less* rational when they turn to political questions. If a consumer acts on the basis of irrational beliefs, he bears the full costs of the errors. If a citizen votes on the basis of irrational beliefs, in contrast, he bears only an infinitesimal fraction of the costs. In markets, rational expectations is a private good; in politics, it is a public good.

Like rational ignorance, rational irrationality is relevant to matters other than public choice. Caplan (2001c) suggests, in particular, that religious beliefs often fit the same basic pattern. Most religious adherents are highly certain of their religious beliefs, in spite of their unfamiliarity with rival doctrines. But in most cases, religions focus on questions with little practical relevance. Unless one wishes to be a professional biologist, for example, how you would hurt your career prospects by embracing creationism over evolution? Here again, then, people might retain irrational beliefs indefinitely because the material costs of error are minimal. In a sense, rational irrationality provides an economic account of the parallels between political ideology and religious faith emphasized so eloquently by Eric Hoffer in *The True Believer* (1951).

Rethinking political failure. Caplan (2001c) emphasizes that rational irrationality allows for a great many political failures that rational ignorance cannot sustain (Wittman, 1995). Rational irrationality can take many public choice intuitions about political failure and put them on a stable theoretical foundation.

Consider, for instance, the common argument that voter ignorance of international economics leads to protectionist policies. This story has been shot down on the grounds that purely random errors resulting from lack of information should cancel out. If voters are ignorant about international trade, leading some to overestimate the benefits of protectionism and others to underestimate them, there is no reason to expect the equilibrium platform to be biased in a protectionist direction. In contrast, if voters are rationally irrational, they could systematically tend to overestimate the benefits of protectionism, driven perhaps by xenophobia. Their systematic overestimate would in turn push the political system to adopt the protectionist policies that voters believe to be beneficial.

Indeed, such policies could in principle win *unanimous* support (Caplan, 2003). Suppose, following Becker (1958), that all voters have identical preferences and endowments. If protectionist policies prevail, each voter is \$1000 worse off than under free trade. But each voter gets \$10 of surplus from believing in the economic benefits of protectionism. Then a voter is better off holding this irrational view as long as -\$1000*p + \$10 > 0, where *p* is the probability of voter decisiveness (Brennan and Lomasky, 1993). As long as p < 1%, each and every voter will put his faith in protection and vote accordingly, leading to a per capita loss of \$990.

Critics of rational ignorance arguments point out, in addition, that voters have a variety of simple strategies for coping with their own ignorance. The most obvious is "When in doubt, vote no." When voters learn that a politician advocates programs of unknown quality, they could automatically count such advocacy against them. Admittedly, this argument sounds strange and forced. But why? A natural explanation is that voters' problem is irrationality rather than ignorance. In a sense, they want to be fooled. If they were buying a used car, they would apply extra caution to compensate for their own ignorance. When they vote, however, they rarely bother. They want to *believe* that new programs will make the world a better place. Questioning that assumption would disturb their worldview without significantly raising the probability that better programs prevail.

In many brands of public choice, special interests are presumed to be the driving force behind inefficient policy. What makes this approach problematic is that inefficient policies are frequently popular (Caplan, 2002, 2001a). The public pays little attention to the details of trade policy; but when they do hear about protectionist measures, they are usually supportive. The same goes for many of the policies economists question, from price controls to drug regulation. Rational irrationality provides a simple alternative account of political failure: The main cause is not special interests, but voters themselves. This hardly implies, however, that counter-productive policies are somehow efficient. Democracy creates a pervasive voter-on-voter externality. The fact that most individuals choose to pollute does not imply that laissez-faire delivers the socially optimal level of pollution. Similarly, the fact that most individuals vote in favor of a policy does not mean that democracy delivers socially optimal policy.

RECIPROCITY

The concept of reciprocity assumes peculiar importance in a world where there is no external authority to enforce agreements, that is, in a Hobbesian state of nature. In many game-theoretic situations, reciprocity permits the emergence and stability of cooperative outcomes, even in a lawless world when agreements between the players are not enforceable. Not surprisingly, the principles of reciprocity gain particular practical and historical importance in the field of international law, given the absence of an overarching legal authority with compulsory jurisdiction to enforce agreements. Reciprocity has effectively become a meta-rule for the law of nations, an essential principle for the practice of sovereign nations. Many structural similarities exist, in fact, between the emergence of legal rules in a lawless environment and the formative process of international law, including the lack of a supreme legislative body. The rules governing international relations are left to the spontaneous interaction of states (custom) or to contracts expressly entered into (treaties).

1. Reciprocity Constraints and the Rules of Social Interaction

Game theory is a useful tool for the study of the behavior of sovereign states, since it focuses on interactions where parties can determine only their own strategies and thus have no direct control of the outcome.

According to the theory of norms, there are two formative elements of spontaneous social rules: (1) the practice should emerge out of the spontaneous and uncoerced behavior of various members of a group, and (2) the parties involved must subjectively believe in the obligatory or necessary nature of the emerging practice (*opinio iuris*). The first element is essentially a rather standard assumption of rational choice, while the second element may be viewed as a belief of social obligation, emerging in response to game inefficiencies, in support of rules of behavior that avoid aggregate losses from strategic behavior.

While these elements represent two necessary conditions for the emergence of customary rules, they do not provide much information on the remaining conditions for the emergence of efficient custom. Some additional structural conditions for the emergence of spontaneous social rules are necessary, whenever the strategic conditions of the game are such that socially optimal outcomes are not achievable through Nash strategies.

The stylized settings considered below shed light on the more problematic cases of conflicting incentives with inconsistent individual preferences over alternative outcomes. In conditions of stochastic or induced symmetry, spontaneous processes of law formation may be successful even in the presence of originally misaligned individual interests of the Prisoners' Dilemma type and of the asymmetric Battle of the Sexes type.

1.1. The Ideal Setting: Structural Reciprocity (Perfect Incentive Alignment)

Perfect incentive alignment occurs when the parties' rankings of preferences converge toward a mutually desirable outcome. This condition implies that neither party has an incentive to defect unilaterally, nor has a reason to fear defection by the other party. Structurally symmetrical situations are relatively easily characterized by stable relationships of mutual cooperation. Because strategies that maximize individual expected payoffs also maximize group welfare, no one has any reason to challenge the emerging equilibrium.

The perfect alignment of interests can be induced either (i) endogenously or (ii) exogenously. The former case implies that the players naturally find themselves in such a heavenly relationship. The latter case implies that the parties have been able to overcome a conflict of interests through exogenous devices. Such is the case of an exchange supported by a perfect contract enforcement mechanism. Paradoxically, therefore, there is no need for law or norms in an environment already characterized by perfect incentive alignment, as contracts and social arrangements are self-enforcing.

The perfect alignment of individual interests, however, rarely occurs in real life situations. In the absence of proper enforcement mechanisms, even a Pareto improving exchange opportunity creates a temptation for shirking and *ex post* opportunism. When shirking and post-contractual opportunism becomes a dominant strategy for one or both players, the exploitation of opportunities for mutual exchange becomes difficult or unobtainable (Kronman, 1985). The absence or inadequacy of contract enforcement mechanisms leads to the search and eventual emergence of alternative safeguards.

The following discussion focuses on conditions of reciprocity and role-reversibility as alternatives to the above described structural harmony.

1.2. The Golden Rule: Induced Reciprocity (Symmetry Constraint)

Golden rules of reciprocity can be thought as the result of a successful binding of each player's strategy to that of his opponent. Automatic reciprocity of the golden-type creates a symmetry constraint on the players' strategies, producing an important change in the traditional results.

Unlike the atomistic world of non-strategic economics, suboptimal equilibria may emerge in a game theoretic setting because players are only allowed to choose strategies, and cannot single-handedly determine outcomes. Because of the potential accessibility of off-diagonal, non-cooperative outcomes, players are tempted to defect from optimal strategies, generating outcomes that are Pareto inferior for all (Buchanan, 1975).

By eliminating the accessibility of the asymmetric outcomes of the game, golden rules of reciprocity induce the parties to choose strategies after taking into account the effect of a reciprocal choice of the other player. In other words, golden-type reciprocity renders the reward for unilateral defection unobtainable. As a result, no rational player will employ defection strategies in the hope of obtaining higher payoffs from unilateral defection, nor will rational players be induced to select defection strategies as a merely defensive tactic. Automatic reciprocity mechanisms thus guarantee the destabilization of mutual defection strategies and the shift toward optimizing cooperation. Two figures will illustrate this point.

Figure 1 depicts the equilibrium obtained in the absence of a reciprocity constraint. Two players are faced with a cooperation problem. Strategies I, II, and III represent three levels of cooperation (with strategy I being the highest level and strategy III being the lowest). Even though mutual cooperation at level I generates the highest aggregate payoff, strategy III dominates in equilibrium, as it is shown by the Nash arrows for the two players. For a similar argument relying on tit-for-tat strategies in iterated games, see Axelrod (1981, 1984).

This equilibrium should be contrasted with the outcome induced by a reciprocity constraint as illustrated in Figure 2.

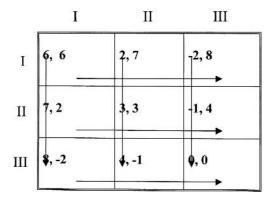

Figure 1: A cooperation problem without constraint.

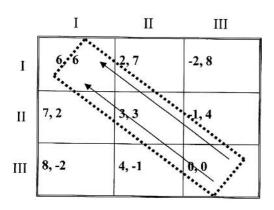

Figure 2: A cooperation problem with a reciprocity constraint.

Figure 2 shows the effect of a reciprocity constraint on the equilibrium obtained in Figure 1. By eliminating the accessibility of asymmetric outcomes, golden-type reciprocity compels the parties to take into account the effect of the opponent's reciprocal choice when selecting their optimal strategy. In this way, the dominance of strategy III obtained in Figure 1 is transformed in a dominance of strategy I, with optimal levels of cooperation for the two players.

Interestingly, where custom is recognized as a primary source of law, mechanisms of automatic reciprocity are generally regarded as meta-rules of the system. The so-called law of nations (the system that governs the relationship between states) serves as an example. The process of voluntary recognition of rules by sovereign states implies that, absent a commonly accepted standard of conduct, lawless freedom applies. Lawless environments are characterized by structural reciprocity. In its original form, custom emerges in the absence of an established legal system or commonly recognized rule of law.

Rules of reciprocity are among the oldest principles of customary law. In the absence of law, reciprocity implies that parties can do back to others what has been done to them, subject to the limits of their reciprocal strengths. Ancient customs of retaliation, based on conceptions of symmetry and punitive balance, provide an intriguing illustration of the principle of reciprocity at work. While practices of literal retaliation are formally discouraged, the principle of reciprocity is recognized as a crucial pillar for the process of international law formation.

Often, situations of post-contractual behavior capable of modifying states' obligations arise in the law and practice of international relations. The international law process provides states with numerous occasions for opportunistic behavior, including hold-out strategies and free-riding. Left unconstrained, states' unilateral defection strategies would dominate in equilibrium (Figure 1). For example, having signed a treaty, states may introduce unilateral reservations at the time of ratification. Standards of compliance in treaty implementation also rely heavily on the subsequent practice of states. The post-contractual behavior of states can shape and modify the content of an already finalized agreement, or even abrogate a treaty.

To cope with this reality, basic norms of reciprocity have emerged as international customary law. Art. 21(1)b of the 1969 Vienna Convention articulates an established custom of reciprocity, creating a mirror-image mechanism in the case of unilateral reservations: "Legal Effects of Reservations and of Objections to Reservations: A reservation established with regard to another party ... modifies those provisions to the same extent for that other party in its relations with the reserving state." The effects of this automatic reciprocity mechanism are similar to a tit-for-tat strategy without the need for active retaliation by states: whenever a treaty is modified unilaterally in favor of one state, the result will be as if all the other states had introduced an identical reservation against the reserving state. By imposing a symmetry constraint on the parties' choices, this rule offers a possible solution to Prisoners' Dilemma problems.

As an additional illustration, one can think of a voluntary contribution game between several people for the realization of a common project. If the benefits from the realized project are non-excludable, the various players are faced with a usual public good problem, with dominant free-riding strategies. As an application of a golden-type reciprocity constraint, imagine that the parties agree (and credibly commit) to a "lower denominator" matching grant solution. Every player agrees to contribute to the common cause an amount equal to the least of the other players' contributions. The players are now faced with a choice of strategy subject to a credible reciprocity constraint. By unilaterally defecting (i.e., offering a contribution of zero), each player can precipitate the failure of the joint enterprise. No player can obtain the unilateral defection (temptation) payoff, because by withholding or reducing the amount of his contribution, each player causes a mirrorimage revocation or reduction of the other players' contributions. Thus, although no player can unilaterally determine the success of the joint enterprise (because unanimous participation is necessary), each individual player can determine its failure. Under most circumstances, this arrangement is capable of preventing unilateral defection and free-riding strategies from dominating in equilibrium. The ability of each player to lower the minimum denominator in the group adds robustness to the cooperative solution in spite of the apparent fragility occasioned by the unilateral veto effect of the reciprocity rule.

As an important consideration, one should note that, while the principle of reciprocity solves conflict situations characterized by a Prisoners' Dilemma structure (in both symmetric and asymmetric cases), golden-type reciprocity is on its own incapable of correcting other strategic problems. When a conflict occurs along the diagonal possibilities of the game (such that the obtainable equilibria are already characterized by symmetric strategies), a reciprocity constraint will not alter the dynamic of the game. Reciprocity constraints are effective only where incentives for unilateral defection are present. This reciprocity will be ineffective for Battle of the Sexes games and unnecessary in the Inessential Game and Perfect Incentive Alignment cases.

1.3. The Silver Rule: Stochastic Reciprocity (Role Reversibility)

Silver-type reciprocity requires a stochastic symmetry in the relationship between two or more players. This stochastic symmetry could result from a random distribution of asymmetric payoffs in an iterated game or, more commonly, it could result from an alternation of roles among the various players.

Unlike golden-type reciprocity, silver-type reciprocity further necessitates a pre-commitment of each player to a meta-strategy for the entire duration of the play. That is to say, a player cannot adopt different strategies at different nodes of an iterated game, but must choose a strategy (be it pure or mixed) that he will unconditionally follow for entire duration of the supergame. Under such conditions, the optimal meta-strategy will be that which maximizes the present value of the expected flow of payoffs from the supergame. In situations of silver-type reciprocity with a relatively high probability of future interaction and a relatively low time preference, cooperative strategies will be more likely to dominate in equilibrium.

An important consideration in most analyses of spontaneous cooperation is the discount factor, which serves two purposes. First, it acts as a function of the players' time preference. Faced with very high time preference, players in a repeat game become less likely to give up part of their present payoff for an expected increase in the payoffs from future interactions. As time preference increases, the present discounted value of future payoffs decreases. Where time preference is infinite, payoffs from future interactions have zero value. Second, the discount factor is a function of the probability of future interactions. When the probability of future interactions is low, players are less likely to give up part of their present payoff for an expected increase in the payoffs from future iterations. As the probability of future interactions increases, so does the present expected value of cooperation.

One should further note that, unlike golden reciprocity, silver reciprocity does not in itself correct repeated Prisoners' Dilemma problems. Indeed, even if the players found themselves in such an iterated game, silver-type reciprocity would not alter the usual results obtained in the Chainstore paradox (Selten, 1978: 127–159) and the Folk theorem (Fudenberg and Maskin, 1986: 533–554). Conversely, silver-type reciprocity is capable of correcting other strategic problems that the golden-type rule cannot effectively address, such as the asymmetric Battle of the Sexes game.

The history of customary law provides illustrations of silver-type reciprocity at work. During the formative period of the medieval mercantile law, traveling merchants acted in the dual capacity of buyers and sellers in order to exploit price differentials between various medieval markets. In their commercial dealings they committed themselves to following a set of rules and customs that would govern all their future business transactions. This privately created body of law, known as the law merchant (lex mercatoria), applied indiscriminately to commercial contracts entered into by professional merchants, without possibility of a dual standard. If those rules were biased in their favor of merchants in their role as sellers, they would have the opposite effect when the same merchants acted as buyers, and vice-versa. In this setting, Fuller (1969) observed that frequent role changes fostered the emergence of mutually recognized and accepted duties in a society of economic traders: "By definition the members of such a society enter direct and voluntary relationships of exchange.... Finally economic traders frequently exchange roles, now selling now buying. The duties that arise out of their exchanges are therefore reversible, not only in theory but in practice" (Fuller, 1969: 24).

In this mercantile context, role reversibility changed an otherwise structurally asymmetrical situation (i.e., buyer v. seller) into one that was stochastically symmetrical, eliminating the temptation to articulate one-sided rules. The law merchant therefore illustrates a successful system of spontaneous and decentralized law.

The emergence of cooperative strategies for the supergame requires, as indicated above, an effective precommitment of the players to a single strategy (pure or mixed) to be followed for the entire duration of the game. This will ensure that the *ex ante* choice of a given rule will not be followed by an *ex post* breach of the rule, once the roles are reversed.

In real life, where relational rules are violated following role reversal, norms of social reprobation play a collateral yet crucial role in sanctioning case-by-case opportunism. Likewise, a merchant who invokes a particular rule when buying yet refuses to abide by the same rule when selling would be regarded as violating a basic norm of business conduct, and would suffer reputational costs within the business community. The group's ability to impose a sanction depends on the recordation of an individual's past behavior. Reputation serves as a source of collective knowledge regarding past actions (Benson, 1992: 5–7; Greif, 1989). Conditions of role reversibility, coupled with norms that generate disincentives for the adoption of opportunistic double standards, are therefore likely to generate optimal rules via spontaneous processes.

2. Conclusion: The Nature of Reciprocity

Reciprocity constraints of the golden type serve an important function when applied to simultaneous or sequential Prisoners' Dilemma games. At the origin of the problematic results of the Prisoners' Dilemma lies the fact that players cannot choose outcomes, but rather only select strategies. Outcomes are beyond the control of any individual player, generated instead by the combination of selected strategies.

Reciprocity constraints of the golden type eliminate this problematic feature of the game by preventing asymmetric combinations of strategies. Under a golden rule of reciprocity, players know that by selecting a strategy, they are actually determining the outcome of the game. The incentives for unilateral defection are eliminated because the reciprocity constraint would transform a situation of unilateral defection into one of mutual defection with reciprocal losses for both players.

Regarding the silver rule of reciprocity, one should think that, following the same optimization logic they employ for all economic choices, individuals choose among alternative rules of behavior. They are unlikely to reveal strategic preferences when individual interests are not aligned. Traditionally, such strategies are viewed as hindrances to the spontaneous emergence of cooperation. Strategic preference revelation has no effect in situations of role reversibility or stochastic symmetry (Parisi, 1996). Because the expected costs and benefits of alternative rules are the same for all members of the group, each member has the incentive to agree to a set of rules that benefits the entire group, thus maximizing his expected share of the wealth.

In long-term human interactions, reciprocity and closeknittedness provide individuals with an optimal set of incentives for choosing optimizing strategies. Recent analyses indicate that individual incentives are more likely to be aligned where the horizons of individual maximization are extended to include the payoffs from future interactions and there is a concern for the well-being of close members within the group. The presence of reciprocity constraints allows for a far more optimistic prediction of spontaneous order. This insight is consistent with the prediction of evolutionary models of social interaction, where low discount rates for future payoffs and the close-knittedness of the group are found to be positively correlated with the emergence of optimal social norms. These conclusions are qualitatively similar to those discussed above for the case of role reversibility. Repeat game situations with role reversibility, reciprocity constraints, and structural integration facilitate the emergence and recognition of rules of custom. In consideration of reciprocal constraints undertaken by the other members of the community, individuals who frequently exchange roles in their social interactions have incentives to constrain their behavior to conform to socially optimal

norms of conduct. An even stronger logic explains the emergence of cooperation in situations of induced reciprocity. In both cases, the non-idealistic and self-interested behavior of human actors is yet capable of generating optimal norms.

REDISTRIBUTIVE POLITICS 1

Most governments redistribute funds. Indeed it seems likely that a particular type of redistribution accounts for the original foundation of the institution of government. We have no direct records of government of the founding days, but it seems likely that an individual with a special talent for the use of violence decided that he would tax his neighbors instead of simply working for his income. Once the chief had established himself he would find it useful to create a certain number of public goods. He would object to competition whether from other tribesmen who want the property of others or from neighboring tribes. Thus establishing a police and court system to prevent competition from within the tribe, and military forces to prevent outside competition seems reasonable. Something in the way of a very simple road system would also pay from the standpoint of the tribal ruler.

Although this involves wealth going from one person to another without voluntary agreement on both sides, it is not what we normally mean by redistribution. Usually "redistribution" is nominally intended to help the worst off members of society. In fact, however, the government frequently uses its powers to increase the well-being of people or institutions already well-off. In this contribution, I use the word "redistribution" in a more general sense in which there is government movement of wealth from one person or group to another regardless of their initial wealth. If we examine political redistribution throughout history we find many cases in which the redistribution actually is from people who are poor to people who are much better off. The current American farm program is an example, and the tax support which the medieval church received is another. Of course there are some poor farmers and there were some poor monasteries. But most of the transfers until very recently went to people who were reasonably well off.

There is a further case in which redistribution does not seem to be aimed at supporting the poorest individuals. Citizens of most of the Western countries and the more prosperous of the Eastern countries like Japan and Singapore have much higher incomes than the citizens of countries like India and Bangladesh. The transfer of wealth from people who are perceived as wealthy in the United States to those perceived, as being poor in United States is a shift of wealth around among the top 20 percent of the world's population. Only a little wealth is redistributed from the citizens of the United States or Switzerland to the citizens of Uganda or Ethiopia. There does not seem to be any explanation for the actual patterns except simple nationalistic self-interest.

Until recently, I was a professor at the University of Arizona in Tucson. I knew many people mainly in the political science department who were very strongly in favor of taxing the wealthy in order to help the poor. In conversation I would point out that 100 miles south of Tucson there was an international border with Mexican incomes being very much lower than the incomes of people in United States who received such transfers. I never was given a rationalization for this pattern by these aggressive believers in income redistribution. In general they refused to discuss the matter. Since we are a country where speech and, in this case, silence are unregulated, there was nothing I could do to straighten the matter out. To repeat, vigorous self-interested nationalism is the only reasonable explanation.

The more wealthy nations do in fact transfer some money to citizens of the poor nations, but this is a small fraction of the money that they transfer to their own citizens they regard as poor by the standards of their own country. It is also true that the wealthier members of the population are taxed heavily, to the extent that they fail to avoid taxes. People, who are poor by American standards, even if wealthy by the standards of poor countries, receive some transfers which can be considered as payments from the rich. Lebergott's calculation of such transfers go back to 1830 and they show that the poor, unemployed or sufferers from other misfortunes did about as well from government relief in terms of share of national income as they do today.

The really big transfers in the modern welfare state, leaving aside such things as the farm programs, come by way of Prince Bismarck's invention, the Social Security programs. These are essentially compulsory insurance programs with a redistributive component. The average U.S. citizen pays approximately 15 percent of his income throughout his working career into the so-called social security trust fund. Prince Bismarck and Frankin Roosevelt were both brilliant politicians, albeit without many scruples. They believed correctly that they could fool the workers by collecting half of this directly from the workers and the other half by a tax on their employers. Of course the employers reduce the wages enough to pay the tax. Politically, however, the program worked very well. The workers are fooled so they vote for a program that they think costs them half as much as it does.

To clarify the matter for the United States, let us assume that instead of the tax and payment by the federal government, Congress had simply required that each citizen pay six percent of his income to a private insurance company of his choice for the purchase of an annuity for his old age. Further let us say that your employer is also required to pay six percent of the worker's wage to the same insurance company which will be added to the payments for his annuity. Note that I am ignoring the special provision for medical insurance for older people and some impoverished people. This is simply to make the example easy to follow.

Since the insurance company would invest the premiums in interest-bearing securities and would actuarially compute the number of its policyholders who would die, the return would be apparently considerably more than the return on the current Social Security payments. This of course is simply an example of another way of permitting the person paying in to get an investment return on his payments. In practice, however, over time average incomes rise as a result of technical progress. Congress has from time to time increased the tax payments and the pension to keep up. As a result, the average retired person gets a pension that is not too much below what he would get if his payments had been invested and the interest added to his pension.

This however is the average person. The pension was originally adjusted to the payments which had been made in, so that upper-income people received more money when they retired. This arrangement has been adjusted so as to provide for a limited transfer from upper-income people to lower income people. Still, it is not radically different from an arrangement under which individuals are required to purchase annuities. Thus this procedure is more a transfer for the individual from his youthful and middle age income to his retirement than from the rich to the poor.

There are however significant transfers and redistributions which are not in essence a redistribution of income over the life span of individuals. The farm program has already been mentioned and people who are unemployed or ill may receive significant payments. There are other cases of transfers. People in the military for example are underpaid while on active service and then receive generous pensions when they leave. They also have medical service provided free. Here again it is a transfer along the lifetime income stream without necessarily changing the total income over the life.

Why the transfer, however? Normally it is discussed as a sort of charity with the poor and elderly the beneficiaries. There is no doubt that this is part of the explanation. Most governments have transferred money to the poor almost regardless of the form of government. There are bioeconomic reasons why this may be true. Further, of course, religious considerations may be important and we may simply indoctrinate children with this preference. Statistics show voluntaty gifts to charity of 2 or 3%. But the fact remains that many of the transfers go to people who are not poor. I have mentioned the agricultural program, which is much worse in Europe and Japan than in United States. There are however many other programs which benefit particular enterprises or persons who are not poor.

It seems certain then that charitable motives are by no means the only reason for redistributive programs. In general there are three possible reasons for voting for transfers in a democracy. The first of these is charity and desire to help those who are not as well-off as the median voter. The second is simply the consequence of successful rent seeking. The third is a feeling that too much inequality is politically dangerous. In practice, although direct transfers to people who use their votes to get them are important, they are much smaller than the Bismarckian transfers which are normally referred to as the welfare state. The rapid growth of government expenditures in most democratic countries in the 20th century is mainly the result of these Bismarckian expenditures. Even here, it is likely that much of the political drive for these expenditures comes from the beneficiaries. As pointed out above the method of taxes used to support them is deliberately deceptive. In United States the so-called gray tigers are active in getting support and the program is referred to as the "third rail of American politics." A politician who touches it dies.

It is easy to argue in favor of charitable distributions to the worst off part of society. It is also easy to argue for transfers from the upper-income groups to fund them. Indeed the members of the upper income part of society may be in favor of such transfers, and indeed make many voluntary transfers. If the forceful transfers were repealed it is possible that the voluntary transfers from the wealthy would approximately make up for that. Most people do not want to try the experiment.

Looked at ex-ante the Bismarckian system for helping the old by transferring money through the Social Security system would not seem to the very sensible. People now drawing the pensions, did not however buy the type of insurance mentioned above in their younger days. Thus the younger people would have to continue supporting the existing older people so the burden on them would be high. It would only be in the next generation that there would be no net transfer between generations. There is also the fact that the age distribution of the population is changing, so that the number of young people per aged person is shrinking. The tax on the younger people per capita will have to be the sharply raised.

Still discontinuing the system would be painful. Apparently everybody over the age of 50 would lose if the program was simply abolished and those under that age would gain. Of course many of the people under 50 have parents who are drawing pensions and would find it desirable to supplement their parents income out of their own pockets if the pensions were repealed. Altogether the system we have although lacking any real justification, as an effort to help the poor or injure the wealthy appears to be politically invulnerable (Tullock, 1970, 1983, 1986, 1988).

REDISTRIBUTIVE POLITICS 2

All policies have distributive consequences, and redistributive motives drive a good deal of politics. There are many pathways for redistributive policy. Some of these work through labor markets (as in the wage setting institutions of some corporatist regimes), or regulation of products and prices, or provision of public services. This essay focuses, instead, on a type of explicit redistribution in democratic polities, *viz.*, policies that directly redistribute income among people through a system of taxes and transfers.

Much of the work on the positive theory of this kind of redistribution has relied on a "workhorse model" in which the parameters of a linear income tax function are chosen by majority rule (Romer, 1975; Roberts, 1977; Meltzer and Richard, 1981). People differ in their endowments or income-earning capacities. Taxes are levied in proportion to before-tax income, and are redistributed in the form of a lump-sum transfer ("demogrant") to everyone. Even though this appears to be a rather special kind of redistributive scheme, it is a good place to start, for several reasons. (1) It is the simplest framework that allows for progressivity, in the sense that average tax rates are increasing in income. The higher is the demogrant, the greater the progressivity and higher the degree to which income is redistributed. (2) Considerations such as incentive effects of taxes and transfers can readily be incorporated in the analysis. (3) The political problem can be reduced to one of choosing a single tax parameter: either the tax rate or, equivalently, the size of the demogrant. This makes the analytical problem of establishing voting equilibrium much easier than in settings with more policy dimensions.

In models of this type, the usual prediction is that the political equilibrium under majority rule will be the tax policy (or degree of redistribution) most preferred by the citizen with median before-tax income. For an interesting range of special cases, this result can be sharpened further to the following: For actual income distributions, the median is typically below the mean. This means that, for the pivotal voter, the "tax price" of a dollar of transfers is less than a dollar. The further away the median is from the mean, the lower is this tax price. The equilibrium level of redistribution will be decreasing in median before-tax income (for a given average before-tax income) and increasing in average before-tax income (for a given median). In other words, as the median before-tax income gets further from the average, the amount of politicallyenacted redistribution will increase. The ratio of median to mean income is one measure of income inequality: the lower this ratio, the greater the inequality. So the result can be interpreted to mean that, at least in democracies, we should expect to observe more redistribution where, *ceteris paribus*, there is greater inequality in before-tax distribution will be more equal when there is more before-tax inequality.)

An important point in connection with the above results is that they concern a majority-voting equilibrium. The segment of the population that does not vote - perhaps because they do not have the right to vote or because, for other reasons, their political importance is systematically very low - will not affect the collective choice. So the relevant distribution of income in the interpretation of the results is the distribution of income among the politically effective population. Increased political participation by low-income groups - due, for example, to extension of the franchise together with political mobilization - will lower the median before-tax income relative to the mean. This will increase the equilibrium level of redistribution. (Of course, there may be a considerable lag between the time of enfranchisement and the mobilization required to have an effect on policy.) On the other hand, holding the effective median before-tax income constant, a fall in the income of those below the median will lead to less redistribution.

Cross-country comparisons are fraught with difficulties, but recent work by Milanovic (2000) sheds some light on these hypotheses. He looked at data on factor incomes (before taxes and transfers) in 24 democracies over the period 1974-1997. He compared these with disposable incomes (after taxes and transfers). Unremarkably, the distribution of disposable income is generally more equal than that of factor income — evidence of the pervasiveness of redistribution in democracies. But, in addition, this reduction in inequality is greater in countries with higher beforetax inequality. This is consistent with the hypotheses of the basic model. At the same time, Milanovic's data also suggest that people in the middle of the factor-income distribution gain very little from redistribution. This implies that, overall, the pure majoritarian framework assumed by the median-voter setup may not be quite the right model of the political process.

The standard model has been elaborated in many ways. Here I will note only a few main issues that have attracted attention recently: multiple jurisdictions, uncertainty, and endogenous formation of beliefs about the incentive effects of redistribution.

One can consider redistributive politics when there are many jurisdictions, each of which can redistribute within its own borders. Bolton and Roland (1997) use the lineartax framework to examine how redistributive politics can affect the stability of federal arrangements. A majority of a region's residents may prefer to stay (or become) politically independent, rather than be subject to the transfers that would occur under the redistributive policy chosen by a unified government. Political support for secession in a region is more likely when there are significant interregional differences in income distribution and the efficiency gains from unification are relatively small. Such secession threats can sometimes be forestalled by adjustments in the redistributive policy of the central government. This may mean increasing redistribution to gain the support of lower-income regions; in other situations it may mean reducing redistribution in response to the political pressures of relatively high-income regions.

When people can move across jurisdictional boundaries, the incentive effects of taxes and transfers include locational decisions. Redistributive politics can induce sorting of households among jurisdictions. In a metropolitan area with many communities, this can be one of the sources of income stratification (i.e., clustering by income groups), even when people do not have a direct preference to live among others of similar incomes (Westhoff, 1977; Epple and Romer, 1991; Epple et al., 2001). This sorting, in turn, limits the extent of redistribution that can occur when taxing authority is decentralized.

Returning to the single-jurisdiction framework, incorporating uncertainty into the analysis can change some of the predictions of the standard model. (For a consideration of redistribution and uncertainty in a multi-jurisdiction framework, see Persson and Tabellini (1996).) When income streams are uncertain, redistribution acquires a "social insurance" motive. This kind of insurance typically pays benefits in the event of a "negative shock" such as unemployment. Suppose that insurance is a normal good. Then increasing inequality (holding mean income constant) lowers the median voter's demand for social insurance. At the same time, it increases the demand for direct redistribution, as in the standard model with no uncertainty. The net effect on redistributive policy is ambiguous, and will depend on details such as the degree of risk aversion. Moene and Wallerstein (2001) present a model in which one obtains a U-shaped relationship between redistribution and inequality. When inequality is low, the insurance aspect predominates and increasing inequality leads to less redistribution. At higher levels of inequality, the direct redistribution motive is stronger and increases as inequality grows. Bénabou (2000), in a different model in which the

insurance motive plays an important role, also derives such a U-shaped relationship. Moene and Wallerstein provide empirical evidence that supports this relationship, using data on social expenditures in 18 countries.

Uncertainty can also play a more subtle role in shaping people's attitudes toward redistribution. Suppose that individual before-tax incomes are the result not only of costly individual effort but also of inherited factors (or "opportunities") and luck. For a given level of effort, someone with better luck or more affluent social background will, on average, generate more income. From an individual's point of view, the link between effort and income is uncertain. Piketty (1995) analyzes a linear-tax model of this type, where people rationally use observations about the income dynamics of their own families to form beliefs about the incentive effects of taxation. Since someone with poor parents is more likely to have low income than someone with rich parents (holding effort constant), people with different histories will form different beliefs. Those who come to believe that effort is important will be less willing to support redistribution than those who think predetermined factors or luck are more important. In this framework, people with the same income (and same underlying preferences) can therefore have different attitudes (or, more precisely, induced preferences) toward redistribution, and these differences can persist in a dynamic equilibrium. The equilibrium choice of redistributive policy will still correspond to the median of preferred tax rates, but the pivotal voter need no longer be someone with median before-tax income. Two countries with similar current income distributions but different histories can therefore have different current redistributive policies.

The median-voter framework of the standard model applies most cleanly to direct democracy, or to systems with first-past-the-post elections contested by two votemaximizing political parties. With proportional representation and more than two parties, the analytical task of deriving politico-economic equilibrium is more complicated. Policy depends on legislative bargaining among parties. Relative bargaining strengths of the parties depend on electoral outcomes. The economic choices and voting decisions of the population depend, in turn, on forecasts of legislative bargains. In general, the pivotal voter in such a setting will be endogenously determined, and the results one obtains are likely to be quite sensitive to how the model is specified. Austen-Smith (2000) develops a linear-tax model in which three parties compete under PR. Each party represents an economic interest group or occupational category. (Parties are assumed to be "ideological" and do not change their interest-group allegiances.) Redistributive policy affects choices of occupations, which in turn affect the relative

electoral strengths of the parties. For a plausible range of cases, Austen-Smith shows that the PR policy equilibrium leads to more redistribution than would occur in a two-party majoritarian setting. This seems to be consistent with the stylized facts from the U.S. and Western Europe.

Another departure from the standard model is to move away from the essentially one-dimensional policy space of that framework. In one such formulation, voters care about a non-economic issue (such as race relations or religion) as well as about their own economic well-being. Two parties compete by taking positions on both issues, so that a platform consists of a redistributive policy as captured by a proposed tax rate in the linear-tax framework, together with a stance with respect to the non-economic dimension. Suppose that parties are again ideological, in the sense that they maximize the expected post-election well-being of particular groups of voters. So, as in Roemer's (1998) analysis, a "Left" party might represent the anti-clerical poor while a "Right" party stands for the pro-clerical rich. If there are enough pro-clerical poor voters, it may be optimal for the Left party to moderate its stance on redistributive policy — i.e., make it economically more conservative. Because the two policy dimensions cannot be unbundled, redistributive platforms - and the resulting policy equilibrium — in the two-dimensional setting end up being different from what they would be in the absence of the non-economic dimension. An increase in the salience of the non-economic issue can cause a party to deviate further from its ideal point on the redistributive dimension. Which party is affected more in this way depends on the distribution of voter preferences over the two dimensions. Roemer (1998) suggests that in the U.S. there was an increase in the salience of non-economic ("values") issues from the mid-1970s to the mid-1990s, together with a move by the Democratic party toward a less-redistributive platform.

Even restricting the focus to explicit redistribution, a broad range of issues remain to be analyzed. For example, the dynamic interactions among political participation, redistributive politics, and economic performance are only beginning to be understood. (See Bénabou (2000) for a start in this direction). On this and other fronts, there is great scope for further theoretical exploration together with detailed empirical work that draws on the implications of theory.

REGULATING GOVERNMENT

The common perception is that one of the primary functions of government is to assure the proper functioning of market economies by regulating a wide range of private economic activity. This perception is quite the opposite of the type of regulation that is needed. Regulation is needed for market economies to function properly, but it is regulation *of* government, not regulation *by* government that is crucial.

We are not arguing that private economic activity requires no regulation. It is obvious to anyone who understands the degree of coordination required among literally hundreds of millions, indeed billions, of individuals to create even a modicum of wealth (much less the amount that those of us lucky enough to live in capitalist countries enjoy routinely) that a great deal of economic regulation is required. But the most effective economic regulation is provided by the information and motivation contained in market prices. The communication that takes place through market prices motivates people from all over the globe to pursue their own interests in ways that do the most to promote the interests of others.

Yet, a strong case can be made that government is necessary for a market economy to function properly. Without collective action backed up by the threat of government coercion, the coordination and cooperation that is the hallmark of properly-functioning markets can be undermined by a number of prisoners' dilemmas — situations in which it is in the interest of each to make choices that are destructive to the interests of all. A market economy, it is argued, requires the protection of private property against domestic predators; the enforcement of contracts; the provision of critical public goods such as national defense (protection of private property against foreign aggressors); the internalization of major externalities such as those associated with serious pollution problem; and possibly the financing of certain types of infrastructure where the costs of charging each user an amount corresponding to his use would be exorbitant (e.g., city streets).

For the purposes of our argument, we accept the case that without government forcing people to contribute to some collective goods, the prisoners' dilemma temptations would result in less than the efficient amounts of them being provided, although we readily acknowledge that strong opposing arguments can be made. For example, see, Friedman (1989: Chs 28-31) and Benson (1990) for arguments that private property can be protected and contracts enforced by strictly voluntary arrangements, or Coase (1974) who pointed out that lighthouses, a widely used example of a public good that requires government provision, were widely provided privately in eighteenth-century England. But even if you accept that government coercion is necessary to overcome the prisoners' dilemma that would otherwise prevent the optimal provision of the above goods, the case favoring that coercion is subject to far more qualifications than commonly realized - qualifications that explain the necessity of regulating government if markets are to work properly.

While it is theoretically possible for government to use its coercive powers to resolve the prisoners' dilemmas that prevent the optimal provision of certain collective goods, the exercise of that coercion creates other prisoners' dilemmas that can be, and often are, more destructive than the ones supposedly eliminated. Consider some examples.

If government is to produce the services that people value most, but which supposedly won't be provided through the private market, consumer/taxpayers must be able to accurately communicate their preferences to political authorities. Voting is surely the best way for the general public to transmit information on which government services they believe are worth more than the cost. While voting may be the best way to keep politicians informed on the wide-ranging preferences of the public at large, it suffers from a serious problem by putting each voter (or potential voter) in a number of prisoners' dilemmas.

For example, citizens would be better off collectively if they all became well informed on the positions of political candidates vying for their votes, and on the issues the winning candidate will decide upon, and then cast their vote accordingly. Suppliers provide better service when their customers are well informed, and this is true whether the suppliers are politicians or used-car dealers. But there are costs to becoming politically informed and each voter knows that, as opposed to becoming informed on a private purchase, his political choices will have no effect on the government services he receives or how much he pays for them, no matter how informed his votes. This is true no matter what he thinks other voters will do, unless he foolishly expects the highly unlikely possibility that other voters will split their votes evenly, in which case his vote will be decisive. So the rational choice for each citizen is to avoid the cost of becoming politically informed (which is reflected in polls showing that most people are woefully uninformed about candidates and issues) even though the resulting widespread "rational ignorance" leads to the worst outcome for citizens in general. Uninformed citizens are left vulnerable to the political exploitation of specialinterests, as will be discussed momentarily.

Even if information were freely acquired and citizens were fully informed politically, they would still be in a voting prisoners' dilemma. There are private costs incurred by those who take the time to register and vote. These costs are not large, but they are far larger than any private benefits realized from shifting political decisions in the direction the voter prefers, a benefit that is effectively zero given the miniscule probability that any one vote will be decisive in an election. So even though it would be collectively rational for all informed voters to go to the trouble to vote, since this would keep politicians more responsive to the general concerns of the public, voting is irrational (a least for the purpose of affecting the outcome) from the perspective of each voter. This prisoners' dilemma is commonly referred to as "rational apathy."

A natural response is that rational apathy cannot be a serious prisoners' dilemma since many people do vote, which means that they must realize personal benefits from voting that aren't captured by the effect their votes have on election outcomes. This argument has merit, but it tells us that those voters who avoid the prisoners' dilemma of ration apathy do so by becoming entangled in another one. Some people realize an expressive benefit from voting that has nothing to do with the election's outcome. They simply feel good about expressing themselves in favor of, or in opposition to, particular policies and candidates. And because no individual vote is likely to affect the outcome, the cost of achieving expressive satisfaction through voting is effectively zero for each voter. So if it makes a person feel good about himself to support "helping the poor" or "protecting the environment," he will likely vote for government programs that purport to accomplish these noble goals (or for candidates that support them) no matter how much these programs will cost him in higher taxes if they pass. The tax cost has little influence on his voting decision since that decision has no affect on whether a proposal passes. Of course, if a majority of the voters yield to the temptation of "expressive voting" then all taxpayers end up paying much higher tax bills than any of them would vote for with a decisive vote. But, because of the prisoners' dilemma that expressive voting creates, each voter judges himself better off getting his "expressive voting" benefit no matter how he thinks others will vote. See Brennan and Lomasky (1993) for a more complete discussion of expressive voting.

Once voters empower government to take more of their money for noble purposes, they find themselves in another prisoners' dilemma. Making sure that their tax money is spent to actually accomplish the advertised objectives requires that taxpayers follow up on their votes by monitoring how politicians and bureaucrats spend that money. Although taxpayers would be collectively better off if all contributed to the cost of monitoring, each taxpayer is better off not contributing, no matter what she thinks others will do.

The resulting lack of taxpayer oversight means that once a government program has been approved, always in the name of accomplishing some noble purpose, organized interest groups working behind the scenes will make sure the program is implemented so that it does more to benefit them than to accomplish the noble purpose. Because these groups are relatively small and have a dominant interest, they are able to overcome the prisoners' dilemma that prevents the general taxpayer from organizing for effective political action. Of course, members of organized interestgroups could, like voters, use their political influence with noble social goals in mind. But, because an interest group's political actions are far more decisive than a vote, using its influence to promote social goals is extremely costly in terms of sacrificed private benefits.

But interest groups also find themselves in a destructive prisoners' dilemma because of their ability to gain private REGULATORY TAKINGS

benefits at public expense through political influence. Piracy is profitable when the victims are many and the pirates are few. But everyone is worse off when almost everyone becomes a pirate and few are left shipping the goods. And today almost everyone is a member of some interest group that is benefiting from some government program that harms the general public. But even though everyone would be better off if all such groups reduced their claims on others, no group is motivated to do so. Who wants to lower their Jolly Roger and go back to shipping the goods when he is surrounded by pirates?

A government regulated only by the right of everyone to vote is an unregulated government — a government that soon destroys the market economy and the freedom and productivity that are impossible without the socially benevolent regulation of private property and market prices. Unless government is regulated by constitutional limits that prevent most political activity that would win majority support, voting becomes little more than the means by which voters choose who represents them in the mutually destructive attempt of each to live at the expense of each other. These constitutional limits take the form of substantive restrictions that prevent government from doing particular things (such as taking private property without just compensation, and then only for genuinely public purposes), and restrictions that put procedural roadblocks in the path of government action (such as the executive veto, judicial review, and supra majority votes).

Unfortunately, political democracy has been elevated in the public mind as the primary means of protecting human rights (Bethell, 1998: 335), with preventing government from doing anything a majority votes for (or would vote for) being seen as undemocratic. This represents a dramatic shift in public opinion from the healthy skepticism toward political actions that prevailed during the founding of the American republic and which continued to prevail in large measure until the end of the nineteenth century. This shift in public opinion is a serious threat to constitutional regulation of government. As Henry Simon (1951: 20) observed: "Constitutional provisions are no stronger than the consensus that they articulate. At best, they can only check abuses of power until moral pressure is mobilized; and their check must become ineffective if often overtly used."

REGULATORY TAKINGS

[N] or shall private property be taken for public use, without just compensation. (U.S. Const. Amend. V)[W]hile property may be regulated to a certain extent,

if regulation goes too far it will be recognized as a taking. (Pennsylvania Coal v. Mahon, 260 U.S. 393, 415 (1922). Justice Holmes)

The Takings Clause of the Fifth Amendment of the United States Constitution is the basis for regulatory and non-regulatory takings claims. The Clause allows government — federal, state, or local — to take private property only if government uses it for a legitimate state interest and justly compensates citizens for what it takes.

Governments may take property by physically appropriating (condemning) it or by taking title to it. Such outright takings are an old prerogative of the sovereign, and are referred to as the "eminent domain" power. When a government entity physically appropriates, or invades, property (e.g., when land is flooded in order to build a dam) a *per se* taking exists.

In an eminent domain case, a court considers whether or not an appropriation of private property, by physical invasion or by title transfer, occurred; whether the property was taken for a public use; and if so, whether the government paid the owner just compensation (Eagle, 2001). If all of these conditions exist, the appropriation is constitutional.

In cases involving a regulatory taking, property is not appropriated physically. Rather, by regulation, a government reduces the range of permissible uses to which the citizen may put his property. Such restrictions oftentimes reduce the value of the property substantially. A regulatory taking exists, for example, when a state government enacts legislation forbidding all building, or other use or development, of property that previously could be developed (Lucas v. South Carolina Coastal Council, 1992).

Not all government actions that prevent property owners from using their property as they wish are regulatory takings. When a government enforces property-use restrictions that existed when the owner acquired the property, there is no taking and the government need not compensate the property owner.

In a regulatory-takings case, a court will follow a balancing approach introduced by Justice Holmes in Pennsylvania Coal and reiterated in the 1978 Penn Central case. Courts will make an *ad hoc*, factual determination of the unique circumstances of the case, paying close attention to the following three concerns: the nature of the government action; the severity of the economic impact of that action; and, the degree to which the action interferes with the property owner's reasonable, investment-backed expectations (Pennsylvania Central Transportation Co. v. New York City at 124).

Richard Epstein notes that takings jurisprudence is both complex and paradoxical (Epstein, 1998). Over time, takings jurisprudence developed in ways that provide citizens with strong protection against physical intrusion, or the taking of title by government entities. At the same time it affords relatively little protection to persons whose properties are subjected to strict limits on uses (Lawrence, 1990). Thus, some sticks in the bundle of rights that make up common-law property rights, such as the right to be free from unwanted physical invasion, receive much greater protection than do the "use" and "development" sticks.

Both regulatory and non-regulatory takings place the rights of private citizens to use their property as they wish in conflict with the desire of government officials to use this property differently. In particular, specific privateproperty rights typically compete with the state's police powers. Over the past century, as the scope of these powers has expanded the conflicts between government actions and private-property rights have multiplied.

From a public-choice perspective, government's increasing size and scope raises the specter of special-interest groups lobbying for the use of police powers to gain access to property rights that they would otherwise have to purchase (Fischel, 1988). If the costs associated with the lobbying activity are less than the expected benefits to the interest group of acquiring property on the market, then groups will use the political process to seek rents via property regulation (Levmore, 1990).

Uncompensated takings present a variety of problems including, as Epstein notes: decreased investment activity, unfair distribution of "gains" from the coerced transfer, and decreased overall economic efficiency as properties are redistributed to a lower-value use from owners who place higher values on them (Epstein, 1998). These various drawbacks lead Epstein to note that the compensation requirement, "force[s] the state to internalize the cost of its initiatives. Just compensation just operates as a pricing mechanism in a world of compulsory purchase" (Epstein, 1998: 564).

However, special-interest groups continue to resort to the political process to acquire private property. This very real problem is illustrated by the case of Casino Reinvestment Dev. Auth. v. Banin, 320 N.J. Super 342 (1998), involving an attempt by developer Donald Trump to use the state's eminent domain power to acquire land he wished to use for a parking lot at one of his casinos. Interest group lobbying may also help explain the popularity of wetlands' regulations in the United States. These regulations, particularly section 404 of the Clean Water Act, limit the ability of homeowners and developers to use their property, in order to protect a resources — wetlands that environmentalists value. The regulation shifts the costs of wetlands' protection from environmentalists and others who place some value on wetlands protection to property owners, who may place very different values on these resources (Ceplo, 1995).

The problem that lies at the heart of efficiency concerns as they relate to regulatory takings is that of differential valuation. Using the wetlands example, if special-interest groups lobby government to restrict the use of private wetlands it is clear that they place some value on the control of private-property rights. We can infer that special-interest groups value the protection of wetlands, or the restriction of property rights, up to the amount they are willing to spend in lobbying efforts. But it is not clear that these special-interest groups value the property rights as highly as do the rights' holders. After all, the property owners paid for their land and would, presumably, be willing to sell the land, or certain rights to use the land, at some price.

If government regulates and restricts the use of private wetlands transfers value from property owners, and gives it to individuals who are unwilling to pay market prices for the resource. Relying on the regulatory process to accomplish their ends, interest groups limit their transaction costs to those associated with lobbying. If they succeed, interest groups who rely upon regulatory action to accomplish their ends avoid the costs associated with purchasing rights from myriad owners. Importantly, such non-market transactions restrict the flow of information concerning alternative uses of resources that market prices convey.

Developing a strict rule that private-property owners must be compensated when government takes property rights goes some way toward addressing the efficiency concern outlined above because the requirement forces government, through the taxpayers, to bear the costs of restricting or altering property use. If government must pay for the property rights it takes, then government officials must calculate which rights are worth the price of compensation. The compensation requirement will not eliminate the problem posed by interest group lobbying; interest groups will still seek, and politician still provide, regulation. But because government revenue has alternate uses, a compensation requirement will more tightly constrain the urge of officials to regulate property uses.

A compensation requirement does not, however, impose the costs of regulation directly on the interest groups that lobby for them. So, in the case of wetlands regulation, if government were required to compensate owners of private wetlands for the loss of value caused by regulation, taxpayers as a whole would bear the cost of protecting the resource; private owners would not be forced to bear this cost alone. Environmentalists would still accomplish their goal of restricting the use of property that they do not own at a cost to them that is less than the full cost to the general fisc. Thus, while compensation for regulatory takings would improve matters, it would not eliminate interest group politics.

Differential valuation is also an issue when courts examine the "reasonable, investment-backed expectations" of private property owners whose property is regulated. Beginning with the Pennsylvania Coal decision and followed by the Penn Central, Lucas, and Palazzolo, takings jurisprudence developed in such a way that courts will find no compensation requirement for owners whose property is regulated if, after the regulatory action, the property retains some value.

The questions of who defines "reasonable," and which types of investments will be considered relevant, are clearly important, but have not yet been directly addressed by the courts, although the Supreme Court has noted that reasonableness will be determined in light of state property law (Lucas v. South Carolina Coastal Council, 1992, footnote 7). As Steven Eagle notes: "Regulatory schemes ... are subject to an upward spiral. The more regulation there is, the more regulation the public may expect, and the more regulation is permitted in accordance with the public's expectation" (Eagle, 2001: 914) And as Eagle points out, this "upward spiral" of regulation leads to a "downward spiral" of diminishing expectations concerning the protection of private-property rights.

Another issue that presents some difficulties is the "parcel as a whole" doctrine. This doctrine requires courts faced with regulatory takings claims to consider the value of affected property in its entirety. If the entire parcel retains some value, the taking is not compensable. For example, if a 50-acre parcel contains a 20-acre area of wetlands, and if the property owner is unable, due to a regulatory scheme, to develop the 20 acres of wetlands, a court

will consider the value remaining in the other 30 acres of land before making a compensation decision. If the 30 non-wetlands acres retain value, the owner will receive no compensation for the loss of value associated with the regulation of the 20 wetlands acres.

Until relatively recently, the Supreme Court was reluctant to find that a compensable taking occurred when government did not take either physical possession of or title to private property (Eagle, 2001). Regulations that reduced a property's value were typically not found to be compensable takings. So, for example, in the 1887 case of Mugler v. Kansas, the Supreme Court found that a state statute forbidding the manufacture of alcohol was not a compensable taking of a formerly lawful private brewery. In a 1915 case, the court reviewed a Los Angeles statute that outlawed brickyards and brick kilns in certain parts of the city. The case involved a brick maker named Hadacheck who was arrested and imprisoned for continuing to make bricks on his property. Arguing that his actions did not constitute a public nuisance, Hadacheck claimed the government action took approximately 90% of his property's value. Despite this fact, the court refused to find a taking and held that the City did not have to compensate Mr. Hadacheck (Hadacheck v. Los Angeles, 1915).

Not until 1922 did Justice Holmes make his nowfamous comment that government regulation might go "too far" and effect a taking. Despite the comment, the Supreme Court did little to enforce the takings clause against the growing use government police powers. Four years after Holmes' statement, the Court allowed a broad zoning ordinance to stand in Village of Euclid v. Ambler Realty Co., despite the fact that the new regulation reduced the value of the property by 75%, and substantially altered the owner's rights to use their property. Six years later, the Court decided that a Virginia law requiring all red cedar trees located within two miles of any apple orchard be cut down, if the cedars had cedar rust, did not "take" property from a man who was forced to cut down a large number of cedar trees on his property (Miller v. Shoene, 1928).

Because of this reluctance to limit governments' use of police powers, actions such as zoning ordinances, rentcontrol laws, a host of environmental laws, civil forfeiture laws, historic preservation laws, and others were found to be valid under the U.S. Constitution, so long as the state could articulate a "rational basis" for such regulation. Charles Rowley sees this development as a "process of constitutional disregard ... [by which the Supreme Court] justices enabled the legislature to suborn the U.S. economy from capitalism to socialism as that legislature pursued its own ambitions to become the presidium of a rent-seeking, transfer society" (Rowley, 1992: 103).

This position of exceptional deference to the government's extension of its police powers culminated in the 1978 case of Pennsylvania Central Transportation Co. v. City of New York. The case involved New York City's Historic Preservation Law, which required owners of historic buildings to maintain the exteriors of these buildings, and which forbade their alteration without prior approval by the Historic Preservation Commission (O'Hara, 1995). The plaintiff, Penn Central, owned Grand Central Station in New York, a designated historic landmark. The company entered into a lease with another company, UGP Properties, to rent air space over the terminal so that a fiftystory office building could be built. The lease was entered into after passage of the Historic Preservation Law and the court upheld the City's denial of approval for building over the space.

Applying the *ad hoc*, factual analysis to the case, the Court found the plaintiffs could not establish a "taking" simply by showing that they had been denied the ability to exploit a property interest that they believed was available for development. The Court found that the Landmarks Law did not interfere with the terminal's established uses or with the plaintiffs' key expectation concerning its use of the parcel. Further, the development restrictions were substantially related to the promotion of the general welfare. These restrictions not only permitted reasonable beneficial use of the landmark, i.e., reasonable return on investment, but also provided the plaintiffs with other opportunities to improve the terminal site and other properties it owned (as Epstein says in his landmark work, Takings, "'reasonable return' on investment is simply a euphemism for the confiscation of private property, bit by bit and year by year." Epstein, 1985: 188).

Rowley notes that the decision not only "demonstrated an appalling ignorance of the nature of property rights and of the meaning of the eminent domain clause, but a shrewd understanding of the dominant political agenda of the legislature and its special interests at that time" (Rowley, 1992: 115). It was not until the 1980s that the court began to limit ever-expanding use of police powers to regulate a wide variety of activities.

In a case from 1980, Agins v. City of Tiburon, the Supreme Court articulated a two-prong test for deciding if a regulatory action had unconstitutionally taken property. The first prong asks if the regulation advances a legitimate state interest. Next, a court must ask if the regulation denies the property owner economically viable use of his land. In the case, the plaintiffs owned very valuable property overlooking San Francisco. The city rezoned the land for single-family residence or open space only, rather than condemning it, because it believed condemnation would be too expensive. The property owner alleged that the zoning amounted to a taking. The Court disagreed. The Agins test is often applied in cases of facial changes to a statute or regulation, where a plaintiff claims that "on its face" the regulation fails to advance a legitimate state interest or takes all economic value from an owner. If a statute or regulation meets the Agins facial challenge, it might still be challenged under the Penn Central balancing test "as applied" to a particular plaintiff.

1987 was a watershed year for takings jurisprudence, with the Supreme Court deciding four cases involving regulatory takings. Three of these decisions finally breathed life into Justice Holmes' statement that government regulation could go "too far." One case continued the tradition of strong deference to government use of police powers to restrict property use.

In First English Evangelical Lutheran Church of Glendale v. County of Los Angeles, the Court found that a temporary taking of property had occurred and that the plaintiff should be compensated for its loss. This decision resolved the question of whether or not just compensation is a remedy for a regulatory taking as opposed to a simple invalidation of the offending statute or ordinance (Lawrence, 1990). It is also seen as an elevation, by the Supreme Court, of substantive as well as procedural protection for private-property rights (Siegan, 1997: 124).

The facts of the case are these: in 1979 the County of Los Angeles passed an ordinance prohibiting the building or reconstruction of any structure in a particular flood-prone area, pending further study. In 1981 the interim ordinance was replaced by a permanent ordinance that allowed limited construction or reconstruction in the floodzone. The plaintiff church had run a campground in the area since 1957 (in 1978, during a severe flood, all the buildings at the campground were destroyed). The church subsequently filed suit, alleging that the ordinance took all use of their property.

The Court assumed, for purposes of reaching a decision, that the ordinance took all use of the church's property. It was held that invalidation of the ordinance alone would be insufficient to compensate the plaintiff for its loss, and so compensation was due despite the fact that the county government did not invoke its eminent domain powers and despite the fact that the taking was temporary, not permanent.

Also in 1987, in Nollan v. California Coastal Commission, the Court invalidated an attempt by the California Coastal Commission to tie the granting of approval for shorefront development to a requirement that property owners dedicate a public easement across their private beaches. REGULATORY TAKINGS

The Nollans leased, then purchased, beachfront property, one-quarter mile from a county park and public beach. A run-down cottage was located on this property. The Nollans wanted to tear the cottage down and build a two-story home. They applied for a permit to build, and the Coastal Commission approved the permit on condition that the Nollans allow the public to walk across their property. This condition was imposed in recognition of a California statute that required public access in case of new development or certain instances of reconstruction.

The plaintiffs argued that the regulation worked a per se physical taking, because the public-access requirement might lead to constant public presence on their property. Further, they argued that the regulation imposed upon them the costs associated with creating a public benefit. Justice Scalia, writing for the majority, found that the regulation did create a per se taking and so the Court did not need to balance interests in making a compensation determination. The court also discussed the issue of whether or not the Nollans were being asked to bear the costs of creating a public benefit. Applying the Agins test, the Court found that there was no "essential nexus" between the regulation's means (an easement over private property) and its ends (public access to the ocean). Thus, the regulation did not advance a legitimate state interest; therefore, it was an unconstitutional taking.

Nollan introduced the idea that there must be a nexus between government means and ends when it regulates property use. It also established the idea that a regulation that negatively affects property use must substantially advance a legitimate state interest. This requirement significantly less deferential to the use of government's police powers is the older, rational-basis requirement. By raising the bar on what was acceptable government regulatory behavior, the Court gave property owners increased abilities to challenge government actions limiting property uses.

In Hodel v. Irving, the Court determined that part of a federal statute, the Indian Land Consolidation Act of 1983, which restricted the ability of Native Americans to devise small interests in land to their heirs violated the Takings Clause. The court noted that the legislation might, in fact, serve a legitimate government interest in resolving the problem of very small landholdings among Native Americans. The court also noted that, given that most of the land was leased, there were few investment-backed concerns that might be affected. Despite this, the Court found that taking a traditional stick from the bundle of property rights — the right to pass property to one's heirs — was such an extreme measure that it was a taking, for which just compensation must be paid, despite the fact that the value of property affected was small. In a concurring opinion,

Justice Stevens stated: "[t]he Fifth Amendment makes no distinction between grand larceny and petty larcency" (Hodel v. Irving, 1987: 2089).

Finally, in Keystone Bituminous Coal Association v. DeBenedictis (1987), the Court determined that a Pennsylvania law prohibiting coal mining in certain cases where ground subsidence might occur is not an unconstitutional taking of property. Mine operators and individual coal companies who were, as a result of the law, forced to leave substantial amounts of unmined coal in the ground, brought the suit (Siegan, 1997). The Court found that the State of Pennsylvania asserted genuine public interests in preserving land and a variety of public and non-commercial buildings, including dwellings. Thus the statute advanced a legitimate state interest. Additionally, because it did not prohibit all mining of coal, the plaintiffs were left with some economically viable use of their land. Moreover, the Court analogized mining in cases where there was a threat of subsidence to a public nuisance, and noted that the government could legitimately act to prohibit such nuisances. As the nuisance exception to takings jurisprudence was well established, the Court determined that no compensable taking had occurred.

In Keystone, the Court found no taking and so the case did not provide as much protection of property rights as the mine owners would have liked. However, the Court's acceptance of the principles surrounding the judicial review of takings claims first elaborated Agins v. City of Tiburon represents "an approach generally more protective of property rights than had long existed in that hallowed tribunal" (Siegan, 1997: 114). The approach was borne out in the later 1987 decisions of First English, Nollan, and Hodel and in the subsequent, much-publicized cases of Lucas v. South Carolina Coastal Council and Dolan v. City of Tigard.

In Lucas, a 1988 state statute was found to take all economic value of a piece of property, triggering the just compensation requirement of the Fifth Amendment. The statute prohibited the building of any permanent habitable structure on certain ocean-front property in South Carolina. The plaintiff spent close to \$1 million to purchase two ocean-front lots in 1986 before the statute was enacted. The purpose of the law was to create a natural buffer against high-tides, storm surges, and hurricanes, thus protecting natural habitat, promoting tourism, and preserving the South Carolina beach and dune system (Siegan, 1997).

The plaintiff argued that the statute rendered his property valueless and that therefore, his property was taken. The state claimed that development of the property would create a serious public harm and that compensation is not due to owners when government acts to prevent such harm. In the majority opinion, Justice Scalia wrote that when regulation deprives an owner of all economically viable use of land, a *per se* taking occurs and the government must compensate the owner unless the regulation deals with a nuisance, or the regulation is a part of the state's background principles of real property law (Callies, 1996).

Lucas is a landmark decision in which the Court placed some (highly specific) limits on the government's ability to take property through regulatory action. The case was hailed by property-rights advocates as a major victory. Coupled with the 1987 pro-property rights cases, the Court seemed poised to roll back decades of restriction on the liberty of citizens to use their property. This impression received further support in the 1994 case of Dolan v. City of Tigard.

In Dolan, the plaintiff, who owned an electric and plumbing supply store wanted to demolish one building and replace it with a larger one and a parking lot. The property was located in a business district zone so that the city could restrict development to take transportation and other public needs into account. The city's zoning requirements obligated property owners to meet a 15% open-space requirement. Dolan's permit was approved by the city planning commission on condition that she dedicate a 15-foot easement to be used for a storm-drainage system, and also that she dedicate an eight-foot easement for a pedestrian and bicycle path. The commission found that the easements were reasonably related to the increased use that the property would generate.

Mrs. Dolan sued, arguing that the easements took her property. She also argued that, after Nollan, partial takings are constitutional only if an essential nexus exists between the restriction and the proposed action. Here, she contended, there was no such nexus.

The Supreme Court reversed the ruling of the Oregon court. It found that the city did not show a reasonable relationship between the easements and Mrs. Dolan's proposed construction. This "reasonable relationship" requirement amended the first-prong of the Agins test that an essential nexus exist between the regulation and legitimate state interests. The Dolan decision requires courts to ask not only if the regulation advances a legitimate state interest, but also if the means and ends of the regulation are reasonably connected. The Court said that there must be a "rough proportionality" between these means and ends, a proportionality that was not evident in the Dolan case.

With the Dolan decision the Supreme Court might have reached the limits of its willingness to revive protection of private-property rights. In two subsequent takings decisions, Palazzolo v. State and Tahoe-Sierra, the Court further clarified when regulatory action will require compensation, and when such action will be constitutionally sound.

In Palazzolo, the Court considered the following: if regulation was in place before an owner purchased property, was the owner barred from bringing a regulatory takings claim? The Court also considered the issue of economic viability. How much value need remain after regulation for property to have economic viability? At issue in Palazzolo were 18 acres of coastal wetlands. The owner, Mr. Palazzolo, filed a variety of building/development permit requests for this land over the course of more than 20 years. From 1960 to 1978, Mr. Palazzolo was sole shareholder of Shore Gardens, Inc., which held title to the property. From 1978 on, he owned the property outright.

In 1960, the Town of Westerly approved a plat for the property, subdividing it into 80 lots. Some of the lots were sold, but these parcels were located on "uplands" that could easily be developed. No parcels in the wetlands area were sold. In 1962, Mr. Palazzolo submitted a request to dredge a pond on the property. This application was returned because it was incomplete. In 1963, Mr. Palazzolo submitted another request to build a bulkhead, dredge the pond, and fill the wetlands. When this application was filed, there was no requirement that the state approve the filling of a wetland, however, there was a requirement that a person wishing to dredge a pond obtain approval from the Division of Harbors and Rivers. For reasons that remain unclear, Mr. Palazzolo did not fill the wetlands at this time.

In 1965, Rhode Island passed a wetlands protection act that required that the Department of Natural Resources approve all requests to fill coastal wetlands. In 1966, Mr. Palazzolo once again applied with DNR to dredge the pond, fill the wetlands, and build a beach facility. This request was approved in 1971, but then the approval was revoked. Mr. Palazzolo did not appeal the revocation. In 1971, the Coastal Resources Management Council was created. In 1977 this agency forbade the filling of coastal wetlands unless it approved the project.

In 1983, Palazzolo submitted a proposal with the CRMC to dredge the pond and fill his wetlands. This proposal was rejected and the rejection was not appealed. Tenacious, if nothing else, Mr. Palazzolo submitted another request to build a beach facility in 1985. This request was denied, appealed by Mr. Palazzolo, and the appeal denied.

Mr. Palazzolo filed his takings claim in 1986. The Supreme Court of Rhode Island determined that his claim was not ripe, because of faults found with his previous applications. Because Mr. Palazzolo's applications were not complete, the Rhode Island court determined that he had not yet received a final decision concerning the application of the wetlands-protection regulations to his property. Further, the state court found that "a regulatory takings claim may not be maintained where the regulation predates the acquisition of the property" (Palazzolo v. Rhode Island, at 715). In other words, the court said that because of changes in the regulatory regime in the 1960s, Mr. Palazzolo had notice, when he REGULATORY TAKINGS

became the property's owner in 1978, that his title was limited by wetlands development restrictions. The court also held that Mr. Palazzolo retained some economic viability in the property because he could build on the uplands parcels and because he could make an open-space gift of the wetlands portion, worth about \$150,000.

Mr. Palazzolo appealed to the Supreme Court. The Court held that, in fact, Mr. Palazzolo's claim was ripe, because the CRMC reached a final determination when it denied his 1983 and 1985 applications. The Court further held that Mr. Palazzolo's acquisition of title after the wetlands protection regulations took effect did not bar his takings claim. The Court rejected the Rhode Island court's rule, suggesting that to adopt it would be to absolve the state of the need to defend against excessive and capricious land-use regulations in all cases of post-regulatory transfer.

Finally though, the Court found that Mr. Palazzolo did retain significant economic value in his land because he could build on the upland portion. Applying the Lucas rule, Mr. Palazzolo was not deprived of *all* economic viability of the property, and so the Court remanded the case for further consideration which, as of this writing, has not been finalized. The Court did point out, though, that in cases where owners are not able to show a categorical (i.e., 100%) taking, "[t]he economic impact of the regulation on the claimant and ... the extent to which the regulation has interfered with distinct investment-backed expectations' are keenly relevant to takings analysis generally" (Eagle, 2001. Cumulative Supplement, 43).

Most recently, in Tahoe-Sierra Preservation Council, Inc. v. Tahoe Regional Planning Agency (2002), the Supreme Court again addressed the issue of regulatory takings. In a decision viewed as a set-back for property owners, the Court held that a temporary moratorium on building is not a taking.

The case involved a challenge to restrictions placed on construction at Lake Tahoe. The plaintiffs were hundreds of individuals who purchased undeveloped lots around the lake, with the expectation that they would be able to build. The Tahoe Regional Planning Authority imposed two moratoria, lasting 32 months, on building in the Lake Tahoe Basin while it studied the impact of development in the area and crafted a land-use plan (August, 1981–August, 1983 and August, 1983–April, 1984). Property owners brought suit, alleging the moratorium took their property, and that under the Lucas rule they should be compensated. At trial, the court found that there was no partial taking under the Penn Central test, but that under Lucas there was a categorical, if temporary, regulatory taking.

On appeal, the Ninth Circuit distinguished Tahoe from Lucas, noting that in Lucas the regulations at issue

prohibited all development in perpetuity, while in this case, the moratorium, although lengthy, was temporary. Therefore, no categorical taking had occurred. Instead, a "temporal slice of the [plaintiffs'] fee interest" had been impacted. Further distinguishing Tahoe from First Evangelical Lutheran Church the court noted that the issue in the latter case was a remedial one: the proper way to calculate compensation for a taking, not the determination of whether such a taking had, in fact, occurred.

The Supreme Court affirmed the Ninth Circuit's decision. It held that the mere enactment of the regulations implementing the moratoria did not constitute a *per se* taking of the landowners' property. The Court determined that the issue of whether a taking occurred depended upon consideration of the landowners' investment-backed expectations, the actual impact of the regulation on the landowners, the importance of the public interest involved, and the reasons for imposing the temporary restriction. Thus, the Court relied upon the *ad hoc* balancing test of the Penn Central. (But, in Tahoe, the Court found that the owners did not challenge the trial court's finding that there was no partial taking, so the Court did not revisit this issue.)

Additionally, the Court suggested that adopting a categorical rule that any deprivation of all economic use, no matter how brief, constituted a compensable taking would impose unreasonable financial obligations upon governments for the normal delays involved in processing landuse applications and would improperly encourage hasty decision making. This was unacceptable to the majority and so a categorical rule based on the Lucas reasoning was rejected.

Tahoe, along with Palazzolo, signals at least a modification of the movement towards increased protection of private property rights by the highest court. Nothing in the plain language of the Fifth Amendment, or in economics, justifies government refusals to compensate property owners for the value losses caused by such regulation. The market value of such losses can be determined. And when a deprivation is less than complete, a diminution in value may also readily be determined. The Tahoe and Palazzolo cases, therefore, leave in unjustified scope for government regulation, permitting government to regulate and take property in violation of the Constitution.

In conclusion, current takings doctrine most vigorously protects owners against physical invasions, while regulatory takings that result in less than complete economic deprivation are permitted. Partial takings, after Dolan, are permissible, but only if an essential nexus exists between the government restriction and the state interest being pursued. And finally, regulatory takings that take all value, but that are temporary, are not unconstitutional. Thus, despite the 1987 decisions and the subsequent cases in the 1990s, in most cases governments will not be required to compensate property owners if a regulation impairs the owner's right to use his land. The result is that property owners with regulatory takings claims still face a substantial burden to overcome the presumption that government police powers are being exercised constitutionally. Property rights remain at odds with government police powers.

RENT DISSIPATION

The "rent" whose dissipation is the subject of this item is the rent derived by rent seeking, not the rent on buildings or farms, etc. This is a relatively recent category in economics, because the discovery of the whole phenomenon of rent seeking is recent (Tullock, 1967). Modern states devote a great deal in the way of resources to activities or expenditures that benefit only narrow groups. It is probable that although each of these activities benefits only a small and distinct group, there are so many of them and they are so widely distributed that almost everyone benefits from at least one, and pays for many others well in excess of any benefits received.

The farm program is an excellent example of rent seeking in action. The farmers and associated industries lobby government heavily for farm protection policies. The government responds munificently. Very large amounts of money are transferred to farmers by the rest of population, partly in the guise of direct government subsidies and partly in the form of price floors. Government outlays, in response to rent seeking on the part of interest groups, accounts probably for more than 50 per cent of total government expenditures. This total must be augmented by the cost of inefficient regulations imposed in response to rentseeking outlays. These latter restrictions, designed to benefit special groups, do not appear in the budget, but they are significant.

Most economists are agreed that these benefits are not distributed solely as the result of the goodwill of benificent politicians. They are mainly the result of active lobbying or something worse by the potential beneficiaries. The problem of rent dissipation is to discover how these things are paid for. This is not to imply that they are necessarily responses to bribery or other forms of massive corruption.

Anyone visiting the capital of any major country, Washington for example, must be aware of the wide range of expensive entertainments and restaurants. Lobbyists provide major support for these services by entertaining and dining politicians and their staffers in the expectation that their generosity will be repaid through the legislative and/or the regulatory process. But large though that industry is, it clearly could not absorb even a small part of, let us say, the farmers gains from government action. Further, although the politicians are paid off partly through votes, it is clear that a representative of a metropolitan area does not gain votes directly from the farm program. Nevertheless many such representatives vote for programs that do not benefit their own constituents..

The explanation is simple although not widely known. It is the phenomenon of logrolling. In essence congressman from one district pay for things for their district by voting for things for other districts. The author of this note lives in Washington DC. Many in this area feel that we need another bridge across the Potomac and do not want it to be a toll bridge. Some of them are naive enough so that they think it can and should be provided free by the federal government or the state of Virginia if there are no tolls. In fact, of course, the residents of Washington will be taxed to pay for many bridges among them there may be one over the Potomac. The logrolling bargain is made negotiated by congressmen through their committees and their caucuses.

Although almost everybody knows about logrolling it is seldom dealt with carefully in traditional political science texts. Further congressmen normally only mention the things they get for their district when addressing their constituents. On occasion they will say that they had to vote for something in other districts in order to get something for their own. But mainly the individual voters are not told directly how they have paid for the project. Getting them however is vital to the congressmen. Congressman Watts, an important black member of the Republican hierarchy in the House has decided to withdraw. Apparently one of the reasons for this is that a large self propelled gun which was to be manufactured in his district has been canceled. Thus some of his constituents will lose jobs. His response, if that is what it is, surprises no one.

The rents then are in fact provided in the currency of other rents. I seek for, and perhaps receive, a bridge across the Potomac. Directly this is a free benefit for me, but I may be paying for dikes along the Mississippi or in the modern environmental age, the removal of such dikes. Whether I make a net gain or a net loss reflects largely the skill of my congressman and various random events in the negotiating process. On matters like roads it is probable that I do not do too badly in the overall compromise. But the allocation of government funds is very far from wealth maximizing for society or evenly distributed across the population.

Roads and many other things provided by the government are positively beneficial even if provided in a less than optimal way. There are other things the government does that are clearly harmful even if they happen to be evenly distributed. I mention the farm program one aspect of which is raising the price of milk. This could be regarded as an anti-baby action although clearly that is not its motive. Similarly the rest of the farm program does not directly match injury to the food eating population.

Protective tariffs are a clear-cut case of a government policy that, with minor exceptions, impose net costs on society. They are returns to rent seeking by usually small minorities paid for by various types of logrolling. It is a clear-cut example of the government production of "illth" (a word invented by John Stuart Mill as the opposite of "wealth").

This note deals with rent dissipation in a democratic and specifically American context. It will be found however in almost all kinds of political process. The dictator after all must keep the officials happy, and simply paying them is expensive. If he allocates road funds in such a way that the road leading to the hacienda of a prominent general is improved, this may be a cheaper way of getting his support than direct payment. The distribution of road funds in a dictatorship may not differ very much from that which would be found in a democracy. Trading of favors is important in all governments, and is not obviously avoidable. We must accept governments as we find them and internal trading among their officials is normal. We can hope to develop mechanisms for reducing the amount of rent dissipation, but we should not pretend that governments and lobbyists who stand to lose money and votes from their introduction are likely to respond positively to reforms that are designed to increase the overall wealth of society (Tullock, 1967, 1993).

RENT EXTRACTION

You had better hold on Hold on to what you got. (Joe Tex, 1965)

Formal economic analysis of rent extraction is a relatively recent development in public choice theory (McChesney, 1987, 1998). The basic model of rent extraction has been found useful in related fields where price theory is applied to analyze regulation. For example, it has been called "one of the most influential [developments] in law and economics of the last decade" (Sidak, 1998: 657).

As part of the Virginia School approach to political economy, the concept of rent extraction traces its intellectual roots to the seminal work on rent seeking by Tullock (1967). Whereas rent seeking is based on the idea of private individuals benefiting themselves through the political process, rent extraction points out that politicians are themselves players in the regulatory auction. Further, politicians have more than one strategy to benefit themselves. They gain not only when compensated by successful rent seekers, but also by threatening private individuals or groups with losses and then allowing themselves to be bought off rather than make good on the threats. Private wealth is extracted in the process.

1. Overview

William Mitchell (1988: 107) identifies the particular contribution of Virginia School public choice as its "theory of the failure of political processes." Given the costs and rewards facing politicians and bureaucrats, "inequity, inefficiency, and coercion are the most general results of democratic policy formation."

Part of the "inequity and inefficiency" to which Mitchell refers stems from rent seeking by favored groups. The idea that politicians can create rents for some groups (e.g., via tariffs for steel producers) at the expense of others (steel purchasers) is now well explored. (See entries by Tollison and by Tullock, this volume.) In the simplest rentseeking models, gains from legislation go to the highest private bidders. Losses accrue to those who do not bid enough to stave off the legislation.

Complementing the fundamental rent-seeking model, rent extraction focuses on the political "coercion" mentioned by Mitchell. Recognition of the rent extraction strategy starts with the realization that (a) as rational maximizers, politicians are interested in transferring wealth to others only to the extent that it generates benefits for themselves; (b) if politicians can transfer wealth to others, they can transfer it to themselves; and (c) that there are various ways to transfer wealth to government actors. Therefore, politicians must be seen as more than mere passive auctioneers of rents (McCormick and Tollison, 1981). They actively seek wealth-increasing opportunities, like everyone else. A fully-specified model of political behavior takes into account the many ways a politician's property rights allow him to improve his situation, net of the costs of doing so.

Outside politics, *homines economici* improve their lots in two fundamental ways. First, they can contract or otherwise cooperate voluntarily, leaving both sides better off (Axelrod, 1984). But much human interaction is non-cooperative (Schelling, 1960). One can improve his situation at the expense of another by just taking the latter's wealth, for example.

So it goes in politics. A person can contract with politicians for special favors — that is the essence of rent seeking. But a politician with the power to bestow those special favors often has the power to take wealth for himself while leaving the other side worse off. In fact, he can take for himself merely by threatening private parties' wealth, then allowing himself to be bought off.

Consider a tax increase. Politicians have the constitutional ability to levy taxes, and taxes on income already earned or other wealth already in place offers an attractive taxation target. But an ability to tax necessarily entails the discretion *not* to tax, that is, to propose taxation but then not levy the tax threatened. Proposing onerous legislation and then — for a price — agreeing not to push or even to withdraw the legislation proposed is the essence of rent extraction. Rent-extracting games are observed routinely as part of tax legislation proposals: private individuals pay, not for special favors, but to avoid disfavor (Doernberg and McChesney, 1987).

Likewise, consider threats of price controls, such as those that the Clinton administration proposed for the medical, pharmaceutical and insurance industries in 1993–94. Had these measures been imposed, the costs to the affected industries would have been enormous. In each industry, there are large stocks of specific capital, including human capital, which generate income flows over time. Quasirents are earned as compensation on prior investments (education, product research and development). But just as wealth previously earned can be confiscated by taxation, expected future returns can be imperiled by price controls such as those jeopardized by the Clinton's. Rather than submit to the price controls threatened, the industries that would have suffered paid millions over to politicians to avoid them (McChesney 1997: Ch. 4).

Politicians have figured out any number of other ways to extract private wealth (Beck et al., 1992). Yandle (2001: 600),

for example, notes the "not-in-my-back-yard" response to proposed pollution-control measures. "[T]he politician can indicate that electric utilities are being targeted for dramatic reductions in sulfur dioxide emissions. Then, instead of the industry organizing to seek favors or rents conferred by regulation, the industry organizes and lobbies to deflect or soften the proposed rules."

Regardless of the tactics chosen, the strategy of rent extraction is essentially the same. Proposed government action (e.g., a legislative bill to be voted on) that imposes costs on a person or group presents the putative victims with a choice: pay up for relief of the threat or endure the consequences. If the expected cost of the threatened act exceeds the value of what the parties threatened must surrender to avoid legislative action, they rationally will hand over the payment demanded of them.

Thus, in a public-choice approach to government, rent seeking is to rent extraction as bribery is to extortion. In a rent-extraction/bribery game, potential beneficiaries from political action compensate politicians for their gains. In a rent-extraction/extortion game, potential victims pay politicians not to impose losses. The implications for the payers are completely different — a gain versus a loss — but the politician gains in either sort of game.

2. Politician Rent Extraction vs. Private Rent Seeking

Distinguishing rent extraction from rent seeking is not always easy, as both involve payments to politicians. "Bribery and extortion substantially overlap....The same envelope filled with cash can be both a payment extorted under a threat of unfairly negative treatment and a bribe obtained under a promise of unfairly positive treatment" (Lindgren, 1993: 1700). But politically the two are quite distinct strategies for raising money, as politicians themselves recognize. They label their rent-extracting proposals (i.e., bills submitted just to elicit money *not* to enact the bills) with names like "juice bills" or "milker bills." Ralph Nader has referred to some such proposed legislation as a "cash cow" for politicians.

The necessary conditions for rent extraction are the same as those for rent seeking. There must exist potential gains to some person (or group) from using political power to transfer wealth to himself (or itself). Second, the benefits of the transfers must outweigh the costs of achieving them. In principle, both the benefits and costs of political wealth transfers are a function of anterior constitutional rules concerning political transfers. Rules that protect private citizens from transfers reduce the benefits and increase the costs of both rent seeking and rent extraction. Such constitutional protections have weakened considerably in most developed nations (e.g., Anderson and Hill, 1980), increasing the extent of both rent seeking and rent extraction.

However, rent extraction differs from rent seeking in three ways. First, the principal beneficiary from a successful rent-extraction strategy is not a private person or group, but politicians themselves. Private payments *not* to legislate tax increases or price caps go directly to politicians. That is, rent extraction is a two party game between politicians and would-be private victims, compared to rent-seeking, which involves three parties: potential winners, potential losers and the politicians who decide the winners and losers.

Second, rent extraction is typically more difficult to detect than rent seeking. Rent seeking ordinarily requires specific legislation or regulation to shift one group's wealth to another. Rent extraction, to the contrary, requires only a threat of action to induce payment from would-be victims. Successful rent extraction is measured by what does *not* result in legislation or regulation. Thus, more rent extraction will take place than can be observed.

The difference in observed amounts of rent seeking relative to rent extraction is all the greater, given the different process costs attached to the two strategies. Enacting rent creating proposals typically requires satisfaction *ex ante* of high-cost procedures (hearings, votes) and will be subject to predictable *ex post* obstacles (court challenges, bureaucratic amendment). The American steel industry's success in winning tariff protection in 2002, for example, was the result of a sustained campaign of lobbying, political contributions and the like before the fact. After Congressional enactment and presidential signature, however, it still faced court tests and bureaucratic interpretation of its complicated definitions and procedures.

From a politician's standpoint, the beauty of rent extraction is precisely that it is primarily covert, and procedurally low-cost. It is virtually costless to submit a bill that threatens tax increases, price caps or other private wealth, current or future. It costs little, either, to withdraw the bill (or let it die for lack of support), once the requisite payments are made to forestall the bigger loss that actual passage of the legislation would entail.

3. The Social Costs of Rent Extraction

The money surrendered by those who otherwise would suffer by the political actions threatened is only a transfer. But rent extraction has real economic costs, measured along several margins. The very process of mounting the threat and then negotiating over its removal entails deadweight losses. Even when threats are ultimately bought off, then, the threatened firm is left worse off (Beck et al., 1992). Perhaps most important costs of rent extraction are its longer-term effects. The private wealth (current or expected) that politicians can credibly imperil derives from productive private investments. Potential rent extraction represents an expected future levy reducing the net benefit of the investment today. At the margin, therefore, the specter of rent extraction reduces the amount of investment made, just as any tax reduces the amount of the activity taxed. Potential rent extraction is also costly in altering the types of investments made. At the margin, the specter of future threats increases the relative returns of investments that are less visible to would-be extracting politicians.

Thus, rent extraction in more advanced economies is analytically no different from outright nationalization in less prosperous countries. In the former setting, politicians demand (and get) a fraction of an individual's or firm's wealth. In the latter situation, politicians take a larger fraction, perhaps the entire investment. Regardless of setting and amount taken, however, politicians have the effective ability to take some or all of the wealth over which they preside. Any stock of relatively immobile private capital offers potential gain from regulatory threats. The short-term costs in negotiating over just how much will be taken, and the longterm effects on investment incentives, are straightforward.

Once the political opportunities and social costs of rent extraction are appreciated, other aspects of basic public choice theory are seen in a different light. A group's ability to organize, for example, is seen as unambiguously good in the rent seeking model. But the extent of organization, while useful for seeking rents, also offers politicians lowercost opportunities to extract the group's existing wealth (McChesney, 1991). In a world where both rent seeking and rent extraction strategies are part of a politician's total portfolio of wealth-maximizing choices, group organization is not unambiguously desirable.

RENT SEEKING

1. Introduction

Rent seeking is the socially costly pursuit of wealth transfers. The concept of rent seeking was introduced to the economics profession by Tullock (1967). In his original presentation the basic idea that transfer seeking could lead to social costs was so simple that it has been automatically assumed that the idea had to have clear precursors in the literature. Nonetheless, even though one can find vague resemblances to the idea in many earlier writings, no one has uncovered a forerunner to Tullock's idea. His 1967 paper represents an original and important development in economic theory.

The early doctrinal development of the theory of rent seeking proceeded as follows. Krueger (1974) gave the field a name in her paper "The Political Economy of the Rent-Seeking Society." Although she presented some empirical estimates of the costs of rent seeking, Krueger's paper was primarily theoretical in nature, showing how rent seeking can lead to social costs in the adoption of policies to restrict international trade. Krueger was unaware of Tullock's paper. Posner (1975), who was aware of Tullock's paper, wrote the first empirical paper about rent seeking. His estimates suggested that the social costs of rent seeking in the regulated sector of the U.S. economy could be substantial. Finally, in an effort to solidify the earlier contributions and to stimulate work in the field, Buchanan (1980) and Rowley et al. (1988) published collections of papers on rent seeking that have been both widely cited and influential in the subsequent development of the field.

The remainder of this essay will detail the various aspects of the theory of rent seeking as it has evolved since Tullock's seminal paper.

2. Definitions and Semantics

Tullock originally framed his theory of rent seeking in contrast to the prevailing wisdom in the late 1950s and early 1960s, which held that the deadweight costs of monopoly and tariffs were empirically quite small. Harberger's (1954) famous calculations on the extent of monopoly power in the United States is a good example of this type of thinking. Monopoly as a source of market failure evidently was on the verge of being trivialized. Tullock advanced an argument that rectangles as well as triangles matter in the calculation of the social costs of such policies as tariffs and monopolies; that is, Tullock introduced the concept of a trapezoidal society.

Tullock's point was simple though full of potential pitfalls. He argued that expenditures made to capture a transfer were a form of social cost. The social cost arises because the resources used for transfer seeking have a positive opportunity cost somewhere else in the economy with respect to engaging in positive-sum activities. Transfer seeking is at best a zero-sum activity in that it simply shuffles dollars among people and groups and is probably negative-sum if traditional deadweight costs result as a by-product of such activities. Social costs clearly arise in the process by which resources are shifted from positive-to-zero- and negative-sum activities. Rent seeking thus embodies a social cost in terms of the foregone product of the resources employed in rent seeking.

Several points should be kept in mind. The theory of rent seeking does not condemn all types of profit seeking. As Buchanan (1980) articulated clearly, traditional competitive profit seeking or entrepreneurship in the competitive model (seeking quasi-rents) does not qualify as rent seeking. Such profit seeking is productive; it creates value such as new products. Rent seeking is unproductive; it destroys value by wasting valuable resources.

Normally, the concept of rent seeking is applied to cases where governmental intervention in the economy leads to the creation of artificial or contrived rents. Seeking such returns leads to social costs because output is fixed by definition in, for example, a government regulation. Entrepreneurship in this setting can only be said to be negative; it will simply dissipate rents and lead to no increase in output. Nonetheless, it is possible to conceive of rent seeking as taking place in a nongovernmental setting. Buchanan (1983), for example, argued that the rivalry of siblings for an inheritance can lead to rent-seeking activities within families, although Anderson and Brown (1985) offer a critique of this approach based on the idea that parties in this case are simply maximizing their utility.

Another point to keep in mind is that to the degree that the process of rent seeking involves the provision of utility or real income to participants in the process, these benefits should be netted out against the cost of rent seeking. As Congleton (1988) has argued, if the rent seeker takes the regulator out to dinner, the value that the regulator places on the dinner must be subtracted from the social costs of rent seeking. In-kind provisions, of course, come with excess burdens attached.

Once artificial rents have been created, it is hard to avoid the implication that rent seeking will occur along some margin. If a tax deduction is offered, tax shelters will be created and used. If civil servants are paid a wage in excess of their marginal revenue products, queues will develop for government jobs. All of these processes involve the use of scarce resources to seek transfers; the process is relentless.

3. Theory

Posner (1975) stated the first version of a rent-seeking game, describing a constant-cost game in which the probability of winning is proportional to investment and the available rents are exactly dissipated. He posited risk-neutral bidders, a fixed prize, and a given number of bidders. Where, for example, the pool of rents equals \$100,000 and there are ten rent seekers, each bidder will offer or expend resources of \$10,000 to capture the rents. In Posner's model rent seeking is analogous to buying a lottery ticket with a one in ten chance of being successful. Under such conditions rents are exactly dissipated; \$100,000 is spent to capture \$100,000.

Posner's exact dissipation hypothesis is popular in the literature because it makes empirical work easier. A rectangle is a definite area whose value can be reasonably estimated. Moreover, Posner's model is robust with respect to the free entry and exit of bidders (Higgins et al., 1985). That is, it naturally generalizes to a concept of a long-run equilibrium of bids and bidders. Rents are perfectly competed away with an endogenous number of bidders, and the prize to the winning rent seeker represents only a normal rate of return on his rent-seeking investment.

This does not mean, however, that all or even most rentseeking contests are perfectly competitive in nature. Tullock (1980) presented classes of models where rent seeking is imperfectly competitive in the sense that the competitive process for rents leads to over- or under-dissipation of the available rents. That is, more or less than the value of the rents is expended to capture them. Rent seeking in these models does not take place under constant-cost conditions. These cases are interesting, and they are generated by assumptions about risk aversion, limitations on the number of bidders, imperfect information, and so on.

As between Tullock's analysis of over- and underdissipation possibilities, the overdissipation possibility does not seem to be very plausible, at least in the setting of repeat play games. In this case, rent seekers are somehow led to bid more than the value of the prize. That is, they would be better off by not playing the game in the first place.

Underbidding, where rent seekers in the aggregate spend less than the value of the prize, is another matter. There are several plausible bases for underbidding equilibria, including risk aversion (Hillman and Katz, 1984), comparative advantage among monopolizing inputs (Rogerson, 1982), and game-theoretic considerations (Tullock, 1980).

4. Measurement of Rent-Seeking Costs

There are numerous empirical results on the social costs of rent seeking, depending on the methodology, coverage, and economy analyzed by the author. Krueger (1974) suggested that 7 percent of Indian GNP was wasted in rent seeking and 15 percent of Turkish GNP was lost due to rent seeking for import licenses. Posner (1975) estimated that as much as 3 percent of U.S. GNP was lost due to the social costs of monopolization through regulation. These are obviously substantial sums of money in any economy. Cowling and Mueller (1978) derived an estimate that the rent-seeking and deadweight costs of private monopoly in the United States were 13 percent of gross corporate product.

Subsequent empirical work in this area has proceeded along several lines. A reasonable amount of work has followed the lead of Krueger in seeking to examine the rent-seeking costs of trade intervention in various economies. In general, these works come up with higher numbers than Krueger. Magee et al. (1989: Ch. 15) provide a survey of this research.

Other work has attempted to estimate the costs of rent seeking for economies as a whole. This analysis has taken two general forms. First, there are the lawyer regressions. Various authors (see, for example, Murphy et al., 1991) have added lawyers in various regression formats set up to explain GNP or rates of growth in GNP, both in the United States and across countries. The robust conclusion of this work is more lawyers, lower growth, lower GNP. Some of these admittedly simplistic regression estimates suggest that lawyers reduce aggregate income by as much as 45 percent. Nontheless, lawyers are a key input in the rent-seeking process across societies.

Eschewing a regression-based approach, Laband and Sophocleus (1988) attempted an aggregate, sector-by-sector accounting of rent-seeking costs in the U.S. economy. They counted expenditures on such items as locks, insurance, police, and the military as being driven by rent-seeking or rent-protecting incentives. On this basis they estimated that almost one-half of the U.S. GNP in 1985 was consumed by such costs. Their approach will surely be controversial. A small sample of the categories that they treated as rentseeking costs include crime prevention (FBI), police (corrections), restraint of trade (FTC), residential investments (locks), commercial investments (guards), educational investments (library theft), property-rights disputes (tort litigation), and government (defense, lobbyists, PACS). Following an accounting-like procedure, these authors go sector-by-sector to obtain their estimates of rent-seeking costs.

As with all empirical work, these various approaches are only as good as the theories and models upon which they are based. Buying a lock, for example, is a response to the security of property rights in a society. This security can be produced in a variety of ways (including moral exhortation), but in the face of the relevant probabilities, buying a lock can hardly be seen as an unproductive investment. Given the prevailing ethos, a lock protects property rights, and the protection of property rights enhances the productivity of resources over what they could produce without the lock. To argue that one can be wealthier without locks and lawyers implies that there are feasible reforms in behavior that will reduce such costs. This is certainly believable, but this is exactly the burden that estimators of the costs of rent seeking face. The lock and the lawyer are only wasteful to the extent that these resources can be feasibly reallocated to more productive uses. Alternatively, contributions to churches should be regarded as substitutes for locks.

In principle, the cost of rent seeking is simply the increase in GNP that would result if a feasible way to reallocate resources from locks and lawyers to more productive uses could be found by a political entrepreneur. This figure could be high or low, but it is probably low given the ability of rent-seeking inputs to resist such reallocations. And the mere resistance of the inputs is yet another reason not to waste resources attempting such a reallocation (Tollison and Wagner, 1991).

A related concept is Tullock's (1975) transitional gains trap. In this case regulatory-created rents are dissipated by cost-increasing competition (e.g., more airline flights at a given time of day), so that consumers and producers are "trapped" in a situation from which no Pareto-like improvement is possible. Producers make normal returns on their investments after rent dissipation, and consumers pay higher than competitive prices. The capital losses facing producers in this case preclude a Paretian argument for deregulation.

5. Rent Protection

Not only do individuals use real resources to seek transfers, but they also sometimes use real resources to protect their rents from encroachment by other rent seekers. In contrast to rent seeking, this behavior is called rent protection. The basis for such behavior is clear. Not all "suppliers" of wealth transfers find it economically rational to allow their wealth to be taken away (why spend a dollar to save a dime?). Some will find it worthwhile to fight back (spend a dollar to save two dollars).

Virtually all welfare analyses of monopoly and regulation ignore rent-protecting activities of organized opponents of such governmental programs. A more general welfare analytics will include traditional dead-weight costs, rent-seeking costs, and rent-protecting costs. An important contribution to this literature in recent years has been McChesney's (1997) concept of rent extraction. He has generated results on rent seeking in which regulation or legislation is threatened and then withdrawn as a way to stimulate the formation of interest groups from which politicians can exact tribute. In other words, politicians are passive actors in the theory of rent seeking, whereas they are pro-active in the formation of interest groups in the theory of rent extraction.

6. Rent Seeking and the Distribution of Income

There will not be an equal distribution of rent-seeking ability in a society. Thus, the mechanism by which rents are assigned is likely to affect the distribution of wealth to the extent that Ricardian rents are earned in rent seeking. Consider a regulatory-hearing mechanism for assigning rents and suppose that some lawyers or economists earn inframarginal rents in rent seeking. On average, these individuals will be wealthier than their marginal competitors and wealthier than they would be without a rent-seeking mechanism of the particular type that rewards their skills. The choice of such a transfer mechanism increases the demand for lawyers (and possibly economists) above that which would hold with (say) an auction mechanism for assigning monopoly rents. So, first of all, the mechanism will alter the distribution of wealth by occupation. Moreover, if the requisite talents of the favored occupation cannot be reproduced at constant costs, the inequality of wealth in society may be further affected. For example, suppose the qualities of a good businessman/speculator are more fungible among the population than the qualities of a good lawyer; then inframarginal rents will accrue to the best of the legal profession in regulatory hearing cases. With an auction no Ricardian rents would be earned. The distribution of wealth would differ between these two societies as a consequence.

7. Conclusion

Tullock's theory of rent seeking is a novel and important development in economic theory. Time will tell, but it is possible to say now that rent-seeking theory offers a way for economists to understand better the positive and normative effects of government in an economy. For a long time this analysis was only about triangles. Tullock lifted our vision to rectangles and trapezoids (Tollison, 1982).

RENT SEEKING AND POLITICAL INSTITUTIONS

1. Introduction

Gordon Tullock's (1967) analysis of "The Welfare Costs of Monopolies, Tariffs, and Theft" revealed that these outcomes are more inefficient than implied by traditional welfare economics, because individuals use scarce resources to secure these undesirable outcomes. To secure tariffs, resources are devoted by domestic firms who may profit from trade protection, and to avoid them, by those who expect to be harmed by import duties. Obtaining monopoly power often requires similar investments to secure and avoid government-enforced entry barriers. In the case of crime, the aim of rent seekers and rent avoiders is not to influence government policy, but involves a similar sort of conflict. Criminals invest resources to redistribute resources from owners to themselves and owners invest resources in locks and guns to foil the efforts of potential criminals. Tullock points out that the total output of valuable goods and services is necessarily smaller than would have been the case if those resources had been used to produce new consumer goods rather than wasted in games leading to inefficient outcomes. Static welfare economics had *under measured* the losses generated by tariffs, monopoly, and theft by focusing attention on final outcome and neglecting the processes by which those outcomes were generated (Posner, 1975).

The private advantage of rent seeking is largely determined by the "rules" of the rent-seeking contest. These "rules" determine both the acceptable range of rentseeking methods and the payoffs of private investments in rent-seeking contests. To the extent that existing formal and informal rules can be modified or new formal rules introduced rent-seeking losses can clearly be reduced (or increased) through institutional design. The "rules of the game" are simply another name for the array of formal and informal institutions under which the rent-seeking contest takes place (Congleton, 1980, 1984). Institutions can both induce and curtail rent-seeking activities.

2. Institutions and the Rent-seeking Society

To see how institutional design affects the magnitude of rent-seeking efforts and losses, consider the following characterization of a rent-seeking society. Suppose that the expected payoffs from contest j are of the form: $R_{ij} =$ $s_i(f_i(x_{ij}), g_i(x_{oj})) P_i - c_i(x_{ij})$, where x_{ij} is the investment by the i-th rent seeking in contest j and x_{oj} is the investment of all other rent seekers. P_i is the prize or profit at stake, f_i and g_i are influence production functions, c_i is a cost function reflecting the value of resources in other non-rent-seeking activities such as farming and leisure. Function s_i is a sharing rule or probability function for contest *j*. It is normally assumed that model rent-seeking contests are such that relative influence rather than absolute influence determines shares of the prize, or the probability of winning the entire prize. If all players simultaneously double their influence, each player's share of the "prize" is unaffected.

Nonetheless, investing in rent-seeking contests can be entirely rational in the sense that self-interest leads individuals and groups to play such socially unproductive games as a means of securing private advantage. The typical rent seeker will invest in rent-seeking contests up to the point where: $c_{j xi} = P_{j sj} F f_{j xi}$ across all games. That is to say, rent seekers devote resources to a rent-seeking contest up to the point where the expected marginal advantage in pursing the prize equals its marginal opportunity cost, which implies that marginal returns are equalized across rent-seeking contests. The level of investment in each game is affected by the magnitude of the prize, the sharing rule, and the production of influence functions, which partly determine $s_i F$ and f_{ixi} .

Note that both the production of influence and the effect of influence on a player's share of the prize, f_{jxi} and $s_j F$, are partly determined by the efforts of other contestants and *partly by the institutions* that determine how influence can be produced and how the prize will be divided (for example, winner take all or proportional shares). Both the institutional setting and the magnitude of P are usually assumed to be exogenous.

The assumed structure of the sharing rule and influence production functions implies that a grand prisoner's dilemma exists. All players would be better off if every rent seeker's investment was reduced by the same proportion, because this pattern of reduction would not affect individual shares in the prize(s), but would free resource for other more valuable uses. In such contests, *essentially all the resources invested in these contests are wasted*, insofar as they are consumed by the influence-production processes without increasing the quantity or variety of available goods and services. However, no individual has an interest in reducing his own investment in a rent-seeking contest unless the others do the same.

Informally solving this form of the prisoner's dilemma is not an easy task, because as the players reduce their efforts, the advantage of rent-seeking investments tends to *increase at the margin for each individual player*. "Cheating" on whatever informal rules come to be adopted becomes an increasingly attractive option as effort levels decline.

The ability of affected groups to devise and implement formal rules to curtail investments in these unproductive games remains in the interest of all those in the game, insofar as costs can be reduced for all (including the winners). For example, institutions that eliminate the possibility of influence, by setting $f_{ixi} = 0$, or that eliminate the effect of "influence" on individual shares of the pie, by setting $s_i F = 0$, eliminate all interest in rent-seeking contests by eliminating the gains from rent seeking. The institutional design question is whether such institutions can be adopted, and whether they necessarily reduce rent-seeking expenditures or simply redirect conflict into other channels. Unfortunately, the same incentives tempt individuals to cheat in the ordinary play also exist at the level of institutional reform. Each participant at a constitutional convention naturally prefers rules that increase their own influence relative to potential rivals (Wagner and Tollison, 1991). Moreover, efforts to curtail one form of rent seeking may simply divert efforts to other equally wasteful contests as marginal returns in other "unregulated" games are re-equated.

3. Institutional Remedies for the Rent-seeking Dilemma

The rent-seeking literature has demonstrated that a number of institutions can affect the extent of rent-seeking expenditures. For example, if the prize in a particular contest decreases, all rent seekers will realize smaller marginal benefits from their rent-seeking activities in that game. A smaller prize induces each rent seeker to invest less in the game of interest, which also diminishes the total investment in rent seeking in the most commonly analyzed games. Consequently, political arrangements that reduce the fraction of national resources distributed in response to rent-seeking efforts tend to attract smaller individual investments in rent seeking from all rent seekers. Here we may note that private property rights, civil and political liberties, and a takings clause all bound the domain of government policies and tend to reduce the level of rent-seeking loss relative to governments where the domain of public policy is larger (Buchanan, 1980; Rowley et al., 1988).

The size of the prize sought by rent seekers is also affected by laws that protect rents once obtained. For example, monopoly contracts may be enforced by a nation's judicial system or not. If cartel agreements are not enforced, increased uncertainty about the value and durability of a monopoly privilege tends to reduce the expected value of the prize and, thereby, the level of effort invested to organized monopolistic organizations, or to create entry barriers.

In addition to political and legal institutions that affect the size of the prizes potentially available to rent seekers, rent-seeking contests are also characterized by institutions that determine how individual and aggregate rent-seeking efforts produce influence and how influence affects the distribution of the prize or the probability of winning the prize. The manner in which influence is produced by the efforts of individuals, $f_i(x_{ii})$, and groups is partly determined by procedural rules that determine legitimate methods of producing influence. For example, access to policy makers may be unrestricted, determined by familial ties, political activism, reputation, or lottery, and so forth. Regulatory deliberations may invite only a few people or groups to comment on proposed regulation or many. Campaign contributions may be explicitly linked to votes on pending legislation or only implicitly linked. Bribery may be legal or illegal, and, if illegal, enforcement may be more or less intense. In all these cases, the ability of any interest group to influence the policy outcomes is partly

determined by its own efforts, partly those of other groups, and partly by the institutional setting. The institutional setting determines the general productivity of some forms of influence relative to others, and may favor some groups relative to others. For example, entry barriers in rent-seeking contests often reduce rent-seeking losses for those in the game, but imply that some groups cannot win the prize, (Corcoran, 1984).

In addition to the institutions that determine the productivity of alternative methods of producing influence, there are others that determine how the influence produced can affect the assignment of the prize in the contest of interest. In contest environment sketched out above, function s_i specifies how influence affects the distribution of the prize among rent seekers. This may be based upon the relative production of influence, or describe a probability function for winning the entire prize is affected by their relative efforts, $S_i = s_i(f(x_{ij}), g(x_{oj}))$.¹ The process that determines the allocation of the prize may be made by a generality rule, a true lottery, a single policy czar, or a committee. Such a committee may choose the winner(s) of the contest using unanimous agreement or majority rule. The prize may be awarded all to one player, distributed only among all those who participate, or distributed within an industry or to all citizens. If the prize is shared, the amounts given out may be equal or unequal, and the shares may be affected by rent-seeking efforts or not.

In all these cases, it is clear that both the decision and allocative rules have effects on both the kind and extent of the rent-seeking investments made by each individual rent seeker, and, consequently, on the aggregate rent-seeking losses. For example, majority rule tends to attract smaller investments in rent seeking than one-man rule, and winner take all apportionment rules tend to attract greater efforts than proportional share games or lotteries (Congleton, 1983).

Other institutional characteristics of the setting in which the rent-seeking contest is played also affects the size and scope of rent-seeking activities. For example, federalism tends to reduce the size of the prize contested and reduce the number of rent seekers who participate in a particular game (insofar as players must reside within the jurisdictions of interest). Both these effects tend to reduce rentseeking expenditures (Warneryd, 1998). Participation in rent-seeking contests may be sequential as when eligibility for a final prize is determined from a sequence of games (Baik and Lee, 2000).

All these analyses demonstrate that the modification of formal institutions is one method by which rent-seeking losses can be controlled, even if rent-seeking losses cannot be avoided altogether. Moreover, several models of the emergence of civilization from anarchy argue that political and legal institutions are adopted in order to escape from the Hobbesian jungle, which is an unmitigated rent-seeking society. In these analyses, political and legal institutions are invented "whole cloth" as a means of reducing the waste of resources in rent-seeking games (Tullock, 1972; Skogh and Stuart, 1982; Skaperdas, 1992; Hirschliefer, 2001).

Rationality implies that efforts to devise institutions to address the problems will tend to reflect the potential net advantage of solving particular rent-seeking problems. If losses are large, great efforts are worth undertaking. If the costs of solving a problem are low, less effort is necessary to solve the problem. It seems clear that rent-seeking games that generate large losses that can be easily avoided will be revised through institutional reform or ordinary legislation. Laws may be adopted which restrict transfer of real property to nonviolent and voluntary means. Murder, theft, dueling and street racing may be declared illegal and punished. Bribery may be outlawed and violators exiled or jailed. Other productive forms of conflict may be promoted by enforcing contracts and devising transferable packages of use rights.²

If the cost of adopting loss reducing institutions is also large, wasteful rent-seeking contests may remain unsolved. For example, violent conflict between nations over boundaries often involves large scale losses, but history suggests that those losses are very difficult to eliminate completely. Moreover, conflict over policies within a nation are inevitable as long as governments are able to adopt policies that have distributional consequences. Insofar as nearly all policies have distributional consequences, it is unlikely that domestic rent-seeking loses can be completely eliminated, although they can be reduced by intelligent institutional design. There are problems for which institutional solutions to rent-seeking losses are unlikely to be adopted, and others for which the solutions adopted are unlikely to work in the long run.

4. Institutions and Rent-seeking Costs

If the welfare economists prior to 1967 under counted the cost of tariffs, monopoly, and theft, it is possible that Tullock and others exploring the normative implications of rent-seeking have overstated them. Given human nature, both rent-seeking and *cost-avoiding* efforts by *all available means* are to be expected. If the costs of rent-seeking can be reduced, it is clearly in the interest of those involved in rent-seeking contests to reduce them in some way. If these costs cannot be reduced, they would not be costs in the sense that economists use the term but rather technological facts of life analogous to ordinary production or transactions costs (Buchanan, 1969). Both lines of argument

RENT-SEEKING GAMES

imply that the true cost of rent-seeking tends to be smaller than suggested by the literature on rent-seeking contests.

The second of these possibilities, what might be called the "transactions cost" argument, is clearly false. Rentseeking losses can be controlled in a variety of ways as noted above. Formal and informal institutions can reduce rent-seeking losses by changing the rules and rewards of rent-seeking contests. Such rules affect the relative returns of rent-seeking activities within a particular contest and also across the wide range of contests that might be played. In this sense, rent seeking is clearly a costly activity.

Whether policy-relevant rent-seeking costs exist or not depends on whether existing formal and informal institutional arrangements have already reduced rent-seeking losses as much as is humanly possible. Analysis of rentseeking contests can direct our attention to reforms that could make us all better off in settings where new institutions can be devised that reduce the losses associated with rent-seeking games. On the other hand, if rent-seeking losses have already been minimized, analysis of rentseeking advances the conservative policy agenda of defending existing institutions that curtail those losses. *In either case, a thorough understanding of rent-seeking contests is clearly central to our efforts to devise more effective institutions and to understand the institutions that we already have* (Tollison and Congleton, 1995).

ROGER D. CONGLETON

NOTES

- 1. The most common specification of this relationship resembles a lottery where one's probability of winning the prize or one's share of the prize depends on the number of lottery tickets purchased, xi, relative to total ticket sales, $S = x_i / (\Sigma_i x_i)$.
- 2. Note that the efforts of firms who compete in well-functioning markets resembles rent-seeking as far as firms are concerned. However, competition in markets tends to increase the size of the prize to be distributed, and distribute much of that prize to individuals not directly involved in the contest, namely to consumers.

RENT-SEEKING GAMES

Models of rent seeking consider players who engage in a contest, with each expending costly effort to increase his chances of winning a given prize. The effort can take many forms, such as campaign contributions, bribery, and advertising. The prize can also take many forms: passage of a favored policy, the grant of a profitable defense contract, or the reduction of a tax. Rent-seeking models can thus be applied to many issues which involve firms and individuals competing to transfer wealth.

The theoretical literature focuses on how much effort each player exerts, on how aggregate effort compares to the value

of the prize (that is, the degree of rent dissipation), on how aggregate effort varies with the number of participants, and on how different rules for allocating the prize affect effort.

The theory of rent seeking relates to the theory of auctions. But the emphases and some of the assumptions differ. Rent seeking supposes that the effort represents a social cost rather than a transfer (see Tullock, 1967; Krueger, 1974; Posner, 1975; Bhagwati, 1982; Tollison, 1982). And whereas much of the work on auctions looks for rules which would maximize the seller's expected revenue, in rent seeking the design of a game is usually taken as fixed. Lastly, most analyses of auctions suppose that a bidder is uncertain about the values other bidders place on the object, whereas models of rent seeking usually supposes that these valuations are common knowledge.

In the following we will consider three types of contests.

1. Tullock Contest

Consider *n* firms competing for a prize. For simplicity, suppose they value the prize identically, at 1. For the Tullock contest (Tullock, 1967) let firm *i*'s effort on rent-seeking be y_i . Each of the other firms spends *y*. A firm's probability of winning the prize equals the ratio of its spending on rent seeking to total spending by all firms on rent seeking. Thus, firm *i*'s expected profits are $y_i/\sum_{j=1}^{n} y_j - y_i$.

This formulation is analytically tractable, but does not maximize social welfare or the benefits to the agency awarding the prize. Skaperdas (1996) offers an axiomatic justification of a more general contest success function:

$$\frac{y_i^{\alpha_i}}{\sum_j^n y_j^{\alpha_j}}.$$
(1)

The Tullock form supposes that $\alpha_i = 1$ for all *i*.

In a Nash equilibrium for the Tullock contest, firm *i* chooses y_i to maximize its expected profits, so that y_i must satisfy the first-order condition

$$\frac{\sum_{j \neq i} Y_j}{\left(\sum_{j}^{n} y_j\right)^2} = 1.$$
(2)

In equilibrium, all firms spend the same amount, so that y satisfies

$$y = \frac{n-1}{n^2}.$$
(3)

Total spending on rent seeking is thus (n-1)/n, and rent dissipation is incomplete — though for large n it approaches unity, for n = 2 it is 1/2.

The basic Tullock model has been extended in many directions, with emphasis on rent dissipation. Risk aversion

can either decrease or increase rent seeking effort (see Konrad and Schlessinger, 1997). The ambiguity is the consequence of two effects of increased spending on rentseeking. First, an increase in effort reduces wealth in all states of the world (whether the player wins the prize or not). Second, increased effort also increases the likelihood of the favorable outcome of winning the rent-seeking prize, and so provides a form of self-insurance. More risk averse persons will seek more insurance by spending more on rent seeking to increase the likelihood of success, but they will also be inclined to spend less on rent seeking because of its inherent riskiness.

When there are only two identical players, the ability of one player to commit to his effort before the other does makes no difference to the outcomes, but if the two players place different values on the prize, the outcome of the sequential game differs from the simultaneous game (Dixit, 1987).

2. All-Pay Auction

The literature offers a different model, which predicts full rent dissipation even with only two players — the all-pay auction. Such an auction resembles conventional auctions in supposing that the highest bidder wins the prize. But it differs from most auctions in supposing that both the winner and the losers must pay their bids. A reasonable interpretation is that firms make contributions to politicians, with the firm which spends the most winning the prize. (See Hirshleifer and Riley, 1992; Hillman and Riley, 1989; Baye, Kovenock, and de Vries 1993, 1996.) This is the contest form that appears when $alpha = \infty$ in the contest success function (1).

We can readily see that no equilibrium in pure-strategies exists in such a contest: for if firm 1 spent y, then firm 2 could win for sure by spending $y + \varepsilon$, with ε arbitrarily small. Instead in a Nash equilibrium contenders choose their rent-seeking outlays as a mixed strategy: that is, the Nash equilibrium is a probability distribution from which contenders draw their efforts at random. For any number of identical participants exceeding one, expected aggregate spending on rent seeking equals the value of the prize: rent dissipation is complete.

3. Menu Auction

The menu auction model of governmental decisions was introduced by Grossman and Helpman (1994). In this model each firm confronts the government with a contribution schedule, which maps every policy vector government may choose into a payment from the firm to the government (or politician).

One element of an equilibrium is a set of contribution schedules such that each firm's schedule maximizes its expected profits, taking as given the schedules of the other firms. Suppose a politician adopts that policy which maximizes his utility, which for our purposes means that he maximizes the payments he will receive.

In such a game, the contribution schedules will be locally truthful: each firm sets its contribution schedule so that the marginal change in the contribution for a marginal change in the probability that it wins the prize equals the firm's benefit from the change in this probability. It can also be shown that the contribution schedule is linear, with an intercept of 0. That is, each firm offers to pay x for getting a share x of the prize (or, equivalently, for the probability x of winning the prize). This means that, as in the all-pay auction, rent dissipation is complete.

4. Asymmetric Valuations of Prize

By the envelope theorem, if different players place different values on the prize, then the player with a higher valuation must have a higher expected utility. Say this player values the prize at V_H . Since his utility cannot be negative, his effort cannot exceed the probability of winning the prize. But this means that the efforts of other players must be less than V_H , and rent dissipation cannot be complete.

Notice that when firms are identical, both all-pay auctions and menu auctions extract the full surplus of firms. Thus, no auction mechanism can give the agency a higher return. And the same holds if the firms differ. In any mechanism which extracts the maximum possible surplus, the marginal firm earns zero economic profits. An inframarginal firm will earn profits equal to the difference between its valuation of the prize and the valuation to the marginal firm. Both mechanisms yield that result; both therefore also predict the same value of expected payments. Empirically distinguishing between the two auction models of rent seeking is thus difficult.

RENT SEEKING IN DEVELOPMENT

The term rent seeking was coined by Anne Krueger (1974), and her discussion of the issue placed it squarely in a development context. In particular, she modeled rent seeking as a competition for import licenses when quotas are used to restrict international trade. This type of trade restriction has been widely used in developing countries. Further, as discussed below, rent seeking may arise in response to a wide array of other policies which have also been frequently used by developing countries. Thus, it was quickly realized that the phenomenon identified by Krueger was of major importance to developing economies.

The precise definition of rent seeking has proved to be elusive, as the term has been applied to a very wide range of activities. For the purpose of the discussion here, I will consider rent seeking to be a subset of what Bhagwati (1982) has dubbed Directly-unproductive profit-seeking (DUP) activities, where the government policy (e.g., the level of the import quota) is taken as given, and rent seeking arises in response to this fixed policy. This working definition corresponds well with the rent-seeking game developed by Tullock (1980) and may also include monopoly seeking which was first discussed by Tullock (1967). It does not include tariff seeking as first described by Tullock (1967) and later developed by many authors.

Krueger's insight appears to have a clear policy implication: if the level of protection of a domestic industry is taken as given, a tariff is preferable to a quota, since a quota gives rise to rent seeking. Bhagwati and Srinivasan (1980) introduce the concept of revenue seeking under which individuals spend real resources in an attempt to obtain the revenue raised by a tariff. While there may be a general sense that rent seeking for import licenses is likely to be more costly than revenue seeking, ultimately this is an empirical question.

Price controls have been widely used in developing countries and are another policy which may have high rentseeking costs attached. When binding price controls cause a shortage, black markets tend to develop. In addition, the gap between the official price and the black market price implies that there is a rent associated with being able to purchase a good at the official price. One way rent-seeking can be manifested in this case is a rationing of the good by the expenditure of time, i.e., waiting in line. (See, among others, Deacon and Sonstelie [1989].)

Krueger provided first estimates of the cost of rent seeking in developing countries. She estimated that the costs of rent seeking associated with the trade regime were 15% of GNP in Turkey in 1968 and 7.3% of national income in India in 1964. Mohammad and Whalley (1984) take a broader look at rent seeking, by including investment licensing, price controls and labor market controls in addition to quota restrictions in the trade regime when they estimate the costs of rent seeking. They estimate that the costs of rent seeking range between 30 to 45% of Indian GDP in 1980/81. Krueger and Mohammad and Whalley assume that rents are fully dissipated, while the actual extent of rent dissipation is an unresolved question which has been debated in the literature following Tullock's (1980) contribution.

Rent seeking can raise the economic costs of distortions imposed on the economy by the government. However, it also has the potential to reduce welfare when it occurs in response to policies which would otherwise be welfare enhancing. The International Coffee Agreement (ICA) is a vehicle by which rich consuming nations provide disguised foreign aid to poor producing nations by agreeing to pay higher prices for coffee. The signatories agree to buy their coffee only from ICA members who restrict sales in order to raise prices. This is an arrangement which should benefit the exporting members of the ICA which are poor to middle income developing nations. The restriction in the sale of coffee within the ICA is achieved through the use of export quotas. Bohman et al. (1996) suggest, at least for the case of Indonesia, that costs associated with rent seeking for the export quotas may outweigh the benefits of higher coffee prices.

After Krueger's work, it was recognized that rent seeking could cause large reductions in the level of income in developing countries, but in the context of Solow type growth models, rent seeking would not affect an economy's long run rate of growth. Since the mid 1980s, when the work of Paul Romer (1986, 1990) revived the field of growth theory, the search has been on for explanations of the widely varying growth experience found in the developing world. Several authors have since incorporated rent seeking into endogenous growth models.

In a research and development based model of growth, Grossman and Helpman (1991) find that quota induced rent seeking always reduces the growth rate by causing the removal of resources from the productive sector of the economy. As a result, less research and development takes place and growth is slower. In Sturzenegger and Tommasi (1994), entrepreneurs may devote effort to innovation or to a rent-seeking contest in which they may obtain a subsidy from the government. When political access is distributed unequally across the sectors of the economy, the authors find that less effort is devoted to the rent-seeking contest and that the growth rate is higher as a result.

Murphy et al. (1991) develop a model in which growth results from knowledge spillovers. In particular, productivity growth is determined by the most talented individual located in a sector in the previous period. In this model, rent seeking always reduces the level of output, and may reduce the growth rate of the economy. This depends on the technology of rent seeking and on whether it induces the most talented individual in the economy to become a rent seeker. The authors provide a crude test of their model by regressing cross-country per capita growth on college enrollments in law and engineering, where the law enrollments are taken as a proxy for talent allocated to rent seeking. They find that per capita growth is negatively related to law enrollments and positively related to engineering enrollments.

Pecorino (1992) develops a model of growth driven by the accumulation of human capital. There are two rentseeking technologies in this model. Under the first, agents seek rents from within the productive sector of the economy. These agents do not specialize in rent seeking. Under the second technology, agents specialize in the rent seeking activity and acquire (socially) unproductive human capital which enhances their ability to seek rents. Rent seeking undertaken by specialists reduces the level, but not the growth rate of output. Rent seeking undertaken by individuals otherwise engaged in productive activity does reduce the economy's growth rate. Productive human capital is effectively unemployed during the time these agents spend seeking rents. As a result, the rate of return on investment in human capital and the growth rate of output are both reduced. As with the result of Murphy et al. (1991), the specifics of the of rent seeking technology determine whether or not rent seeking has long-run growth effects.

Recently, the topic of corruption has attracted a great deal of attention in the development literature. Rent seeking and corruption are closely related for two reasons. First, as discussed by Krueger (1974), competition for government positions in which bribes may be obtained can be considered a form of rent seeking. As a result, there may be resource costs associated with bribes that might otherwise be considered a pure transfer. Second, policies which give bureaucratic discretion in the award of economic rents (e.g., import licenses) will tend to encourage corruption. Shleifer and Vishny (1993) relate the costs of corruption to the industrial organization of bribe taking. Competition among bribe takers selling government inputs which are perfect substitutes can drive bribe taking to zero, but decentralized monopolists selling complementary inputs will lead to very high costs associated with bribe taking. Shleifer and Vishny argue that the need to keep corruption secret is one of the reasons that it is damaging to growth. Mauro (1995) presents empirical evidence showing that there is a negative relationship between corruption and growth which is manifested through the investment channel. For an in depth discussion of corruption and development, see Bardhan (1997).

Agents engaged in rent seeking may acquire human capital which is specific to this and other DUP activities such as tariff seeking, but which may not be easily transferable to activities in the productive sector of the economy. (See, e.g., Krueger, 1990: 210–213.) If this is true, it may have important implications for economic reform, and may help explain why reforms are difficult and prone to failure. Conlon and Pecorino (1998) develop a model in which there is both rent seeking and lobbying for import protection through the use of an import quota. The use of an import quota leads to rent seeking. Sector specific skills cause the labor market for rent seekers and lobbyists to be segmented from the market for labor in productive sector of the economy. A reform which reduces available rents leads to a negative feedback effect through an increase in the lobbying activity. As a result, the distortion in the trade regime is worsened and the initial fall in rents may be partially offset. By contrast, a reform which targets the lobbying activity will reduce the trade policy distortion and may reduce the levels of rents. A positive feedback effect (the reduction in available rents) is possible, but not guaranteed under a reform which targets lobbying, while a negative feedback effect (increased lobbying activity) is guaranteed under a reform which targets the rent-seeking activity.

Rent seeking is an important development issue because policies which can give rise to rent seeking have been very widely used in the developing world. Rent-seeking activity reduces the level of productive economic activity in the economy and may reduce the growth rate as well. The same policies which lead to rent seeking are likely to foster corruption. This is an additional avenue through which these policies may retard growth.

THE RULE OF LAW

The great Question which in all Ages has disturbed Mankind, and brought on them the greatest part of thos Mischiefs which have ruin'd Cities, depopulated Countries and disordered the Peace of the World, has been, Not whether there be Power in the World, nor whence it came, but who should have it.

John Locke

Western political thought has been dominated, since the beginning, with an interest in the procedures by which political power is applied. Theorists as early in the history of the field as Aristotle were primarily concerned not with what a state does, but how a state once entrusted with power will make decisions. In other words, according to what rules will political power be exercised. Perhaps even more dominant than political theory has been the example of the semitic tradition of submission of magesterial authority and citizens alike to *ex ante*, written law. One of the critical products of this ferment, applied with varying degrees of consistency, over the past 2500 years of Western history has been the political and legal doctrine that has come to be known as *the rule of law*.

There are two ways that political and legal power can be applied. One way is for coercive power to be exercised by rulers according to their discretion and in reaction to events as they arise. This has been called the application of "discretionary power" or "the rule of man." The alternative norm — the rule of law — demands that the actions of political and legal bodies be bound by a body of *ex ante* laws. Thus the "rule of law" literally means "rule by the law," as opposed to "rule by those in power." The rule of law, as a principle, is ultimately meant to constitute a seal between the application of coercive power and the justification for its use. In some sense, public choice theory can be viewed as an analysis of the effects of breaches in this seal.

But this is only the broadest way of understanding a term generally used with a much more nuanced meaning. There are implications of the norm as described above that are considered more important than others and are generally more descriptive of the benefits attributed to the norm. This more descriptive criteria for the rule of law says that the use of political and legal power must be applied, ahistorically, impersonally, and generally. It is these three features impersonality, a historicity, and generality — that make up the norm as it is conventionally used.

The rule of law first of all implies that law is applied impersonally. That is, the law is not created in order to satisfy the preferences of any individuals. The impersonal nature of the rule of law creates a seal between the application of political and legal power (which is necessarily in the hands of persons in positions of leadership) and the justification of the use of that power (which is assigned to the law itself). This is perhaps the most important aspect of the rule of law as it effectively bars the arbitrary use of power. The scope of the use of power is bound and delimited by a fixed source that has neither personality nor preference. Therefore the application of power cannot be used as a means for attaining individual ends. The implications of this aspect of the rule of law should be clear for public choice theorists. If the rule of law is perfectly applied, it is not possible for political action to be a result of personal preferences. Because public choice fundamentally studies political leaders as fulfillers of personal preferences, public choice is fundamentally the study of breaches in the seal constituted by the rule of law.

This depersonalization is accomplished via the law's fundamental *a historicity* and *ex ante* character. The rule of law is said to be in place only in circumstances where applications of power are bound by rules set forth *prior* to any of that power's applications. The *ex ante* nature of law under the rule of law can be read in one of two ways. The law can fulfill the norm by having been developed prior to its applications in historical time. Alternatively, and more broadly, this *a historicity* can be read as a demand that law be independent of events in the world. That is, the rule of law is said to fulfill its *ex ante* character only if law is created without reference to or motivation from particular circumstances or individuals. In either case, under the doctrine, the law must have a certain independence from the particularities of history.

The flip side of the depersonalization of the law implied by the rule of law is the general nature of the law. This third feature of the rule of law has been called the generality norm. Because law must be developed without regard to particular events in the world, and applied without regard to the preferences of its appliers, it cannot apply discriminately. The rule justifying an exercise of power can never be unique to a particular individual or even a particular grouping of people. It must apply generally. This, too, implies a fundamental seal constituted by the rule of law — under the generality norm, all persons are safe from the arbitrary use of power against them especially on the basis of particular characteristics.

It must be kept in mind, however, that these characteristics of the rule do not imply that the law cannot make distinctions among groups. In fact it is certainly possible for the ex ante body of law to single out groups on the basis of gender, race or even ideology and still conform to the rule of law. The salient feature of the rule is only that these laws must not waver on the basis of particular individuals or individual groups in historical time. They must be blind to particular individuals, and not necessarily to groups defined ex ante to the law's applications. It is also important to note that the rule of law does not necessarily do away with the need for a legislature or judiciary. Political and legal leaders ultimately must still interpret and apply the law under the norm and the publication of new laws are possible within the framework. But the scope of law, the social and economic spheres it may affect, and the reasoning behind any future legislation are set up and controlled by a body of law that is defined prior to any such applications. The actions of the political and legal authority are ultimately bound, shaped and justified by an impersonal, non-historical and general body of law.

There are several results of the application of the rule of law that make it a desirable norm. One of these is that the law is made to be ultimately predictable. Because the law does not change as quickly as the preferences of leaders, it is relatively consistent over time. If the law is given in a written form this is especially true. However, even the common law has a consistency to it because it changes only very slowly over time - or at any rate, more slowly than discretionary law. The upshot of this predictability is that individuals under a regime of rule of law can make social and economic plans under the assumption that the basic rules of social interaction are not subject to change. This stability allows individuals to, especially, make long term plans, whereas under discretionary law, long term planning is a risky and uncertain thing. It is this aspect of the rule of law that lead Hayek to refer to it as an "instrument of production" (1945, 1973).

The rule of law also implies that no individuals have coercive power over others. That is, as Hayek argues, individuals have some degree of liberty from the will of other persons. Because all coercive power is held by the state, and the state is governed by *ex ante* law (which has no personality and therefore no personal conflicts), coercive power can never be used to bend the will of one person to the will of another. Conflicts of interest under the rule of law must be resolved using some set of fixed procedural rule and cannot boil down to coercive conflict. Within the bounds of the fixed law, individuals must settle conflicts peacefully and mutually. Thus the rule of law alone accomplishes much of the liberal program. Individuals have fundamental freedom, at least from the will of other individuals. This freedom, with open recourse to political conflict barred, allows for the development of a contractual rather than coercive system of relationships between individuals. And, importantly to economists, this is the *sine non qua* of markets. As Hayek puts it: "The classical argument for freedom in economic affairs rests on the tacit postulate that the rule of law should govern policy in this as in all other spheres" (1960, 220).

Neither the liberal program nor Pareto improvement is necessarily accomplished by the rule of law, however. A body of *ex ante* law can, after all, still demand the enforcement of illiberal policies. Laws, for instance, enforcing segregation, punishing consensual sexual acts, or banning criticism of the state are all perfectly consistent with the concept of the rule of law. Neither does the rule of law ensure any degree of Pareto efficiency. Government can still legitimately block Pareto improvements and even cause Pareto regresses under the norm. Thus while the rule of law implies freedom from the will of other persons, it does not imply freedom from coercion by the state (see, e.g., Hasnas, 1995).

Finally, the rule of law is generally taken to imply public knowledge of the law by all individuals subject to the law. This feature of the rule of law is less clearly derived from the doctrine itself. However, it is difficult to imagine an implementation of the doctrine without a public understanding of the law. Because, by the generality norm, no individuals have a privileged relationship to the law, all individuals must be capable of holding others accountable to the law. Although the ex ante law in principle dictates the process by which enforcement of the law happens, it also must apply to those enforcers. The solution to this problem — who will enforce the law on the enforcers of the law — is a motivating subject of Constitutional theory and political economy (see Buchanan and Tullock, 1962 and Buchanan, 1975). Knowledge of the law allows the possibility of electoral or literal revolutions against those leaders who do not themselves obey law. Constitutional theory - like public choice theory — can be viewed as a study of the mechanisms that hold the rule of law in place. Mechanisms in constitutional theory such as the division of power allow for an alternative to revolution by creating game-strategic balances between branches of enforcers of the law. These mechanisms, too, generally rely on an informed population since they are predicated on the idea that political and legal leaders will leverage the public's knowledge of the law as an implicit threat against power seeking political rivals.

The classical defenses of the rule of law have usually been connected to the strands of liberalism, egalitarianism and rationalism inherent in political philosophy over the course of the field in the West. The traditional desire for a rational political order demanded that law not be governed by the passions (read: preferences) of leaders, for reason and the passions were believed to be opposed to one another. Thus rational law had to be set up ex ante and based on philosophy in order to avoid taking on an arbitrary character in the hands of political leaders. Plato's ideal republic was a construction of reason and one of the major concerns of the Republic was the development of leadership that would not corrupt and would remain subservient to its rational law. Egalitarian concerns motivated the construction of the rule of law through the generality norm in Aristotle, for example, who was concerned, in great measure, with the balancing of power among the classes in the polis in order to generate temperate law. Finally, as has been mentioned, the rule of law is a necessary but not sufficient condition for most forms of liberalism that have dominated political thought since the enlightenment. Thus the provision of liberty from the coercive will of other persons has also been a classical defense for the rule of law. Exemplary here are the arguments and intuitions behind the liberality of the body of common law that formed the English constitution. All of these pieces of the classical defense are rooted in the West's fundamental suspicion of those in power.

It is this suspicion, too, that lies at the root of the two major justifications for the rule of law offered by political economists in the twentieth century. The first of these is that the rule of law, interpreted strictly, does away with the possibility of political economic problems such as rent seeking. As has been mentioned, the rule of law, by depersonalizing the law, creates a seal between personal preferences and political power. Political leaders are incapable of applying coercive power discriminately. But without the ability to apply some sort of discriminatory political power, political leaders have nothing to sell to rent seekers. Other political problems like vote buying are likewise barred by the doctrine. Once again, candidates have no political currency with which to purchase support; the growth of government is controlled by the ex ante law and not the appliers of the law. The political economic problems of interest to public choice theory only arise when the generality norm is violated because the rule of law has been weakened in some way (see Buchanan and Congleton, 1998).

The second of the contemporary political economic justifications of the rule of law, offered by Hayek (who was also concerned with a defense of liberalism generally) favors the rule of law as a precondition for the blessings of the extended order of the market economy. In Hayek's thought, the rule of law creates an atmosphere of predictability that allows long term economic plans to develop. Capital formation, trading conventions and extensive price systems are impossible without a stable institutional environment to grow in. Further, as has been mentioned, without the rule of law, confiscation and arbitrary punishment, fueled by rent seeking, become viable (and often less risky) alternatives to production and contracting. But this alternative is ultimately a zero sum game, offering none of the growth and innovation offered by markets.

Indeed, there has been some evidence presented in the modern growth literature that the rule of law is strongly connected to growth and thus concludes that Hayek's conjecture about the rule of law as an instrument of production may indeed be right (see Barro, 1997 and Mahoney, 2001). This modern literature fits with historical explanations that place the emergence and adoption of a rule of law - which provided secure and predictable backdrop for economic actors instead of the uncertain and arbitrary backdrop that characterized unbound political rulers — as a primary cause for the economic growth experienced in West from the middle-ages onward (see Birdzell and Rosenberg, 1986). The difficulties of the transition from socialism in East and Central Europe and the former Soviet Union throughout the 1990s, and the failure of development in Africa and other less developed regions has led to a renewed appreciation of the underlying institutional regime required for economic growth. It is now not uncommon for economists to conclude that without private property and freedom of contract, encrusted in a rule of law, and economic actors will be thwarted in their attempts to realize the mutual gains from exchange and economic growth will be stalled as the economic and financial institutions required for advanced material progress will fail to emerge (La Porta et al., 1998). The question that now has moved to center stage of political economy scholarship is how does one successfully grow a rule of law in these reforming economies (see Rubin, 1997).

RULES VERSUS STANDARDS

In crafting laws, lawmakers cannot effectively foresee all the particular circumstances to which their laws could apply. This renders legislation general in nature and incomplete as a matter of practical necessity, leaving an unavoidable margin of discretion to judges when interpreting laws and applying general principles to the specific situation at bar (Posner, 1989). To guide judges through the margins of discretion, lawmakers may opt to incorporate rules or standards into the laws they write. The functionality of these rules or standards, the consequences of their incorporation into laws, and their significance from an economic perspective, are all the subject of the present study.

A "standard" is the legal or social criterion that adjudicators use to judge actions under particular circumstances. In that sense, standards are circumstantial; they are openended, allowing the adjudicator to make a fact-specific determination such as whether a driver used "reasonable care" in given situation. Standards such as reasonableness are largely intuitive, which makes them easy to understand for the general public. A "rule," conversely, withdraws from the adjudicator's consideration the circumstances that would be relevant to decision-making according to a standard. Rules are more specific than standards; they create bright line tests such as whether a driver exceeded the speed limit of 55 miles per hour. Greater specificity decreases the flexibility of a rule, often at the expense of an optimal fit between the coverage of a rule and the regulated conduct.

When legislators choose between rules and standards, they must consider when, and at what cost, the rules and standards should be applied to specific situations. For instance, rules require advance determination of the law's content because of the high degree of specificity involved in their formulation. Lawmakers must perform research in advance to determine the appropriate rule to create, ex ante. Therefore, rules are more costly for legislators to promulgate than general standards, which require less specificity. Standards, however, are more costly for legal advisors to predict or adjudicators to apply because they require determinations of the law's content ex post. Hence, in the event of a car accident where the driver was traveling more than 55 miles per hour, liability would be automatic under a 55 miles per hour rule. However, under a standard such as "reasonableness," the judge or jury would have to determine the facts and circumstances at the time of the accident, and decide whether to impose liability. The application of a standard is more fact specific, but naturally less consistent in the long run. Thus, from an ex ante perspective, rules are typically optimal, and from an ex post perspective, standards are typically optimal.

1. The Problem of Judicial Interpretation

The optimal degree of specificity of laws has been a frequent subject of debate for centuries. Legal theorists have long attempted to formulate principles that should guide judges when interpreting incomplete legal precepts. In ancient Greece, Aristotle (350 B.C.) realized the unavoidable necessity of incomplete laws. He advocated the doctrine of original intent in legislative interpretation, suggesting that, given the unavoidable incompleteness of legal rules, techniques of legislative interpretation should be developed to give guidance to judges and interpreters when applying such general laws to specific circumstances. In the process of legislative interpretation, judges should fill the void of the letter of the law with the finding of how the original lawmakers would have specified the rule in light of the specific facts, if they had foreseen the problem and dealt with it explicitly.

Incompleteness of legal rules is not only a matter of unavoidable necessity. At times, incomplete legal precepts can be purposefully enacted as a way to delay the decisionmaking process, transferring to the judiciary some of the tasks that would otherwise have to be carried out *ex ante* by the legislature. In this setting, Jeremy Bentham (1776) addressed the question of optimal specificity of laws, providing fertile ground for the modern debate on rules versus standards. Bentham's idea of a two-tiered system, where the public learns of the general rules while the judges hear individual cases with some freedom to depart from the *ex ante* rule, provides a good example of the possible role of purposeful incompleteness of legal rules. In Bentham's world, judicial discretion would not necessarily depend upon the lack of specificity of the *ex ante* rule, but could well coexist with detailed and fully specified *ex ante* rules, since judges would have some adjudicatory flexibility when applying the *ex ante* rule to the case (see, e.g., Dan-Cohen, 1984; and Parisi, 1992).

Going beyond Bentham, it is true that the use of standards would allow the judiciary to adhere to more flexible decision rules, with the option to deviate from conduct rules in specific circumstances. This approach would avoid running into the limits of the two-tiered analysis, given the fact that if too many decisions are issued against the original meaning of the rule, the *ex ante* value of the rule may be corroded with an emerging public distrust in the legislative and judicial functions of government. With rational expectations, the general public would anticipate the likely *ex post* interpretation of the rule, with a further corrosion of the *ex ante* function of the legislative enactment.

The recognition of the unavoidability of incomplete laws is an important stepping-stone towards the discovery of optimal specificity of laws. Within the margins of reasonable foresight, lawmakers have some choice on the degree of specificity of legal rules. Laws that are not fully specified upfront impose greater implementation and decision-making costs by judicial and administrative bodies at a later stage. The optimal degree of specificity of law thus critically depends on the relative costs and political advantages of lawmaking by different branches of government. The evaluation of comparative advantages in lawmaking necessarily rests on the full understanding of the public choice implications of alternative allocations of lawmaking power. Erlich and Posner (1973) conjecture that when the rule is statutory and the conduct to be regulated is politically controversial, the cost of promulgating a rule is highest. The formulation of a statutory rule requires negotiation among the legislators. The analysis of transaction costs in other contexts suggests that the costs of legislative negotiation are likely to be substantial due to the number of legislators whose agreement must be secured. The costs of negotiation will be even higher when the proposed rule is controversial. Transaction costs increase with the number of parties whose agreement is necessary for the transaction to occur. The presence of so many parameters that affect the choice of optimal degree of detail of legal rules has led Diver (1983: 76) to conclude that, while some laws may better serve their purpose as rules and others as standards,

"[g]eneralizations about optimal rule precision are inherently suspect."

1.1. Under-Inclusion and Over-Inclusion Problems

From an efficiency perspective, there are both under- and over-inclusive effects that occur when deciding to implement a rule to specific circumstances that were not specifically envisioned by the lawmaker. Ehrlich and Posner note that coupling a rule with a standard can solve the problem of under-inclusion. For example, it can thus be made unlawful to drive more than 70 miles per hour *or* to drive at any speed that is unreasonably fast given the particular circumstances of the case. While under-inclusion can be remedied by backing the rule with a standard, the result of adding a standard can diminish the benefits of legislating with rules, namely the low cost for adjudicators in determining when an individual has violated the rule.

When implementing a rule or a standard, there are also over-inclusive effects. The problem of over-inclusion is frequently dealt with by allowing enforcement officials to waive *ex post* the application of the rule or standard (e.g., speeding violations can be excused in case of emergency, etc.). As a matter of theory, a rule could be formulated with sufficient level of detail to contemplate all the possible exceptions, excuses and justifications. In practice, however, it may be less possible to envision *ex ante* all possible contingencies, or too costly to allow case-by-case exceptions to be made at the enforcement level.

The problems of over-inclusion and under-inclusion are more serious the greater the heterogeneity of the regulated conduct, and the faster the rate of change of the regulated environment. Kaplow (1992) suggests that even an activity that may appear homogeneous and objectively ascertainable such as speeding contains overriding elements of heterogeneity. The reasonableness of speeding depends on the particular circumstances of the case. A single speed limit, or even a number of speed limits contingently set in consideration of particular circumstances, would by necessity lead to occasional under-inclusiveness or overinclusiveness. The lack of a perfect fit between the ex ante legal rule and the circumstances of the case occasions potential social losses. Over-inclusion and under-inclusion impose social costs that vary according to the relative size of the value of the regulated activity and the gravity of the negative externalities of the activity, absent legal constraints. In this context, Ehrlich and Posner suggest that minimizing the social loss function with respect to potential under-inclusion and over-inclusion costs maximizes efficiency and predict that rules will be more common in areas of homogenous conduct.

2. Rules, Standards, and the Social Cost of Lawmaking and Adjudication

Law and economics scholars have often considered the criteria for determining the optimal degree of specificity of legal rules. Scholars who have entered the debate have utilized instruments from optimal decision theory, public choice theory, and constitutional political economy, with differing and often antithetical results. Much attention has been paid to the difference between standards and rules in the law and economics literature. Generally, scholars have postulated that laws articulated as "standards" leave a greater margin of discretion to judges and administrative agencies in the implementation of the legal norms. To the contrary, "rules" are laws that are specified upfront with a greater level of detail and thus leave a lesser margin of discretion in the implementation of such norms.

There are, of course, costs and benefits to governing with rules or with standards, and such costs should be taken into account in choosing the optimal specificity of a law. Such variables that bear on the choice of optimal degree of specificity of legal rules include the law's intended objective, the frequency of the application of the legal rule, and the total cost of lawmaking, net social welfare, and the cost of legal advice.

The law's intended objective is important because if the law's purpose is deterrence of specific conduct, criminal or otherwise, rules are typically preferable (Diver, 1983: 77). This is because laws written with deterrence in mind send strong, clear signals to the population at large that certain conduct will yield certain consequences, regardless of extraneous or mitigating factors. Where deterrence is not the primary goal, standards are often more appropriate (Diver, 1983: 77). When crimes have already been committed, for example, lawmakers may prefer to equip adjudicators and enforcers with specific standards that permit the consideration of extraneous or mitigating factors. Rules and standards may come together in this way so that rules efficiently govern conduct and standards govern punishment (see Dan-Cohen, 1984).

The frequency of a law's application is important to consider in determining optimal specificity so that lawmakers can strike the right balance between promulgation and enforcement costs. If a law is frequently applied, enforcement costs will tend to be higher than promulgation costs. This necessarily means that rules will be more efficient than standards when the law is frequently applied. Since legislators must absorb promulgation costs only once, standards have the potential to cost significantly more because adjudicators accrue enforcement costs each time there is a violation (Kaplow, 1992: 577). Rules are also more efficient because individuals are more easily able to learn about them, thus improving their chances of complying with the rules instead of violating them.

The total cost of lawmaking is another factor that economists weigh heavily in determining the optimal specificity of legal rules. Ehrlich and Posner have advanced the notion that total cost (i.e., promulgation cost, enforcement cost, and all other costs) should ultimately control a legislature's determination. As stated before, rules require a high degree of specificity and therefore have higher promulgation costs which may include detailed research (Kaplow, 1992: 570). Standards, on the other hand, will be costlier to enforce for adjudicators, draining more resources from the judicial system (Kaplow, 1992: 577). Adjudicators must give content to standards, which is a key factor in high enforcement costs (Kaplow, 1992: 570).

Economists concerned about net social welfare tend to favor rules because they guarantee greater certainty, consistency, and predictability to private parties (Sullivan, 1992). Sullivan argues that rules promote judicial economies by minimizing the need for a detailed consideration of facts and circumstances each time a law is applied (Sullivan, 1992: 63).

The cost of legal advice is a final factor in determining the optimal specificity of legal rules. For standards, this cost — meaning the cost of consulting with an attorney to determine whether certain conduct violates the law — is higher than it would be for rules (Kaplow, 1992: 571). Attorneys will convey a more concrete understanding of the consequences of an actor's conduct where rules are concerned, because they are easier to apply *ex ante*. Given the cheaper cost factor, more individuals are likely to become informed in a regime dominated by rules (Kaplow, 1992: 574).

2.1. Rule, Standards and Information Costs

Economists note that there is an information cost associated with promulgating and enforcing rules and standards, particularly with regard to compliance with rules and standards. Under rules, informed individuals can fully identify the content of the law since legal provisions are fully articulated up-front and, as a result, individuals may more easily conform their behavior to the law. Rules are precise and it is easier to conform conduct to a precise rule. Under a standard such as reasonableness, what is "reasonable" under the circumstances can vary widely. Applying standards may require some guesswork by less experienced legal actors. As a result, standards tend to be more costly for individuals to interpret when deciding how to act. When individuals can determine the application of rules to their potential acts more clearly, their conduct is more likely to reflect the previously promulgated rules. This is because standards will be given content and substance only after individuals act. Under rules, individuals are more likely to be informed, and under standards, individuals are likely to be relatively uninformed. Kaplow suggests that uninformed individuals act based on their best guess about how the law will apply to their contemplated conduct. Informed individuals, on the other hand, act based on actual knowledge of the law.

2.2. Lawmaking as a Production Function: The Optimal Scale Problem

The law making process is, in a sense, a production function with both fixed and variable costs. In this way, the creation of the law can be thought as the fixed cost investment in the production of legal order. Lawmakers choose the level of specificity of legal rules by allocating fixed capital in the production process (Parisi and Ghei, 2001). A greater level of specificity of the law generally increases the cost of creation of the law, but requires lower implementation costs by courts and administrative agencies. Thus the greater the fixed investment (i.e., the more specified the law is), the lower the variable costs for its implementation will be.

Further, Parisi and Ghei note that lawmakers choose the timing of legal intervention and revision of legal rules. In this production analogue, the lawmakers' choice corresponds to the investment decision in the fixed production capital and the choice of timing of replacement of obsolete capital. The degree of specificity and the timing of legal intervention are critical control variables for the social planner's attempt to maximize the net present value of legislation. Parisi and Ghei illustrate how the optimal balance of timing and specificity is affected by exogenous parameters such as (a) the expected frequency of application of the legal rule; (b) the degree of uncertainty in the regulated environment; (c) the extent to which lawmaking costs are irreversible (i.e., sunk); and (d) the time preference rate of the social planner.

The choice of a well specified rule is likely to require a larger up-front investment, but has lower operating costs later. Enacting a rule requires a large outlay in the initial acquisition of information, but because the rule is simple to understand and apply, the operating costs are low. A standard requires a smaller investment initially, as it requires less information and legislative detail to enact. However, it requires larger outlays in its enforcement, in that it is more costly for individuals to acquire information about a standard and it requires greater implementation and interpretation efforts by the courts.

In this context, Kaplow suggests that regulation is sometimes served better with a rule, and other times better served with a standard, depending on frequency of application of the relevant law. For legal issues that arise frequently in settings with common characteristics, a rule would tend to be desirable. Because learning about a rule is cheaper, individuals may spend less in learning about the law and may be better guided by a rule since the law's content can be readily ascertained. Conversely, where legal issues rarely arise and the circumstances are varied, designing a rule that accounts for every relevant contingency would be wasteful, as most of such hypothetical circumstances would never arise in actual cases. Since rules have a higher fixed cost than standards, whereas standards generally have a higher variable cost, Kaplow shows that when frequency is low, a general standard is preferable.

The solution to this lawmaking problem generates several implications concerning the patterns of lawmaking under different legal, social and economic conditions. This leads to the hypothesis that legal systems respond to exogenous changes in the external environment by adopting varying patterns of lawmaking, thus maximizing the value of a legal intervention. This hypothesis provides the basis for further consideration of the likely departures from such optimal lawmaking pattern due to specific public choice failures.

2.3. The Obsolescence Problem

It is important to consider that circumstances change with time. Thus, an important cost of legal regulation by means of rules is the cost of altering rules to keep pace with social, economic or technological change. For example, the development of the air bags and anti-lock brakes on vehicles altered the relative costs of accident avoidance. Such changes and advancements can even render rules obsolete. Posner and Ehrlich suggest that the more detailed a rule is, the more often it will have to be changed. For detailed rules, the cost of change is high.

Obsolescence, however, is not as much of a problem with governance by standards as it is with rules. Standards are relatively unaffected by changes over time since a standard indicates only the types of circumstances that are relevant, and not particular, specific circumstances. The reasonableness standard directs the decision maker to determine, *ex post*, what behavior by the parties would have minimized the sum of the expected accident costs and the accident avoidance costs. This concept can be followed despite that the optimal course of conduct changes immensely with time. The optimal rule maker, then, would use more specific rules when there is a stable environment, and general standards when there is a fast rate of change.

Enacted legal rules are subject to obsolescence given the changes in the external environment. Detailed rules are more sensitive to exogenous, unforeseen changes in the regulated environment and thus are more prone to obsolescence. Ehrlich and Posner note that detailed judge made rules of liability, derived from standards and characteristic of the nineteenth, century have given way in this century to detailed traffic and other safety codes that, through the doctrine of negligence per se, operate as rules of tort liability as well as standards. The rise in the rate of economic and technological change over time has increased the cost of the judicial process. While the judicial process is not well suited to the rapid alteration of rules, a general standard can accommodate more change. However, the first adjudication under a standard constitutes a precedent for future enforcement proceedings and nearly transforms the standard into a rule.

2.4. Lawmaking under Uncertainty

An important dimension of the optimal specificity problem concerns the conditions of uncertainty that exist in the enactment of any law. The fundamental premise of recent law and economics research is that lawmaking can be analogized to an investment, where the process of lawmaking imposes a present cost in the expectation of future benefits (Dixit and Pindyck, 1994). In the presence of uncertainty, legal systems can thus be viewed as making investment decisions that create present lawmaking costs and which generate uncertain future benefits. With this in mind, the creation of legal rules often imposes initial lawmaking costs that are at least partially sunk.

The assumption that initial lawmaking costs are at least partially sunk is based on the simple observation that lawmaking costs cannot be recovered if the enacted rule proves to be ineffective or undesirable at a later time. In general, there are a variety of sunk costs in lawmaking. First, there are the obvious costs of legal intervention, which include the direct legislative and political costs, publication, and notice costs. Second, there are the learning costs for courts, enforcement agencies, lawyers and general public. These costs may be substantial and are for the most part irreversible, given the limited value of having learned a law, once the law is repealed. Third, there may be sunk costs of legal innovation whenever there is a change in the existing set of legal entitlements, given the disequilibrium that is likely to take place as a result of legal changes. Finally, there may be institutional costs involved in the change in the legal rule. For example, there may be sunk costs associated with the discontinued operation of an existing rule, given the lost value in the specialization of legal operators and other sunk investments by law enforcement agencies.

The irreversibility of lawmaking costs has important implications for our understanding of optimal lawmaking behavior. It makes lawmaking especially sensitive to various forms of uncertainty over the future costs and benefits derived from the enforcement of the new rule and the rate of change of the regulated environment that may induce obsolescence in the enacted rule.

Quite notably, any model of optimal lawmaking that fails to consider the option value of delaying innovation is necessarily assuming — explicitly or implicitly — that the legal system can avoid all the above sunk costs, and can abrogate and enact laws without sunk expenditures. For most real life applications, however, there are likely to be substantial sunk costs involved in regulatory or legal innovation, which necessitate a revision of the net present value rule in the context of lawmaking. Like in any investment decision, there is the choice on the timing of the investment. Lawmakers need to choose the timing for legal intervention. Given uncertainty about future returns, investment can be postponed to acquire more information. Likewise, legal intervention or revision of current rules can be postponed. But delays in such investment decisions often come at a cost, given the forgone benefits of the investment in the immediate future.

As the emerging investment theory literature has amply shown (see e.g., Pindyck, 1991), the ability of an investor to delay an irreversible investment profoundly changes the logic to be followed in reaching a decision on whether to invest. Traditionally, investment theory under uncertainty suggested that given such tradeoff of costs and benefits, an investment should be carried out whenever it generated a net increase in present value. These conclusions have been revisited in light of option pricing theory (McDonald and Siegel, 1985; Pindyck, 1991) which have revealed that the optimal choice of an investment under uncertainty is not the one generated by net present value calculations, but the one generated taking into account the full value of the option to invest. The results of the investment literature have important implications for the choice of optimal timing in lawmaking.

Given the different sunk investment of a rule as opposed to a standard, the option value of delaying legal intervention varies in the two cases. Thus, in the presence of uncertainty and sunk investment costs, the lawmaker is faced with a wedge between the economies of scale obtainable with the implementation of a specified rule and the increased value of the foregone option to postpone the lawmaking decision.

The dual optimization problem facing the lawmaker, then, is that of determining the optimal level of specificity and timing of intervention in consideration of the above factors. The understanding of the optimal timing problem presented in Parisi and Ghei, in conjunction with the optimal specificity problem presented in the previous law and economics literature (Erlich and Posner, 1973; Schwartz and Scott, 1995; and Kaplow, 1992), would serve as building blocks for a more complex model of lawmaking where timing and degree of specificity are allowed to vary simultaneously. The two optimization problems can then be set up to tackle the interesting problem of the simultaneous choice of optimal timing and specificity of legal rules. Indeed, at any point in time, lawmakers decide their legislative action controlling both the timing and the degree of detail of legal rules, with a likely awareness of the important interrelationship between the two variables.

2.5. Optimal Timing and Specificity of Legal Rules: Bridging the Gap

Parisi and Ghei have also tackled the issue of optimal timing of lawmaking using the insights of option pricing theory. Parisi and Ghei observe that the choice of optimaltiming in lawmaking should be derived considering the option-like characteristics of lawmaking decisions. The authors show that the net present value methodology is inappropriate for dealing with lawmaking decisions under uncertainty. They reach their conclusion by illustrating the different results obtained considering the option value of deferring legal intervention, showing how the resulting lawmaking rules depend on various parameters of the regulated environment.

Building upon the contributions in the existing literature, the problem of optimal specificity can be reconsidered in a dynamic fashion, examining a world where there is a single supreme lawmaker whose business it is to create law. Differently from the existing models in the literature, the lawmaker has two major control variables: first, the option to innovate (or delay intervention); second, the choice of either fully specifying the rule *ex ante* (i.e., choosing a "rule" in Erlich and Posner's terminology) or to state the law in general terms, which requires an *ex post* interpretation of the law (i.e., choose a "standard" in Erlich and Posner's terminology).

3. Conclusion: Policy Implications

As discussed extensively above, the use of rules versus standards has broad implications on judicial interpretation

and the cost and benefits of lawmaking. But choosing the optimal specificity of legal rules also has an impact on public policy that is useful to consider. Legislatures enact general laws that affect large classes of individuals, whereas litigation in the judicial system has a more focused and limited impact. Legal decisions made in the legislatures lack precedential value and therefore affect only interested parties. From a public choice perspective, lobbying before legislatures presents a collective action problem that would be avoided in the case of judicial decision-making.

As a policy matter, Schäfer (2001) suggests that the use of rules over standards has the advantage of reducing corruption, concentrating human capital, and cutting down on court delays caused by complex decisions. Schäfer's conclusions are based primarily on the idea that rules-based systems are preferable in developing countries. Using China as an example, Schäfer declares that efforts there to find the optimal degree of specificity of laws are unsuccessful because the judiciary is composed of largely untrained or unqualified personnel. Adjudicators apply the standards haphazardly and so frequently that no clear signals are sent to the public.

Schäfer's argument depends critically on the debatable premise that legislatures are inherently less corrupt and better informed than the judiciary. Additionally, the regulated environment in developing countries may be more volatile than those of industrialized countries. Volatility of the external environment creates an increased opportunity for obsolescence of legal rules. This in turn would render standards preferable to specific rules, prevent the legislature from constantly having to incur the cost of legislative amendment to modify previous legal enactments after each new development in the external environment.

SELF-INTEREST

"It is not from the benevolence of the butcher, the brewer, or the baker, that we expect our dinner, but from their regard to their own interest." (Adam Smith, The Wealth of Nations, p. 14.)

1. Introduction

The self-interest assumption has an impressive pedigree in economics. From Adam Smith to Gary Becker it has been the lynchpin of many models of human behavior. Put simply, "self-interest" postulates that individuals, in making economic choices, take into account only their own well-being and ignore the welfare of others. The proviso that individuals act in this way simplifies and clarifies arguments wonderfully.

However, it is important, at the outset, to clear up a common misunderstanding of the term. In the Public Choice tradition, choice is assumed to be governed by preferences. Sometimes, self-interested behavior is interpreted as any choice driven merely by one's preferences. This must be contrasted with the meaning, in the current literature (Cox et al., 2001; Rabin, 1993; Sen, 1977; Hoffman et al., 1994). In the literature, self interest reflects an (empirical) assumption restricting preferences to those which rule out direct concern for the welfare of others. Of course, any such self-interested actor needs to take into account how the changed welfare of others leads to objective circumstances affecting her own welfare. Such consequential interactions are not ruled out by the self-interest assumption. Indeed, acting to obtain such benefits is usually referred to as 'enlightened self-interest.'

By cutting out consideration of others' welfare from the economic agent's calculus, the self-interest assumption allows the theorist to focus solely on the effects of choice on the chooser. It allows for a theory of choice in which each individual's preferences are separable from those of others: the interactions of individuals' preferences need not be considered.

This simplification has allowed economic theory to model the logic of market choices by considering the direct valuation to the traders of the goods and services exchanged. Models of choice need not take into account the particulars of: from whom a particular person is buying, to whom that person is selling, or what the effect of the transaction is on another party. This modeling has fostered the development of a clear distinction between the positive analysis of economic behavior and the normative concerns of welfare economics. For example, by assuming self-interest, in any given situation, one can identify both the likely market outcome, and any associated externalities. Externalities are parsed out of the actors' decisions and can be separated for purposes of public policy analysis.

2. The Complexity of the Alternatives to Self-Interest

Relaxing the self-interest assumption allows others' well being to enter directly into one's decisions. This shift forces the theorist to specify precisely how others' welfare enter into the decisions. Many possibilities arise. Increasing the welfare of some others might be positively valued, some of the time, and negatively some of the time. In either case, exactly how much value is to be placed on the others' welfare would have to be specified. And of course, the relationship could be different for each pair of actors. To complicate matters further, individuals may also be concerned about the distributional properties of a given exchange: say about some notion of 'not being bested,' or of fairness of distribution. The list of factors that might appear once the theorist peeked into the other-regarding box could be very long indeed.

So it is not surprising that for a very long time models of economic decision making held firmly to the selfinterest assumption. And the fruits of adhering to this spare model have been plentiful. General equilibrium theory (Arrow and Hahn, 1977), Samuelson's models of public goods (Samuelson, 1954), and, indeed, most major results in the field have flowed from the simple behavioral assumptions of rationality *and* self-interest. Becker, 1981, has even modeled family behavior on the basis of self-interest.

3. The Empirical Problem of Self-interest

But there has always been a problem: self-interest is never more than an approximation of observed behavior. Taken literally, *in extremis*, the self-interest assumption involves essentially socio-pathic behavior: it implies that one would take any payoff, no matter how small, even if it caused horrendous harm to others but was free of direct consequences to one's-self. In most contexts the implications of selfinterested behavior are not damaging, and *can* be observed, regularly. But everyday observation and common sense also reveal countless acts of seemingly unselfish behavior among friends, family, and even casual strangers. And alas, acts of enmity and revenge can also be found. Other-regarding behavior, both benevolent and malevolent, is easy to find if one only looks for it. A few theorists who, as early as the 1950's (Valavanis, 1958 and Preston, 1961 were among the earliest), began producing preliminary models of other-regarding behavior recognized this stubborn fact.

Casual observation also contradicted the predictions of some early models in the Public Choice field. Olson (1965) argued that voluntary contributions to public goods would not occur in large groups without selective incentives, but charitable donations violating that prediction were easy to observe. A similar anomaly was found in voting. Despite the predictions of some models to the contrary, voters, even in very large electorates, vote (Downs, 1957; Barry, 1970 gives some early comments concerning the difficulties). Extensions of the self-interest model to moral philosophy (consider the movement toward ethical egoism in the late 50's as captured by Feldman, 1978; Kalin, 1970; and Medlin, 1957) and political philosophy, sped the development of criticism. Self-interest was seen as too impoverished an assumption to capture the moral side of behavior, and hence was deemed to be an inadequate model of human psychology (Frankena, 1963). A few theorists proposed models of other regarding preferences to deal with the anomalies (Frohlich, 1974; Sen, 1977; Margolis, 1982) but little empirical work existed at that time to test their constructs.

4. Experimental Empiricism and Current Responses

But it wasn't until the applications of the rational choice model to non-market problems caught on in other disciplines that economists and other users of preference models of behavior seriously questioned self-interest. The testing of theories of collective action, or public goods problems, often modeled as a Prisoners' Dilemma Games, led to a body of controlled observations that appeared to contradict the self-interest assumption. Individuals were found, consistently, to contribute to attempts at providing public goods in unorganized groups. The scope of the anomalous behavior varied by context, but rarely was it less than 15% (1995; Dawes, 1980).

The growth of experimental economics and the desire to test the results in game theory provided the motivation and the mechanism for direct formal tests of the self-interest assumption. Miller and Oppenheimer (1982) argued that experimental data regarding committee behavior required a reformulation of the independent preferences hypothesis. Frohlich et al. (1984) demonstrated that, in a simple money allocation experiment, individuals exhibited a variety of other-regarding behaviors, ranging from altruism, through malevolence. Meanwhile results from ultimatum games (see Dawes, and Richard, 1988 and Roth, 1995 for a relatively comprehensive review) turned up anomalous results in which subjects rejected offers of cash, seemingly, on the basis of an unfavorable comparison of their proposed payoff to that of the allocator. The persistence of these anomalies sparked the hypothesis that the anomalous behavior in ultimatum games was an artifact of the implicit bargaining strategic structure inherent in the ultimatum games. To deal with this, economists developed a genre of experiment called dictator experiments. These removed all strategic elements from the interactions. But the ensuing series of experiments revealed persistent other-regarding behavior. Experimentalists began to identify aspects of the choice environment which affected the form of other-regarding behavior (Hoffman et al., 1996; Eckel and Grossman, 1996; Frohlich et al., 2001; here again, see Roth, 1995, for a comprehensive overview of the earlier literature).

The next step was a series of attempts to account for the observed data manifesting other-regarding behavior. (Rabin, 1993, Fehr and Schmidt, 1999; Cox et al., 2001 among others.) Each was posited on a multi-functional utility function, but none has achieved predominance. At this writing, the status of the self-interest assumption is under attack. While it may continue to enjoy prominence in certain theoretical areas where it appears to be a reasonable approximation to reality, (such as in large market interactions, etc.) theorists are attempting to identify how to model behavior in situations in which its failure generates unacceptably inaccurate predictions.

SELFISH GENE

The "selfish gene" is a biological term that has considerable application in the human sciences. Paradoxically, the selfish gene may lead people to engage in apparently charitable behavior. Before dealing with the details of this however it is important to note that human behavior is only controlled by genetic inheritance in the most general way. Human beings walk on their feet, not their hands, wear clothing in cold weather because they have no fur, and in many other ways their genes control their behavior. Genes exert control over the behavior of human beings, however, to a lesser degree than nature controls the physical design of human beings. Nevertheless, some degree of control occurs.

Genes are transmitted from generation to generation and they will only be translated if the individual controlled in part by them acts in such a way as to stay alive and reproduce. Thus the gene, to speak as if it thought things through, wants more genes duplicating itself in the next generation. In fact of course it has no preferences at all, but if it does increase the number of the duplicates in the next generation then it will thrive. Thus to refer to the gene as selfish is showing some poetic license, but does not actually mislead biologists. Economists and public choice scholars should accept this notion on the same terms.

The intriguing feature of this kind of "selfishness" is that it leads to behavior that appears to be unselfish, even generous. To take a famous example Mr. Smith has a certain gene and there is a 50 percent chance and that his sibling also has it. Thus if the genes of Mr Smith cause him to sacrifice his life to save three siblings, the number of genes providing for such a sacrifice would be larger in the next generation. Action on the part of the gene to save copies of itself, albeit at the sacrifice of itself, is what is referred to as selfish behavior in a gene. Naturally this example is an extreme one. Still parents sacrificing for their children are less extreme examples of the same phenomenon. In general any action that reduces one's expectancy of producing viable genes in the next generation while suitably increasing the likelihood of such genes being produced by someone else, implies that those genes will be more frequent in the next generation and hence will multiply over time.

All of this is good biological theory. Since human beings are a biological species it should apply to them.

Most biologists think that it does, and I see no reason to doubt that. Nevertheless except in close family relations I do not conclude that it has a great deal of influence on human behavior. This is unfortunate because a greater degree of generosity and kindness would make the world a pleasanter place. But there is no reason to believe that evolution selects traits in terms of their pleasantness. If an individual is too generous he will have fewer descendents than if he displays just the right amount of generosity. The right amount is not zero, in most cases, but outside the family it comes close to that.

GORDON TULLOCK

SEPTEMBER 11, 2001

War is a mere continuation of policy by other means. (Carl von Clausewitz, [1832] 1976: 87)

Except at harvest-time, when self-preservation enjoins a temporary truce, the Pathan tribes are always engaged in private or public war. Every man is a warrior, a politician and a theologian.... Every village has its defence. Every family cultivates its vendetta; every clan, its feud. The numerous tribes and combinations of tribes all have their accounts to settle with one another. Nothing is ever forgotten, and very few debts are left unpaid. (Winston S. Churchill, [1930] 1996: 134)

Afghanistan has almost always been on the verge of disintegration. Straddling the mountain passes that link the plains of India with Central Asia and beyond, it was a frequently moved pawn in the Great Game played out in the late nineteenth century between the British and Russian empires, each seeking a buffer zone against the other's expansionist aims. Before that, Afghanistan sat astride the path of vital East-West trade convoys moving over the famous Silk Route. More recently, control of the Afghani mountain passes has been sharply contested by local warlords and Mafia-like criminal organizations trafficking in drugs and contraband. Foreign powers, great and small, have long sought 'spheres of influence' in this 'strategic frontier' (Pigou, [1921] 1941: 27), sometimes intervening directly, but more often by courting tribal warlords with money and guns.

The proximate cause of Afghanistan's descent into chaos at the close of the twentieth century was American neglect in the wake of the withdrawal of Soviet troops in 1989, bloodied in a decade-long conflict with the mujaheddin, and the subsequent overthrow, following the USSR's collapse in 1991, of its puppet regime in Kabul (Rashid, 2000: 21). Fighting one of the Cold War's eleventh-hour battles by proxy, the United States had supported the mujaheddin generously with some \$4 to \$5 billion worth of modern weaponry (ibid.: 18), including 900 Stinger missiles (ibid.: 44), which it funneled covertly to them through the Pakistani government's Interservices Intelligence (ISI) agency. Victory won, 'the Americans... washed their hands of Afghanistan...' (Elliot, 1999: 24), leaving a country 'divided into warlord fiefdoms' over which 'all the warlords... fought, switched sides and fought again in a bewildering array of alliances, betrayals and bloodshed' (Rashid, 2000: 21), and 'ordinary Afghans with a widespread feeling of having been betrayed' (Elliot, 1999: 24).

Into this power vacuum stepped the Taliban. A series of military successes over tribal factions contending for local or regional supremacy, crowned by the capture of Kabul in September 1996, triggered hopes that peace and stability would finally be restored, at least to Afghanistan's southern provinces. To Pakistan, 'desperately keen to open up direct land routes for trade with the Central Asian Republics...' (Rashid, 2000: 26), and to the United States, interested both in a strategically located partner to its anti-Iran policy and in a regime that would help ensure the success of a joint American-Saudi-financed, trans-Afghanistan natural gas pipeline long delayed by civil war (ibid.: 46), the Taliban seemed to be a godsend. Neither country was much off-put by the Taliban's virulent anti-modernism and subjugation of women implemented under a strict interpretation of the Sharia law. Not until feminist pressure was brought to bear on the Clinton administration in late 1997 did US policy begin turning around, a reversal soon solidified by the Taliban's refusal to endorse the pipeline project (ibid.: 176).

Despite its need for continued American aid, Pakistan remained faithful to the Taliban because, under Mullah Omar, the regime kept its promise of restoring 'peace', albeit the peace of authoritarian repression. By eliminating the petty warlords who had disrupted the lucrative smuggling trade over the southern mountain passes, the Taliban overcame a tragedy of 'anticommons', arising from multiple rights to exclude (Buchanan and Yoon, 2000). Roving bandits were displaced by a stationary bandit (McGuire and Olson, 1996). In 1993, travelers on the 130-mile-long route from Quetta to Kandahar 'were stopped by at least 20 different groups, who had put chains across the road and demanded a toll...' (Rashid, 2000: 22). Soon after entering the fray in late 1994, 'the Taliban cleared the chains from the roads, set up a one-toll system for trucks entering Afghanistan at Spin Baldak and patrolled the highway from Pakistan. The transport mafia was ecstatic...' (ibid.: 29). Tolls fell to 'an average of 6,000 rupees (US\$150) for a truck traveling from Peshawar to Kabul, compared to

30,000–50,000 rupees, which truckers paid before' (ibid.: 191). Although the Pakistani economy was heavily damaged by the widespread evasion of customs' duties the Taliban facilitated, the 'enormous nexus of corruption' that emerged in Afghanistan's neighbor ensured governmental complaisance (ibid.).

The roots of September 11, 2001, go much deeper than the Soviet Union's collapse, however. A fundamental problem is cartography. Afghanistan, like many of the nation-states fashioned from the carcass of the Ottoman Empire in the aftermath of the First World War (Fromkin, 1989), is an artificial construct. Its southern border was drawn in the late nineteenth century by Sir Mortimer Durand, the colonial government of India's foreign secretary, expressly to divide the Pashtun (or Pathan) tribe's homeland in half, thereby establishing a buffer state on India's northwest frontier. When the Pashtunis who found themselves on the Indian side of the Durand line failed to integrate themselves quietly under the Raj, the North-West Frontier Province (NWFP) was sliced off from the Punjab to establish a second, inner buffer. These two 'tribal belts' were formally incorporated within the boundaries of Pakistan when that nation separated from a newly independent India under the Partition Plan effective 14 August 1947; the Durand line stood (Hilton, 2001).

Afghanistan's northern border was drawn by Josef Stalin. Formalized in the 'Settlement of 1922', a series of treaties between the Soviet Union and its southern neighbors (Fromkin, 1989: 559), the new boundary lines carved up a region, 'comprising modern day Tajikistan, southern Uzbekistan and northern Afghanistan', that had been 'one contiguous territory for centuries' (Rashid, 2000: 146). Like Sir Mortimer Durand, Stalin was apparently keen to create his own buffer zone against the Pashtuns (and the Raj) by stranding sizeable Tajik and Uzbek populations in what thenceforth was northern Afghanistan.

What emerged was the map of a wholly synthetic nationstate comprising at least 20 distinct ethnic groups. Heading the list are the Pashtuns, concentrated in the south and accounting for between 30 and 40 percent of the total Afghani population. Then there are the Turkmen, Tajiks and Uzbeks of northern Afghanistan, a region less populous than the southern Pashtun provinces, but containing '60 percent of Afghanistan's agricultural resources and 80 percent of its former industry' (ibid.: 55). Nuristanis, claiming descent from the armies of Alexander the Great, dominate the western provinces, while remote, mountainous central Afghanistan is the homeland of the Hazaras, 'distant offspring of the armies of Chingiz Khan' (Elliot, 1999: 52–53).

The map's failure to respect customary tribal territorial claims and to accommodate existing regional trade patterns

and social networks has had disastrous consequences for Afghanistan, as it also has had in much of sub-Saharan Africa (e.g., Rowley, 1999). In both cases, members of some close-knit ethnic groups find themselves on opposite sides of new, unwanted national borders; others are compelled to share ground with their enemies of old. Ethnic violence is the predictable outcome as each group seeks control of local, regional and national levers of political power. Strongmen rise and fall as their supporters gain the upper hand. Political authority is exercised, not by sharing power with rivals, but by repressing them.

A factional disease demands a republican cure. Short of redrawing the map of Central Asia, as has been proposed for sub-Saharan Africa (Kimenyi, 1999), the cycle of ethnic conflict can only be stopped by constitutional means. A federal system of government that shifts most political decision-making authority away from the center toward regions having a high degree of autonomy, combined with a representative legislature empowered to resolve tightly defined questions of national policy, offers a time-tested way of accommodating the diverse insular interests of an ethnically heterogeneous polity (Frey and Eichenberger, 1999). The history of the Middle East in general (Friedman, [1989] 1995; Lewis, 1995), and of Afghanistan in particular (Lewis, 2001), suggests, however, that even republican forms of government may be unworkable. Indeed, the UNsponsored transitional government already has drawn fire from Uzbeks angered at the appointment of Tajiks by interim Prime Minister Hamid Karzai, a Pashtuni, to head the high-profile defense, foreign affairs and interior ministries (Schaeffer, 2001). Starting with existing national borders, new constitutions that provide for orderly means of secession and self-determination may be the only troublefree path to regional political stability.

The 'spongy no-go area between Pakistan and Afghanistan, a land of fierce and complicated tribal loyalties and equally ferocious tribal feuds, of gunrunning, drug dealing, and smuggling...' (Hilton, 2001: 60), provided a natural refuge for Osama bin Laden, the architect of September 11, 2001. Awash with money and weapons, some of which had been supplied to bin Laden directly by the United States to help equip the camps he built to train mujaheddin units during the Soviet invasion (and to establish theological colleges — madrassas — to inoculate them with Islamist zeal), the region evolved into a terrorist nursery. After the Soviets withdrew, bin Laden redeployed his military infrastructure in support of the Taliban's drive to restore Pashtunis to their self-claimed place as the rightful rulers of Afghanistan.

His reasons for doing so are bound up in the constellation of theological, cultural and political crosscurrents that have plagued the Middle East for millennia. One of the most important of these is Wahhabism, a movement launched in the eighteenth century by Muhammad ibn Abd al-Wahhab (1703-1787), an Arabian cleric who fathered 'a campaign of purification and renewal. His purpose was to return the Muslim world to the pure and authentic Islam of the Prophet, removing and, where necessary, destroying all later accretions' (Lewis, 2001: 59). Wahhabi doctrine was embraced by the House of Saud, the rulers set over Arabia by Britain in the interwar period. The Taliban's rejection of modernity, a central tenant of that doctrine, attracted covert support from at least some members of Saudi Arabia's royal family, to whom bin Laden had developed close ties (and amassed a personal fortune) through his father's construction business (Rashid, 2000: 131-132). Bin Laden's involvement with the Taliban was also animated by the centuries-old sectarian division between Shia and Sunni Muslims, grounded in a doctrinal dispute over the proper line of succession (hereditary versus elective) to the Prophet Muhammad. The Talibans are fiercely Sunni. Seeing a threat to its own security in the collapse of the Afghan state, neighboring Iran, the only nation where Shias constitute a majority of the population, backed the opposition forces (ibid.: 196-206).

At the end of the day, bin Laden became the Taliban's single most important financial backer, supplying an estimated \$100 billion in cash and military assistance to the Afghan regime over the past five years. These monies came not from his own bank account, but 'from three primary sources: legal and illegal businesses or front companies bin Laden operates directly or indirectly; tribute payments he receives from several Persian Gulf states, companies or individuals that give him funds so he and his al Qaeda supporters will stay out of or minimize activities in their countries; and entities that are masked as charities' (Woodward, 2001). The Taliban leadership's economic dependency on bin Laden helps explain why they continued to protect and shelter him after September 11 rather than save their own necks (ibid.).

The withdrawal of US support for the Taliban in the late 1990s added to bin Laden's list of grievances against the 'Great Satan', a list that includes the American victory over Iraq in the Gulf War, the continued presence of US troops in Saudi Arabia after Kuwait's liberation, America's *rapprochement* with post-Khomeini Iran and, not least, its long-standing support of Israel (ibid.: 133). Bin Laden became a household name in August 1998, following the bombings of the US embassies in Kenya and Tanzania, which claimed 220 lives. He may also have had a hand in earlier attacks against American interests. Bin Laden has been blamed for the 18 US soldiers killed in Mogadishu, Somalia, in 1993; for a 1995 bombing in Riyadh, which caused the deaths of five American servicemen; and for another 19 Americans killed in Dhahran in 1996. His involvement is suspected in bombings in Aden in 1992 and at the World Trade Center in 1993, in a plot to kill President Clinton during his 1994 state visit to the Philippines, and in a plan to destroy 12 US civilian aircraft in 1995 (ibid.: 134–135).

September 11, 2001, was the unforgettable pinnacle of Osama bin Laden's campaign of terror. A preliminary effort to assess the economic impact of that day's events suggests that the attacks on the World Trade Center and the Pentagon imposed immediate costs exceeding \$100 billion, in the forms of property damage and values of lives lost, and of up to \$2 trillion in lower future corporate profits (Navarro and Spencer, 2001).

A reasonably alert US intelligence service would have been better prepared. Bin Laden had already demonstrated American vulnerability to a terrorist strike on its homeland. Nonetheless, an administration weakened by the Monica Lewinsky affair and lacking basic foreign policy expertise (according to Elliot, 1999: 76, Secretary of State Madeline Albright was so uninformed about Afghanistan that, during her first trip to the country, she had to be told the names of the different Afghan parties) failed to avert tragedy.

Neither did the airline industry heed the alarm bells that had been ringing 'since 1988, when a bomb in a suitcase destroyed Pan Am Flight 103 over Lockerbie, Scotland ...' (Yeoman and Hogan, 2002: 43). As a matter of fact, the industry's lobbyists - a cadre counting, among others, ten former members of Congress, two former transportation secretaries, three former officials of the Federal Aviation Administration and the wife of Senate Majority Leader Tom Daschle - have worked hard to water down or defeat every subsequent proposal to beef up airport security, 'including the recommendations of two high-profile presidential commissions' (ibid.: 42). For example, apparently worried about the costs of implementing new security procedures and of annoying the flying public, the airlines fought a plan floated in the midst of the 1996 presidential election campaign by Vice President Al Gore, chair of the White House Commission on Aviation and Security, to require the affirmative matching of all passengers with their baggage. In the weeks following the Vice President's decision to reverse course and accept the industry's weaker alternative proposal, calling only for monitoring the baggage of 'suspicious passengers', the airlines contributed some \$500,000 to the Democratic Party (ibid.: 45).

Interest-group politics thus stalks explanations for why and how commercial aircraft were so easily turned into weapons of terror on September 11. Even now, the airlines warn that unprecedented focus on security threatens to delay the implementation of promising accident-prevention technologies, such as air-turbulence detection devices, and they have apparently convinced the Bush administration not to require prospective employees of the new federal airport security service to have high-school diplomas (Pasztor, 2001).

While terrorism is probably as old as mankind, its modern use as a strategy for influencing public opinion and public policy by groups lacking the means to wage war on a national scale can be traced to 1967, when Israel captured the West Bank and Gaza Strip, thereby angering supporters of Palestinian statehood. The end of the Cold War and the breakup of the Soviet Union added fuel to the terrorist fire as ethnic factions maneuvered for regional autonomy (Enders and Sandler, 1995: 215). Terrorism is likely to continue for the foreseeable future in the Middle East and Central Asia as diverse groups forced for a century or more to live on a map drawn by foreign powers, their ancient conflicts suppressed temporarily, first, by Ottoman and Persian, and, later, by British, French and Soviet hegemony, 'regroup to create new political identities for themselves'. After all, 'it was only at the end of the nineteenth century, with the creation of Germany and Italy, that an accepted map of western Europe emerged, some 1,500 years after the old Roman map started to become obsolete' (Fromkin, 1989: 565).

Pakistan threatens to become the next powder keg. Allowing itself to become the key staging area for the Taliban's incursions into Afghanistan, Pakistan was also complicit in that group's assistance to the Kashmiri separatist movement in next-door India (Rashid, 2000: 186). What goes around comes around. Demands for independence or autonomy on the part of the Kurds, 'a scattered, tribal people who inhabit the plateaus and mountains where Iraq, Iran, Russian Armenia, and Turkey now overlap' (Fromkin, 1989: 503), 'which had been on the agenda in 1921', but 'somehow disappeared from [it] in 1922' (ibid.: 560), remain unfulfilled. Ethnic grudges are not in short supply.

The tools of economics can be applied fruitfully in analyzing terrorist behavior and in assessing alternative antiterrorism policies. Terrorists are rational actors who select their targets and modes of attack cost-effectively, and respond predictably to changes in the expected benefits or costs of terrorist action (Enders and Sandler, 1995). The design and implementation of public policies toward terrorism accordingly merits careful thought, lest terrorists be given incentive to husband their limited resources by committing fewer, but even more dramatic acts than that which riveted the world's attention on September, 11, 2001. While priority clearly must be assigned to protecting innocent lives and property by suppressing al Qaeda and similar terrorist networks, as well as their sponsors in, among others, Egypt, Iraq, Libya, Pakistan, Saudi Arabia and Somalia, the public choice lesson of September 11 is that new national boundaries and new constitutions promise the only lasting solutions to the terrorism of the twenty-first century.

SINGLE-PEAKED PREFERENCES AND MEDIAN VOTER THEOREMS

Many important choices are made by majority rule. However, as is widely known, Condorcet (1785) discovered an important problem with majority rule: For a given set of alternatives, it may be the case that, for each alternative, there is some other alternative which is preferred by a majority of the eligible voters. For a simple example where each alternative can be beaten under majority rule, see (for instance) Kelly (1988: 16).

The problem discovered by Condorcet has led researchers to identify assumptions about voter preferences which imply that there is an unbeaten alternative. The best known assumptions (about voter preferences with unbeaten alternatives) are ones where the voters have what are known as "single-peaked" preferences.

The distinguishing feature of single-peaked preferences was described in Black (1948: 24), where this special term was first introduced. His description was specifically for a "committee considering different possible sizes of a numerical quantity and choosing one size in preference to the others." The following description was for any particular member of the committee:

Once he had arrived at his view of the optimum size, the farther any proposal departed from it on the one side or the other, the less he would favor it. The valuations carried out by the member would then take the form of points on a single-peaked or 1-shaped curve.

Significantly, Black (1948) established that (when the members of a committee have single-peaked preferences) if a committee member's most preferred alternative is (in a certain specific sense) a median for the corresponding

distribution of the members' most preferred alternatives, then that alternative is unbeaten under majority rule.

Black's reasoning can also be used in certain other settings where public choices are made (for instance, Black noted that his reasoning has similar implications for an analogous model of multicandidate elections). Drawing on research that has built on Black's work, this entry will *both* discuss some of the key assumptions and results in Black's original research *and* state assumptions and results for a more general model (which applies to various settings where public choices are made).

1. Alternatives, Individuals and Preferences

Black (1958) stated: "By a *committee* we will mean any group of people who arrive at a decision by means of voting" (p. 1). He also stated: "A *motion* we define as any proposal before a committee which it may adopt or reject by a method of voting" (p. 1). Black also assumed that the committee has a finite number of members and that each member has preferences on the set of motions.

The more general model for this entry will use the following notation and assumptions.

X will denote a set of alternatives. $N = \{1, ..., n\}$ will be an index set for a finite set of individuals who get to vote on the alternatives. For each $\tilde{i} N$, R_i will be a binary preference relation on *X*, where xR_iy means "*x* is at least as good as *y*, for *i*". xP_iy will mean "*x* is preferred to *y*, for *i*" (i.e., xR_iy holds, but yR_ix does not). It will also be assumed that R_i is an ordering on *X*— that is, R_i is

- (i) complete (For all distinct $x, \tilde{y} X: xR_i y$ or $yR_i x$),
- (ii) reflexive (For all $\tilde{x} X: xR_i x$),
- (iii) transitive (For all x, y, \tilde{z} X: $[xR_iy \text{ and } yR_iz]/[xR_iz]$).

[Note: The terms that have been used for assumptions about preferences vary from one reference to another (see, for instance, the discussion about terms in Sen (1970: 8–9)); the specific terms listed above are the ones adopted by Sen (1970: 8–9)].

1.1. Examples

Two simple examples will be used to illustrate various aspects of the material in this entry. In the next paragraph, they will be used to illustrate the assumptions stated above. Later on, additional features will be added to the examples — so that they can be used to illustrate other things. In order to keep the discussion as clear as possible, the examples have been tailored to illustrate the basic concepts and theorems that are covered.

Both of the examples will have the following common features: A committee is considering the budget of a particular government agency. The set of alternatives available to the committee is $\{r, s, t\}$, where *r* denotes retrenchment (with large budget cuts), *s* denotes the same budget as at present, and *t* denotes a tremendous increase in the agency's budget.

Example 1. There are three individuals, i = 1, 2, 3, on the committee. Their preferences are rP_1sP_1t , sP_2tP_2r , and tP_3sP_3r respectively (where xP_iyP_iz means: xP_iy , yP_iz , and xP_iz).

Example 2. There are four individuals, i = 1, 2, 3, 4, on the committee. i = 1, 2, 3 have the same preferences as in Example 1 and i = 4 has rP_4sP_4t .

2. Utility Functions and Linear Orders

The preferences of the four individuals used in the two examples can be represented by the following utility functions:

$u_1(r) = 3,$	$u_1(s) = 2,$	$u_1(t) = 1,$
$u_2(s)=3,$	$u_2(t)=2,$	$u_2(r)=1,$
$u_3(t)=3,$	$u_3(s)=2,$	$u_3(r)=1,$
$u_4(r) = 3$,	$u_4(s) = 2,$	$u_4(t) = 1$,

(where the subscript denotes the individual whose preferences are being represented).

For graphing a voter's utility function in a Cartesian plane, it will be helpful to have a way of "lining up" the elements in X (so that we will know what order they should be put in when we locate them on an axis). For instance, if the elements are the real numbers, they could be potentially "lined up" by using a weak inequality (or) or by a strict inequality (< or >). More generally: As in Rubin (1967) and Denzau and Parks (1975), the way in which the elements in X will be "lined up" can be made precise by specifying a binary relation, o, on the set X which is

- (i) complete (For all distinct $x, \tilde{y} X: x_0 y$ or $y_0 x$),
- (ii) transitive (For all x, y, $\tilde{z} X$: $x_0 y$ and $y_0 z$]/[$x_0 z$]), and
- (iii) anti-symmetric (For all x, ỹ X, [x₀y and y₀x]/[x and y are not distinct]).

As in Rubin (1967) and Denzau and Parks (1975), this relation will be called a "linear order."

Some references (for instance, Mas-Colell et al. (1995: 801)) assume that the relation used to "line up" the alternatives has properties (i)–(iii) *and* is reflexive (For all $\tilde{x} X$: x_0x) — as with the weak inequalities for a set of real numbers. Some references (alternatively) assume that the

relation has properties (i) and (ii) *and* is irreflexive (For all $\tilde{x} X$, it is not the case that $x_0 \cdot x$) — as with the strict inequalities for a set of real numbers. References where this second approach is used include Arrow (1963: 77), Fishburn (1970: 487; 1972: 94–95; 1973: 75, 102), Kelly (1988: 29), and Moulin (1988: 225, 263–264).

The first approach explicitly assumes that the relation has properties (i), (ii) and (iii) *and* adds an assumption. The second approach explicitly assumes that the relation has properties (i) and (ii) *and* assumes that the relation is is irreflexive. Since the second approach uses a relation that is transitive and irreflexive, the relation is also antisymmetric (see, for instance, Fishburn (1973: 72–73)). Hence, when either of these approaches is used, the relation has properties (i), (ii) and (iii). So these two approaches are special cases for the definition of a linear order used by Rubin (1967) and Denzau and Parks (1975).

In a linear order, some (or all) of the comparisons can be "strict" comparisons. A strict comparison in a linear order will be denoted by the symbol $<_0$. More specifically, for a given linear order.₀ (on the set *X*) and any pair *x*, \tilde{y} *X*, we will be using $x <_0 y$ to mean: $x_0 y$ holds, but $y_0 x$ does not hold.

In the examples, the interpretation of x_0y will be "x is either to the left of y or in the same place as y." In the examples, the interpretation of $x < _0y$ will be "x is to the left of y." So, in the examples, the linear order $_0$ will give us a way of lining up the alternatives from left to right when graphing a voter's utility function. For the examples, it will be assumed that the linear order is: r is to the left of s, s is to the left of t, and (hence) r is to the left of t (i.e., $r < _0s$, $s < _0t$, and $r < _0t$).

3. Graphing the Voters' Utility Functions

In the examples, the utility function for any given individual \tilde{i} {1, 2, 3, 4} can be graphed as follows. First, place *r*, *s*, and *t* on the horizontal axis with *r* to the left of *s* and *s* to the left of *t* (corresponding to the linear order being used for the examples). Second, letting the vertical axis be measured in utility units, place dots at the three points with the following Cartesian coordinates (*r*, *u*_i(*r*)), (*s*, *u*_i(*s*)), and (*t*, *u*_i(*t*)). Third, draw lines connecting (*r*, *u*_i(*r*)) with (*s*, *u*_i(*s*)) and connecting (*s*, *u*_i(*s*)) with (*t*, *u*_i(*t*)).

When the graphs are drawn, it becomes clear that, for each individual, the three dots "take the form of isolated points on single-peaked curves" Black (1948: 24).

In the examples, if you start at the leftmost alternative (r) and move to the right, you can see that:

(i) for i = 1 and i = 4, the curve that you have drawn consistently goes down [from (r, u_i(r)) = (r, 3) to (s, u_i(s)) = (s, 2) and then to (t, u_i(t)) = (t, 1)];

- (ii) for i = 3, the curve that you have drawn consistently goes up [from $(r, u_3(r)) = (r, 1)$ to $(s, u_3(s)) = (s, 2)$ and then to $(t, u_3(t)) = (t, 3)$];
- (iii) for i = 2, the curve that you have drawn first goes up [from $(r, u_2(r)) = (r, 2)$ to $(s, u_2(s)) = (s, 3)$] and then goes down [to $(t, u_2(t)) = (t, 1)$].

Thus each curve is "one which changes its direction at most once, from up to down" Black (1958: 7).

When each voter has a most-preferred alternative, this statement implies that each voter has a single "peak" for his preference ordering. In the examples, this property can be seen by looking at the graphs for the voters' utility functions.

4. Single-Peaked Preferences

Black (1948: 24–25) used the following terminology (in the context of his committee model):

"We shall refer to the motion corresponding to the peak of any curve — the most-preferred motion for the member concerned — as his optimum." Black's concept of an "optimum" can be extended (so that it applies to any individual's preference relation R_i) by using the following more general definition: $\tilde{x}_i X$ is an optimum for $\tilde{i} N$ if and only if $x_i P_i y$, for all $\tilde{y} X$ — { x_i }.

As in Black (1948, 1958), in what follows it will be assumed that each individual in *N* has an optimum. In the examples, the committee members' optima are $x_1 = x_4 = r$, $x_2 = s$, and $x_3 = t$.

In the preceding paragraphs, the preferences of the four individuals in the examples have been used to illustrate the idea behind the concept of single-peaked preferences. Assuming that each voter *i* has an optimum x_i , the concept itself can be stated precisely as follows (following Denzau and Parks (1975), for instance): R_i is "single-peaked with respect to₀" if and only if, for each pair $y, \tilde{z} X$,

$$[y <_{O} z \& z <_{O} x_{i}]/[zP_{i}y]$$

and

$$[x_i < _{o}y \& y < _{o}z]/[yP_iz].$$

5. Comparisons Based on Majority Rule

We will consider certain pairwise comparisons (of alternatives) that are based on majority rule. More specifically, we will consider comparisons where a majority of the nonindifferent voters prefer one particular alternative to another. The statement that $\tilde{x} X$ "gets a majority over" $\tilde{y} X$ will mean $|\{\tilde{i} N : xP_iy\}| > |\{\tilde{i} N : yP_ix\}|$, where |A| denotes the number of elements in (or "cardinality of") the finite set A. In Example 1: *s* gets a majority over both r and t. In Example 2: no alternative gets a majority over every other alternative — but, at the same time, there is also no alternative that gets a majority over either r or s.

6. The Population of Voter Optima

Since each voter has an optimum, the voter optima constitute a population (as that term is used in Statistics). This population can be summarized with a probability distribution as follows: The distribution of voter optima is the discrete probability distribution $P(\blacksquare)$ on *X* that satisfies

$$\mathbf{P}(x) = |\{i \ N : x_i = x\}| / \mathbf{n}, \text{ for } \tilde{x} X$$

In this distribution: For any $\tilde{x} X$, P(x) is simply the proportion of voters for whom x is the best alternative. In Example 1, the distribution of voter optima is: P(r) = P(s) = P(t) = 1/3. In Example 2, it is: $P(r) = \frac{1}{2} P(s) = P(t) = \frac{1}{4}$.

When thinking about a distribution it is sometimes helpful to measure its center by using the concept of a median. In this context, a median will be defined in the following way: $\tilde{m} X$ is a median for the distribution of voter optima with respect to._o if and only if

$$\mathbb{P}(\{\tilde{x} X: \tilde{x}_{0}m\}).\frac{1}{2}$$

and

 $P(\{\tilde{x} X: m_0 x\}), \frac{1}{2}.$

Other references that have applied the same statistical notion of a median to distributions of voter optima include Black (1948, 1958), Fishburn (1973), Denzau and Parks (1975), Enelow and Hinich (1984) and Mueller (1989). In general: *If* the underlying statistical notion of a median is applied in a setting where (as in the context being studied here) (1) discrete probability distributions are used to summarize populations and (2) a population can potentially have an *even* number of things in it, *then* there is the possibility of having more than one median (see, for instance, Johnson et al. (1992: 51)). Because of this possibility, some statistical references use an alternative notion of a "median" for a discrete distribution which will assure that there is a unique median (see, for instance, Johnson et al. (1992: 42) — although that approach will not be adopted here.

Recall that, for the examples, the linear order is: r is to the left of s, s is to the left of t, and (hence) r is to the left of t (i.e., $r < _{o}s$, $s < _{o}t$, and $r < _{o}t$). In Example 1, there is a unique median m = s (the unique alternative that beats every other alternative). In Example 2, there are two medians m' = s and m'' = r (the two unbeaten alternatives).

A voter whose optimum is a median for the distribution of voter optima (with respect to a linear order) is, accordingly, called a "median voter" (with respect to the given linear order). In Example 1, i=2 is the unique median voter. In Example 2, every individual except i=3 is a median voter.

7. Median Voter Theorems

The following two "median voter theorems" are generalizations of results that were established by Black (1948: 27, 28, respectively) in the context of his committee model. Proofs of these theorems are provided in Denzau and Parks (1975).

Theorem 1. Suppose that X is finite, each voter has an optimum, each voter's preference ordering is single-peaked with respect to._o, and *n* is odd. Then the voter optimum x_i gets a majority over every other alternative in X if and only if x_i is a median for the distribution of voter optima (with respect to._o).

Corollary 1. Suppose that X is finite, each voter has an optimum, each voter's preference ordering is single-peaked with respect to_{.0}, and *n* is odd. Then the voter optimum x_i gets a majority over every other alternative in X if and only if *i* is a median voter (with respect to_{.0})

When the premise for Theorem 1 is satisfied, the discrete distribution of voter optima necessarily has a unique median. Therefore Theorem 1 implies that, when its premise is satisfied, there exists a unique voter optimum which gets a majority over every other alternative. Theorem 1 and this implication are both illustrated by Example 1 (where *n* is the odd number 3 and $x_2 = s$ gets a majority over both *r* and *t*).

In Example 1, i = 2 is a unique median voter. However, while Theorem 1 implies that (under its premise) there is a unique voter *optimum* that beats every other alternative, Corollary 1 implies that (under the same premise) there are cases where there is more than one *median voter*. For instance, suppose $N = \{1, 2, 3\}$ and $rP_i sP_i t$, for each $\tilde{i} N$. Then r is a unique voter *optimum* that beats every other alternative *and* each voter is a *median voter*. When the premise for Theorem 1 is satisfied and there is more than one median voter, it follows from Theorem 1 that each median voter has to have the same optimum.

Theorem 2. Suppose that X is finite, each voter has an optimum and each voter's preference ordering is singlepeaked with respect to_{.0}, and *n* is even. Then there is no alternative in X that gets a majority over the voter optimum x_i if and only if x_i is a median for the distribution of voter optima (with respect to_{.0}).

Corollary 2. Suppose that X is finite, each voter has an optimum, each voter's preference ordering is single-peaked

with respect to_{.o}, and *n* is even. Then there is no alternative in *X* that gets a majority over the voter optimum x_i if and only if *i* is a median voter (with respect to_{.o}).

When the premise for Theorem 2 is satisfied, the discrete distribution of voter optima has at least one voter optimum that is a median and no more than two distinct voter optima that are medians. Therefore Theorem 2 implies that (when its premise is satisfied) there is at least one voter optimum that is unbeaten and no more than two distinct voter optima that are unbeaten. Corollary 2 implies that (under the same premise) there may be more than two median voters. These observations are illustrated by Example 2 (where *n* is the even number 4, voters 1, 2, and 4 are the median voters and the optima that are unbeaten under majority rule are $x_2 = s$ and $x_1 = x_4 = r$).

In some settings where voting is used, there is an individual (such as a committee chairman) who can break ties. If the premise of Theorem 2 is satisfied, there are two distinct optima that are unbeaten *and* we add the assumption that there is an individual in N who can break ties, then the unbeaten optimum that is closer to that individual's optimum will be the final decision.

It should be noted that Arrow (1963), Fishburn (1970, 1972, 1973), Sen (1970), Denzau and Parks (1975) and others have proven some closely related theorems (which have premises that are variations on the ones used above).

It should also be noted that Black (1948) predicted that his theorems would "provide the basis for a theory of the equilibrium distribution of taxation or of public expenditure" (23). Significantly, his theorems (and extensions of them) have been widely applied in studies of the public sector — see, for instance, Atkinson and Stiglitz (1980: ch. 10)) the plus the references that they cite.

THE SOCIAL COST OF RENT SEEKING

Consider two entrepreneurs: Smith and Jones. Each has \$10 million to invest. Smith invests his money in a shoe factory. Gross sales of shoes each year come to \$3 million; operating expenses are \$2 million annually. Thus, Smith makes a nominal profit of \$1 million per year. However, Smith could have invested his capital in a restaurant, earning a net return of \$500,000 per year so relative to the next-best alternative use of his capital, Smith is earning a 5 percent rate of return on his investment. That is, consumers value his production of shoes more, \$500,000 per year more, than they value the dining services provided by the restaurant. Smith becomes a wealthy man by making the right decision about what consumers value. Smith's wealth, then, is a reflection of the value he creates for society.

Jones invests her money in bribing ... er successfully explaining to Alabama politicians why they should give her a tax break worth \$1 million per year. (It doesn't take much money to 'explain' things to Alabama politicians). Jones also has an opportunity cost of \$500,000 per year, as she could invest her \$10 million capital in the same restaurant that Smith could invest in. Relative to her opportunity cost, Jones is, like Smith, earning a 5 percent rate of return on her investment. Thus, from the perspective of the two individuals, their behavior is identical — each 'invests' available capital in the highest-return employment.

However, in terms of social welfare, the two entrepreneurs are completely different. Whereas Smith's profits result from his creation of previously unrealized value for society, Jones' profits do not reflect value created for society. Critically, they are derived only from redistribution of existing wealth, not from creation of new wealth (Baumol, 1990; Bhagwati, 1982; Hirshleifer, 1994). Even though Jones put only her own capital at risk, in lobbying for the tax break, this action is socially harmful. How so? Because her capital could have been employed in producing restaurant services that society valued, on net, at \$500,000 per year. Employment of Jones'capital in an activity that society valued at zero, 'costs' society \$500,000 worth of value that otherwise might have been realized. This unrealized potential value is the social cost of rent seeking (Tullock, 1967).

We know that rent seeking takes place, so there is a cost borne by society. The question is, how significant is the social cost of rent seeking? There have been three general approaches taken to answering this question. One approach is indirect: if we can specify the relationship between rent seeking activity and the size of the rents to be had, then identification of the aggregate amount of governmentallyarranged wealth transfers permits conclusions to be drawn about the magnitude of the implied social cost. This approach easily has drawn the most attention of Public Choice scholars (Tullock, 1971; Browning, 1974; Krueger, 1974; Posner, 1975; Paul and Wilhite, 1991; Dougan and Snyder, 1993). In theory, fully-informed and rational individuals would, collectively, spend 100 percent of the value of the expected transfer, less an ordinary rate of return, in efforts to achieve/block the transfer. That is, there would be complete dissipation of the expected rent(s). However, even slight deviations from the assumption of full information can lead, in theory, to over or under-dissipation.

Theory notwithstanding, our everyday experience seemingly suggests that successful rent seekers do not pay much for the wealth transfers that politicians arrange for them (Tullock, 1988, 1989, 1997). The most obvious example of this is the disparity between the amounts of money special interest groups donate to politicians and the value of legislative protection provided. The latter typically is many multiples of the former. However, the fact that the observed 'price' of special favors seemingly is low does not mean that the social cost of rent seeking is low or that rents are not substantially dissipated away in efforts to capture them.

Unobserved investments in the rent seeking process may loom large in the final reckoning of social cost. Such investments not only may take non-cash forms, they also may not even flow to politicians in control of the political apparatus that determines the supply of rents. Labor unions and other special interest groups commonly provide labor and votes for politicians. They also provide commercial

advertisements in support of a politician and/or against his opponent(s). They invite (and pay) politicians to speak to their organizations. They invite politicians to lunch, sporting and entertainment events, and the like (Laband et al., 1994). They provide well-paid jobs for the politician's family members and friends. But these investments that target specific politicians only are made after identifying the imperative to do so in the first place. Such imperative derives either from identifying an opportunity to gain rents or perceiving a threat that some other special interest group is lobbying for political action that would be harmful to your group. Timely identification of both opportunities and threats requires constant investment in information about current events and activities in the world generally, and especially in all branches and levels of government, not just by active rent seeking entities, but also by everyone who wishes to avoid being victimized by the rent seeking efforts of others. It simply must be the case that such investments by all potentially affected parties, even though they may be small on the margin, are enormous in the aggregate (Laband and McClintock, 2001).

Even if the relationship between the size of the rents and the degree of dissipation was well understood, which it is not, imputation of the social cost of rent-seeking from determination of the size of the rents understates the social cost. This is because resources also are expended by individuals who seek to become suppliers of the rents themselves (this has, of course, been a major cause of wars throughout history) and thus the beneficiaries of subsequent rent-seeking activity (Buchanan, 1980). The next two approaches avoid this mis-measurement problem.

A second approach to gauging the social cost of rent-seeking is direct measurement of rent-seeking expenditures. For example, one could identify the expenditures in a given year for all federal and state licensed political lobbyists, expenditures by individuals seeking public office, donations by special interest groups to political campaigns, and so forth. This accounting approach yields estimated expenditures on wealth redistribution activity in the U.S. in the hundreds of billions of dollars annually in recent years (Laband and Sophocleus, 1992; Laband and McClintock, 2001). Remember, these are expenditures that could have been, but are not, put to use in producing positively-valued goods and services.

A third approach to assessing the social cost of rentseeking is historical or comparative analysis of the effects of rent-seeking on a country's economic performance. The theory is straightforward: as more of a nation's resources are devoted to rent-seeking rather than productive activity, less real economic growth is forthcoming (Olson, 1965; Murphy et al., 1991; Rauch, 1994). Although researchers do not measure rent-seeking activity directly, they use the presence of institutional structures that facilitate or inhibit rent-seeking activity as a proxy for the activity itself. The strong and consistent finding by researchers is that the economic performance of countries with strong protectionist regimes is markedly lower than the economic performance of countries in which competitive forces are not stifled (Olson, 1965; Ekelund and Tollison, 1981, 1997).

SORTITION

[T]he appointment of magistrates by lot is thought to be democratical, and the election of them oligarchical ... (Aristotle, *Politics*: 1294b, 5–10)

Sortition is decision by a random process, such as the drawing of lots. It was widely used by the ancient Greeks. In Athens, in the fifth and fourth centuries B.C., virtually all administrative positions (excluding a few requiring specialized abilities, such as military leaders) were filled by lot. It was also used in renaissance Venice and Florence. Those governments employing sortition were administered more regularly, honestly and successfully than contemporaneous states utilizing other methods, and, in fact, compare favorably to modern states (Headlam, 1933: 173; Finlay, 1980: 29; Queller, 1986: 4, 8). Any comparison between ancient and modern states is, of course, impeded by the dramatically more expansive role of modern states.

As Aristotle noted, the Athenians considered selection by lot as essential to democracy. They believed other known methods of election were inherently susceptible to manipulation by organized interest, and would prevent rule by the demos (Headlam, 1933: 12–32, 177). Greek critics of the lot (including Socrates) were also critics of democracy, generally, and criticized the lot *because* it was democratic (Headlam, 1933: 13–14).) In renaissance Italy, Florence employed sortition more broadly than Venice and, as a result, was regarded as more democratic (Gilbert, 1968: 473). Election by lot, there, was considered coincident with liberty and equality. One of the purposes of the lot was to diminish the powers of the magistrates, thus retaining governance by the people, rather than a ruling political class (Hansen, 1992: 236).

The Greeks recognized decision by lot as a defense against faction (Aristotle, *Rhetoric to Alexander*: 1424a, 13–16; *Politics*: 1303a, 15–20; Headlam, 1933: 38), as did the Venetians and Florentines (Finlay, 1980: 31, 38; Queller, 1986: 6). The random element in the selection process reduces the return to political rather than productive enterprises. Sortition may also reduce political violence relative to voting, by removing the benefit of

eliminating a few key voters in close elections (Levy, 1991: 146–147).

The role of chance in sortition is sometimes interpreted as revealing divine intent (Plato, *Laws*: Book III, 690c; Book VI, 759c; Homer, *The Iliad of Homer*: 3:316, 7:161; Proverbs 16:33; Hansen, 1990: 58; Headlam, 1933: 4–8).

There are a variety of ways in which an element of randomness can be incorporated into a collective decision making procedure. One familiar manner is the use of a random method, such as a coin toss, to select an alternative where a voting procedure fails because of a tie. Other methods of incorporating some degree of randomness include voting where some of the alternatives considered are lotteries across single-valued alternatives, as well as the single-valued alternatives themselves (Zeckhauser, 1969; Fishburn, 1972; Machina, 1985). A more sophisticated decision technology, sometimes called the average rule, is discussed in Coleman (1973), Intriligator (1973, 1982) and Freixas (1984). Individuals are permitted to express their preferences as vectors. These vectors can represent the probabilities with which an individual believes they would be most satisfied with the alternatives covered, or may represent a weighted ranking which reflects they strengths of their preferences. For instance, each voter might be given 100 votes which they may allocate however ever they choose across the set of alternative (they may choose to give their most favored alternative 50 votes, their second choice 30, etc.). Taking the average of the weighting for each alternative yields a probability distribution that can be applied to create a social ordering or select among the alternatives. A simpler method is to permit electors to mark their preferences on ballots, but rather than counting them, draw one at random, which becomes the social choice. This is sometimes referred to as a proportional lottery (Fishburn and Gehrlein, 1977; Gehrlein, 1991; Gehrlein and Berg, 1992) or proportional majority voting (Mueller, 1989).

In the Social Choice literature, spawned by Arrow's seminal impossibility theorem (Arrow, 1950, 1963), various criteria have emerged by which to evaluate the desirability of collective decision-making technologies. Procedures incorporating a degree of randomness often perform well under these criteria. Arrow's theorem states that any social welfare function that is complete, transitive, defined for all individual orderings, exhibits a positive association between individual preferences and the social preference, and is independent of irrelevant alternatives, must either be imposed or dictatorial. In fact, Arrow himself noted that probabilistic decision methods are not necessarily subject to his famous proof (Arrow, 1963: 20–21). Nandeibam (2000) shows that it is possible to construct probabilistic criteria corresponding to Arrow's

deterministic ones, such that a class of decision mechanisms satisfies the criteria (i.e., is neither dictatorial nor imposed).

With reference to Arrow's criteria, sortition is not decisive, in that there is not a unique outcome for any given set of votes. From the same set of expressed preferences, the procedure may select alternative A one time, and alternative B the next. Sortition is complete, in that for any given set of alternatives, one of which is to be randomly selected, a selection can be made. This is in contrast to voting, which fails to select among alternatives in those instances resulting in a tie.

Sortition, unlike voting systems, can be independent of irrelevant alternatives. Susceptibility to irrelevant alternatives is observed when third party candidates, with no chance of winning, siphon votes away from a major candidate, such that the winning candidate is not the first choice of a plurality of the voters. Under sortition, any alternative that is included could potentially be drawn, regardless of the low probability of such an event. Therefore there are no irrelevant alternatives to be independent of.

Collective decision mechanisms that are not independent of irrelevant alternatives are susceptible to manipulation through preference falsification. Participants may be able to improve the outcome of the election by misrepresenting their preferences. This weakness is common to all voting systems deciding among three or more alternatives, except those incorporating a significant element of chance (Gibbard, 1973; Satterthwaite, 1975; Barberà and Peleg, 1990). Some forms of sortition, including the proportional lottery, however, are strategy-proof (Kelly, 1977; Barberà, 1978, 1979). Decision technologies that are susceptible to misrepresentation of preferences will be biased towards voters who have less regard for honesty as a normative standard. The accurate revelation of preferences has value beyond determining the outcome of a particular election, as in guiding the development of future policy proposals. Decision technologies that are less vulnerable to manipulation would seem preferable, ceteris paribus.

Forms of sortition, including the average rule and proportional lottery, are unanimous. If all lots are marked with the same alternative, it is selected with certainty. These forms of sortition are also strongly monotonic. That is, an increase in the relative standing of an alternative in the individual rankings of one or more electors increases the probability of that alternative being selected. This is in contrast with decisive voting procedures where, although an increase in the relative standing of an alternative in individual rankings cannot reduce the probability of an alternative being selected, it only increases the probability of selection when that alternative was within one vote of being tied. This strong monotonicity in these forms of sortition means that there is a benefit in seeking as near a unanimous consensus as possible in the selection or development of any proposed alternative. This is unlike plurality voting mechanisms, where consensus beyond a plurality of voters has no effect on the probability of success.

Sortition is typically anonymous and neutral. All voters are treated identically, as are all alternatives. Sortition is not transitive. If alternative A is selected over alternative B, and B over C, it is not certain that A would be selected over C. In fact, because of the random element, if A is selected over B, it is not certain that in an additional drawing from the same lots that A will be selected over B again.

Stochastic decision methods are currently accepted in some applications, and not in others. A more or less random selection of jurors is generally regarded as acceptable. During the Vietnam conflict a lottery was used to determine who would be conscripted. A coin toss before the kickoff of football games is accepted as an appropriate device to determine who will receive the ball. Fishburn (1978) offers a list of characteristics relating to the acceptability of lotteries as decision mechanisms. He cites (1) a set of two or more qualifying agents that have met some criteria, (2) a prize (or duty) to be awarded to one of the candidates, (3) more or less homogeneous attitudes towards accepting the prize or duty, (4) general acknowledgement of an equal right to receive the prize (or evade the duty), and (5) the lack of a competition to persuade others that one candidate is more deserving of selection than the other. Fishburn notes that he knows of no circumstance that does not meet these five criteria in which decisions are currently made stochastically.

Political contests clearly do not meet Fishburn's fourth and fifth characteristics. It is interesting to note, however, that renaissance Venice, which did employ selection by lot, did attempt to have their collective political decisionmaking meet those criteria. Politicking was forbidden in Venice. It was illegal for Venetians to suggest that they themselves, or anyone else should be nominated to the pool of candidates or electors, from which selection would be made by lottery. So great was concern regarding political intrigue advancing the interests of one clan or faction over another, that virtually all social gatherings where political alliances might be advanced were regulated or prohibited, including large dinners, weddings and baptisms (Queller, 1986: 77–78).

Sortition has the potential to protect against the tyranny of the majority — that is, the threat that a dominant majority will suppress the interests of a persistent minority. Although majorities may shift over time under the plurality-voting rule, it may well be that a few dominant factions rotate power amongst themselves, while the most vulnerable minorities are permanently suppressed. The inherent susceptibility of plurality voting to manipulation makes this unfortunate outcome more likely. The very real possibility that a minority coalition will eventually become dominant can be expected to temper the temptation for any currently dominant faction to exploit its position too aggressively. Under the average rule and proportional lottery a position that is held by 20% of the populace will win out, on average, 20% of the time. On the other hand, the fact that a viewpoint is only held by a minority may be interpreted as an a priori indication that it is, in fact, desirable for that viewpoint to be suppressed. Some viewpoints remain in the minority because they are abhorrent to a majority of the populace. One strength of sortition in the balancing the interests of minorities and majorities is that it can be implemented such that the probability of an alternative being selected is proportional to the strength of support it has. It is also possible for sortition to be implemented such that an alternative must receive some minimum level of support to be included in the lottery.

Stochastic decision mechanisms severely impair the effectiveness of efforts to affect the outcome of collective decisions. For this reason, the returns to rent-seeking efforts are significantly lower where sortition is employed. Therefore, the proportion of resources directed to rent-seeking, as opposed to productive efforts, should be markedly lower in societies that employ probabilistic decision mechanisms. The inverse relationship between the degree of randomness in collective decision making, and the amount of resources directed to capturing transfers (as opposed to creating wealth) is a theme that runs through Tullock's *Efficient Rent-seeking* article, and the literature that surrounds it (Tullock, 1980; Lockard and Tullock, 2000).

Sortition served well those states that used it as a collective decision making technology, where it was regarded it as the very essence of democracy. It restrains the growth of an independent political class, impedes manipulation of the political apparatus, impairs factional discord, restrains state power, protects vulnerable minorities and reduces rent-seeking. Decision methodologies incorporating some degree of randomness hold promise for addressing instances of governmental failure revealed through the public choice analysis of political institutions.

STANDARD OIL AND MICROSOFT: ANTITRUST LESSONS

Until the mid-1970s, American antitrust regulators and courts too-often confused "competition" with "competitors." Today this confusion occurs much less frequently. The reason is twofold: first, sensible economics is more likely to guide antitrust's application, and second, consumer welfare (rather than producer welfare, or "democratic values," or some other goal unrelated to competition) is now the near-exclusive standard by which antitrust regulation is judged. But improved as it is, in this writer's view antitrust's benefits still fall short of its costs. The need for government to ensure that competition prevails is not at all obvious, while the actual record of antitrust regulation being used to stymie competition is long and clear.

Support for these two claims is found in two of the most famous antitrust cases — the first coming early in antitrust's history (*United States v. Standard Oil, Inc.*, 1911), the second occurring very recently (*United States v. Microsoft Corp.*, 1999). Despite being separated by nearly ninety years, these two cases share important similarities. Both cases involved highly visible companies in new industries on technology's frontier, and both companies were founded and led by outspoken, aggressive entrepreneurs, each famous for the unprecedented fortune he amassed in business. Also, each firm was accused of using unfair and ruthless means of garnering the large market shares that each enjoyed. Chief among these allegedly illegal means of exclusion is predatory price-cutting.

Indeed, Microsoft's Bill Gates is often compared with Standard Oil's John D. Rockefeller (Murray, 1998). Unfortunately, the comparison is with the mythical rather than the real Rockefeller.

1. Standard Oil

John D. Rockefeller founded Standard Oil in 1870. That year, Standard sold 4% of all kerosene sold in the United States and the price of kerosene was 26ϕ per gallon. By 1885, Standard's market share approached 85% and each gallon of kerosene sold for 8ϕ . Kerosene's price continued to fall — to just under 7.5 ϕ in 1890 and to 5.91 ϕ in 1897. Also, Standard's market share continued to rise. This share was about 90% for much of the 1890s.

The steadily falling price of kerosene (Standard's chief product during its formative and its controversial years) reflected Standard's steadily increasing production efficiency. Standard's average cost of refining a gallon of kerosene in 1870 was 3¢. Fifteen years later, at 0.452¢, this cost was less than one-sixth of its 1870 level.

Not surprisingly, the petroleum-industry's output rose during this time. In 1880, output was 840 million gallons of kerosene; by 1897 output had more than tripled to 2.6 billion gallons (Boudreaux and Folsom, 1999: 557–560).

Standard's dramatic cost cutting resulted largely from the obsession of Rockefeller and his lieutenants for efficiency. Many of the practices that critics highlighted as evidence of Rockefeller's ruthless quest for monopoly are, when considered dispassionately, better seen as benign cost-cutting measures that harm only those rivals who were unable or unwilling to match Standard's intrepid drive for efficiency. For example, by exercising extraordinary quality control over the production of its refineries, Standard saved money by self-insuring. And because of the large volume that it shipped, Standard was able to self-insure its products against being damaged in transit. Also, Standard integrated backward into barrel production (including buying large tracks of timber), which cut its marginal cost of acquiring barrels by nearly 62% (Armentano, 1982: 58).

Did Standard augment its undoubted commercial and industrial acumen with monopolizing tactics? No. For a half-century following Standard's forced break-up in 1911, unchallenged opinion held that much of Standard's success was achieved through predatory pricing — that is, pricing below cost with the intention of ruining rivals in order to gain monopoly power in the future. A now-classic study by John McGee, however, found no evidence of predatory pricing by Standard (McGee, 1958). Subsequent research (both empirical and theoretical) supports McGee's finding (Easterbrook, 1981; Elzinga and Mills, 1989).

But none of Standard's successes — not its pioneering organization of the petroleum-refining market; not its creation of several products that never before existed (e.g., petroleum jelly); not its immense size; not its significant market share; not even its obsessive drive for continuing efficiency improvements — carved out for it a market free of competition. Standard's share of the market for refined-petroleum products began to fall in the late 1890s. By 1907 (the year President Theodore Roosevelt's administration inaugurated its antitrust case against Standard Oil), its market share had fallen from about 90 percent (in the late 1890s) to 68 percent. By the year (1911) that the United States Supreme Court upheld the break-up of Standard, its market share had fallen further, to 64 percent (Boudreaux and Folsom, 1999: 560).

The judgment of *Wall Street Journal* writer Alan Murray (1998) that "[o]nly after the government busted the Standard Oil trust did anything like free-market competition return" is clearly mistaken. Historians Ralph and Muriel Hidy (1955: 477) more accurately noted that "even before the breakup of the combination, the process of whittling Standard Oil down to reasonable size within the industry was already far advanced."

In summary, two features of Standard's success are noteworthy. First, it was the result of unusual acumen, creativity, and entrepreneurial and administrative drive, rather than the result of tactics that can fairly be described as monopolizing; second (and supporting the first) never did this success yield monopoly power for Standard, if "monopoly power" is understood to be the ability to harm consumers.

This second claim might strike many readers as preposterous, for how is it that a firm with such overwhelming market share — in excess of 90% for several years in the late 19th century — can be said *not* to possess monopoly power?

This question and its answer are vital to a proper understanding of competition, and, hence, to a better understanding of the *Microsoft* case.

2. The Market Process

Markets exist in time. A snapshot of a firm's market share no more reveals the realities of a market than does a snapshot of a jet reveal the realities of flight. Some facts are revealed, but the essentials of the phenomena remain unexposed. A large market share might be evidence of unusual ability to please consumers — that is, a special skill at behaving competitively — or it might be evidence of discordant special privileges. The closest we can come to telling if a large market share is evidence of consumers being well served or of consumers being harmed is to look at the firm's actual treatment of consumers.

Only if the firm raises its (real) prices and cuts its output is it reasonable to conclude that it possesses monopoly power. But if the firm cuts its prices and *increases* its output, the most plausible conclusion is that the firm has no monopoly power. Neither of these conclusions is ever correct beyond question; reality is too complex for such strong statements. But each of these conclusions is the *best* that non-omniscient observers can offer. Any other conclusions are more likely to be mistaken.

Because Standard Oil consistently (and considerably) cut its real prices and expanded its output, we have no reliable evidence that it possessed monopoly power. A monopolist likely would not have acted in this way. The available evidence of what matters most — Standard's pricing and output practices — screams "competition."

It will not do to assert that Standard *could* have raised its prices and cut its output. Of course it *could* have done so. But what would have happened if, contrary to actual fact, it had acted like a monopolist?

We do not know for sure. Perhaps price hikes and output restrictions would have raised Standard's profits even higher without significantly increasing the speed at which rivals threatened its market share. But no one has ever been in a better position to make this assessment than were Rockefeller and his fellow executives at Standard back in the late 19th century. Presumably, they wanted to maximize their firm's net present value; I assume (reasonably) that they were genuine profit-maximizers. So the fact that Standard did not behave as a monopolist points to the conclusion that Standard was in fact no monopolist — or, at least, that Rockefeller and other executives at Standard did not believe Standard to be a monopolist. Almost any firm can increase its immediate profits by restricting output and raising price. The local Holiday Inn probably *could* inform the guest who requests an extranight stay that the price of this extra night is five percent higher than is the price he paid for each of the previous few nights. After all, the guest probably won't want to go to the trouble of packing his bags and finding another motel just to avoid paying a five-percent premium. But while such a price hike would raise Holiday Inn's immediate profits, it is likely to diminish its profits in the long-run because rival motels will become relatively more attractive to consumers. Firms are forever sacrificing immediate opportunities for higher profits in exchange for a longer stream of expected higher profits.

The mere ability to raise price and increase profits in the short-run is not sufficient evidence of monopoly power.

No one today can say for sure what reasons motivated the decisions of Standard Oil's executives. Perhaps they were simply too daft to recognize the enormous monopoly power that their large market share bestowed upon them. Perhaps they feared government retaliation if they took advantage of their monopoly power. Or perhaps — and this reason strikes me as the most sensible — they understood that if they ever acted like a monopolist, the dynamic forces of competition would quickly enough destroy their large market share and reduce their firm's net present value.

The historical record shows that even without behaving like a monopolist, Standard's market share was eventually cut by rivals. So there is sound reason to believe that Standard's executives understood that their market "dominance" was never as indomitable as many people simply assumed it to be. For them to act like a monopolist likely would have revealed that Standard was indeed not a monopolist — and that acting like one without really being one causes profits more quickly to fall rather than to rise.

3. Microsoft

The history of Microsoft is remarkably similar to that of Standard Oil. In just a few years of its incorporation, Microsoft become one of America's most famous companies and a massive presence in a new industry regarded as essential to the country's economic and military vitality. And its founder, Bill Gates, like J.D. Rockefeller, became well-known by the public and detested by his rivals.

Two other similarities are critical. First, the prices of products sold by Microsoft, like those sold by Standard Oil, fell steadily since Microsoft's founding. Second, Microsoft's business practices, like those of Standard Oil, were denounced by its rivals and by the government as predatory and otherwise aimed at choking off market opportunities for other producers.

The price (in constant 1999 dollars) of Microsoft's operating-system software (MS-DOS, then Windows) fell steadily and significantly during the 1990s — from \$225 in 1990 to \$106 in 1998 (McKenzie, 2001: 40). At the same time, the quality and number of tasks performed by this software steadily increased.

Significant drops in real prices and improvements in quality occurred for nearly all of the products Microsoft offered. Especially telling is the fact that prices in those markets in which Microsoft offered software products fell faster than in those markets in which Microsoft did not offer such products (Liebowitz, 1998; Liebowitz and Margolis, 1999: 153–157).

As for charges of predation, they ring hollow. Space does not permit a detailed review of the many reasons advanced by critics for believing that Microsoft's pricing policies were out of line with the interests of consumers. Certainly, software prices over the years have radically fallen. But to assess current claims of predation requires peering into the future, because while it is occurring predatory pricing in practice is indistinguishable from competitive pricing.

The most compelling evidence on this matter is supplied by George Bittlingmayer and Thomas Hazlett (2000), who examined how the share prices of software firms (excluding Microsoft) moved with each change in Microsoft's fortunes on the antitrust front. Examining current share prices (which are set by the expectations of millions of investors) is perhaps the closest we can come to peering into the future.

Bittlingmayer and Hazlett found that the market valuation of firms complementary to Microsoft — both hardware and software producers — fall whenever Microsoft's fortunes on the antitrust front grow dimmer and rise whenever they brighten. This evidence suggests that investors do not generally believe that Microsoft's actions threaten to monopolize those markets in which it competes. The reason is that monopolization by Microsoft would raise consumers' full cost of computing and, therefore, reduce the demand for products supplied by hardware and software producers. Firms complementary to Microsoft would suffer. The fact that investors in these firms respond negatively to antitrust actions against Microsoft is powerful evidence that Microsoft's actions are competitive rather than predatory.

And if Microsoft's actions are competitive, this fact, in turn, casts doubt on the prevailing wisdom that Microsoft enjoys monopoly power. Like Standard Oil, Microsoft does serve a substantial share of a market, but unlike a genuine monopolist, it does not raise prices or restrict output. The soundest conclusion, therefore, is that Microsoft is no monopolist.

Much of antitrust's intellectual support comes from mistaken history. Standard Oil was clearly no monopolist, if by monopolist we mean a firm that raises prices, restricts output, and reduces consumer welfare. And nor is Microsoft a monopolist. The time has come for economists to devote more time to looking at actual market performance of realworld firms and less time spinning out esoteric scenarios of possible harm that can emerge from vigorous competition.

STATE-SPONSORED MURDER AS A RENT-SEEKING ACTIVITY

State-sponsored murder is quite common. In the 20th century, some 170 to 360 million innocents were murdered by their governments, and the 21st century is not starting off well. These killings are more than four times those of war. The Soviets, Communist Chinese, and the Nazis killed on an appalling scale. The rogues' prize goes to the Khmer

Rouge, who liquidated a third of the population of Cambodia. But, no continent is free of killing. When the state murders the general population, the term is democide; when it murders minorities, it is genocide.

1. The Demand for Democide

There is a rough inverse relationship between per capita income (GDP) and the amount of state-killing. Where per capita income is low, life is viewed as cheap. Where income is high, states are constrained, since killing the population is dear. This suggests that price (measured by a unit of real gross domestic product destroyed) constrains the amount of state-sponsored murder.

Democide mainly occurs in authoritarian regimes. Terror is a signal that the price of opposition is high. The benefit of democide is continued rule; the cost is destroyed output. A cold calculus suggests that a rational dictator will murder the population to the point where the marginal benefit equals the marginal cost. Marginal benefit in this context is continued rule and a share in the rents that dictators generate through centralized political and economic control plus any pleasure obtained from inflicting terror. Marginal cost is the incremental national output lost from the killing. Civilized people view government-sponsored murder as demented, the acts of barbarians and sociopaths. But, many aspects of life that we judge as bads, nevertheless, obey the law of demand.

Does democide obey the law of demand? Yes, it does. For my sample of 31 nations that killed 10,000 or more of their citizens, I find that a one percent increase in price (the logarithm of RGDP) is associated with a 1.4 percent decline in the number of citizens murdered. The regression coefficient is highly significant, and about half of the variation in democide is associated with the logarithm of per capita RGDP. (Scully, 1997)

So, there is some evidence that rising per capita income constrains murder by the state. This fact may help us understand the slowdown in the pace of killing in the Soviet Union and China. Under Stalin, about 43 million were murdered; after him, about 8 million. Under Chairman Mao, 35 million died; since then, less than a million. While economic performance was poor under socialism, there was some growth and economic advance. Comrades were getting more expensive to liquidate.

And, there is some crude historical evidence, as well. In the 13th century, 32 of 360 million people were murdered about 9 percent of the population. And, this was a time before gunpowder. In the 17th century, the killing rate had fallen by half. In the 19th century, about 44 million were killed (3.7 percent of the world's population). Alas, the fascists and communists reversed the trend in the 20th century, when 7.3 percent of the world's population were killed. Absent the 75 million killed by Hitler, Stalin, and Mao, about 2.5 percent of the world's population perished at the hands of their governments.

2. Democide and Genocide as Rent-seeking Activities

Humans prefer to dominate, and they dominate those they distrust and dislike. Antipathy may be official policy or it may arise spontaneously and be tolerated by government. The extreme form of antipathy is murder; less pernicious is discrimination. Enmity has economic implications. Discrimination transfers income from the minority to the majority, and is a form of rent-seeking.

Among authoritarian states, restrictions on minorities are fairly common. Such domination and rent-seeking arises through restrictions on occupational choice, denial of education, licensing, confiscation of land, nationalization of business, and so on. The dominant group earn rents from sanctioned restrictions, and has a vested interest in maintaining them. The rulers benefit from maintaining domination (bribery and corruption are endemic throughout the authoritarian world). Thus, part of the motivation for maintaining rule is to protect the rent-seeking capacity of the dominant group. Politicians extract a fee for providing the use of the coercive power of the state for that service.

Murder is the extreme form of enmity. Terror has been usefully employed to enforce ideology (the Inquisition, the Cultural Revolution, Muslim fundamentalism, etc.) or policy (e.g., the Soviet collectivization scheme). It is employed by authoritarian states to maintain power. Terror has an obvious chilling effect on enemies.

While it is impossible to know the value (not necessarily, pecuniary) of democide to the officials who have practiced it, it is possible to crudely calculate the lost national output arising from it. Democide makes life and property insecure. Such insecurity lowers savings. Reduced capital formation lowers the rate of economic growth. I hypothesize that the path of per capita income in nations that practice democide is below the path of income in nations that do not engage in it. By making comparisons of the paths of per capita income it is possible to estimate the order of magnitude of this form of rent-seeking activity.

3. Evidence

In principle, the rent-seeking loss associated with democide can be calculated by comparing the evolution of the economy before and after the democide with its path during the killing. But, that comparison would be dubious. Political murder often is not infrequent. We would not know whether the path of per capita income prior to democide is free of political uncertainty or whether people fully recovered from it after. A better comparison would be with the growth path of countries that are broadly similar in political and economic development, but that have not committed democide.

To eliminate differences in income among countries, per capita real gross domestic product data were converted to indices, with 1960 as the base year. To compare growth paths, a comparison sample of non-democidal nations with a more or less similar stage of economic and political development is required. My comparison sample contained 23 countries (e.g., Egypt, Ivory Coast, Morocco, Dominican Republic, Jordan). A composite index was obtained by weighing each RGDP by its population share and summing. There are 33 democide nations in the sample (e.g., Algeria, Ethiopia, Rwanda, Guatemala, Iran, Pakistan). These nations were converted to an index of a representative democidal nation by weighing as described previously. Dividing the index of the democidal nations by the index of the non-democidal nations yielded an average value of 0.81. Thus, democidal rent-seeking is estimated to cost 19.2 percent of GDP.

To insure that the result is not a figment of the mix of comparison nations, I constructed a sample of eleven other mostly freer, less-developed, non-democidal nations (e.g., Botswana, Barbados, Jamaica, Fiji). The path of the index of this sample of nations lies above that of the index of the 23 autocratic, non-democidal nations. This is not surprising, since it is known that nations with freer institutions grow more rapidly than nations with less freedom.

It may be that the effect of democide on the path of real per capita income is not uniform across countries or continents. The scale of the killing may differ, people's attitude toward it may vary, and some may be better informed about what is going on. On this basis, Africa has suffered the most. Democidal rent-seeking is estimated to reduce per capita income by 25 percent. There is not much difference between Asia and Latin America (18.6 and 18 percent, respectively). Of the countries that were examined separately, the range was 18.2 percent (Philippines) to 61.6 percent (Angola).

4. Conclusion

Democide and genocide seemingly are activities of majority group domination and authoritarian rule. Statesponsored murder on a large scale has a long history. Despite crude weaponry, the Chinese emperors from the Chin dynasty (221 BC) to the Ching (1911), exclusive of the Mongols, murdered 34 million. The Mongols did in 30 million in a tenth of the time. (Rummel, 1992, 1993)

But, exclusive of communist democide, there has been a historical decline in the rate of state-sponsored murder. I believe that this is due to rising per capita incomes, which make the cost in terms of lost national output too high, rather than to more humanity among dictators. Comparison of the growth path of the representative democidal nation with that of the representative non-democidal nation indicates that state-sponsored murder reduces national wealth by about 20 percent.

STRUCTURE-INDUCED EQUILIBRIUM

Why so much stability? (Tullock, 1981)

The Marquis de Condorcet (1785), who ultimately lost his head to Dr Guillotin's infamous invention, was the first known scholar to recognize that political outcomes under simple majority rule are inherently unstable (Rowley, 1987). Consider the problem of dividing a gift of \$100 among three persons (Mueller, 1989: 63–64). Suppose that two of them reach an agreement to split the \$100 between themselves, with \$60 going to one and \$40 to the other. The third person, who receives nothing, has an incentive to strike a bargain with the second, offering a split of, say \$50-\$50, which makes both of them better off than they would be under the initial proposal. Faced with desertion, the first person can destabilize the new coalition by offering to accept \$45 for himself, leaving \$55 for one of the others. And so on. While it can easily be shown that the Nash equilibrium to this zerosum, pure redistribution game is an equal division of the \$100 between two of the three players, the identities of the members of the winning coalition are indeterminable a priori. The game has three possible (and equally likely) outcomes, namely (V_1, V_2) , (V_1, V_3) , and (V_2, V_3) , where the Vs denote the voter-players, and it is impossible to predict ahead of time which of these outcomes, if any, will emerge.

The theoretical possibility that simple majority rule can lead to an endless series of changing winning coalitions a phenomenon known as 'cycling' — was revisited by Charles Dodgson ('Lewis Carroll') ([1876] 1987) a century after Condorcet first recognized it. Lost once again, the message from the eighteenth century French academicians ultimately was retrieved by Duncan Black (1948). Kenneth Arrow (1951) and other modern public choice scholars have since studied cycling at length (see Enelow, 1997, for a summary of the literature). Despite the theoretical possibilities, however, majority rule outcomes seem to be remarkably stable in practice. Committees, legislatures, and voters actually make decisions by simple majority rule and these decisions are not usually plagued by endless cycling. Why so much stability (Tullock, 1981)?

One answer to Tullock's question is that institutions exist which help prevent majority rule decisions from being subject to renegotiation or which facilitate the formation of stable winning coalitions. Equilibrium is induced by structure (Shepsle, 1978; Shepsle and Weingast, 1981). There are several possibilities in this regard. The most obvious of these involves the designation of an agenda-setter, someone with the authority to determine the order in which issues are brought to a vote. Supplemented by a set of mutually agreed-to constraints on the collective decisionmaking process, such as those provided by Robert's Rules of Order, which limit the possibility of defeated proposals resurfacing, the agenda-setter can block embryonic cycles. Of course, the agenda-setter may also use his authority to manipulate the order of votes in ways that produce outcomes more consistent with his own preferences than with those of the majority (McKelvey, 1976; Munger, 2001: 229-236). The agenda setter's position may confer fewer advantages in parliamentary systems, however, owing to the existence of multiple equilibria within the governing coalition (Helpman and Persson, 1998).

Stability in majority rule decision-making is also promoted by the common practice of adopting 'reversion points', or fallback positions that serve as baseline alternatives to the proposal being considered (for a general discussion, see the papers collected in Shepsle and Weingast, 1995). Spending reverts to its current level if a proposal to increase an agency's budget is defeated, for instance. The accepted interpretation of the law stands (*stare decisis*) unless the court votes affirmatively to overturn it. Baseline budgeting, deference to legal precedent, and similar such decision rules help avert cycling by reducing the dimensionality of the decision space. Only certain options compete against one another at a given time. In the limit, each vote is one-dimensional, namely a choice between the status quo and a well-specified alternative to it. Only two outcomes are then possible. Either the alternative fails to attract the support of a majority, in which case the status quo prevails, or the alternative dominates the existing equilibrium and the majority votes to displace it. If in the latter case the victorious alternative is adopted as the reversion point for subsequent decisions, the chances of cycling back to the status quo ante become remote.

This begs an important question: how is the dimensionreducing decision rule selected in the first place? If voters are sophisticated, they will foresee that restrictions on the range of options they are permitted to choose among also limit the range of possible outcomes, perhaps eliminating some of their most preferred alternatives from contention. As such, the adoption of a reversion point is itself a collective decision-making problem that transforms a superficially one-dimensional vote into a two-stage game (see Ordeshook, 1986).

By limiting the range of options voters may select among and, hence, making it less likely that the existing majority coalition will unravel, reversion points tend to sustain equilibrium outcomes. Logrolling, or vote trading, provides another source of stability in majority rule decisions (Stratmann, 1997). Individuals exchange their votes on collective decisions in which they have few pressing interests so as to form winning coalitions in support of issues in which they have greater personal stakes. Tullock's (1959) example is instructive. Three farmers face the problem of repairing the roads giving them individual access to the main highway. If maintenance proposals are voted on separately, none of the roads will be repaired because all of the benefits of collective action accrue to a single voter. Farmers A and B will vote against a proposal that requires them to contribute toward the repair of farmer C's access road, A and C will vote against repairing B's road, and so on. However, at least two of the roads will be repaired if the beneficiaries agree to support each other's spending proposals. Farmer B might agree to vote to repair farmer A's road in return for A's pledge to vote in favor of repairing B's, for instance.

Logrolling can facilitate the formation of stable winning coalitions, provided that voters' preferences differ in intensity (farmer A is willing to pay more for B's vote than C is, for example); cycling cannot be ruled out otherwise. (Bernholz, 1973, in fact argues that a cycle in votes will produce a cycle in vote trades.) Additionally, when the benefits of collective action exceed the costs, vote trading can be welfare enhancing in the sense that it enables proposals to be approved that would be bypassed in its absence. On the other hand, when the costs of financing collective benefits are shared equally, logrolling can lead to excessive spending owing to the fact that the members of

the majority coalition do not bear the full costs of their own actions, some of which are shifted to the minority. Downs (1961) and Mueller (1989: 333–334) challenge this conclusion, however.

The observation that agenda-setters, reversion points, and logrolling are all part and parcel of the rules of the game that govern the normal workings of committees, legislatures, and other institutions of collective choice suggests that no one of them is sufficient by itself to ensure stability in majority rule decision-making. Indeed, there are a number of other institutional constraints that impose structure on collective decisions which, along with those discussed previously, evidently play complementary roles in promoting and maintaining majority-rule equilibria. Among these other institutional constraints are the assignment of proposals to subcommittees composed of individuals with strong interests in particular issues who control the items placed on the full committee's agenda, the appointment of independent commissions to work out the details of proposals that the majority has approved in principle, and the use of conference committees to resolve differences between the alternative versions of bills passed by the two chambers of a bicameral legislature (Basuchoudhary et al., 1999). Stability in majority-rule decision-making is also enhanced by the power of the executive veto (Crain and Tollison, 1979b; Carter and Schap, 1987), the brand-name capital of the legislature's majority party (Crain et al., 1988), the independent judiciary (Landes and Posner, 1975; Anderson et al., 1989; Shughart and Tollison, 1998), and the constitution itself (Crain and Tollison, 1979a; Anderson et al., 1990). The 'checks and balances' built into the Swiss political system, the division of responsibilities between the European Parliament and the EU Commission, and the delegation of monetary policymaking to independent central banks seem to have similar purposes and effects (Moser, 2000). In short, many of the institutions of democratic government learned by every schoolchild who studies European and American constitutional systems comprise the structure that induces equilibrium in majority rule decisions.

SUPPLY OF PUBLIC GOODS

According to the theory of public finance built under the "social welfare function" maximisation principle (Atkinson and Stiglitz, 1980), governments must fiscally supply "public goods," i.e., the goods that have a complete or very important indivisibility: so that rivalry in consumption and exclusion of those who do not pay cannot be applicable (Samuelson, 1954, 1955) A general equilibrium system of equations may then be constructed in which, in addition to functions relating to market economy goods offered at their equilibrium prices, functions relating to pure and impure public goods also appear paid by tax prices or other public measures modelled on the nature and size of the relevant market failures. The reasoning goes on arguing that because the benefits of these goods may be enjoyed independently from their tax prices, citizens try to under-assess their preferences so that public goods are under supplied. The same conclusion is reached with a game theory approach in an institutional vacuum, assuming that each individual or group acting independently produces public goods that automatically provide benefit to others affecting their choice: the outcome is a Nash equilibrium characterised by under-production. (Cornes and Sandler, 1986). And the task of politicians committed to the public interest should therefore be that of re-addressing the balance in the allocation of resources between private and public goods. This set of theories, that so many academicians consider so obvious, is greatly misleading.

First of all, the aggregate social welfare function is a myth (Rowley and Peacock, 1975). In democracy, governments represent only the preferences of a majority of the electors, mostly the median voters. Furthermore, politicians are loose agents of them and operate by bureaucracies with their opportunistic behaviour. Parliaments

do not vote on comprehensive social welfare functions but on budgets. And because of the intrinsic looseness of the principal-agent paradigm in representative democracy, what citizens may convey to their political representatives are, at best, sets of preferences. Arrow's theorem of impossibility of consistent choices applies to majority decisions (Arrow, 1951). And the prevailing majority may tax the minorities to finance goods benefiting majority (Wicksell, 1896; Peacock [on Toqueville], 1992; Buchanan and Tullock, 1962). It has been shown that this is also likely to happen under qualified majority, in normal parliamentary decisions, because this voting rule creates a quasi monopolistic situation making the political market non contestable (Forte, 1985). An excess of public expenditures on their benefits is likely to emerge since those who decide and get particular benefits (politicians, bureaucrats, pressure groups) do not pay the costs financed by taxes and debts. The assertion that Governments undersupply public goods because of the intrinsic imperfection of the fiscal nexus in the connection between taxes and public services rests on a wrong assumption. Precisely because public goods are paid by the fiscal nexus, i.e., through a "non market" transaction, disconnecting public goods from their "tax prices" government and bureaucracies are not constrained by the free market demand and financing. And therefore, as William Niskanen (1971) has argued, bureaucracies in search of power, may rationally expand the gross product to the point where the entire consumer surplus is destroyed. Or as I have argued (Forte, 2000), behaving as managers not considering the value for the stockholder, but the gross revenue under constraint of a minimum profit, bureaucrats may expand gross product to a point where citizens-taxpayers are left only with a minimum surplus, just enough to avoid their revolt. X inefficiency and leisure on the job (Peacock, 1983) are also likely to emerge in public bureaucracies. With a prisoner dilemma trap, one can show that the natural rational tendency of individual action, as for public goods, is not to under-supply but to over-supply. Indeed, each individual or group tries to get public supplies to their benefits paid by the general community. At the end everybody gets less benefits than the individual costs. If there is no institutional constraint to this tendency, taxpayers, who do not try to get expenses for their benefits with costs thrown on the community, act irrationally from the individual point of view. As for the prices functions, markets failures derive from imperfections of the signals whereas governments failures derive from the absence of price constraints.

At minimum, public supplies, if undertaken by public entities, should be provided by entrepreneurial organisations imitating, as far as possible, market economy firms and should be monitored with similar product and productivity parameters (Forte, 1983). A likely replay shall be that appropriate parameters here are intrinsically different. Actually public bureaucracies do not like to be organised and controlled with private firms techniques and resist, with their inherent power, to them.

A constitutional choices level must be set forth, with rules that constrain fiscal choices done at the ordinary level. (Buchanan and Tullock, 1962) Competition among governments operating at different jurisdictional levels and at the same level in different territorial areas may improve the chances of electors-taxpayers of having their preferences satisfied, if they have the choice of entering and leaving given governments as a clubs (Tiebout, 1956; Buchanan, 1965). But limits to mobility and imperfect information reduce the possibility of the citizens of considering governments as competing entities. For some public goods the effects spill-over from the area of the supplying "club" to the clubs with jurisdiction in different areas. And systems of taxation cannot be easily forged to connect the supply of goods of each government with tax prices on the members of their club (Oates, 1972; Oates and Schwab, 1988). Public institutions may be improved to develop a broader and bigger application of the club principle, particularly by single good provision (as for instance elementary schools). Nevertheless one must recognise that while, as for the market system, market failures appear as imperfections and limits, as for governments, supplies failures are intrinsic to the possibilities of collective action through democratic choices and the related principalagents paradigms (Moe, 1984), from citizens to politicians and from politicians to bureaucracies. Thus one cannot argue that whenever there is an element of public good, there is a case for a public supply.

Nozick (1974) has shown that for so called pure public goods, as defence, justice and public order, the exclusion of those who do not want (or can) pay for them is technically possible. But, as he has argued, the supply of these goods by private market firms may lead to a monopoly, with a dangerous power of exploitation. Why one may assume that Governments could not exploit an unconstrained monopoly power given to them? Simply because welfare economists impose a nice social welfare function that enlightened politicians are supposed to maximise? In a public choice approach, federalism and clubs, with a multiplicity of competing government units, appear necessary, for the reduction of conflicts of preferences and of the dangers of exploitation (Pauly, 1970). However, it must be recognised that in addition to the monopoly argument a main reason why Government are charged of providing services of law and order in modern states is the

interdependence of utilities of the members of a wide community as for these goods (or bads). Thus, some of them must be supplied uniformly to every one in the given wide community, independently from the specific willingness to pay. And the upper level of Government on the broadest available jurisdiction may appear as the most appropriate one, for some of these goods (Forte, 1977). Interdependence and conflict, not non excludability and non rivalry dominate this issue with a difficult equilibrium (Fedeli and Forte, 2001). On the other hand, since these goods are intrinsically divisible, some of them, may be appropriately left to the private associations: for instance private associations of professionals as the certified accountants, as it may be the case for the "correct accounting rules" for the corporations and groups of companies accounts. In the area of justice, arbitration may replace much of the official courts activities in civil cases and labour controversies, leaving the production of the rules on which to decide to the laws of the parliaments and to the customs.

For such goods as a lighthouse or many roads and tunnels or bridges and public transportation services the theoretical welfare economics argument for public supply are non rivalry, lack of (easy) excludability and external economies. Fixed costs often prevail and therefore pricing at average costs or close to it would imply a great wastage of consumer surplus (Dupuit, 1933; Hotelling, 1938). And even price at marginal cost might be wrong because of externalities as reduction of pollution and traffic congestion by public transportation services. All this is fine in a partial equilibrium analysis. But one must consider that the free provision or the supply in deficit must be paid by taxes or public debt. These too create distortions between marginal costs and prices plus additional welfare losses through transaction costs (Coase, 1946, 1947, 1988). And without the market economy budgetary constraint, X-inefficiency and excessive output may arise. Public economy failure must be compared with the private economy failures to which they are supposed to remedy. As for external economies the case for public intervention by subsidies and tax expenditures is limited by the fact that these have costs and are subject to failures, as stated by Buchanan (1962) in his criticism of the Pigouvian margins as allocation principle. Furthermore contracts among the interested persons, on the basis of improved property legal rules, may internalise externalities (Coase, 1960). The requisite of non excludability may change by a re consideration of the transaction costs involved. Lighthouses, a classic example of non excludable public goods, in the past have actually been financed by a toll on the ships that were approaching the ports (Coase, 1974; Peacock, 1979) and this policy is even more feasible now with electronic means for all the ships that are aided in their navigation. Highways may be financed by tolls and the traffic may be eased by credit cards and telepass. Scientific research and cultural production may have components of public goods: but a reinforcement of legal institutions as patents and copy-right may increase the scope for scientific research and cultural activities with pecuniary remuneration (Forte, 1983, p. 150). Young may not be able to pay for their higher education and their parents may be unwilling or unable to cover these expenses. And one may argue that here there is a market failure, because banks could provide loans to the students to be repaid after graduation when employed if they had adequate information on their future gains and assurance that they would not cheat. But to remedy to this failure student loans scheme may be devised with public guarantee, that have a minimum cost for the government or no cost at all because of the possibility of taxing the incomes of the former students (Friedman, 1955; Peacock and Wiseman, 1964; Barr, 1991; Creedy, 1993). On the other hand, one may argue on public goods arguments, that higher education of merit students, being particularly beneficial to the cultural and scientific capital of the society, should be supported by community. But in fact several private institutions provide fellowships to students with good qualifications, precisely on the basis of these public good arguments, some times for their own interest, some times for prestige reasons and some times for altruism. Paretian redistribution does exist on private rational basis (Hochman and Rogers, 1969). One cannot argue that whenever there is a collective good argument there is a need for a public supply. Individual action by consumers of important shares of collective goods and collective action by non profit institutions may some time do the job.

But are all public goods those with the intrinsic "public nature" of non rivalry and non excludability? One can easily observe that most of the goods *actually supplied by* governments are not of this kind. Education, health, welfare intrinsically are rival and excludable supplies. Externalities may play some role in justifying their public supply, but hardly one may say that the "welfare state imperial construction" rests on external economies foundations. Welfare and education public supplies cannot be justified by non rivalry and non excludability. Their foundation is twofold: the equality of opportunity principle, i.e., a redistribution in favour of those who are unable to pay for these services; and limited rationality as "acrasia" or weakness of will and lack of adequate information for those who can pay for these merit goods. In ordinary choices they tend to under assess their future wellbeing while at as higher level of rationality they understand that this lack of telescopic

sight is against their interest, so that they self constrain their action (Musgrave, 1959; Elster, 1979; Forte, 2000). Paradoxically to remedy the "acrasia" that induces people to overlook the future, grandiose public pension schemes mostly based on a pay as you go system and pervasive public health services funded by the tax system have been created that reduce the propensity of individuals to save for the future. The justification of spoiling the individuals of any responsibility for their health and old age rests only on a conception of the state as a Leviathan. In a different approach, with responsible actors more conducive to economic growth and distributive justice (Buchanan, 1986) a broader room must be left for individual choice about health and retirement providence. In this optic there is no reason to give a more favorable tax regime to the social security contribution and benefits than to the complementary contributions to private analogous insurance and pension funds. But if the foundation of the public supplies are redistribution and self constraint on irrational choices, why a monopolistic government supply should be preferred to other ways of supply with broader room for individual choice?

The main question is then why public goods of the various kinds so far considered should be supplied by public entities (Forte, 1967) rather that by private firms or non profit institutions. The reasons why one should prefer a supply of public goods by public institutions over a supply of them by private entities, given the above considered intrinsic failures of the public production, must be analysed case by case (Peacock, 1984; Blanckart, 1985; Byatt, 1985; Marchese, 1985), without *a priori* case in favour of the public supply as it is often implicitly done, confusing the case for a collective action by "public goods."

For the public goods that are grounded by supply side arguments, as the risks of private monopolies, the case for a public supply may be stronger than for those that are justified on the demand side by imperfect rationality and/or by distributive considerations. Admittedly services as those of external defence imply a political power that cannot be given to private armies. But procurement by outsourcing may be extensively practised, following the Coase-Williamson theory of the firm (Coase, 1937; Williamson, 1975, 1979). In the area of public museums, the service to the public may be assigned by a bid to private firms that shall finance themselves by tickets and other revenues from the visitors, revenues of collateral services and copy rights. Government officials may merely control this activity. As for the conservation of the museums items the Government in charge may rent the service of custody from private organisation and outsource to private professionals

the task of cataloguing the items. Prisons too might be run by private firms under public control paid for their services (Forte, 1967). Historical and artistic buildings as heritage of the past as public good to be preserved for the present and future generation, do not need to be a public property, which often means nobody's property. Private owners, compensated by fiscal benefits on investment and maintenance expenditures, for the public constraints of proper preservation, may do a far better job, with a much lower cost for the Government, because more interested in their properties. Big bridges like that planned to connect Sicily to the continent that certainly shall provide a wide range of positive externalities may be built by project financing based primarily on revenues from tolls with the public subsidy becoming a minor factor. One cannot argue that the tolls shall leave some capacity unutilised, it is likely that they shall avoid the external economies of congestion. And one cannot argue that the government should provide subsidies in an amount equivalent of these externalities and for ever since these externalities shall be enduring. Beside the fact that they are hardly measurable, this is clearly an "all or nothing choice," so that much of the externalities are inframarginal (Buchanan and Stubblebine, 1969). Generally for public works projects with deferred profitability and important externalities private supply by project financing mostly financed by the market may conform to correct allocation principles and may do a better job with a much lower public cost than a public supply. Even for local streets and public lighting where to charge a toll is impossible, private initiative may be called for by project financing: instead of getting prices from the users, the private firms engaged in these activities, may get, by some kind of incentive contract, payments from the government proportioned to the units of services rendered. There is not much difference between a public subsidy to a municipal transportation service and a current transfer paid to private firms that undertake the above described supply of public highways and streets. Truly one might distinguish between "search (public) goods" where the effectiveness of the supply may be observed when it is made, by considering its objective qualities and quantities and "trust (public) goods" where the effectiveness of the supply can be assessed in the individual situations only with prohibitive cost and/or ex post, after a period o time (Tirole, 1988). This last may be the case of the pure scientific research. One may claim that for these trust good would be inefficient to rely on contract with private firms because it is difficult to currently control the effectiveness of the theoretical work done, as the pecuniary remuneration may be an insufficient motivation in pure science. Thus one may argue that this is a typical case of public goods where

a supply by government entities is appropriate. But pure scientific research need not be done by governmental entities only. There are other institutions that, by their reputation, may be "trusted," among the non profit and quasi private as many Universities.

Let us now consider the public goods whose foundation lie on the failures of the market mechanism on demand side, as those in the area of education, arts, health, social security and aid to the "least favoured," where the state, as a paternalistic entity that "knows better," as mostly developed. As for the "welfare" goods that become public because of distributive reasons and imperfect rationality of individuals, prima facie vouchers (Peacock, 1983) and compulsory insurance (and a combination of the two) should be suggested to allow the individuals to be free to choose among the different suppliers. Vouchers appear well suited to health and education expenditures, but as it has been written for the British experience "the voucher was a challenge to the formidable fortress of paternalism, professional corporatism, monopoly and political authority that had long ruled British education. That the ramparts did not fall to the first intellectual assault was almost predictable" (Seldon, 1986, section VI). Compulsory private insurance, with freedom of choice of the insurers, is already applied for automobile accidents. It may be applied for accidents on work. It may be extended to the pensions area for retired workers to replace the pay as you go approach. One may argue that if all European countries that apply the pay as you go system for the retirement pensions schemes where shifting to the private insurance systems with funding schemes, there would not be enough supply of financial products on the market to satisfy this demand. In addition one may argue that a shift to funding schemes while paying the pensions via the pay as you go system is extremely difficult. But retirement compulsory private insurance with funding schemes need not to be alternative to the public system. They may be complementary to them. But it is extremely difficult to make these changes because here too there is a formidable fortress of paternalism, corporatism, monopoly and political authority. As for health one may argue that to replace the public health service with compulsory insurance would cause a perverse selection against the older and those with a bad health conditions. But compulsory insurance with private institutions may be suggested for some professions that have peculiar health risks. Granting that there is case for a basic free public health service, does not follow that this service should be provided by public institutions or that these should behave as monopolies in the territory in which are located. The case for a public supply of hospital services needs to

be demonstrated by specific arguments as economies of scale (if any), better accountability of public institutions as for these delicate trust goods supplies because of the political responsibility and competition (Tirole, 1988). And central government gigantic public monopolies as those theorised and realised in the welfare state policies, hardly shall pass this scrutiny. Here again the voucher system for the free choice of the services may enhance efficiency and effectiveness of the supply.

At best the economic theories of public goods *per se* provide grounds to (not unlimited) public transfers and regulations, not to public supplies and public monopolies by governments and by their enterprises. Why the supply of public goods should be public in the various components of its supply and in its global financing needs to be demonstrated case by case, with the case for a public monopoly as a true exception.

THE SUPREME COURT

For many decades, the attention devoted to the U.S. Supreme Court by positive political analysis lagged behind study of the executive and legislative institutions much like public and media attention. Historians, biographers, and legal theorists provided most of the articles and books regarding the Court. Even among the constitutional framers, the discussions concerning the Court's structure

paled in comparison with the other branches. The main debate turned on the method of judicial selection that the framers thought would best insulate judges from external influences. These debates are related in many sources such as James Madison's notes (Scott, 1893) as well as anti-federalist collections.

In spite of the framers stated intention to insulate justices from political incentives by appointing them for a "term of good behavior," social scientists in economics, political science, and law have increasingly searched for incentive effects on judicial behavior in general and Supreme Court behavior in particular. Baum (1997), Epstein and Knight (1998), and Clayton and Gillman (1998) provide comprehensive discussions of positive explanations of judicial decision making. In the broadest terms, these explanations can be divided along two lines: (i) those stressing incentives internal to the Court, and (ii) those stressing incentives external to the Court.

Among the studies that investigate incentives internal to the Court, "attitudinal" models rely on the personal ideologies of the justices along with the roots those ideologies in the background and experiences of justices. Segal and Spaeth (1993), and Epstein et al. (1998) are examples of this kind of approach that lies on the border between psychology and public choice. A second strand of the internal incentive explanations emphasizes Court rules and traditions. For example, Segal and Spaeth (1996) examine the importance of the doctrine of stare decisis on justice behavior. On a third front developing in more recent years, several authors have directed their attention to bargaining and influence games arising among justices in their search for majority coalitions. Baird et al. (1995) extensively reviews these kinds of game theoretic situations in legal settings. Ferejohn and Weingast (1992a,b) and Wahlbeck et al. (1998) provide empirical analysis of bargaining incentives for judges and Supreme Court justices.

Landes and Posner's (1975) landmark contribution paved the way for the other line of research emphasizing incentives external to the Court. While the contributions cited above can all be viewed as positive political models, this second category initiated by Landes and Posner is more indicative of traditional public choice models in its focus upon the influence of interest groups, legislators, and voters. The Landes and Posner article postulates that the judiciary maximizes the present value of legislation from the perspective of the enacting legislature. In spite of the Court's ability to overturn legislation, Landes and Posner develop the idea that the independent judiciary functions to make bargains struck between voters and legislative more durable. In this way, Landes and Posner turn the stated intentions of the constitutional framers on their head. Rather than limiting interest group politics, the independent judiciary structure promotes and facilitates it. Their empirical support for their model is not extensive. In an appendix they estimate preliminary results for Court reversals, looking at factors such as tenure of justices and the number of bills passed by Congress

Subsequent contributions have more fully developed theoretical and empirical models of external influences on the Court. Some look specifically at the Supreme Court while others examine the federal judiciary at large. The constraints considered include the power of Congress to remove justices, alter the number of justices, and determine judicial branch funding. For example, Toma (1991) finds Congress can signal justices its desires and influence outcomes through the budgeting process. Using data from both the Supreme Court and lower federal courts, De Figueiredo and Tiller (1996) find that Court expansion is linked to political alignment in Congress. In addition to congressional influence, other studies have considered the effects of public opinion on the Court. McCubbins et al. (1995) find evidence that changes in the size of the federal judiciary have had an effect upon legal theories. Gely and Spiller (1992) find that while Roosevelt's court packing threat had little influence on voting behavior of justices, their decisions were closely linked to electoral outcomes. Spiller and Spitzer (1992) explain legal doctrines in terms of the current political environment.

Most contributions analyzing Court behavior have examined majority opinions of the Court or shifts in those majority opinions. A much smaller set of studies examines variations in consensus among justices. Descriptive data compiled by Epstein et al. (1996) documents the abrupt breakdown in consensus after the 1930s as measured by the proportion of cases decided by a one-vote margin, with concurring opinions, and with a dissenting opinion, and others. Posner (1996: 357) identifies the increased caseload facing the Court and the accompanying decline in the percent of cases reviewed as the "standard explanation" for the decline in consensus. As the caseload increases and the percent reviewed declines, the cases selected for review grow more difficult and contentious. However, this explanation is little more than speculative to date in that little or no evidence has been presented supporting the claim. The other common explanation is that statutory change, such as the Judges Bill of 1925, altered jurisdiction over cases and led to greater dissension. Haynie (1992) reviews the evidence.

Beyond these external influences, factors internal to the courts have been used to explain the fluctuation in consensus. For instance, Walker et al. (1988) highlight the role of the Chief Justice in maintaining "consensual norms." Calderia and Zorn (1998) develop an error correction model of dissenting and concurring opinions stretching from 1800 to 1991 and find evidence that the breakdown in consensus can be attributed, in part, to leadership of the court.

In evaluating the explanations of either majority opinions or variations in consensus, surprisingly few contributions have stressed the ex ante screening of Supreme Court justices as a means by which interest groups influence subsequent voting behavior and disagreements between justices. Landes and Posner do include tenure of justices in their model of Court reversals, but it only indirectly measures similarities and differences among justices based on characteristics of the screen. As is well known, the selection screen for the U.S. Supreme Court consists of two primary components - the presidential nomination and the confirmation hearings and vote by the Senate. The influence of this power is seen in the fact that nearly all justices are appointed from the same party as the President. The power of the confirming Senate resides in its effective veto power over nominees. Other than debates about which of these screens influences Court composition most heavily, the importance of these screens for Court outcomes are still largely unexamined.

Another seldom-studied aspect of the Supreme Court is its influence on socioeconomic outcomes. Almost all the attention has focused on effects on the Court rather than effects of the Court. What efforts have been made primarily examine the impact of individual Court decisions or policy shifts on specific issues. Becker and Feeley (1973) is an example. Johnson (1979) broadened the scope somewhat by looking at the effect of the Supreme Court on lower court decision making. The study taking the widest view to date is probably Bussiere (1998), who looks at the impact of the Court on the growth of the welfare state. Rosenberg (1991) considers the potential for broader social impact of the Court.

Beyond the effects of majority outcomes, the variations in Court consensus may also have important, but as yet, unstudied effects. Posner (1996) suggests that greater dissension within the Supreme Court reduces its ability to perform its tasks as efficiently and reduces the consistency and long-run stability of decisions. The importance of stability in basic institutions of political economy for economic development has long been emphasized and more recently confirmed using cross-country studies such as Barro (1997). Where there is broad agreement between justices on a given Court or across Courts over time, the basic rules-of-the game for society remain relatively stable. Divisive decision making within or across Courts amounts to the decision for millions of people resting in the hands of one swing vote on the Court and lack durability. Rather than relying on a relatively stable set of basic rules based on Court consensus, individual and organizational decision makers face greater uncertainty when Court divisiveness increases.

Т

TAKINGS AND PUBLIC CHOICE: THE PERSUASION OF PRICE

The Fifth Amendment of the United States Constitution concludes, "nor shall private property be taken for public use without just compensation." What is known as the "just compensation" or "eminent domain" or "takings" clause is also present (or judicially construed to be present) in every state constitution and in the officially-proclaimed practice of most governments around the world. Yet the takings issue remains controversial, as is suggested by the many treatments of it by scholars who reflect the public-choice tradition (Ellickson, 1977; Epstein, 1985; Farber, 1992; Fischel, 1995; Levmore, 1991; Miceli and Segerson, 1996; Siegan, 1980; Wyeth, 1996). This essay will illustrate how a public choice approach can illuminate some of the important issues. The plan is to explain how the present distinction between physical takings and regulatory takings causes governments to choose too much regulation.

The idea that owners of property should be compensated is relatively uncontroversial when applied to actions in which the government takes physical possession of the property in question, as when it seeks to build a road, a dam, or a public building on private land. Compensable "physical invasion" includes instances in which the government itself takes title (even if it does not occupy the property), entitles private parties to trespass without taking title, or causes a detrimental physical occupation by water or foreign material. In most physical invasion cases, the government attempts first to buy the land (or an easement) on the open market. Unlike most other market participants, however, the government's right of eminent domain entitles it to force reluctant landowners to give up title in return for a court's determination of just compensation. Just how much compensation is "just" is often a matter of controversy (Goldberg et al., 1987; Kanner, 1973), but that something is owed by the government is usually not disputed in these instances.

The more controversial aspects of takings arise when the government establishes or changes a regulation that causes some properties to decline in value. Examples include rezoning formerly residential (but undeveloped) land for open space, restricting economic activity in certain areas because of the presence of wetlands or endangered species, and requiring that underground mining be curtailed to protect surface owners. In these instances, the government usually declines to offer just compensation even though the loss to the owner may be almost as great as if the government had taken the property for a roadway. This dichotomy in compensation practice — almost always pay for physical invasion, almost never pay for regulation — is the focus of this essay.

In the public choice view, government is not a neutral, third-party referee in matters concerning regulations and eminent domain. The scope and content of regulations will depend crucially on how the costs are distributed. This is in contrast to the black-letter law on the subject, which does little to inquire about the political process and usually takes the government's justifications for its actions at face value. The epitome of this deference is the U.S. Supreme Court's view of the "public use" clause, which many commentators regard as prohibiting the government from taking private property (with compensation) and giving it to another party for his private use (Epstein, 1985; Merrill, 1986; Paul, 1987). The Court agrees that takings must be for public use, but it accepts without inquiry almost any legislative declaration that, say, a private shopping center or an automobile assembly plant is a "public use." The possibility that private parties may be operating through the legislative process to further their private interests is largely disregarded.

The public choice approach regards the government as responding to the economic interests of those involved in the process. The obligation to pay will shape the behavior of the government's actions; they are not "exogenous" to the model. In this respect, a government agency's behavior is analogous to that of a private firm. The agency possesses a budget constraint, and officials have to decide whether purchase of certain inputs exceeds the priority of other items in its budget, or whether it is worth requesting the legislature to raise taxes to obtain additional funds to purchase them. In weighing these considerations, the government undertakes the same sort of benefit-cost analysis that private individuals must do when making a purchase: Would the money spent on purchasing the land possibly be better spent on some other project or left in the hands of taxpayers?

In introductory microeconomics, a private firm's decisions about how to produce something depends not just on technology and resources, but the relative prices of those resources. Farmers can produce raw food and fiber, for example, with inputs of land, labor, and capital. If labor is inexpensive, farm owners will hire many workers to plant, cultivate, and harvest their crops. They will substitute towards labor and away from expensive machinery and other forms of capital. If labor becomes relatively costly, however, farm owners will find it worth their while to purchase and employ sophisticated machinery to plant, cultivate, and harvest. The relative prices of inputs will also affect what crops they raise. Those that require intensive husbanding by hand will be planted where labor is less costly, while those that can be tended largely by machinery will be planted where labor is expensive.

The "inputs" for the government must be characterized differently than they would for a private firm. The government often has a choice between accomplishing its goals by acquiring title to land or by regulating it while leaving it in the hands of the private owners. The alternative inputs, in other words, are not labor and capital, but regulation and acquisition.

To provide a concrete example of a trade off, consider government efforts to protect an urban area along a major river from flooding. The government could build floodcontrol dams upstream in order to prevent the floods from occurring. This would obviously involve acquisition of land for the dam and for the area subject to periodic inundation. (As one can see, what the dam does is shift the flood damage upstream to presumably cheaper land in rural areas.) Another way to reduce flood damage in urban areas, though, is to regulate development in flood-prone areas downstream (White, 1986). Such regulation is not entirely paternalistic, in the sense that property owners are prevented from accepting risks of flooding to themselves. In major floods, buildings that become unmoored by the torrent become additional agents of destruction as they hit other buildings and bridges downstream, and personal liability for such damage is nearly impossible to establish after the fact.

As the reader can easily surmise, cost-minimizing flood control programs would most likely involve a combination of regulation of downstream land and acquisition of upstream land to build dams and levies. The difficulty arises from the fact that one input to flood control, regulation, can seem much cheaper than the other, acquisition, if regulation does not require compensation. For example, an optimal amount of flood control might involve a dam that costs \$50 million and regulations that reduce downstream floodplain owner's property value by \$30 million (net of the gain to property value from less flood damage). To be scrupulous in this comparison, it should be noted that the \$50 million for the dam must include, besides the opportunity cost of the resources taken, the costs of condemnation and the excess burden of additional taxes needed to finance the compensation.

Assume now that the same degree of flood control could be had by building no dam at all but adopting more widespread and stringent land-use regulations that impose a net cost of \$100 million. Clearly the former method (dam and moderate regulation) is less costly by \$20 million. But if the government agency charged with flood control does not have to compensate landowners for regulation, it may be tempted to undertake the latter strategy (regulation only), even though it is more costly to society. Moreover, it may be tempted to use its regulatory powers to extend flood "protection" to areas where the costs of such protection exceed the benefits to those protected.

In general, underpricing regulatory activity relative to acquisition in most circumstances induces overregulation and excessive expansion of government activities. The agency responds rationally to the price schedule it faces, just as a firm would expand its labor-intensive activities if it did not have to pay for labor. One exception arises when those burdened by the regulation are politically influential and thus can constrain the agency's choices. Indeed, some historical accounts of the development of just compensation for landowners in England points to the political influence of land-owning barons (Stoebuck, 1972). But the political defense often fails for regulation, since those victimized by the regulation may be a small minority who are not even resident in the jurisdiction, which is commonly the case for suburban landowners (Ellickson, 1977). Moreover, the government agency may be captured by interest groups who receive the benefits of its regulatory activities but do not bear its costs. Such agencies may be sufficiently independent - indeed, may have been deliberately made independent — that they can resist political pressure from those who bear the costs.

The objection voiced by many scholars who are not influenced by public choice is that the government simply does not make such calculations. Defenders of the statusquo (no compensation for regulation) argue that the government is different from a private actor. Government agencies are supposed to promote the public welfare, not make a profit for shareholders. Because the agency is charged with maximizing well-being, it actually does take account of the value of economic opportunities that are foregone as a result of regulation.

There is a situation in which a regulator might actually behave this way. Private developers sometimes acquire large amounts of contiguous land on which to build houses. Prior to selling the houses (or the prepared lots), the developer often imposes covenants that bind the purchasers to observe a list of regulations. These regulations look much like those of a typical government-imposed zoning ordinance, except that the private regulations are often much more detailed and intrusive. They go beyond saying where the houses must be placed and what they can be used for. These private regulations often dictate what kinds of vehicles may be placed in driveways, what color the homes may be painted, and what sort of furniture may be put on the front porch.

Yet the private developer does not pay anyone to accept these regulations. To the contrary, he expects buyers of homes to pay a premium for their existence. He does not have to price his regulations explicitly because he feels the full opportunity cost of them. If he adopts regulations that repel most buyers, it will lower the value of his assets. If he adopts too lenient a set of regulations, buyers will likewise be shy of living in a densely-developed community in which their neighbors may be able to do things that lower their property's value.

It is arguable that sometimes governments behave the same way as private developers do. A small municipality consisting entirely of homeowners and whose land is used only for housing is apt to be governed by members of their own group. If they propose a general regulation that prohibits renting homes to students from a nearby university, they are apt to feel both the benefit and cost of such a decision. The benefit would be a more peaceable neighborhood and hence higher home values, while the cost would be the foregone revenue that each owner might have gotten had she decided to rent her property to students. In this situation, a decision to adopt such a regulation is not much different from that which a private developer would do.

The situation changes greatly, however, when the government agency can subject to regulation the property of people who are not members of the governing faction. Here a more explicit cost in the form of just compensation can be helpful to prevent the excessive use of regulation. I will describe a famous example that came to light in Lucas v. South Carolina Coastal Council, 505 U.S. 1003 (1992).

The South Carolina Coastal Council had in 1988 altered the land-use regulations pertaining to building on private property along the oceanfront beaches of the state. Seaward of a Council-drawn line in the sand, no development of any kind was permitted. The Council was complying with a recently passed state legislation. The legislature cast its rationale for the prohibition on development as a matter of preventing public harms such as beach erosion, storm damage to homes, and destruction of wildlife habitat. In order to insulate the Council's land use decisions from political influence, the legislature decreed that the decisions of the Council were not subject to landowner requests for variances or other exceptions.

David Lucas owned two beachfront lots, each about one-third acre in area, that were within the new zone on which no permanent structures could be built. He had purchased the two parcels prior to the adoption of the new regulations for about one million dollars. The effect of the new regulations was to leave his investment nearly worthless. Having no means of appealing his classification, Mr. Lucas sought in court to compel the state to pay him for the denial of economic use of his land.

The trial judge held the Council's new regulation to be a taking, given that no economic use for Lucas's land remained. The state supreme court reversed. Accepting the state legislature's determination that building along the beach was a "harmful" activity, the state court held that no compensation was due despite the complete wipeout of economic use. Faced with Lucas's Fifth Amendment claim that this amounted to a regulatory taking, the South Caroline Supreme Court declared that regulations meant to prevent "harms," as declared by the legislature, were not compensable.

The U.S. Supreme Court reversed the South Carolina Supreme Court. Justice Scalia's opinion expressed a public-choice insight. He worried that if the Court always deferred to regulatory legislation that prevented "harms," the legislature would go about recasting the language of its regulations to avoid the obligation to compensate. A highway, to use an example not used by Justice Scalia, could be built much more cheaply if existing homes and businesses in a projected right of way could be said to be "harmful" to the public.

And from the road-builder's point of view, such buildings are harmful to his mission. It is not difficult to see how people who specialize in a single activity can persuade themselves that activities inconsistent with their enterprise can be so perverse as to be labeled "harmful." Environmental and planning agencies would seem no different from highway departments in this respect.

Yet if government agencies were given this license, they could obtain property rights of great value that the government would otherwise be unwilling to pay for. Wildlife preserves, scenic views, and open space could be established without the need to compensate owners whose activities were curtailed. They could even leverage regulation into acquisition at low cost by downzoning (under the harmprevention rubric) the desired land and then purchasing it at the now-diminished price. To forestall this opportunism in cases of complete economic wipeout, Scalia's opinion held that such regulations were compensable under the takings clause unless grounded in "background principles" of state law. While the provenance of such principles remains unclear, the thrust of Scalia's idea is that they should sufficiently remote in time as to be removed from verbal manipulation by the present legislature.

The *Lucas* decision is subject to the criticism that its holding can be invoked only against regulations that are so extreme as to leave owners with no viable economic use whatsoever. Few regulators are so dull as to be unable to meet this criterion by, say, allowing a few tents on land best suited for homes, thereby keeping it from being developed. The property owner who can get some economic use by pitching tents but not houses on her land gets nothing under the *Lucas* criterion.

Lucas is not invoked here to explicate Constitutional principles, though. It is to show how perceptions of cost affect government behavior. The eventual outcome in Lucas exquisitely illustrates how government agencies respond to changes in relative prices. The evidence emerged not in the court opinion but in the subsequent settlement of the case. After the U.S. Supreme Court's decision, the state of South Carolina decided to settle the case by purchasing Mr. Lucas's two lots. What did it do with the lots whose development it had argued was irreparably harmful to the environment? Well, it had just paid almost a million dollars for them. It decided to recoup its money by selling them to a developer to build houses upon (Fischel, 1995, ch. 1; Lucas, 1995). The state even declined the offer by an inland neighbor who sought to purchase one of the lots (for about eighty percent of the asking price) and keep it undeveloped in order to preserve his seaward view. When I revisited the site with Mr. Lucas and his attorney, Jerry Finkel, in March of 2000, there was a large house on one of the lots, and the other was still on the market.

Some see this story as an example of government hypocrisy — professing one thing but doing another. Public choice tends to make one less judgmental, even of this remarkable about-face. The Lucas outcome is an example of how the price one has to pay affects behavior. Prior to the Lucas decision, South Carolina perceived the price of Lucas's lot (and others like it) as being low, since it did not expect to have to pay for them. At that price - zero dollars and zero cents - even the least environmentally-sensitive legislator would have to concede that environmental values that is, alternative uses for the state's money — needed to be given up to preserve the coast. The legislature did not have to risk the wrath of voters by raising taxes to pay for the lots. All it had to do was pass a regulation, whose burden fell upon a small number of landowners.

Once the state came into possession of the land, however, it had reason to pay attention to its market price relative to its environmental value. Agents of the new owner (the state) now surely noticed that the properties in question were among the few lots along several hundred yards of this beach that did not already have large homes upon them. They are packed side-by-side, so that Lucas's vacant lots look like two missing pickets in a long fence. The state's agents then surely noticed that developers were willing to pay nearly half a million dollars for each of the lots, and the state's agents did what rational and faithful public servants should do: They sold the lots to developers.

The state had not changed its intrinsic values. It valued the environment no less after the case than before. The state simply responded to the higher price of preserving this tiny (less than one acre) stretch of the beach and did the sensible thing. It is no more hypocritical for them to have done so than it would be for an owner of a farm to switch from human pickers to mechanical pickers once the wages of farm laborers went up.

The just compensation clause can viewed as a device that keeps government officials from excessive enthusiasm. Having to pay money out of scarce budgetary resources makes officials calculate whether it is worthwhile to undertake a particular project. By applying methods of analyzing individual choice to the public sector, public choice offers insights into an important constitutional question that other approaches might not.

TERM LIMITS 1

Term limitation is an institutional option in representative democracy that, if taken, sets some maximum amount of time that an individual can serve in some public office. In contemporary America, for example, the president, most state governors, nearly half the states' legislators, and some 3,000 officials at the local level are term limited. Why these laws exist and what effects these laws have are questions that have spawned a large literature in economics and political science. I survey this literature elsewhere (López, 2002a). Here I will focus on two aspects of term limitation that both describe its essence and also provoke unresolved issues.

1. The Tenure-Turnover Trade off and Welfare Effects of Term Limits

Consider a president who is popular enough to win his re-election bid. Voters benefit from the job experience that the president gains from being in office a long time. But the president would benefit from being able to dissuade effective challengers, and this is a skill that may be acquired, along with job experience, from being in office a long time. If the president then uses this electoral security to his own benefit rather than to better representation of his constituents, voters would be harmed.

Now consider a Member of Congress who is popular among his district constituents. Voters benefit from him accumulating job experience with greater tenure. But his tenure relative to the tenure of other members is also valuable if it means he can bring higher net benefits to the district (perhaps in the form of an increase in net transfers). But the member would benefit, like the president, from erecting some barriers to effective challengers. If the member then uses this electoral security to his own benefits, and fails to represent constituents' preferences along the way, voters are again harmed. These hypothetical examples illustrate the tenureturnover tradeoff that voters face and that term limitation addresses. Rapid replacement of politicians is costly to voters because inexperienced people run the government. In legislatures, it is costly for voters to replace their representative too frequently because their representatives do not stay in office long enough to acquire important powers to direct net transfers toward the district. These are turnover costs. In contrast, it is costly to leave officials in office for too long because they may erect entry-barriers to effective challengers and pursue their own ends. They may also impose excessive deadweight loss on the economy in directing rents to themselves and their electoral constituents. These are tenure costs.

Term limitation is a mechanism for keeping tenure costs low and therefore a benefit to voters. However, term limitation also increases turnover costs. Theoretically, the optimal term limit would be set at the length of tenure at which the marginal tenure cost just equals the marginal turnover cost (cf. Adams and Kenny, 1986). Thus, the welfare effects of adopting term limits are conceptually straightforward. However, complications arise in estimating the tenure and turnover costs. More serious complications arise when the tenure and turnover costs of one political entity (such as a state or congressional district) depend systematically on the tenure and turnover costs in other entities. This is the case with legislative and congressional term limits.

The welfare effects of congressional term limits depend firstly on whether legislators from all districts are term limited. In state legislatures with term limits, every legislator is term limited. A strong case can be made that a reduction in average tenure with a preserved distribution of relative tenure is welfare enhancing; at least it would explain why voters might support term limits (Dick and Lott, 1993). But the welfare effect would still depend on the concavity of voter utility over turnover and tenure costs (e.g., Lee, 2002). In the case of Congress, however, 23 states unilaterally passed term limits during a wave of state-level reform in the early 1990s. (The Supreme Court later struck down these laws.) This almost certainly would have harmed voters in the term-limited districts to the benefit of voters in the non-limited districts. So why did voters in these states pass term limits? This is an issue that is not well understood (López, 2003). And it runs parallel to related and equally puzzling question.

2. Supporting Incumbents and Term Limits

The Congressional incumbent reelection rate exceeded 90% for all elections in the 1990's. Yet opinion polls in the

mid-1990s routinely indicated supermajority support for term limits among voters. And voters revealed strong preferences for term limits at the voting booth: term limits on state legislators and Congress passed 22 of the 23 times they appeared on state referenda.

Why might voters support incumbents and also support legislative term limits? Here again the tenure-turnover tradeoff comes into play. Because districts compete for net transfers vis-à-vis one another, and more tenured legislators are typically more productive in acquiring net transfers, it is primarily relative tenure that is valuable to voters in a given district. Now suppose that increased tenure enables legislators to capture rents instead of passing them on to constituents. That is, legislators become electorally secure and begin to shirk as they acquire more tenure. Voters in all districts would capture welfare gains from a general reduction in tenure. But the importance of relative tenure creates a free-rider problem: if all districts agreed to replace their incumbent through electoral defeat, each would then have the incentive to cheat. Term limitation is the mechanism to enforce such an agreement (Dick and Lott, 1993). Hence, voters are not behaving inconsistently when supporting incumbents and universal term limitation.

Unilateral term limitation is a separate case, and the more puzzling as well. Is it rational for voters to support their own incumbents while voting to limit the terms of their own Congressional delegation? The free-rider argument only explains universal term limits, and further research on this topic has been inconclusive (see López, 2003 for discussion). It is possible, then, that this conundrum presents the opportunity to uncover more advanced strategic motivations behind voter support for institutional change. Consider that five of the 23 states that passed term limits did so conditional on a majority of the other states also doing so. Sophisticated behavior was also evidenced when Congress considered term limits. Prior to the Supreme Court decision that struck down the unilateral state laws, a representative's vote on term limits was systematically related to whether he or she was from a state that had unilaterally self-imposed. But when Congress considered the same bill two years later, the vote was unaffected by whether the state had self-imposed (López, 2002). In general, a district's support for term limits has exhibited a clear awareness of whether other districts have supported them or will support them. A promising direction for theoretical research would be to model multiple districts in a sequential game with payoffs related to tenure-turnover costs in each district, whether the district had passed term limits, and whether other districts had. Such a game could generate hypotheses relating states' support for term limits to population, income, net transfers,

homogeneity of constituents, and other seemingly important variables.

3. Empirical Work

Most empirical work involving term limitation seeks to estimate the effects of term limits on dependent political variables (such as tenure, party balance, shirking, and the value of holding office), policy variables (such as constitutional features and fiscal stability), and economic variables (such as growth). Close to no empirical work has sought to explain the origins of term limits, for example by estimating the likelihood of a state passing term limits. Why did certain states pass term limits while others did not? Of theoretical significance to this would be, among other variables, the state's net transfer profile and the tenure of its delegation. Since term limits laws were passed via referendum/ initiative, a variable that indicates whether the state constitution allows for referendum/initiative would also be of theoretical significance. This estimation is prevented by the fact that every state that allows for referendum/initiative also passed term limits. As such, we are left with the uninteresting result that states passed term limits because their constitution featured a direct democracy institution. However, if term limits and direct democracy are determined by different political-economic processes, then this result is also wrong. If they are determined differently, the likelihood of term limits should be estimable using instrumental variables. This depends on whether exclusion restrictions can be convincingly argued and reliably measured for the estimation of the instrument. Future empirical work could take up this question, as well as the efficiency effects of term limits, toward valuable contributions to our understanding of the origins and effects of term limits.

TERM LIMITS 2

A term limit is a statutory or constitutional restriction on the number of terms that an individual is allowed to hold a particular elected office. The term limit may or may not be grandfathered. Full grandfathering allows officeholders at the time that term limits are enacted to be exempt from term limits, whereas limited grandfathering allows such officeholders to be treated as if they have previously served no terms. Some term limits allow an individual who is forced out of office by term limits to hold the same office again after a specified period of time has elapsed while many do not. In recent years there has been heated debate over the desirability of term limits.

1. Historical Background

The concept of a term limit goes back at least to Aristotle, who praised the merits of a legislature of citizens with each holding office for a short time. This frequent succession of citizens in an office is referred to as rotation in office. Term limits were not uncommon in colonial America and, although not included in the United States Constitution, were debated at length during the Constitutional Convention. Indeed, George Washington was widely praised for retiring from the presidency after two terms. While voluntary rotation in office was commonplace in the U.S. Congress until the late nineteenth century, Polsby (1968) documents the rise of the career congressman and the institutionalization of the Congress that took place thereafter. Not only did the average number of terms served by congressmen steadily increase over time, but the Congress itself developed an increasingly complex committee system accompanied by growth in congressional staff and the rise of the seniority system.

Although today the prevalence of professional politicians indicates at best a modicum of enthusiasm on their part for rotation in office, term limits do exist for many state and municipal elected offices. Most states have term limits for governor. Term limits also have been imposed in a large number of states and municipalities, many in the 1990s, on the offices of state representative, mayor, and city councilman. At the federal level the twenty-second amendment to the U.S. Constitution limits a president to two elected terms.

The two elected federal offices that are notably free of term limits are U.S. senator and U.S. representative, and it is the question of the imposition of term limits for these offices that has generated the most controversy in recent years. In the early 1990s twenty-three states passed voter referenda or laws limiting the number of terms that their congressmen could serve. These referenda and laws subsequently were overturned by the U.S. Supreme Court in 1995 in *U.S. Term Limits, Inc. v. Thornton.* Although there is little question that public support for term limits exists, it is not obvious that this support is an explicit cry for term limits or an expression of frustration with the way that government has been operating.

2. Issues Surrounding Term Limits

The focus of debate in recent years has been on the likely effects of term limits imposed on congressmen. Some important issues raised include the impacts of term limits on the composition of the Congress, the type of legislator who will serve, the degree to which legislators will faithfully represent their constituents' interests, and the level of federal government expenditures or the size of government. The issues are not necessarily independent of each other. Analysis is difficult because the absence of term limits on congressmen throughout the history of the Congress means that there are no data on the behavior of congressmen under term limits. Consequently, analyses are normative, theoretical, or indirect when empirical.

2.1. Composition of the Congress

Legislative tenure almost certainly will be reduced if term limits are imposed. Reed and Schansberg (1994) estimate that a six-term limit for congressmen will reduce the expected number of terms served by a congressman from 8.9 to 3.2 with the maximum being 6.0. Furthermore, there initially will be large influxes of freshman congressmen every twelve years (six terms), but the magnitudes of these influxes will dampen over time. There will be times after the imposition of term limits when the Congress will have historically high percentages of inexperienced congressmen.

It should be noted that these estimates of the effect of term limits on expected tenure are based on historical continuation rates (for the period 1985 through 1991) for congressman and do not take into account how the term limits themselves can alter behavior and therefore continuation rates. Grofman and Sutherland (1996) argue that strong challengers may postpone running for office until term limits force an open-seat election, while Francis and Kenny (1997) argue that term limits in a higher office (e.g., the U.S. Senate) may encourage more holders of lower office (e.g., the U.S. House) to run for higher office by generating more open-seat elections for higher office. More generally, the probability of reelection depends on the degree to which congressmen serve their constituents' interests, and term limits may alter congressmen's incentives to serve those interests.

A related implication of term limits is the likely demise of the seniority system, under which committee chairmanships are assigned on the basis of length of tenure in office, because the number of congressmen with the maximum possible seniority may well exceed the number of committee chairmanships. It is not clear what would replace the seniority system.

Finally, there are partisan implications of term limits. Gilmour and Rothstein (1994) conclude that term limits will impact the partisan composition of the Congress by favoring Republicans. This is because in recent years Democratic incumbents have had lower retirement rates and higher reelection rates than Republican incumbents and Republican challengers have been more likely to win open-seat elections than Democratic challengers following the retirement of incumbents from their respective parties. The relative magnitudes of the parties' retirement rates, reelection rates, and open-seat election rates taken together favor Republicans under the forced-retirement regime of term limits.

2.2. Type of Congressman

Term limits will impose the rotation in office that had once been voluntary. It has been argued (Petracca, 1996) that rotation in office guards against concentration of political power in the hands of career legislators and professional politicians and is consistent with the belief that in a democracy governance should be carried out by amateurs who shortly return to their lives as private citizens. Presumably such citizen-legislators, understanding that they are free from the task of continually seeking reelection and that they shortly will return to the private sector to live under the rules contained in their own legislation, would be more inclined to represent the true interests of their constituents and to not pursue their private interests and would be less susceptible to influence from special interest groups and their promises of campaign contributions.

The logic of this argument is not convincing. Why should a mandated limited time in office, effectively the constraint that it is not possible to make a career of that office, cause these citizen-legislators to better represent their constituents interests and to not pursue private gain? This is a particularly relevant question because the threat of not being reelected constrains legislators to take the interests of unorganized constituents into account (Denzau and Munger, 1986). In order to make the claim that term limits will produce a legislature of citizen-legislators more inclined to represent constituent interests it would be necessary to make a convincing argument that term limits will influence the self-selection of citizen-candidates in this manner. No such argument has yet been made. Indeed, it has been argued that the interruption of a private sector career in order to serve a brief time in office under term limits may attract a higher proportion of independently wealthy individuals and opportunists than does the current system without term limits (Polsby, 1991).

It also is not clear that term limits actually will lead to a legislature of amateurs, let alone amateurs who efficiently and faithfully represent their constituents. It is more likely that term limits will not discourage politically ambitious people from running for office but will instead channel their ambitions in different directions. In lieu of the prospect of a potentially long career in Congress, the congressman will consider how to optimally manage a career that may include a succession of different political offices or periodic stints working in the private sector, perhaps as a lobbyist for firms with interests before the Congress (Garrett, 1996). While the congressman's decision-making calculus will give weight to the interests of his constituents, it necessarily will give weight to the interests of his potential future constituents or private-sector employers as well. Furthermore, the limited time horizon in office under term limits implies that the congressman has both less time to learn and less incentive to invest time in learning the substance of the issues being considered by the Congress because a shorter time horizon means a shorter time to collect the returns from such an investment.

2.3. Representation of Constituents' Interests

There has been considerable debate on whether and to what extent term limits will alter the level of shirking by congressman. "Shirking" refers to a congressman's failing to fully represent the interests of his constituents. A congressman whose interests do not coincide with his constituents' interests has an incentive to shirk. The threat of not being reelected by the voters because of this shirking acts to reduce shirking. However, a "last-period problem" arises when a congressman, knowing that he is in his last term in office and therefore does not have to face reelection, can costlessly shirk as much as he likes and will do so if his interests do not coincide with his constituents' interests. A last-period problem does not arise for a congressman who is defeated for reelection because this congressman is not aware that he has served his last term in office until after defeat, whereas a potential last-period problem does arise for every congressman who retires from office. If voters can detect shirking earlier in a congressman's career,

then it is likely that the last-period problem will not be important because congressmen who are inclined to shirk will be defeated for reelection before their voluntarily leaving office. Studies by Lott (1987, 1990) and Van Beek (1991) indicate little difference between congressmen's voting on legislative bills in their last term before retirement and their voting on legislative bills in their previous terms served, thereby suggesting that voters do tend to remove shirking congressmen from office prior to voluntary retirement.

Term limits, which would force many congressmen to leave office prior to electoral defeat, guarantee that the lastperiod problem will arise more frequently. The relatively short three-term and six-term limits that have been suggested for congressmen likely will cause the degree of shirking associated with the last-period problem to increase nontrivially by not giving voters enough time to remove shirking congressmen prior to their last terms before forced retirement under term limits. These term limits also will prematurely remove from office those congressmen who are inclined to shirk little and whom the voters would like to retain in office.

Focusing only on the last period is, however, an oversimplification. Although shirking by a congressman will be greatest in the last period because the reelection constraint is no longer binding, shirking likely will occur throughout a congressman's career.

Dick and Lott (1993) argue that tenure itself can be a source of shirking. A congressman with longer tenure has greater seniority on committees and likely has developed greater ability to utilize the rules of the Congress and greater skill at logrolling. These factors will increase the ability of the congressman to transfer wealth to his district from the rest of the country relative to a congressman with shorter tenure. Voters are therefore reluctant to remove from office a congressman with relatively long tenure. This allows the congressman to shirk with respect to other interests of the voters without unduly risking electoral defeat. The longer a congressman's tenure, the greater is the potential amount of shirking by a congressman without endangering reelection. By forcing all congressmen to leave office after a specified number of terms, term limits make it less costly for voters to discipline their congressmen at the polls. Dick and Lott believe that the resulting reduction in shirking will more than offset the increase in shirking generated by the last-period problem occurring more frequently under term limits.

While Dick and Lott make valid points that shirking can increase with tenure because the ability to transfer wealth increases with tenure and that term limits can reduce shirking from this source, their contention that any increase in shirking induced by term limits will be only in the form of more last-period shirking reflects too narrow a focus. Bender et al. (2001) argue that given a finite time horizon in office a congressman will optimally shirk throughout his congressional career (i.e., there is a time path of optimal shirking). In this dynamic context optimal shirking means that in each term the congressman's degree of shirking reflects a tradeoff between the benefit of additional utility from additional shirking in the current term and the cost of the reduction in expected present value of the utility received in future terms from the reduction in probability of reelection at the end of the current term induced by additional shirking in the current term. The less time remaining in the horizon, the smaller is the cost of electoral defeat and therefore the larger is the optimal amount of shirking. Term limits reduce the time horizon of the congressman and therefore raise his optimal amounts of shirking in each of his terms in office. The threat of electoral defeat becomes less effective in controlling shirking when term limits are present because the return to not shirking is diminished by the reduced time horizon under term limits. This impact on shirking is magnified to the extent that the reduced return to lower shirking causes the pool of potential candidates to consist of candidates who are on average more inclined to shirk. Term limits not only increase shirking by existing congressmen but also encourage potential shirkers to run for office.

2.4. Size of Government

Over the years both the average tenure of congressmen and the level of government expenditures, a proxy for the size of government, have been increasing. Some proponents of term limits argue that they will reduce the size of government based on a presumed positive and causal relationship between tenure and spending. It has been hypothesized that the longer that congressmen are in office the more likely they are to be drawn into a culture of spending or shirk more by supporting legislation for more spending than their constituents desire or develop more expertise at logrolling. However, Reed et al. (1998) test these hypotheses and find at best weak evidence that a relationship between congressional tenure and support of government spending exists and consequently little empirical support for the proposition that term limits will reduce the size of government.

3. Conclusions

The list of issues above is not exhaustive. Certainly the impact of term limits on the influence of lobbyists and on

the relative power of the executive and legislative branches of government could be added to the list. The unavailability of data on the behavior of congressmen under a termlimits regime precludes direct empirical testing of all of the issues. This inability to test directly the hypotheses about the impacts of term limits may continue to leave the desirability of term limits an open question.

TERRORISM

Terrorism is defined as 'the systematic employment of violence and intimidation to coerce a government or community into acceding to specific political demands' (The New Shorter Oxford English Dictionary, 1993). Whether or not such an act is viewed as good or evil depends on particular circumstances and involves a normative judgment.

For example, during the early stages of the French Revolution, adherents or supporters of the *Jacobins* advocated and practiced methods of partisan repression and bloodshed in the propagation of principles of democracy. Many French citizens viewed such terrorist acts favorably, at least until the Revolution of 1789 descended into the Terror of 1793–94 under the Directorate dominated by Danton, Robespierre and Marat (Hugo, 1874, 1998). Yet these same terrorist acts were viewed throughout as evil by most members of the French Aristocracy and by many others loyal to the Crown and fundamentally opposed to French republicanism.

Similarly many Irish American Catholics revere and fund acts of terror perpetrated against the United Kingdom by the *Irish Republican Army*, whereas the large majority of United Kingdom citizens view these same acts as evil applications of atheistic, Marxist-Leninist dogma.

Most recently, the governments of several countries in Africa and the Middle East, notably Afghanistan, Somalia, Iraq, the Yemen, Sudan, Libya, Syria, Pakistan, Iran, and Saudi-Arabia, have nurtured and financially supported the training of terrorists broadly defined as members of *al Qaeda* to enable them to launch a sequence of successful terrorist attacks on the United States and to threaten similar attacks on other advanced Western nations. Yet, the vast majority of citizens of all civilized, advanced nations despise *al Qaeda* as the epitome of evil, indeed as the Godless perpetrators of torture, pillage, enslavement of women and mass murder and mutilation.

1. The Heterogeneous Nature of Terrorist Groups

Terrorist groups manifest themselves in a wide variety of shapes and sizes. Some groups, like the *Irish Republican Army, La Cosa Nostra Fatah, Hamas and Hezbollah, Baader-Meinhof* and *The Shining Path*, are geographically concentrated and culturally and politically homogeneous.

TERRORISM

Other groups, like *al Qaeda* are geographically dispersed and culturally and politically diverse. More rarely, terrorists take the form of lone individuals, like the *Unabomber*, who respond violently, perhaps to mental illness, perhaps to perceived personal failure to perform satisfactorily in civilized society.

Small homogeneous groups organize their activities rather like the special interest groups depicted in Mancur Olson's (1965) logic of collective action. They overcome the free-rider problem that confronts all organizations pursuing goals that are public goods or bads, in part by privatizing the benefits from collective action and in part by enforcing supply either through physical intimidation or by moral suasion. Because they operate illegally and cannot enforce contracts through the legal system, they must rely heavily on networks of trust, based either on religious fanaticism or on excessive greed for wealth, but always reinforced by violence against individuals and the families of individuals who seek to defect from or to betray the group. In such circumstances, individuals who join a tightly knit terrorist group confront the equivalent of a serious transitional gains trap that strongly deters exit (Tullock, 1975).

Large, heterogeneous terrorist groups confront more serious difficulties in building membership and in deterring defections and betrayals. Mancur Olson (1965) predicted that large groups pursuing goals with pronounced publicness characteristics tend to be less successful than smaller, more homogeneous groups unless they are organized for some other purpose that provides private benefits to their members. In essence, such terrorist groups by-product terrorism by providing selective benefits.

For example, the *al Qaida* leadership preys on illiterate, simple-minded male drop-outs drawn primarily from a range of Middle Eastern countries (but also from Europe, North America Africa, Australasia and Asia) by indoctrinating them in fanatical Islam, by focusing hostility towards such 'Western values' as capitalism and individualism and by promising each terrorist such Heavenly pleasures as rivers of sweet honey and holy wine, 72 virgin brides and free passes to Paradise for 70 of his friends and relatives should he die in an attack on the Infidels. Of course, not all terrorists are sufficiently stupid as to believe in such nonsense. Many are coerced into engaging in suicide attacks by threats of torture or by death threats to their families should they refuse to serve coupled with promises of long-term financial support for their dependents should they successfully complete their mission.

Senior members who actively plan or execute terrorist attacks are provided with affluent lifestyles and international travel that are unattainable through ordinary market transactions. The *Fatah* motivates its membership into

launching suicidal attacks on Israel by promising the establishment of a socialist State of Palestine and the removal of the Jewish occupation. *Hamas* and *Hezbollah* motivate membership by promising the elimination of Israel from the map of the Middle East.

Large terrorist groups that are not grounded in one nation state clearly confront serious problems of free riding that cannot be overcome solely by reliance on selective benefits. To effect supply, the larger umbrella organizations, such as al Qaida, encourage the emergence of a network of much smaller cells motivated and trained through a wide range of geographically dispersed training camps. The network externalities provided by the umbrella group allows such a terrorist group to obviate the impact of changing national borders that otherwise would tend to weaken the internal cohesion of the group (Olson, 1982). The small nature of each cell also allows cell leaders to foster an atmosphere of trust and a fear of exit conducive to high risk-taking among the membership. Because the cells operate independently of each other, the identification of any one cell by the victims of an act of terrorism does not automatically or easily expose other cells or the umbrella organization to effective retributive action.

Furthermore, pan-Islam disposes adherents of that faith to view themselves as Muslims first, and as citizens of particular countries second. Clearly, this doctrine helps *al Qaeda* and other multi-national terrorist groups to overcome the logic of collective action.

2. Linkages with Nation States

Terrorist groups often enjoy the geographical protection and financial support of countries that share common terrorist objectives but that desire to avoid the international sanctions that would be invoked by overt action. Such has been the case of successive governments of the Irish Republic that until recently provided covert support for the *IRA*. It continues to be the case in Palestine, with respect not only to *Fatah* but also to *Hamas* and *Hezbollah*. It is clearly the case of Iraq, the Yemen, Syria, Pakistan, and Saudi-Arabia with respect to *al Qaeda*.

The relationship between terrorist groups and nation states, however, is more complex than a simple sharing of hatreds. The insecure governments of certain nation states pay off terrorists within their borders to avoid destabilizing military attacks and/or to secure their support in attacking border enemies. Such is the case with Egypt, Saudi-Arabia, Pakistan, and the Yemen with respect to *al Qaeda* and of Palestine with respect to *Hamas* and *Hezbollah*.

The temporary controlling authorities in such failed states as Somalia, the Yemen, Sudan and, most spectacularly,

Afghanistan go yet further, allowing themselves to be purchased by such well-funded terrorist groups as *al Qaeda*, placing themselves on the payroll of the terrorists and effectively becoming handmaidens to their designs. The public choice analysis of such hijacked states does not yet exist. Inevitably, a relevant literature will emerge in the wake of September 11, 2001 (Shughart, 2003).

3. The Goals of Terrorists

By the nature of its terrain, terrorism undoubtedly attracts the services of a number of mentally unstable individuals, whose behavior cannot be subjected systematically to economic analysis. For the most part, however, such individuals are the exception rather than the rule, and, typically, do not achieve significant leadership roles in substantive terrorist groups. They do not do so because terrorist groups pursue rational goals that would be subverted or nullified by unpredictable behavior. Those who are mentally disturbed are used by the rational leaders of terrorist groups, as are the ignorant, religiously indoctrinated fanatics who seek an early entry into Paradise, and or who seek large financial side payments to their families, as compensation for engaging in acts of self-destruction.

The leaders of all successful terrorist groups are rational actors motivated by the maximization of some combination of expected wealth, power, fame and patronage, much in the way of other members of society. They differ markedly from most other individuals with respect to their attitudes towards risk, typically manifesting risk preference in relatively extreme forms such as a relatively low regard for human life and a relatively low level of genuine attachment to associates and colleagues. Because these latter preferences differ so markedly from those of other individuals, their behavior appears to be irrational. Fundamentally, however, this is not the case.

Individuals with similar preferences and attitudes towards risk occupy many legitimate areas of activity. Examples include William Jefferson Clinton in politics, Michael Milken in stock trading and Jimmy Bakker in the populist religion market. Such individuals respond to perceived rewards and penalties, albeit while skirting the edges of potential personal disaster.

Terrorist leaders likewise respond rationally to expected costs and benefits. They can be deterred or diverted by actions that manifestly lower the net expected benefits of terrorist attempts (Shughart, 2003). Their rational goals imply that they seek to impose the maximum possible terrorist cost for any given outlay of resources (Enders and Sandler, 1995). Because they operate in environments unregulated by any rule of law, their behavior is less constrained as it edges towards extremism than typically is the case of those with similar pathological symptoms who remain more or less within the civilized sectors of society.

4. The Relevance of Religion

Many of the Middle Eastern terrorist groups, notably al Qaeda, the Palestinian Islamic Jihad, Hamas and Hezbollah organize themselves around the rhetoric of a radical interpretation of Islam and seek to impose this religion on Middle Eastern countries that are deemed to have betrayed the Muslim faith. It is doubtful whether the affluent leaders of these groups, for example Osama bin Laden in the case of al Qaeda, or Dr. Rathi Abd al-Aziz and Sheikh 'As' ad Bayyud al-Tamimi in the case of the Palestinian Islamic Jihad, have any serious use for the Muslim faith other than as a device for attracting followers. Certainly their respective life-styles do not conform to the stringent standards required by that faith. Such, however, is not the case for the large majority of their footsoldiers.

Although it is currently politically correct to refer to Islam as a peaceful religion, this is a less than accurate interpretation even with respect to its less radical versions. Contemporary Muslim faith, rather like medieval Christianity, is very rule oriented, in the sense that it sets out precise requirements for prayer, fasting, alms and economic exchange.

This type of rule-oriented doctrine leads to dogmatic and precise rule-following behavior on the part of ignorant and ill-educated Muslims and provides a fertile breeding ground for terrorism when manipulated by charismatic leaders. Such strict adherence to doctrine also fosters conflict between Islamic sects on the basis of relatively minor differences of interpretation. For example, Shias consider Sunnis to be apostates and vice versa.

Unlike Christianity, the Muslim faith has experienced no modernization to accommodate the requirements of a developing world. Indeed, contemporary Islamic thought is impoverished as a consequence of the suffocation of Muslim intellectual activity since the tenth century (Kuran, 1995, p. 176). As Kuran notes (ibid.) the Islamic scholar Mohammed Arkoun makes two distinctions in characterizing public discourse in the Islamic world. One is between the *thinkable* and the *unthinkable*, the other between the *thought* and the *unthought*.

Noting that past generations of Muslims treated key tenets of the European Enlightenment as unthinkable, Arkoun argues that present generations of Muslims cannot even conceive of applying the methods of historical criticism to sacred texts and cherished traditions (ibid.). In consequence, the 'resurgence of Islam is taking place on the If Arkoun is correct, he provides an explanation of the process through which educated leaders of terrorist groups secure such a powerful grip over the minds of their followers. By transferring beliefs from the realm of the thinkable to that of the unthinkable, social pressures within the group induce the withdrawal of those beliefs from public discourse. Members of the group become progressively less conscious of the disadvantages of what is now publicly favored and increasingly more conscious of the advantages. As a result, private opinion moves against the publicly disfavored alternatives. This offers an explanation of why groups go to extremes.

5. The Relevance of Geography

With the singular and important exception of *al Qaeda*, modern terrorist groups typically emerge within specific countries to eliminate governments that are perceived to be inimical, on religious, political or other grounds, to the goals of their leadership. The evidence strongly suggests that the large majority of countries that attract such terrorist groups are relatively small countries, surrounded geographically by other countries.

Hosts that manifest dictatorial oppression, religious conflict, periodic wars and periodically changing borders are especially attractive to such parasites. Countries that have access to sea routes and, therefore, that benefit from the comparative advantage of international trade, appear to be relatively less attractive as potential hosts. Presumably, the perceived economic advantages of trade outweigh the trade-destructive rhetoric of fighting for Islam typically utilized by terrorist leaders to motivate the local population into violence.

Many of the host countries are vulnerable to terrorism because they are the victims of artificial geographical boundaries imposed by former colonial Empires without regard to ethnic composition. Such is the case within much of the Middle East and much of sub-Saharan Africa (Rowley, 2000). Such synthetic nation-states, especially when they do not federalize in order to reflect customary tribal preferences, predictably result in ethnic violence and become breeding grounds for terrorist parasites (Shughart, 2003). The single party systems and outright dictatorships that dominate much of the Middle East and sub-Saharan Africa are highly attractive to pathological terrorist leaders not least because such politically vulnerable regimes tend to pay off rather than to confront terrorists by offering them safe harbor and subsidized access to economic resources.

6. The Asymmetric Nature of Terrorist War

In the early twenty-first century, the United States is the world's only superpower, comparable in terms of military dominance to the ancient Roman Empire during the first two hundred years, A.D., and to the British Empire at its peak in the mid-nineteenth century. In principle, it should be invulnerable to its enemies, credibly capable of annihilating them should they dare to challenge its private space. Yet, the United States is peculiarly vulnerable to terrorist attack ironically because its human and physical capital is so valuable.

The term 'asymmetric warfare' was coined first in the USSR during its unsuccessful attempt to defend its imperial seizure of Afghanistan against the 'Holy Warriors' of the *Mujahedeen*. The term entered into the US military lexicon only in 1995 defined with elegant simplicity as 'not fighting fair' (Bray, 2002, p. 25). Asymmetric warfare implies that singularly weaker forces are capable of imposing devastating costs on a massively stronger enemy without necessarily fearing the ultimate penalty of a nuclear or a nuclear-equivalent response. September 11, 2001 was the first manifestation of this phenomenon. This may prove to be the foretaste of yet more spectacular devastations should the terrorist presence not be substantially eradicated by forceful American action.

In order to understand the varying degrees to which terrorists engage in violence and the varying levels of devastation that they are prepared to impose it is important to distinguish between two types of terrorist groups, namely those that are stationary and those that are non-stationary (McGuire and Olson, 1996).

Stationary terrorists, such as the *IRA*, *Fatah*, *Hamas* and *Hezbollah*, that operate from well-defined territories and seek to advance the interests of members within the same or closely adjacent locations, predictably will engage in strictly localized and limited terrorist attacks. To engage in nuclear, biological or chemical attacks of any magnitude would be to run significant risks of harming their own members as well as of inducing equally devastating retaliations from those harmed. In a sense, rational stationary terrorists that have an *encompassing interest* (Olson, 1993) in the territory within which they operate are constrained from acts of widespread destruction.

Of course, if terrorists establish themselves as parasites on a host that believes that victims of terrorism will not retaliate by annihilating the host population — as was the case with *al Qaeda* in Afghanistan prior to September 11, 2001 — these constraints will not apply. For such terrorists have no encompassing interest in the host country from which they operate. Non-stationary or roving terrorists operating through networks of inter-active cells located secretly in many countries are the most dangerous of all, since such cells have no encompassing interest whatsoever in the countries from which they operate and confront minimal risks of major retaliation even if their location is discovered following a terrorist attack. This is the reason the American victory in Afghanistan over Taliban and *al Qaeda* forces in the months following September 11, 2001 is only a first step in the war against terrorism. The non-stationary cells of *al Qaeda* located, it is estimated, in some forty to sixty countries world wide are significantly more dangerous than were those located in Afghanistan under the leadership of Osama bin Laden and Mohammed Omar.

Because rogue states like Iraq and Pakistan may be willing suppliers of weapons of mass destruction both to stationary and to non-stationary terrorist groups, the war on terrorism cannot be deemed to be successful until their autocratic leaders have been removed and their political systems have adjusted to secure individual liberties, private property rights, limited government and the rule of law.

7. The Cost of Terrorism

Because of the nature of an asymmetric war, terrorists are able to impose very high costs on their enemies at seemingly trivial costs to themselves. September 11, 2001 is the most extreme example to date of this asymmetry. It has been estimated that the successful attacks launched on that day against the United States may have cost the terrorists no more than \$200,000. (The terrorist lives lost were at most costless since the perpetrators were expediting their journey to Paradise).

The present value of the economic damage to the United States economy, however, has been estimated to be perhaps as much as two trillion dollars (Navarro and Spencer, 2001). Immediate costs, counting the value of lives lost, property damage and lost production are well in excess of \$100 billion. The annual cost of airport and airline antiterrorist measures is estimated to be in excess of \$40 billion. Although the initial stock market estimates of the collapse of market capitalization undoubtedly were excessive at \$2 trillion, nevertheless, the loss of investor confidence (animal spirits) together with the drag on economic incentives likely to ensue from greater government involvement in the economy and from larger budget deficits predictably will extract a savage toll on the rate of growth of the US economy over the following several years.

Since September 11, 2001 involved only a very limited strike at localized US assets, and since credibly *al Qaeda* agents have access to weapons of widespread destruction, the expected cost of terrorism to the United States and to its other seriously committed allies is dramatically higher than the two trillion dollar estimate by Navarro and Spencer, at least in the absence of a successful war on the terrorist network. Yet, in an environment in which weapons of mass destruction become ever cheaper and easier to hide, the very notion of a successful war against roving networks of terrorists is at best likely to prove ambiguous.

Fundamentally, moreover, the economic costs of terrorism against the United States pale into insignificance by comparison with the loss of liberties and the erosion of the rule of law that the war on terrorism inevitably imposes. The American criminal laws, already badly crippled by complex rules of discovery, by excessively lax bail facilities, by televised trial circuses and by a decrepit jury system (Tullock, 1997) are clearly incapable of dealing effectively with accused terrorists. Inevitably, the administration has resorted to a *de facto* suspension of *habeas corpus* and to reliance on military tribunals in order to skirt the manifest limitations of the American trial courts.

Equally serious are the adverse implications of the war on terrorism for the freedom of movement and protection against search of innocent American citizens. Such freedoms, hard won in the eighteenth century by the Founding Fathers, almost squandered in the mid-nineteenth century during the War of Northern Aggression, and only slowly re-established thereafter, are in process of being shredded once again.

The most significant costs imposed on Americans by the successful terrorist attacks of September 11, 2001 undoubtedly are those arising from the erosion of individual freedoms, private property rights, limited government and the rule of law.

THE THEORY AND MEASUREMENT OF ECONOMIC FREEDOM

Social scientists recognize three broad categories of freedom: political, civil or legal, and economic. A matter of great philosophical dispute is whether freedom or liberty is natural (negative) or human (positive). For example, does one have the right to choose how one labors (a natural right occupational freedom) or does one have a right to a minimum living standard for that labor (a human or positive right that requires government to redistribute economic outcomes on the basis of some notion of distributional justice)? We will not engage in that debate here. I will take freedom to be a procedural concept rather than a notion about positive outcomes. Thus, political freedom is about the right of the polity to choose who governs them, not who governs. Civil liberty is about the right to be ruled by law rather than by man. Rule of law is about fair procedures, and not about fair outcomes or justice. Economic freedom is about the right to organize one's pecuniary affairs with minimal interference by the state, and not about just economic outcomes. While the measurement of political and civil liberty has been with us for four decades or so, the measurement of economic freedom is more recent.

To my knowledge, Freedom House (1987) made the first attempt to measure economic freedom (it did so once,

and then abandoned the project). The organization has had a long involvement in measuring political and civil liberty, with those measures going back to 1973 for virtually all nations. As with previous attempts at measurement, their measures of political and civil liberty are not without controversy. A number of human or positive freedoms and subjective criteria are included among the variables used to construct their ratings. Freedom House's thinking about economic freedom is even more woolly. Broadly, they based their measure of economic freedom on sub-indices of the right to private property, freedom of association, freedom of travel, and the right to information. But, freedom of property contains measures of land reform, which is frequently confiscation without compensation, the extent of social services, and income distribution. Freedom of association includes the right to collude to redistribute income. Freedom of travel includes the degree of discrimination and socioeconomic mobility in society. The right to information includes such attributes as price controls, subsidies, and minimum wage.

A quantitative measure of economic freedom should be more comprehensive and more precise in definition of the attributes that aggregate to an overall measure of economic liberty than is found in the attempt at measurement by Freedom House. Thus one would want to include, among others, such items as the right to private property, freedom of contract, the rule of law, the size of government and its command over resources, the extent of the fiscal state, the degree of government economic regulation of business, labor, and markets, the monetary framework and monetary policy, commercial policy (free trade versus protectionism), and so on.

Along with a colleague, in 1991, (Scully and Slottje, 1991) I published the first set of measures of economic freedom based on a more comprehensive set of attributes, and ones selected on natural or negative criteria rather than on human or positive criteria. In all some 15 attributes went into the construction of the index. The economic freedom index was calculated for 1985, and for 144 nations. The results made sense, in that countries that one would have thought had a high (low) level of economic freedom indeed had a high (low) ranking based on the measure. But, while the index is based on objective criteria, those country rankings in between high and low are a matter of dispute. Nevertheless, the measure of economic freedom that I constructed was significantly related to the rate of economic growth across these countries. That is a reassuring finding, but it is not necessarily definitive about how accurately economic freedom is measured.

Let me give some criticism of my index of economic freedom, which also holds to a lesser degree for the

economic liberty indexes that have followed my effort. In my rankings (the average of the ranks of the 15 attributes), the United States has a rank of 1.0, but so does Ireland, Liechtenstein, and Luxembourg. New Zealand has a rank of 5.73 and Hong Kong has a rank of 11.93, which is not too much better than the rank for Sweden (13.93). Now, most scholars knowledgeable of these countries would rank Hong Kong first in the world and New Zealand fairly low, at least for 1985. Hong Kong, despite being relinquished by Britain to China, remains the freest economy on earth. New Zealand, in 1984, was the most heavily regulated economy outside the socialist block. True enough, marketbased reforms were undertaken in the post-1984 period but this would not have showed up in my measures, in 1985. Ireland was still heavily regulated and taxed in 1985. Liechtenstein and Luxembourg have fairly large public sectors, and certainly would rank below the United States.

In general, the problem with these measures of economic liberty, no matter how objective, is that they can distinguish the free from the unfree, but they are based on attributes that are not sufficiently fine to distinguish degrees of economic freedom among countries that are generally free or not free. This means that more research needs to be undertaken on this topic, and, perhaps, a much wider array of attributes needs to be considered.

The Fraser Institute took over the project on measuring economic freedom. James Gwartney and his associates (Gwartney and Lawson, 2001) have recently published the fifth edition of Economic Freedom of the World: Annual Report 2001. Their measure of economic freedom is the best that is available. For 2001, it is for 123 countries and is based on 21 components. The 7 broad categories of objective measures that go into the construction of the index are: the size of government, the structure of the economy and use of markets, monetary policy and price stability, freedom to use alternative currencies, legal structure and property rights, freedom to trade with foreigners, and freedom of exchange in capital and financial markets. Based on their components, Hong Kong ranks highest (9.4 on a scale to 10.0), followed by Singapore, New Zealand, United Kingdom, United States, Australia, Ireland, Switzerland, Luxembourg, and the Netherlands (8.4). But, Finland, Austria, Germany, and Iceland are not far behind, and clearly there is heavy intervention by the state in these economies. And, Bahrain and Oman rank higher than Spain in economic freedom. Thus, while the Fraser Institute's measure of economic freedom is objective and is much improved over previous measures, it still suffers from a lack of fineness in the components used to construct it. (Rabushka, 1991, Gwartney, Lawson and Block, 1996).

Part of the problem in the construction of economic freedom index is that a trade-off between inclusiveness of

variables and comprehensiveness of coverage is encountered. That is, if you want to include countries such as Madagascar, Myanmar, and so on, not a great deal of objective data is available. Recognizing this problem, the authors have constructed a more comprehensive index of economic freedom for 58 countries. This index is based on 45 components. The main source of expansion of the attributes is the addition of information on the extent of regulation of capital, financial, and labor markets. With the incorporation of these data, some changes in the rankings do occur, and some of these changes make a good deal of sense. For example, Taiwan's rank dramatically improves, while that of France and Italy fall considerably. But, now Italy is not much freer than Egypt or Haiti, and is less free than Argentina and Bolivia. Unfortunately, when one correlates these two measures of economic freedom (the economic freedom index and the comprehensive index), one finds a correlation coefficient between the index ratings of .95 and between the rankings of .94.

Most indices of freedom weigh each attribute equally. Such an egalitarian standard implies, for example, that people have a social welfare function that equally weighs whether property is private or collective or whether the garbage is picked up privately or by the state. Clearly, they do not. So, part of the problem in constructing an aggregate measure of economic freedom may arise from the method of weighing the attributes.

Ideally, one would be able to specify a social welfare function in which rights are ranked lexicographically. Weights based on the relative rankings of the attributes would be employed to construct an overall measure of economic freedom. But, that approach is not possible. Alternatively, the researcher might impose his/her own weights or survey knowledgeable people for their opinions, but this is too ad hoc. There are two objective methods of weighing that attributes that have some theoretical justification and intuitive appeal. Since many of these attributes are correlated with each other, why not take advantage of that fact, and weigh by variances? This is the method of principal components. Each factor (an agglomeration of some of the attributes) is not correlated with any subsequent factors. Alternatively, one can weigh by regression coefficients using instrumental or hedonic estimation. Thus, per capita GDP might be the instrumental variable, and the coefficients of the attribute of economic liberty on per capita income would give a measure of how that attribute is valued. There are some other techniques for finding weights, but they are not suitable in this context.

In the creation of my measures of economic freedom, I constructed measures based on equal, principle component, and hedonic weights. When these indices are correlated

with one another, one finds massive inter-correlation. Thus, choice of the weighing technique had little impact on the rank of economic freedom.

The finding that how one weighs the attributes in constructing an overall measure of economic liberty does not matter particularly may tell less about the problem of weighing than it tells us about the problems of the objective attributes. That is, the objective attributes may be insufficiently fine to reveal much difference within the set of generally free or generally not free nations. Or, they are so inter-correlated with one another that weights are irrelevant. A way of thinking about this issue is that, for the objective criteria that we have, countries that get institutions and policies right get them all right, and countries that get institutions and policies wrong get them all wrong.

TOTALITARIANISM

1. Introduction

Totalitarianism has been defined differently since the 1920s (Schlangen, 1970; Linz, 2000) when the scientific analysis of a presumably new phenomenon began with the takeover of power by Communists in Russia, Fascists in Italy and later by National Socialists in Germany. Four definitions will be mentioned. The first takes the sphere of life subordinated to the dictate of the state as its characteristic. Mussolini's definition in the *Enciclopedia Italiana* (1929: 847 f.) is an example:

for the Fascist everything is within the state and there exists nothing human or spiritual... outside the state. In this sense Fascism is totalitarian and the Fascist state interprets, develops and multiplies the whole life of the people as a synthesis and unit of each value.

This definition has been accepted by scientists like the sociologist Andreski (1965), but has obvious disadvantages.

First, it can include all possible regimes, even democracies. For in a *Total Democracy* there would be no sphere free from government regulation determined by majority voting. Second, a *Theocracy* in which about all aspects of life were regulated by religious prescriptions would also be a totalitarian regime. But in the first case at least a majority has to agree to this all-encompassing state activity, and in the second case nearly the whole population believing in the religion may agree to these regulations.

A second definition (Friedrich and Brzezinski, 1956) employs five characteristics:

- 1. A dominant totalitarian ideology;
- 2. A monopoly party;
- 3. A secret police applying terror;
- 4. A monopoly of information and
- 5. A planned economy.

This definition has also several weaknesses. First, why should a monopoly party and a planned economy be necessary for a totalitarian regime? What happens, if instead a priesthood and an economy restricted by the values of an ideology are present? Second, can terror not be applied by other organizations than a secret police? Third, is an overwhelming influence of the ideology on information not sufficient? Moreover, theories of this kind are too static to account for the rise, the development and the breakdown of totalitarian regimes.

Another definition has scarcely been influenced by those mentioned, but has relationships to the old theory of autocracy (Tullock [1974], 1987). This approach taken by the theory of Public Choice has applied the methods of economics to create formal models, and assumed that a dictator employs government power to maximize his utility under certain restrictions. The utility depends only on the wealth, income or consumption of the dictator, whereas the restrictions refer, e.g., to the means to maintain his power, or make a distinction between whether the dictator is a roving or a stationary bandit (Olson, 1993; McGuire and Olson, 1998). This assumption implies that the latter is more interested in long-term exploitation than the former, so that he exploits his subjects less in the present to be able to use their resources also in the future.

The most advanced of these models has been developed by Wintrobe (1998). He enriches the theory by introducing power besides consumption into the utility function of the dictator and, by using a richer set of restrictions, tries not only to explain ordinary dictatorships, but also totalitarian regimes. The latter are the outcome of great weight given in the dictator's utility function to power as compared to consumption, and of a production function efficiently TOTALITARIANISM

producing loyalty with the help of a well organized party and a strong ideology. In spite of its merits, Wintrobe's model suffers from the assumption that the dictator is mainly interested in power, and that ideology is only a means to maximize it. But ideologies define the very aims of totalitarian regimes. To mention one example: Why should Hitler devote scarce transportation facilities and armed forces to transport people to Auschwitz, when they were badly needed to support the struggling German armies? If power had been his predominant aim, he would never have done so. But his behavior is understandable if ideology entered his utility function.

Subsequently the following definition is preferred (Bernholz, 1997, 2001; Piekalkiewicz and Penn, 1995):

A totalitarian regime is an ideocracy which has not yet reached the aims implied by its supreme values, and which tries to pursue them with the spiritual and secular power available after it has gained domination of a state.

In this definition two concepts, *ideocracy* and *supreme values*, have to be explained. Supreme values are postulated by an ideology to be lexicographically preferred to everything else, even to the life of those believing in them and to the lives of others. An ideocracy is a political system in which all aims in society are subordinated with the help of spiritual and secular power to the rules implied by the supreme values. Besides totalitarian regimes there exist thus other ideocracies, called *mature ideocracies*, in which about the whole population believes in the rules postulated by the supreme values, so that no secular power has to be applied to enforce them, except in rare cases of transgression. For instance, a theocracy is a mature ideocracy in which the supreme values are defined by a religion.

The above definition makes only sense as a building block of a theory. Its usefulness becomes clear by sketching this theory.

2. Origins of Totalitarianism

No totalitarian regime has ever come into being without a powerful *ideology*, a *Weltanschauung*, claiming to be a more or less comprehensive and ultimate explanation of reality (Maier and Schaefer, 1997). Such an ideology contains *supreme values* which it insists have to be preferred lexicographically by all believers, so that no efforts and no sacrifice, even of one's own life or of the lives of others have to be spared to reach the ends postulated. All people able to become believers have to be converted, be they for instance Aryans in the case of national socialist, or proletarians in the communist, or the whole of humanity in Christian or Muslim ideologies.¹ According to certain ideologies some people, however, cannot be converted, like

Jews according to Nazi and capitalists and bourgeois according to Communist ideology. Such groups are enemies of the true creed, and have consequently either to work as subjects of the believers for reaching the ends of the ideology, to be forced into emigration or to be eliminated.

An ideology is usually invented or revived by individuals who win a following by their charismatic personality. Their creed is often contained in holy scriptures whose absolute truth cannot be doubted, but interpreted by a selected leadership.

An ideology is a *necessary* but not a *sufficient* condition for the evolution of a totalitarian regime. For this to arise, *spiritual* and *secular* power have to be combined, that is, the government of at least one country has to be taken over by believers. To reach this end an organisation with a leadership or a leader having the monopoly right to interpret the ideology have to be created. It is needed to win votes in a democracy or to infiltrate armed forces and bureaucracy in authoritarian regimes to grasp power. This aim would be endangered if many believers were allowed to interpret the creed, since this would weaken the *movement* by splitting it up into different sects.

Finally, to be able to grasp power, a severe *crisis* has to occur. For to convert non-believers, they must doubt their present believes and way of life in view of the promises to solve the crisis contained in the ideology.

Even then, a *mature ideocracy* instead of a *totalitarian regime* may develop, if the groups of believers can emigrate to a thinly settled country and create a political system like the Puritans in Massachusetts or the "state" established by the Jesuits in Paraguay. For in this case nearly only believers are present so that no wide-spread force or terror characteristic of totalitarian regimes have to be applied. Consequently, a peaceful regime is established, if the supreme values do not ask for further expansion. It follows that mature ideocracies and totalitarian regimes are both ideocracies, but that the latter in contrast to the former has not yet reached the aims postulated by the respective ideology.

3. Domestic Policies after Gaining Secular Power

If secular and spiritual power have been combined, the supreme values can be enforced, as required by their absolute truth. Opponents have to be converted. If they resist, they as well as non-convertible people (like Jews under the Nazis or Bourgeois and Landlords under Communism) have to be made subservient and used for the ends of the regime, to be driven into exile or to be eliminated. If necessary, brutal force and terror have to be applied. True believers should do this with good conscience since they work (or pretend to do so) for the realization of the supreme values, and not for their own benefit or because they are evil sadists. In fact, they are themselves prepared to sacrifice their lives.

This policy implies the subjugation of all organs of the state, the dissolution or *Gleichschaltung* of all organizations which may hinder or oppose the regime. The legal system has to be adapted to the requirements of the ideology and the judiciary to be made subservient. A different constitution containing the rules prescribed by the creed has to be implemented, which is not a constitution of liberty. In this process the existing organization(s) of believers like a party or a priesthood may play a prominent role. The leaders continue their dominant role, since they have the sole right to interpret the constitution and the meaning of law according to the ideology.

4. The Flourishing and Demise of Totalitarian Regimes

When the totalitarian movement has consolidated its power, converted all potential believers and removed or put to work all inconvertibles for its purposes, it may turn into a mature ideocracy, if its ideological aims do not call for further expansion. For instance, if its ideology is religious, it may turn into a theocracy, like the Israel of antiquity,² Tibet, or Iran since Ayatollah Khomeini.

Things are different if the ideology asks either for a conversion of all people on earth, or for the subjugation of them by a selected group, or for more limited aims, like the unification under one government of all people speaking the same language. Whereas this aim has a chance to be reached after some time by political pressure on and war with other nations, if it is not too ambitious, it is nearly impossible to complete the task of dominating the globe. Consequently, a totalitarian regime with such an aim will either be defeated in war, or has to reinterpret its ideology. This will be easier if a second or third generation of leaders does no longer believe, but only pretends to do so to use ideology to maintain power. A defeat in war is probable, especially since ideology encourages an unrealistic view of power relationships. The defeat of Germany under Hitler is a telling example. The communist regime under Stalin, by contrast, postponed the World Revolution and limited itself to Communism in One Country for the time being. Finally, Deng and Gorbachev began with fully-fledged and, for their regimes, dangerous reinterpretations of the ideology. As a consequence the regime changes its nature and moves towards an ordinary authoritarian or finally perhaps even into a pluralistic or democratic regime. As can be seen

for the Soviet Union, the state may even fall apart in the process. It is, however, also possible that the reinterpretation only removes the expansionary traits of the ideology. In this case a mature ideocracy may evolve.

5. Totalitarian Regimes in History

In Table 1 a list is presented of the regimes in history that have been totalitarian according to the definition given above together with sources. Moreover, the table contains estimates of the numbers of people killed by them. There may be some cases of totalitarianism which are missing. This is especially true for border cases. The Mahdi rebellion in the Sudan in the 19th century was certainly a totalitarian movement which turned into a theocracy. But it was soon after the early death of its founder defeated by the British Empire under the leadership of Lord Kitchener. When Iran was turned into a theocracy (the Islamic Republic) between 10,000 and 20,000 opponents were killed. This means that there existed a short totalitarian period before a mature ideocracy was firmly established. Similar developments happened with the Taliban's effort to establish a theocracy in Afghanistan.

The Christian crusades to Palestine were totalitarian movements, since they were motivated by ideology and led under the banner of the Cross. They led in scarcely two centuries to the death of between 800,000 and 900,000 Arabians. The Crusaders killed between 50,000 and 60,000 Jews and Arabians (Heinsohn, 1998) when they conquered Jerusalem in 1096. But they were not the army of a totalitarian state, except that they founded the kingdom of Jerusalem. The same is true for other crusades.

There is broad agreement among scholars who analysed the question as to which regimes were totalitarian during the 20th century. No such agreement exists concerning the first seven regimes which have been included in Table 1. So justification has to be given, why they fit our definition. Consider first the Mongols. According to Voegelin (1941; see also de Rachewiltz, 1973):

The thesis [in the documents] that Genghis Khan is the only and supreme Lord of the Earth may be considered as part of a dogmatic system explaining the true nature of government in the cosmos... But since ... at least the earthly part of it, is a world in the making, the formula proves to be a claim to rulership for Genghis Khan and to submission by all other earthly powers... It is brimming with dynamic energy and pregnant with the fanatical acts born of the desire to transform the world of man into a likeness of God's rule in Heaven (405).

In such cases of a regrettable lack of understanding for the perfectly peaceful and law abiding intentions of the Mongol Imperial Government who did nothing but carry out an Order of God, punitive expeditions had to be undertaken — like that of 1241, carried into Eastern and Central Europe, which had been the proximate cause for the Papal mission of 1245 (406).

We turn to the Aztecs and quote Conrad and Demarest (1988: 38):

imperial cosmology held that the Mexica must relentlessly take captives in warfare and sacrifice them; the spiritual strength of the sacrificed enemy warriors would strengthen the sun and stave off its inevitable destruction by the forces of darkness. Thus, it was specifically the Mexica's sacred duty to pursue a course of endless warfare, conquest, and sacrifice to preserve the universe from daily threat of annihilation. The new vision of the cosmos accelerated the pace and scale of human sacrifices beyond all previous measure, associating these ancient rites specifically with the Mexica state and the expansion of the Triple Alliance.

The Taiping rebellion in China originated with the creation of a half-Christian movement, the Association of God Worshipper, by Hung Xiuquan, who believed to be the son of god, and his organizer Feng Yun Shan. Hung Xiuquan founded the Heavenly Kingdom of Great Peace and became Heavenly King in 1851. The supreme values of the ideology included a Christian-inspired communism and equality of the sexes. The kingdom's armies conquered Hunan, Wuhan and Nanking, and moved as far as Tientsin before they were finally defeated in 1864 (Michael and Chung-Li, 1966–71).

A description of Geneva, the Muenster Anabaptists and the Inca Empire as totalitarian regimes is presented in Bernholz (1997:185–290), together with the sources.

It remains to discuss the figures in Table 1. Since totalitarian regimes have a strong tendency to suppress and eliminate people who are not convertible according to their ideologies, or who resist the supreme values contained in them, the number of victims killed by these regimes directly or indirectly, that is for instance by forced labour and starvation, is huge. A comparison of the numbers of victims caused by democratic, authoritarian and totalitarian regimes in the 20th century, 2, 26.7 and 138 million

Country	Period	Number of victims (Thousand)	Historical source
Mongols	13–15th Ctr.	29927	Morgan (1986)
Incas	Till 16th Ctr.	n.a.	Conrad and Demarest (1988)
Aztecs	Till 16th Ctr.	1000	"
Calvin's	1542-46	0.058	Choisy (1902), Zweig ([1936], 1983)
Geneva			
Anabaptist's Muenster	16th Ctr.	n.a.	van Dühlmen (1974)
French Revolution (Jacobin Terror)	1794–94	263	Greer (1935), Ladouce (1988)
Taiping Revolution	1851–64	20-34000	Shih (1972), Chesneaux (1973)
Soviet Union	1917-87	61911	Rummel (1990), Courtois et al. (1997)
Nazi Germany	1933–45	20946	Rummel (1992)
Communist regimes:			
China	1949-87	35236	Rummel (1991)
Vietnam	1954-87	1678	Rummel (1996)
Cambodia (Khmer Rouge)	1975–79	2035	Kiernan (1996)
North Korea	1948-87	1663	Rummel (1998)
Poland	1946-48	400	Checinski (1983)
Eastern Europe	1917-89	1000	Courtois et al. (1997)
Cuba	1959–96	15-17	Courtois et al. (1997)
Ethiopia	1974–91	2 000	Human Rights Watch (1990)

Table 1: List of totalitarian regimes

Sources for numbers: Elliott (1972), Dobkowski and Walliman (1992: 167), Rummel (1996: 12), completed and corrected by Heinsohn (1998).

For Calvin's Geneva: Meyers Konversationslexikon (1903).

Note: Figures by other authors diverge widely in some cases, for instance for the Soviet Union even by a factor of 0.5. Still, all estimates agree on general magnitudes.

(of which 110.3 million by communist regimes) (Rummel, 1996:15), demonstrates the deadly nature of totalitarian regimes. In these estimates the victims of the wars are excluded, whose number has been estimated as amounting to 34 million (Rummel 1996: 15).

But not only absolute figures matter. Of the different groups persecuted as non-convertibles, the group of proprietors (capitalists, bourgeois, kulaks) suffered the greatest number of deaths, between 40 and 50 million by communist regimes. But if we look at relative figures of victims, for instance as a percentage of the total population or of the persecuted groups, a different picture emerges. The total number of people killed in Geneva because they did not adhere to the right protestant creed is small, but so was the population of Geneva. And the percentage of the total population killed in Cambodia, about 21% (Kiernan, 1996: 458), seems to be the highest among all totalitarian regimes of the 20th century. If one looks, on the other hand, at the proportion of people killed of groups of victims, the number of Jews, 67% of Jews in Nazi Europe (Rummel, 1996: 120), of Ukrainians (mainly Kulaks), 41% (Conquest, 1986: 306), or Tibetans in Communist China, 33.3% (Rummel, 1996: 120), then these numbers overshadow everything else.

PETER BERNHOLZ

NOTES

- 1. Religions are considered to be ideologies for the purpose of explaining totalitarian regimes. This does not imply that their metaphysical truth concerning last human values is denied.
- 2. This concept was first coined by Flavius Josephus (Contra Apionem 2: 165) around 94 A.D. to contrast the organization of Jewish society with the political systems conceptualized by classical Greek theory. Compare Taubes (1987).

TRADE PROTECTIONISM

If we had a situation where these [steel workers] were our constituents and someone was breaking in their house and raping and robbing and pillaging them, we would want to send in a policeman to do something. In this instance, they [importers of foreign steel] are just coming in and taking their future, they are taking their jobs, they are taking all of their dreams away... We must stand up for the people of this nation. We must stand up with a force of steel and with a backbone of steel. (Mr. Klink, Pennsylvania, *Congressional Record*, 1999)

... the [steel import quota] bill before the Senate is a job killer, a trade war starter, and it is a bill that will destroy 40 jobs in steel-using industries for every one job it saves in steel producing. (Mr. Gramm, Texas, *Congressional Record*, 1999)

1. If Free Trade is Efficient why isn't it Universal?

Explaining trade protectionism has been one of the most fruitful areas for the application of public choice analysis. Economists have long faced a conundrum. If our theory is correct that seldom do deviations from free trade improve economic efficiency, why is it that in the real world free trade is the exception rather than the rule? Public choice analysis provides the answer. In common practice, economists ascribe the property of aggregate economic efficiency to any policy moves that create sufficient gains so that the winner could compensate the losers with something left over, i.e., to any policy which expands the utility possibility frontier beyond the initial equilibrium. In practice, however, such compensation is seldom paid; a policy that expands the utility possibility frontier often makes some worse off. From the standpoint of political economy, policies that potentially raise everybody's utility have much less appeal than policies that actually make everybody better off. Despite the frequency with which international trade theory is mischaracterized, it does not prove that everyone gains from free trade, even when there are no domestic market failures. It proves only that in money terms the gains from free trade in total are greater than the losses, in the sense that there is some set of transfers from winners to losers that could make everybody better off (Willett, 1995). If we assume that most individuals and groups are more interested in their own costs and benefits than in those for their country or the world, then it is perfectly consistent with rational behavior for some individuals and groups to favor trade protection for their industries.

2. Why isn't Protectionism more Prevalent?

Before public choice analysis became widely known, some economists predicted that free trade eventually would reign. These predictions were based on the public interest assumptions that so often dominated discussion of economic policy or else on naïve political science models that predicted that any selective protection measures would be defeated, since a substantial majority would lose from such protectionism. The rent-seeking model of public choice makes quite different predictions. This model stresses costly information and the incentives for free riding that imply many voters will be rationally ignorant or not vote. Concentrated efforts by well-organized producer groups give them incentives to be highly active politically and generally result in more producer than consumer influence on the political process. The prevalence of protectionist tariffs, quotas, and voluntary export restraints (VERs) are a direct result of this process. Thus public choice analysis yields powerful insight into the formation of trade policy.

Despite the importance of its insights, there is a serious problem with such applications of simple rent seeking theory to trade policy. It explains too much!

Having shown how rent seeking theory can explain protection, the current challenge for public choice analysis is to explain why protectionism is not much more prevalent. While the United States does have many formal and informal trade barriers today, they are relatively minor compared with the high levels of protection provided by the Smoot-Hawley tariffs of the 1930s. The story is the same for many other countries as well.

The search for answers to this question has led public choice analysts and political scientists to focus on a wider range of considerations such as the roles of ideas and institutions, the objectives of the executive branch, and the emergence of anti-protection interest groups. It is important to recognize that this richer menu of considerations offers complements to, not substitutes for, rent seeking theory.

3. The National Interest, Interest Groups and Protectionism

Most of the early analysis of trade policy took the country as the basic unit of analysis and focused on calculations of the so-called optimal tariff whereby a country with market power could use trade barriers to improve its terms of trade. Optimality came from balancing these gains against the portion of the standard efficiency costs of protectionism borne by the home country. Retaliation reduces the scope for gains but sometimes they remain positive. Such optimum tariff models were used to provide a rationale for international agreements like GATT to dampen countries' incentives to play such games. However, with the exception of cases of economic warfare, such optimal tariff modeling provides fairly little insight into the actual formulation of trade policies or the best design for institutions to limit protectionism.

Considerably more explanatory power seems to flow from both the standard rent seeking models and modern mercantilist models in which national leaders believe trade surpluses are good for the national economy and/or national power and security. Naturally, for the latter to be an argument for tariffs one must ignore the truth that under a flexible exchange rate or in the long run under the specieflow mechanism, protectionism is unlikely to improve the trade balance, because import tariffs depreciate the currency, expanding net exports. Of course, rent seeking, mercantilism and bad economics are all tied together, for rational interest groups will attempt to take advantage of mercantilist ideologies and bad economics (Ekelund and Tollison, 1981).

Unified rational actor or billiard ball views of nation states also characterize what has traditionally been the dominant school of thought in the literature on international political economy written by international relations scholars. Dubbed realist or modern mercantilist, this approach focuses on the countries' search for power and security and the role of international power structures in shaping outcomes in the international system. It is widely accepted that such views have considerable explanatory power for France, Japan, and a number of the newly industrializing countries. Foreign policy and national security objectives do not always militate for trade protectionism, however. In the United States during the postwar period the idea that liberal trade policies helped promote U.S. foreign policy and national security considerations was a powerful force behind efforts by both Democratic and Republican administrations to promote trade liberalization and fight protectionism (Finger, 1991).

Such foreign policy concerns and learning from the disaster of the Great Depression combined to foster institutional reforms designed to treat trade policy as an aspect of foreign policy, not just domestic policy, and to strengthen the hand of the executive branch relative to Congress in setting trade policy. These are the major explanations for the progressive lowering of US trade barriers during the first several decades of the postwar period. [see Goldstein (1993); Ikenberry et al. (1988); Rowley et al. (1995)].

Willett (1995) argues that the slowing of the U.S. movement toward trade liberalization can be explained by the weakening of both national security concerns and the clout of the executive branch relative to Congress combined with the growth of interest group pressure. Thus while the standard realist interpretation sees the increase in U.S. protectionism as resulting from a strong government, Willett's interpretation sees this process as a result of a weakening of the power of the state relative to domestic societal (rent seeking) pressures.

4. The Public Choice Approach to Protectionism: Some Theory

4.1. Rent Seeking

An important early contribution to the public choice approach to protection is Tullock (1967), which argues that the resources absorbed in lobbying for protection may outweigh the cost of protection itself. Krueger (1974) develops a similar theme. She models the resources sacrificed in the competition for import licenses. But, she stresses the important idea that in many economies government restrictions upon economic activity are pervasive facts of life, giving rise to rents, and people often compete for the rents, a process called rent seeking and one that uses up resources. Bhagwati (1982) notes that in a distorted economy profit-seeking activities, including lobbying for protection, smuggling and competing for import licences, while not directly productive, may be indirectly welfare enhancing, by using up resources that are doing damage elsewhere. Krueger also emphasizes that rewarding rent seekers undermines the faith of the public in the fairness of markets, which leads to more government intervention and hence a vicious circle of ever increasing rent seeking.

4.2. The Median Voter

Markussen et al. (1995, ch. 19) offer an accessible review of the literature and we draw on their discussion. Much of public choice modeling is based on the idea that public officials enact policies to maximize the probability of their being reelected. Suppose that the voters in an electorate are arranged on a line, in order of the level of protectionism that they support. If the level of protectionism is to be decided by referendum, the bill with the most support will be that which appeals to the median voter. If voting is by a legislature, legislators who support the level of protection supported by the median voter will tend to be elected.

In most economies, voters own disparate amounts of capital, so there are a few who own much capital and many who own none, but all voters own similar amounts of the factor labor. Consequently, the median voter is likely to vote according to the interests of labor. The Stolper-Samuelson theorem states that when both labor and capital are mobile between sectors and certain other conditions are satisfied. labor will benefit or suffer from protection depending on whether labor is the country's scarce or plentiful factor. The empirical implication of this is that labor-scarce countries are likely to have higher tariff rates on average than laborabundant countries, even though for all countries, if they are too small to influence world prices, protection is harmful, in the sense that the gainers from free trade could compensate the losers and still be better off. Similar results occur in the overlapping generations model of Gokcekus and Tower (1989). They find that when a labor-scarce country liberalizes, even if all citizens have an identical pattern of asset accumulation over their lifetimes, those who have already accumulated assets are capitalists who will gain from liberalization, while the young, who are workers now but will be capitalists later in life, may either win or lose. If most of the population is young, free trade may be resisted in a laborscarce economy, even though it benefits the whole economy.

Even though free trade alone may be politically unpopular, by combining a trade bill with an income redistribution bill, the bill with the most appeal should include free trade for a country that faces fixed world prices. Moreover, even if world prices are not fixed, the cooperative arrangement with other countries that should meet with the widest approval is free trade combined with an appropriate transfer between nations (Copeland et al., 1989). These mechanisms should limit protectionism.

4.3. The Status Quo Bias

Uncertainty associated with trade liberalization also helps explain why tariffs remain. Those who would be hurt by liberalization are easy to identify. Those who will gain better jobs through expanding opportunities in non-traded and export sectors are harder to identify. Thomas Shelling (1984) points out that voters tend to empathize with the easily identifiable. Consequently, governments may spend large sums of money to rescue one identifiable individual, even though that money could have been better used to save the lives of many unidentified individuals through medical research. Similarly, to the extent that voters empathize with obvious losers from freer trade, there may be little political pressure for trade liberalization, though the opportunity cost of each job protected may be vast. There is also some evidence from experimental economics (Knetsch, 1989) that people tend to value more highly what they own than prospective possessions. Both of these ideas suggest what has been referred to as status quo bias against liberalizing trade policy. This bias is reinforced by Corden's (1974) conservative social welfare function, which implies that society will support policies that prevent falls in real income for any significant group. As Rodrik (1993) points out, this uncertainty may explain "why reforms that are instituted by an authoritarian regime against prevailing political sentiment survive the return of democracy (think of Pinochet's trade reforms in Chile)."

A further implication is that liberalization will be more likely in boom times, when incomes are rising, than in recessions. However, for the counter argument see Rodrik (1985, p. 1487) who argues that "a deep economic crisis relegates distributional considerations to second place behind economy-wide concerns and therefore allows an agenda-setting government to seek trade policy reforms alongside macroeconomic reforms.

4.4. Picking the Form of Protection

Public choice also informs the choice between production subsidies, import tariffs and import quotas as ways to protect import competing industry. The welfare loss per unit of protection to the protected industry from quotas generally exceeds that from tariffs which exceeds that from subsidies. Thus consumers should rank the three policies in the indicated order. Home producers, *protection seekers*, are aware that quotas are less visible than subsidies or tariffs, and consequently are likely to rank quotas above the other two. Those who benefit from government spending, *revenue seekers*, are likely to prefer the revenue raising tariff to the neutral quota, and both are preferred to the revenue absorbing subsidy.

Yet another option is import quotas with the quota rights accruing to foreigners. Some of these are called VERs, or "voluntary" export restrictions, because the foreigners "voluntarily" restrict exports to avoid other forms of protection by the U.S. If set at the appropriate level, VERs turn competitive foreign firms into monopolists. These foreigners' ideal form of protection is a VER set at their ideal level. These quotas, by restricting sales to the U.S. market and jacking prices up, enable foreigners to act as a cartel and buy off foreign resistance to U.S. protectionism (Kaempfer and Willett, 1989). Finally, Krueger (1983) has argued that all forms of import-substituting protection are inferior to export subsidies as ways of encouraging particular sectors, because the former have no budgetary cost, and are therefore more likely to be used excessively.

Becker (1983) provides an elegant solution to the question of why we end up at neither free trade nor autarky. He argues that the level of protection of the import competing sector at the expense of the rest of the economy is a function of the expenditure by lobbies for the two sectors. Each sector will expend time, energy and money on political pressure up to the point of balance between the expected incremental costs and benefits of further lobbying.

From Becker's logic it follows that as the level of protection rises, further incremental increases in protection will yield smaller benefits to the favored sector relative to the costs to the harmed sector. This shrinks the level of lobbying by the former relative to the level of lobbying by the latter, resulting in an equilibrium level of protection. In essence, Becker argues if lobbying is balanced that the political system will tend to generate efficient outcomes.

Consequently, the political process will tend to choose efficiently between tariffs, the various forms of quotas, and subsidies. However, Cassing and Hillman (1985) and Kaempfer and Willett (1989) emphasize that the political process is most likely to coalesce support around the forms of protection that generate the best tradeoff between the goals of those groups who are best able to mobilize rent seeking resources.

Dixit et al. (1997) emphasize the deadweight cost of lobbying. They suggest that the polity may have an incentive to pass a constitutional amendment to prevent the government from using efficient policies (like lump sum taxes and subsidies) to redistribute income, because restricting the choice to inefficient policies may shrink rent-seeking expenditures. Thus, their model suggests a new way by which distorting policies might emerge as a political equilibrium (also, see Rodrik, 1985). A related issue is explored by Panagariya and Rodrik (1993). They build rigorous models to demonstrate that under certain circumstances welfare may be enhanced by forcing the government to protect only through a uniform tariff. Uniformity creates a free-rider problem, which reduces the incentives for tariff lobbying. Second, if there are imported inputs used in import-competing sectors, uniformity again reduces lobbying by those sectors. Finally uniformity may force future governments to limit their attempts to use tariffs to redistribute income.

Irwin (2002, in progress) notes that in the early 1800s, the industrialized North-Eastern U.S. wanted tariffs to protect manufacturers, the developing West wanted tariffs for the revenues they generated, and the agricultural exporting South wanted free trade. But the revenue seekers were able to gang up with the protection seekers to muster enough political power to defeat the free traders. But the protection seekers do not always gang up with the revenue seekers, because as Pincus (1980) notes in the early years of the U.S., protectionists wanted the tariff above the maximum revenue level, while revenue seekers wanted it below.

4.5. Antidumping and Administered Protectionism

In recent years the use of antidumping statutes has become increasingly important. In the U.S. for an antidumping duty to be activated, the U.S. International Trade Commission (formerly the U.S. Tariff Commission) must find that imports have injured the domestic industry and the U.S. Department of Commerce must find that imports are priced unfairly.

"Foreign firms who charge not only higher prices abroad than they do at home, but also higher prices than their domestic competitors, are still saddled with dumping margins of 50 percent and higher. AD no longer has anything to do with predatory pricing. Even more to the point, all but AD's staunchest supporters agree that AD has nothing to do with keeping trade 'fair.' AD has nothing to do with moral right or wrong, it is simply another tool to improve the competitive position of the complainant against other companies." "The ongoing tinkering with the AD statutes has weakened the law sufficiently that little real evidence of injurious dumping is required before duties are levied" (Blonigen and Prusa, 2002).

They argue with precision and passion that U.S. AntiDumping statutes create perverse incentives. "A foreign industry can almost guarantee it will not be subject to AD duties if it charges sufficiently high prices in its export markets. On the other hand, a domestic industry might resist lowering its prices... [and] might lay-off more workers than expected" as high import penetration and low domestic industry employment are used by the U.S. International Trade Commission to infer injury, which is a critical prerequisite for winning an AD case.

Political pressure matters in how the U.S. International Trade Commission handles antidumping complaints. As Blonigen and Prusa note, two oversight House and Senate subcommittees control the USITC's budget and three studies all find that industries located in the districts of oversight committee members receive better treatment from the commission. Hansen and Prusa (1996, 1997) find that an additional oversight representative increases the probability of a finding of injury by about 8 percent. Moreover, they obtain an even more sinister result: "PAC contributions to the oversight members also improve an industry's chances, which suggests that political pressure is generated not just by employment concerns, but also by re-election financing concerns."

Antidumping opens up yet another channel for the distribution of rents. Hartigan and Rogers (forthcoming) find a pattern of insider buying in the two months preceding the filing of antidumping complaints, even though the Securities and Exchange Commission prohibits insider buying on the basis of material information that is not yet in the public domain.

5. Protectionism: Empirical Results

Gawande and Krishna (forthcoming) survey empirical approaches to the political economy of trade policy. Baldwin (1985) finds that, for the U.S., sectors with low wages and a high ratio of labor to output tend to be highly protected. This implies that protection is used to help low-income groups. He also finds that protection levels are positively related to industry employment levels, supporting the *adding machine model* which implies that trade protection for an industry is related to its voting strength. Finally, he finds that protection is inversely related to the number of firms in the industry. This suggests that oligopolistic industries find it easier than competitive industries to overcome the free rider problem to muster protectionist legislation [confirming a result found by Pincus (1977) for the tariff act of 1824].

Dutt and Mitra (2001) empirically explore the Stolper-Samuelson argument discussed above. They find that all countries protect, but an increase in the gap by which the capital-labor ratio of the median family falls short of the average for the country raises protectionist barriers in capital-abundant countries and lowers them in labor-abundant countries, providing tentative support for the median voter theory. Magee and Baldwin (2000) provide further support for the theory, with their finding that a high proportion of less educated workers in an electorate, i.e., a lower endowment of human capital per worker, makes a U.S. Representative more likely to vote for protectionist legislation. Similarly, Kaempfer and Marks (1993) find that votes for fast-track authority (for the Bush administration to negotiate the Uruguay Round and NAFTA) were positively related to the average wage (human capital) and negatively related to labor PAC contributions.

A number of studies have examined the role of campaign contributions to legislators as a determinant of congressional voting on protectionism, e.g., Baldwin (1985), Tosini and Tower (1987), and Fisher et al. (2002). All these studies find that campaign contributions are an important determinant of congressional voting on protection. FGT found that protection can be bought cheaply. One thousand dollars from steel PACs paid to a Republican who is initially receiving no contributions raises the probability that he votes in favor of steel import quotas by 7 percentage points. Similarly, Gawande and Krishna (forthcoming, p. 20) remark how small political contributions are compared to the efficiency losses that trade distortions cause.

Gibbs et al. (2002) explore yet another channel of political influence buying. They find that congressional campaign contributions by the steel industry purchased commentary in the Congressional Record in favor of the steel import quota bill of 1999, with the price of an additional word being quite low: less than \$100.

Tosini and Tower (1987) also finds that a protectionist vote is more likely from a U.S. Senator who faces an election in the near future or a congressman whose electorate suffers from lots of unemployment or whose electorate exports relatively little of its output. Similarly, McArthur and Marks (1998) find that lame duck legislators are less protectionist, concluding that legislators tend to favor the general welfare if it doesn't cost them too much.

Takacs (1981) finds that, for the U.S., unemployment tends to foster higher tariffs while inflation tends to lower them. Irwin (1998) suggests this effect is due to the wide-spread use of specific tariffs, or tariffs that are fixed per unit of good not per unit of value (ad valorem tariffs). However, since the type of tariff used is itself a choice of the policy makers, this counter-cyclical trend in tariff levels is probably intentional on more than one level. That is, not only *are ad valorem* rates raised and lowered in recessions and booms, but protection instruments are used that react in the same way to the economy without needing legislative or bureaucratic adjusting.

Consistent with this research, Magee et al. (1989) find that Republican administrations generate more protection than Democratic administrations do. Their mechanism is Republicans tend to be more ardent inflation fighters, which brings on recession and pressure for protectionism.

The level of protection also depends on who is enfranchised. Hall et al. (1998) find that after women got the vote in U.S. national elections in 1920, tariffs fell. Their explanation is that women purchased the families' consumption goods and blamed tariffs for raising prices, whereas men attributed to the tariff favorable impacts on factor rewards.

Finally, Gardner and Kimbrough (1992a,b) document that, in the U.S., as revenue demands increased, first excise taxes then the income tax were enacted, and both times tariff levels were cut. Once the fixed costs of these two new taxes had been paid, it made sense to rely less on the use of tariffs.

6. Conclusion: The Dracula Effect

Self-serving special interests will always fight to protect themselves. What can economists and political scientists do to limit protectionism? Bhagwati (1988, p. 85) in a marvelous rhetorical flourish articulates what he calls the Dracula effect. Just as Dracula shrivels into nothingness when the morning sunlight hits him, "exposing evil to sunlight helps to destroy it." Similarly, economists for a long time have been illuminating fallacies in protectionist reasoning and documenting the costs and unintended consequences of protectionism. It is only more recently that political economists have shed light on the role of the political process in generating protectionism. All of this analysis combines to convincingly demonstrate that protection is the costly product of a negative sum political game, rather than the product of a government benignly maximizing a social welfare function designed to put us somewhere on the maximal tradeoff between equity and efficiency.

F.Y. Edgeworth (1908), Keynes' predecessor as editor of the *Economic Journal*, anticipated much of the public choice response to various models that justify protection when he wrote in response to Bickerdike's exploration of the idea that the national advantage could be served by the optimum tariff:

Thus the direct use of the theory is likely to be small. But it is to be feared that its abuse will be considerable. It affords to unscrupulous advocates of vulgar Protection a particularly specious pretext for introducing the thin edge of the fiscal wedge. Mr. Bickerdike may be compared to a scientist who, by a new analysis, has discovered that strychnine may be administered in small doses with prospect of advantage in one or two more cases than was previously known; the result of this discovery may be to render the drug more easily procurable by those whose intention, or at least whose practice is not medicinal...Let us admire the skill of the analyst, but label the subject of his investigation POISON.

TRANSITIONAL ECONOMIES

Theories of economic transition were revolutionized by the dramatic events of 1989, when several East European states openly broke with the Soviet Union and expressed desires for more democratic rights and free markets. As Soviet domination of Eastern Europe dissolved, there was not only understandable jubilation in Europe, but also expressions of shock throughout capitals of the world. Radio Free Europe in Berlin exclaimed, "Our jaws cannot drop any lower." By 1991, communism also collapsed in the Soviet Union, and fifteen more states emerged with similar hopes for democracy and markets. With twenty-seven states in Europe and Eurasia interested in establishing free markets and democracy in the early 1990s, policies on transition were rapidly needed to help guide economic reforms.

Initial policy ideas to transform dysfunctional socialist economies in Eastern Europe were derived from basic textbook economics representing the so-called *Washington consensus* (Williamson, 1990). Policy makers who advocated the Washington consensus argued that to initiate a transition to market, governments needed to liberalize prices, stabilize the macroeconomy through tight monetary policy and implement the privatization of state run firms (Blanchard et al., 1991). Ten years of evidence show these policy ideas to be deficient. Price liberalization lead to an unexpected and precipitous fall in output throughout the region that was much longer than anyone anticipated (Kornai, 1993). Stabilization has been very difficult to achieve in many counties due to soft budget constraints associated with state run enterprises and the inability of governments to withdraw generous subsidies and welfare entitlements to citizens. Mass privatization in many countries was frequently stalled or blemished by extensive asset stripping.

We know with the benefit of hindsight, that many deficiencies in policy prescriptions were related to limited understandings of economic change and misunderstandings about the role of economic and political institutions for fostering economic growth. Much has changed since the beginning of the 1990s. Transitional economics now has well-developed dynamic theories of economic reforms that draw heavily on standard arguments in public choice theory (Roland, 2000). This article explores the major contributions of public choice theory to theories of transitional economies by focusing on the dynamics of economic reform programs in East European countries.

1. Transition Types

Prior to 1989, economists had limited experience in the rapid transformation of economies to free market systems and no experience with the type of transformations occurring in Eastern Europe. Although countries such as Chile, Argentina and South Korea attempted significant market reforms in the 1970s and 1980s, they did so under conditions of authoritarian rule. Other communist countries, such as China and Vietnam, introduced incremental economic reforms in existing socialist systems. In each of these cases, when market reforms were introduced, the political institutions of each country remained essentially unchanged. However states in Eastern Europe and the former Soviet Union instituted so called dual transitions, where political and economic systems were changed simultaneously. This meant the scope and degree of change was much wider in East European transitions than almost all previous transitions to market, involving unprecedented changes in institutions of governance and market development (Balcerowicz, 1994; Voorhees, 1995).

The road to free market democracy promised to be long and hard in Eastern Europe. Former communist societies had no private property rights, large and inefficient state run industries, centralized planning of all facets of the economy, misallocation of labor, production and resources. Considerable restructuring efforts would be needed to achieve even limited market functioning. These societies also had no established judicial or regulatory bodies, poorly developed civil societies, and little or no prior experience with liberal democracy (Szacki, 1994). Instituting free elections might take weeks, but overhauling these political institutions would take years with no exact blueprint for what would happen as reforms progressed.

As policy-makers developed new blueprints for the dual transitions occurring in Eastern Europe, it quickly became evident that these states would encounter very new problems during reforms. For example, policy measures designed to help develop markets and eliminate the legacies of socialist planning might conflict with measures introduced to develop democracy. Early research on dual transitions therefore focused on the dynamics of instituting political and economic reforms simultaneously and the problems associated with these dynamics. We begin with the initial constraints facing policy-makers.

2. Constraints on the Transition to Market: Rational Actors

To understand the problems facing new East European governments, first consider the issue of enacting economic reform programs within democratic political arrangements. Using the perspective of a rational voter, we can ask how they might react to economic reform packages. Even if it is assumed that a majority of voters are certain they will benefit from an economic reform program, rational voters, who place sufficiently high discount rates on future gains from reform, will not prefer a reform program to the status quo. The actual constraints on reform minded governments, however, are more severe. Market reforms would result in contractions in existing socialist economies. In addition, there was considerably uncertainty among citizens about the effects of different reform programs on these economies. When these facts are coupled with either risk attitudes among citizens or actual uncertainty with respect to the potential distributive effects on an individual, it is easy to see why rational voters might attempt to resist market reforms. Since their expect utility from reform programs is likely to be small, they will prefer the status quo to new reform programs.

Governments in transitional economies can expect opposition *ex ante* to economic reform programs from rational citizens. If these governments are democratically elected, as all governments in East European transitions, then a natural question concerns how potentially costly reform programs can be initiated within democratic regimes. Transitional economics, borrowing heavily from theories of public choice, provide two general answers to this problem. The first answer focused on compensation or side-payments to citizens in transforming economies (Przeworski, 1991). By providing redistributive transfers (or a commitment to make transfers), governments could compensate losers to change their preferences on reform TRANSITIONAL ECONOMIES

programs. This idea has been explored extensively in different versions of public choice theory including cooperative games, collective action and social choice theory (Ordeshook, 1986; Sen, 1970). However since this strategy was potentially costly, it could also undermine budgetary reforms in transitioning economies. For this reason it was not seriously pursued by most mainstream economists or policy-makers.

The second answer focused on the role of agenda-setters in democratic institutions. Since it is unlikely that a majority of rational voters would prefer reforms to the status quo, policy experts suggested making heavy use of the agenda setting powers of the executive to both craft economic reform packages as well as usher these reform packages through newly established legislatures (Sachs, 1993). By making reform packages take it or leave it offers with few or no amendments, governments avoided the problem of transaction costs associated with democratic bargaining (Black, 1958; Buchanan and Tullock, 1962) as well as problems of cycling in democratic legislatures (Riker, 1982). This strategy would not only facilitate the passing of reform programs in democracies, but would also help obviate the inevitable preference for the status quo shared by most citizens. Governments throughout Eastern Europe used this strategy extensively to initiate reform programs.

Once governments enacted economic reform programs, post-socialist systems would face sustained contractions in the economy. Although the duration and severity of economic contractions was uncertain, policy makers feared that a protracted recession would cause politicians to reverse market reforms when faced with mass political pressure. Transitional economists therefore believed governments would face opposition to reform programs ex post, besides ex ante constraints to the introduction of reforms. Given the possibility of such opposition, policymakers attempted to evaluate the optimality of various strategies designed to move from socialist to market economies (Aslund, 1995; Hellman, 1998; Przeworski, 1991). To evaluate these strategies, policy-makers focused on the speed of reform programs, the potential for reversing reform programs and the probability of political backlash.

3. Transitions Strategies and Transition Dynamics

Policy-makers advocated two major types of reform strategies to deal with potential problems associated with economic reforms in Eastern Europe and Eurasia. One reform strategy, known as 'shock therapy' or the 'big bang' approach to economic transitions, suggested that governments should promote a fast and comprehensive transition from socialism to capitalism (Balcerowicz, 1995; Sachs, 1993). According to this reform strategy, governments should institute a radical process of change that introduced liberalization, stabilization and restructuring measures in an economy simultaneously, and implement these measures as quickly as possible (Lipton and Sachs, 1990; Aslund, 1995). This would lead to spontaneous adjustments to market reforms throughout society and quickly move elements of the economy to a free market system. The main justifications for this plan was to take full advantage of the political opening created by the new political climate after the fall of communism and to use this political capital to help weather the inevitable economic downturn caused by the introduction of market reforms (Balceorwicz, 1995).

In contrast to shock therapy approaches, other transitional economists advocated a more gradual process of transition from socialism to capitalism (Dewatripont and Roland, 1992; McMillan and Naughton, 1992; Murrell, 1992). Under a gradualist strategy, reforms would be carefully sequenced in terms of both the priority and feasibility of implementing reforms. Although both strategies would implement liberalization, stabilization and privatization policies, the speeds of implementation would be different. Gradualist reforms strategies insisted, moreover, on extensive institutional restructuring of economic organizations, early in transition process, whereas shock therapy assumed institutional restructuring should occur later.

There are several potential advantages to gradual reform strategies over 'shock therapy' approaches. First, by instituting gradual reforms, it would be easier to identify those who are worse off in the transition and compensate 'losers' from reform through social programs. This could help prevent a political backlash to reform. Second, by carefully sequencing economic reforms, governments could demonstrate clear policy successes when these policies yielded social benefits. This would make it easier to build political coalitions for future reforms in the economy and help sustain political momentum for economic reforms. Third, if transition policies resulted in mistaken economic outcomes, gradualist strategies could arrest these reforms because reversal costs were lower than 'shock therapy' approaches (Dewatripont and Roland, 1995). Gradualism therefore lowers the cost of experimenting with reform programs and may make the move away from the status quo more acceptable to a majority of citizens over time.

An important point of contention between these different economic reform strategies concerned their respective assumptions on the cost of halting or reversing reforms. Some policy-makers preferred rapid transitions because it was believed that the costs associated with reversing these policies would be very high. Consequently, rapid transitional policies would most likely result in a long-term commitment to a market economy or structural reforms in the economy that could not be reversed by new governments. Other policy-makers preferred gradualist strategies because reversal costs were lower. Gradualist policies could avoid reforms that led to inefficient market outcomes that could not be undone because of high reversal costs. Consequently, correcting or learning from policy mistakes would be much easier for governments committed to gradual reforms in the economy.

4. Public Choice Theories of Reform Reversals

The concepts used to explain why East European democracies might slow, halt or even reverse economic reforms programs, are directly linked to public choice theories of collective action and rent-seeking. One viewpoint suggests that policy reversal would most likely emerge from a coalition of dissatisfied voters and anti-reform politicians (Przeworski, 1991). To understand this viewpoint, recall that as economic reforms progress, they will likely generate higher social costs. Citizens or groups hurt most by reforms, such employees of state run enterprises, unemployed workers or pensioners, will naturally seek special exemptions or special protection from the government.

Unfortunately politicians normally face elections before the benefits of economic reforms materialize; therefore many will be tempted to provide special benefits to favored constituencies to gain electoral support. This could weaken the long-term beneficial effects of reform policies on the economy. Social interests seeking protection from economic reforms therefore pose serious risks to economic restructuring *ex post*. A similar mechanism can be used to explain political backlash against reformers. As the cost of reform materializes throughout the society and uncertainty about distributional costs decreases, opposition to transitional reforms increase. As elections approach, citizens react to the cost of reforms by voting out reform parties and replacing them with anti-reform politicians to halt restructuring policies.

These explanations for policy reversals view the reform of socialist economies as a public good that can be eroded by special interests seeking protections from emerging market forces. An alternative viewpoint suggests that elites will halt economic transitions because they stand to benefit from partial or incomplete reforms of an economy (Hellman, 1998). To understand this argument, we need to remember that post-socialist economies were full of *nomenklatura* bureaucrats who remained extremely strong after the initiation of transitional reform programs (Aslund, 1995). These officials frequently remained in government, continued to run old state enterprises or direct newly privatized firms, banks and industries.

Many of these bureaucrats also enjoyed windfall profits from early and incomplete economic reforms. For example, weak property rights allowed managers to strip their firms' assets. Bankers benefited from profitable arbitrage in distorted financial markets, while local party officials prevented new firms from entering local markets. If a government enforces property rights, legislates additional regulation of financial sectors and strengthens banking laws and enterprise regulations, any additional reforms would reduce or eliminate rents arising from partial reforms. *Nomenklatura* insiders clearly have powerful incentive to prevent such additional reforms to maintain their privilege rents in transitional states.

Besides their economic and political power, the privileged position of *nomenklatura* insiders derives from collective action advantages associated with size. These groups have relatively few members with similar interests, while civil society groups in Eastern Europe are much larger, weaker and more heterogeneous (Howard, 2002). Because the benefits of their rents are concentrated and private while the costs are diffused over the entire society, *nomenklatura* members have stronger incentives to block reforms than civil society groups have to maintain reforms. In contrast to other threats to reform, this rent-seeking insight interprets the problem of economic reform reversals coming from *nomenklatura* insiders who arrest market reforms so they can continue to enjoy monopoly benefits from partial economic reforms.

5. Public Choice and Transitional Economics

Transitional economics focuses on how states can transform their existing economy into a free market system. A decade ago it was commonplace for economists outside public choice theory to discuss market reforms in isolation from the existing rules and institutions that regulated market behaviors. However, the dynamics of transition in Eastern Europe provides a host of examples to illustrate the importance of institutions for the development of markets and the interaction of market development with politics. Public choice has traditionally rejected the idea that markets can be understood independently of politics. After some early policy setbacks, economists have incorporated this principle into their theories of transition.

When considering the dynamics of reform processes, *ex ante* and *ex post* constraints on democratic government are powerful influences on the outcome of reform strategies. *Ex ante* constraints can be mitigated either through compensation packages or various types of agenda control. *Ex post* constraints can be mitigated either by increasing or lessening reversal costs, depending on whether democratic threats to reform are expected to come from popular interest groups or elite rent-seekers. Strategies to reform the economy are selected to deal optimally with these constraints. Whatever strategy is pursued, public choice theories suggest that governments can expect to face different types of collective action problems when implementing reform programs.

TRANSITIONS FROM AUTOCRACY TO DEMOCRACY

1. Introduction

Most countries have been dominated by kings, dictators or oligarchies during most of written human history. Moreover, in many cases such *autocracies* were based on ideologies prescribing supreme values to be followed by all believers, so that they were at the same time mature ideocracies like for instance *theocracies* (Flavius Josephus, 1994–1996: 2, 165) or *totalitarian regimes* (see article on totalitarianism). By contrast, democracy as a political regime has been invented rather late in classical Greece, vanished in the following centuries, and was widely successful only during the last centuries.

This is not surprising, since larger political entities, states, with some exceptions like the Swiss Confederation

or the United States of America, were mostly formed by force (Ruestow, 1950), often by "roving" or "stationary" bandits applying force to exploit a subjugated productive population (Olson, 1993; Olson and McGuire, 1998). And why then should rulers give up their privileges for a broader participation in political decisions? Why should they agree even to be bound by their own laws instead of remaining above the law?

2. Economic Development as Rulers' Motivation to Limit their Discretionary Powers

It is certain that despotism ruins individuals by preventing them from producing wealth much more than by depriving them of what they have already produced: it dries up the sources of riches, while it usually respects acquired property. Freedom, on the other hand produces far more goods than it destroys (de Tocqueville [1835] 1945: 220 f.)

A dictator or an oligarchy afraid of soon losing its power (Olson's roving dictator) has not much interest in saving the subjugated population from extreme exploitation. It is motivated to get as many spoils as possible and to transfer them to safe places for the time after its fall. Things are different if rulers feel certain that they, and perhaps even their descendants, will remain in power for a long, perhaps an indefinite period (Olson's stationary bandits). For if they allow people to retain most of the goods they acquire and convince them that there is no danger of irregular interventions into their business affairs, then individuals will be prepared to save, to invest and to innovate, provided that they believe that this policy will be maintained in the future. As a consequence, the amount of goods produced increases, and with it the value of the share reserved by the rulers (see Roll and Talbott, 2001, and Weede, 1986, for the influence of free institutions on wealth). It follows that rulers are motivated, given these conditions, to set up and to be bound by a system of legal rules.

Moreover, because of these relationships, and of their wish not to be endangered by coups d'etat or violent overthrows dictators have reason to increase the probability of staying in office. This can be done by buying the support of the leaders of the armed forces and of important individuals, by trying to create a hereditary kingdom with a hereditary class of supporters (nobles) or by supporting the regime by an ideology legitimising its permanent existence. The more rulers succeed in this endeavour, the more they will be motivated to take the long-term perspective concerning the development of resources.

But as historical experience shows, such a development towards greater security of rulers to be able to maintain their power in the future, and as a consequence the introduction of some rule of law is not a necessary outcome. If no ideology can be created, that is believed also by the immediate supporters of a dictator, his rule is always threatened by the very leaders of the armed forces, by important noblemen, by influential ministers or even by members of his own family, on whose support the ruler depends. As a consequence, more coup d'etats can be observed in history, which have led to a replacement of one autocratic ruler by another, than changes to other, more pluralistic political regimes. On the other hand, if an ideology is present or can be created, which is believed by the members of the supporting elite, this danger is diminished. But at the same time, the supreme values contained in the ideology may be such that they prevent favourable economic developments (Bernholz, 1995).

3. The Importance of Competition among Several Political Units

Now the states are already in the present day involved in such close relations with each other that none of them can pause or slacken in its internal civilisation without losing power and influence in relation to the rest; and hence the maintenance, if not the progress, of this end of nature is, ..., secure even by the ambitious designs of the states themselves. Further, civil liberty cannot now be easily assailed without inflicting such damage which will be felt in all trades and industries, and especially in commerce: and this would entail a diminution of the powers of the state in external relations... Hence the restrictions on personal liberty of action are always more and more removed, ... And thus it is that ... the spirit of enlightenment gradually arises as a great good which the human race must derive even from the selfish purposes of aggrandisement on the part of its rulers, if they understand what is for their own advantage (Kant [1784] 1959: 31)

It follows from the conclusions drawn that additional factors must be at work to increase the probability that rulers are prepared to limit their discretionary powers in favor of their subjects. So let us ask again: Why should the ruling elite in an autocracy agree to strong and secure property rights, to minimal state intervention, to limitation of taxes, and thus of its own powers to command and to take away goods at their own discretion? But this time we ask the question by taking into account international relations. Given these conditions, sociologist Baechler (1995) and the so-called 'New Economic Historians' have tried to provide an answer (North and Thomas, 1973; North, 1981; Jones, 1981; Bernholz et al., 1998). They stress that 'European disunity has been our good luck.' In Europe, feudalism with its many power centers developed during the Middle Ages and a split opened up between religious and temporal powers. Rivalry arose

among the many rulers to preserve and to extend their powers by foreign policy and military endeavours. This forced them to become interested in the loyalty of their subjects and in economic development to secure a greater tax base and thus stronger armies. However, economic development itself depended on establishing adequate property rights, a reliable legal system, free markets and limited taxes. Consequently, those states were successful in this fierce foreign policy and military competition in the long run who, by chance or by design, made the greatest progress in introducing such institutions. Thus, competition among states forced on unwilling rulers a limitation of domestic powers. The development of competing legal systems, of the rule of law and of safe property rights was helped not only by interstate competition but also by the increasing separation of church and state, by preventing a theocracy (Berman, 1984). These latter events made it impossible, too, that supreme values embodied in earlier religious thinking, like usury laws or the suppression of developments in the sciences and in technology, put obstacles in the path of economic growth. Because of these developments limited government and a pluralistic society arose in Europe as a pre-democratic achievement. First capitalism and later democracy were their progeny.

From Europe these developments spread to other parts of the world, because other countries tried to imitate the successes reached in Europe and in former European colonies like the USA, Canada, Australia and New Zealand. For international competition among states has remained a driving force for the introduction of free institutions until today, motivating rulers like in Japan in the Meiji Era, or Gorbatchew and Deng in the Soviet Union and China since 1979, respectively, to limit their domestic powers to strengthen their economies as a base of international power. Whether the institutional reforms taken were adequate and thus successful is, of course, another question.

4. From Economic Freedom to Democracy

Until now it has only been shown that it is in the interest of autocratic rulers, especially when fierce international political and military competition is present, to allow free markets, safe property rights and a reliable contract law, and not to burden their subjects too much with taxes and regulations obstructing the free play of markets. This implies a wide extension of economic freedom to subjects and a selflimitation of discretionary powers on the part of rulers. But it does not mean that pluralistic or even democratic rights of participation in political decisions are bestowed on the population. Why then should there be a chance that democratic regimes may emerge out of this long process favouring economic freedoms?

It seems that several factors are working in this direction. First, the further developed an economic system, the more complex it becomes. Consequently, an always better education and greater freedom to take decisions have to be granted to individuals, to allow the process of economic growth to proceed. Second, given this situation, more and more people may ask themselves, whether the ruler and the elite surrounding him have the competence to decide the increasingly complicated questions of economic and social policy. As a consequence, and accustomed to the growing sphere of economic freedom they enjoy, they may ask themselves why they should not be allowed to participate in the decisions of political issues. Fourth, because of the complexity of problems to be solved, the ruler himself is dependent on a growing number of experts. All these factors work together with international military and political competition, to incline rulers or to put them under pressure to grant more and more political rights to a growing number of citizens.

The developments sketched seem to have played an important role in many historical cases. Favourable economic developments have preceded regularly the rise of pluralism and democracy, and the surge in the number of democratic regimes during the last two centuries followed in the wake of the growth of capitalistic economic systems. It should also provide food for thought that in modern complex societies democracies seem to have existed and still to exist only in market economies with extended private property, whereas the opposite is not true.

Still, the chain of events described is not a necessary sequence. Dictators may prefer to maintain absolute domestic power at the cost of unfavourable economic developments and the danger of being threatened by foreign powers, or to be unable to extend their power internationally. For the wealth they want or need personally and for their supporters may be available even if the dominated country remains relatively poor. And the small size of a country they dominate may hinder them anyhow to move to parity with superior foreign countries, however favourably their own economy might develop. Finally, if autocracy takes the form of an ideocracy its supreme values may forbid the move to safe private property rights and towards a decentralized market economy. As a consequence a change to an efficient and innovative economic system may be prevented permanently or for decades even in view of international military and political competition (see article on Totalitarianism). A telling example is provided by the persistence of a Communist totalitarian regime in the Soviet Union for about 70 years, though even this system could not withstand reality in the very long run.

5. Other Factors Influencing the Transition from Autocracy to Democracy

One factor preventing or delaying the transition from autocracy to democracy has just been mentioned: Supreme values of an ideology contradicting the requirements of an efficient and innovative economic regime. The resulting economic and, therefore, fiscal and military weakness may even be compensated for an extended period because of some advantages an autocracy experiences compared to democracies. First, it can make up for its economic inefficiency by enforcing a lower level of consumption in favour of higher investments and a higher share of gross national product devoted to military expenditures. Second, in its foreign policy it can follow a more consistent and, if wanted, more expansionary position than democracies, which are in their policies dependent on and limited by parliaments, political parties, interest groups and the consent of their citizens. Consequently, autocracies may be able to defeat or even subjugate democracies of a similar size in the short run. And if this happens they are able to turn them, too, into autocracies, and later to prevent their transition to democracy. This is especially the case if an adequate ideology is available, which helps to overcome resistance and to maintain dominance.

On the other hand, if autocracies and totalitarian regimes do not succeed in time with such policies, democratic market economies will develop more strongly. This means that they will enjoy greater fiscal and military capabilities in the long run, even though their share of government in gross domestic product is sizeably lower than in these regimes. For the higher investment rate can after some time no longer compensate for the greater efficiency and especially innovative potential (for a comparison of the innovative breakthroughs reached in free market vs. communist so-called planned economies see Kornai, 1971: 271–280).

By contrast, the transition of authoritarian to pluralistic and democratic regimes may be furthered by three other factors. First, they may be defeated in war and democracy may be introduced by the victors (as in West Germany and Japan after World War II). Second, after power has been shared with a wider circle of privileged people in a complex society with a market economy, that is when a kind of oligarchy has been reached, infighting may occur between different groups within this political elite. But then it may happen, that the fighting factions seek the support of other segments of the population by promising them political participation. Third, the rulers may be unable to solve a severe economic or other crisis and helplessly step down in favour of a democratic regime. This has happened several times to military regimes in Latin America during the last decades.

Apart from these three, several institutional factors seem to play a role in determining whether efforts are undertaken to transform autocracies into democracies and whether these efforts are successful (Linz, 1990; Linz and Stepan, 1996). Among them it appears to be important whether the country has had a democracy before, whether co-operation between parts of the old regime and the opposition is possible during the transition process and which form of democratic system is envisaged. The transformation process becomes especially difficult if economic institutions have to be changed at the same time together with the political institutions. For since the beneficial consequences of even well-designed economic reforms materialize only after some time, the costs are felt by a great part of the population very soon. Consequently the reformers lose credit and it is necessary that a functioning opposition exists (mostly related to those members of the old regime who have been prepared to abolish autocracy) who can take over the government, and who are willing to adhere to the tenets of establishing the rule of law and democracy and to the fundamentals of economic reforms.

In totalitarian regimes one of the reasons for changes may also be a weakening of the ideology. This is especially probable if the rulers of the second or third generation after its foundation or rejuvenation do no longer believe in it, but only pretend to do so to maintain their dominance. In this case they may be willing to move towards a free market economy by reinterpreting the ideology because of fierce international political and military competition. And in this case the forces discussed above begin to work. Whether, however, the reforms introduced by the rulers are successful depends on their knowledge of the underlying relationships and on the resistance they meet. There remains, therefore, still the possibility that a totalitarian or ideocratic regime ends up not as a democratic but as a simple autocratic regime.

TRIANGULATION

Things fall apart; the center cannot hold....(W.B. Yeats, *The Second Coming*)

When the members of the 104th US Congress took their seats in January 1995, President Bill Clinton faced Republican majorities in both legislative chambers. Forty years of Democratic Party hegemony in the House of Representatives had come to an abrupt end, signifying a political realignment that had eluded even Ronald Reagan's grasp. The Republican congressional victory, usually attributed to the failed health care reform initiative spearheaded by First Lady Hillary Clinton and to the political popularity of the 'Contract with America,' the brainchild of Speaker of the House to be Newt Gingrich (R-GA), was the nadir of Mr. Clinton's first term of office.

Like 'Jason' of the Halloween series of horror movies, Bill Clinton returned from near political death, miraculously reviving his standing in the polls as he had done during his maiden presidential campaign and was to do many times over before leaving the White House in January 2001, by adopting a strategy of 'triangulation.' In ordinary usage, that term refers to the trigonometric method whereby navigators, surveyors and spycatchers determine the position of an unknown point given a known baseline and two Cartesian coordinates. Political consultant Dick Morris is credited for using it to describe the supposedly novel scheme by means of which the president cobbled together a governing coalition from a modern American electorate divided roughly evenly between Democrats, Republicans, and so-called independent voters. However defined (and the term seems to have at least three possible interpretations), triangulation was intended to co-opt the middle of the political spectrum. It is, in essence, a restatement of the median voter theorem, a central principle of public choice deduced by Duncan Black (1948, [1958] 1987).

The median voter theorem can be stated as follows (see Munger, 2001, for a more formal treatment). If voters' preferred outcomes can be arrayed along a single dimension (e.g., left-right), voters' preference orderings are 'singlepeaked' (have unique maxima), and collective decisions are taken by simple majority rule, then the preferences of the voter located at the median of the preference array will be decisive. Any proposal (or candidate) to the left or the right of the median will be defeated in a majority rule election by one positioned closer to the median voter's preferred outcome. Because extreme proposals lose to centrist proposals under the assumptions of the median voter theorem, candidates and political parties rationally will move toward the middle of the political spectrum in order to gain or retain political power.

Subsequent extensions of the theorem showed that the decisive voter need not be located exactly at the center of the distribution of the preferences of the eligible voting population (see, e.g., Hinich and Munger, 1997). Not everyone who can vote does vote. Some voters may be alienated from the process because the positions of the candidates are too distant from the policies they prefer. Other voters may abstain because they perceive no important differences between the candidates' positions. These richer statements of the median voter theorem suggest that candidates will move about in policy space (without the aid, sadly, of a political theodolite), trading expected vote gains against expected vote losses, until their electoral support is at a maximum.

In political context, one meaning of triangulation is illustrated by a (possibly apocryphal) aphorism of President Richard Nixon, 'run to the right and govern to the middle'. The two-stage electoral gauntlet run by aspiring US presidents demands that candidates first secure nomination by the delegates to their parties' quadrennial political conventions. Since these delegates tend to come from the ranks of the parties' most active and most ideologically committed members, successful candidates must position themselves accordingly. Republican presidential candidates will 'run right' during the primary election season in order to appeal to the nominating convention's median delegate, whose political preferences will in general be more conservative than those of the general voting population. Candidates for the Democratic Party's nomination will for similar reasons 'run left.' Once the parties' presidential nominees have been selected, however, both candidates will move toward the center, since victory in the general election demands catering to the median of the preference distribution of all likely voters, which includes Democrats, Republicans, and independents. 'Triangulation' under this interpretation implies that presidential candidates will first shore up their partisan bases and then reposition themselves for the general election campaign. It also implies that, once elected, a sitting president will 'govern to the middle' in order to maximize his reelection prospects.

A second meaning of triangulation suggests that, far from shoring up their political bases, candidates can safely ignore the preferences of the party faithful. Voters located at the extremes of the left-right preference array are unlikely to switch their allegiances to the other party's candidate, no matter how persuasive or charismatic he may be. Hence, candidates for presidential office can triangulate the electorate, increasing their chances of election or reelection, by selectively taking positions that appeal to the median voter, but offend their staunchest supporters. Trading on liberal political credentials secured by stances on core issues, such as abortion and affirmative action, a Democrat such as Bill Clinton can proclaim that 'the era of big government is over' and promise to 'end welfare as we know it,' thereby picking up support from moderate voters without risking the loss of his left-wing nucleus. Knowing that right-wing voters are unlikely to support a liberal Democratic candidate, a Republican such as George W. Bush can likewise safely scold his conservative political base, complaining that, 'too often, on social issues, my party has painted an image of America slouching toward Gomorrah,' and accusing them of wanting to 'balance the budget on the backs of the poor.'

A third interpretation of triangulation comes from Dick Morris himself. In the transcript of an interview with Australian reporter Kerry O'Brien, Morris defined the strategy as an attempt 'to take the best of each party and combine them' (O'Brien, 2000). For example,

The liberals in the US, the left, said, 'We need to have gun control and we need to let people out of prison early.' The Republicans said, 'We should not control guns

and we should keep them in jail.' The public said, 'I want the gun control from the left and the long prison sentences from the right.'

And Clinton said, 'OK, I'm going to give that to you. I'm going to advocate those two steps. And I'm going to forget about the left wanting parole and I'm going to forget about the right wanting no restrictions on guns.' (ibid.)

Whether or not Mr. Morris had accurately gauged public opinion in this particular case, his idea of triangulation seems to be one of identifying policy issues on which voters are sharply divided, and then combining them in ways that appeal to a larger political constituency than could be marshaled in support of either one separately. An alternative construal of Morris's strategy is that of opportunistically appropriating selected policy positions of one's political opponents, yielding ground on issues where the expected political gain is less than expected cost. So, if liberals care more about gun control than they care about prison populations, and if conservatives are willing to back 'reasonable' restrictions on gun ownership in return for stiff sentences for convicted felons, then packaging support for gun control with opposition to tolerant parole policies would defeat consistently hard-left or hard-right positions on both issues.

Bill Clinton's perspective on modern American politics was undoubtedly colored by his experiences during the 1992 presidential election, when Reform Party candidate Ross Perot garnered 19% of the popular vote, perhaps denying George H.W. Bush a second term and propelling a Democrat into the White House for the first time since Jimmy Carter occupied it 12 years previously. Mr. Clinton's election by a less-than-50% plurality of the votes cast may have been reason enough to think that a 'third way' - not Democrat nor Republican — must be found for building a ruling coalition that included a significant fraction of the 'undecided,' 'independent' voters in the middle of the political spectrum. But 'triangulation' is nothing new. Successful politicians have always been required to operate in multidimensional issue space, seeking the location of the median of the distribution of voters' preferences over policy alternatives. The tradeoffs that inevitably must be made in constructing a set of support-maximizing policy proposals are an essential feature of a collective choice process in which the preferences of the median voter hold a privileged position.

U

UNDERGROUND GOVERNMENT: THE OFF-BUDGET PUBLIC SECTOR

Politicians and bureaucrats have a great disaffinity for constraints placed on their discretionary behavior, particularly with regard to their ability to spend and to borrow. Government spending permits politicians to direct benefits to their constituents in general and especially to their political supporters. Debt is favored because repayment occurs in the future (perhaps while others are in office) while the benefits of the expenditures are reaped in the present period. In the United States, both statutory and constitutional restraints on government spending and indebtedness greatly limit the abilities of politicians and bureaucrats at the state and local levels of government to spend and to incur debt. These restrictions historically arose because of the egregious fiscal excesses during the nineteenth century when canals and railroads were under construction. In the heady days of the "robber barons," bonds were issued by state and local governments to attract the railroads, and and the faith of investors, many of whom were foreign ---statutory and constitutional restraints were imposed on the fiscal actions of governments. For example, at the state level of government, forty-five states now have either a constitutional or statutory requirement that the governor must submit a balanced budget; forty require the legislature to enact a balanced budget; and thirty-seven states mandate that the budget signed by the governor must be balanced (Council of State Governments, 2001, p. 260, table 6.3). Thus, the ability of politicians and bureaucrats to spend and borrow are markedly constrained.

In response to fiscal constraints on their behavior, public officials have devised a means to move government activities "off the books" or "underground" by creating "off-budget enterprises" (OBEs) which permit them to evade statutory and constitutional constraints on borrowing. An OBE is a corporation established by a charter from the federal or a state or local government that has significant ties to the governmental entity that charters it. Typically, the members of the board of directors of the OBE are appointed by elected officials in the jurisdiction that established the OBE, so politicians ultimately control the OBE. Because the OBE is an entity separate from the governmental unit that established it, its financial operations are not subject to the statutory or constitutional restraints imposed on government itself. OBEs spend, borrow, hire and fire, contract for services, and engage in all sorts of activities free from the limitations imposed on governments.

As Bennett and DiLorenzo (1983, p. 35) discuss, the first attempt at off-budget activity occurred in the city of Waterville, Maine at the close of the nineteenth century when the city fathers wanted to build a new city hall, but taxpayers rejected the bond inititative required to finance it. Undeterred, the politicians established the Waterville New City Hall Commission, a corporate entity, donated a building lot to the Commission, and hired a contractor who was to be paid from the proceeds of a bond offering made by the Commission. Debt service on the bonds was to be provided from rent paid by the city to the Commission for use of the building. But, because the source of the rent was taxes, "the Commission was held unconstitutional in 1898, because the court ruled that the arrangement was a disguised mortgage that violated the debt limitation imposed on the city by the Maine constitution." Waterville politicians then regrouped to evade the constitutional debt limits that limited their actions. The next year, 1899, the Kennebec Water District was established as a separate corporation — the nation's first OBE - that would issue its own bonds to purchase the private water companies operating in the area. Revenues from providing water services to residents would pay the interest, retire the debt, and finance the corporation's operations. The Supreme Judicial Court of Maine held that this debt was not the obligation of the city or the taxpayers, so the constitutional restriction on borrowing did not apply, and the scheme passed judicial scrutiny (Morris, 1958).

From this modest beginning, OBEs have proliferated in both numbers and activities. The most comprehensive census of these entities is reported in the Census of Governments (U.S. Census Bureau, 1997, p. vii) where OBEs are called "special district governments" (excluding school districts) "that exist as separate entities with substantial administrative and fiscal independence from general purpose local governments ... [These] entities must possess three attributes: existence as an organized entity, governmental character, and substantial autonomy." According to the Census of Governments (pp. vii-viii), the number of OBEs has increased dramatically: "As a group, special district governements are by far the most rapidly growing type of government, rising to a total of 34,683 [in 1997], an increase of about 3,128, or 9.9 percent, since the 1992 Census of Governments. ... [T]he number of special district governments reported in 1997 is almost three times the number ... reported in 1952."

Of significance is the Census Bureau's admission that the reason for the dramatic growth of OBEs is motivated by financial constraints on government: "The increasing number of special districts often reflects financial considerations. As new programs are initiated, or new services required, the establishment of special districts may reduce the need to increase the burden on general purpose governments which may be unable to meet the fiscal requirements necessary to implement these new programs. *Debt and tax limitations are further stimulants for creating special districts* for raising both capital construction and operating expenditure funds." (Ibid., emphasis added.)

OBEs engage in a wide range of activities, including (but not limited to) operating airports, fire protection, cemeteries, hospitals, industrial development, mortgage credit and housing, parking facilities, recreation and parks, electricity generation and distribution, gas and water supply, sewerage, mass transit, and the construction and maintenance of highways. They are generally designated as authorities, commissions, or districts by the governmental body that creates them. OBEs tend to be concentrated in the most populous states: in 1997, 11 states had more than 1,000 OBEs, with California (3,010), Illinois (3,068), Texas (2,182), and Pennsylvania (1,919) having the most. Four states (Alaska, 14; Hawaii, 15; Louisiana, 39; and Rhode Island, 76) and the District of Columbia (1) had fewer than one hundred OBEs (U.S. Census Bureau, p. 13 table 9). A small number of OBEs have been chartered by the federal government, because their operations involve more than one state; most notable is the Port of New York Authority which operates transportation facilities for metropolitan New York City, an area that includes New Jersey.

Another indicator of the economic significance of OBEs is their debt. For state and local governments, two types of debt exist: full-faith-and-credit debt which is approved by the taxpayers in a bond referendum and "nonguaranteed" debt incurred by OBEs. The term full faith and credit indicates that taxpayers have agreed to tax increases if needed to guarantee payment of principal and interest. For OBEs, revenues from operations are pledged in the bond indenture to cover principal and interest payments; the taxpayer does not guarantee repayment, and taxpayer approval is not sought when OBEs issue bonds. Interest payments on both full-faith-and-credit and nonguaranteed debt are exempt from federal taxation.

As shown in Table 1, at the state level of government, nonguaranteed debt issued by OBEs outstanding was a small fraction of voter-approved debt in 1942, the earliest date for which information is available. In 1942, \$5.80 in full-faith-and-credit debt existed for each \$1 of nonguaranteed debt at the state level. By 1970, however, the amounts of the two types of debt outstanding were roughly equal. Since 1980, nonguaranteed debt outstanding has risen by roughly a factor of five while full-faith-and-credit debt outstanding has only increased by a factor of about 2.4. At the local level of government, a similar pattern emerges. The amount of nonguaranteed debt issued by OBEs was nearly equal in 1980 to the amount of voter-approved debt outstanding, approximately \$100 billion. Since that time, however, nonguaranteed debt has risen by a factor of 4.5 while full-faith-and-credit debt outstanding went up only by a factor of three. These trends since 1980 reflect that "Since 1978 ... activists have proposed and passed initiatives limiting taxing and spending by state governments in the United States" (New, 2001, p. 1). Off-budget activities conducted by OBEs, that is underground government, was the natural response of politicians and bureaucrats to these tax and expenditure limitations (Bennett and DiLorenzo, 1982).

A number of disquieting public policy issues arise in the context of off-budget enterprises. First, if the activities of OBEs are truly in the public interest, why does the public not vote on the bonds issued by these entities? Indeed, full-faith-and-credit debt always carries a lower interest rate than does nonguaranteed debt, for lenders demand compensation for the higher risk of default of nonguaranteed bonds. Thus, capital cost considerations favor the elimination of OBEs and the movement of their activities onbudget. Of course, the sticking point is the constitutional and statutory limitations on government debt which lead to the creation of OBEs in the first place. But those restraints raise an important issue: If these contraints are no longer relevant, should OBEs be used to evade them?

Second, politicians assert that OBEs provide superior service to the public because they are far less bureaucratic and offer much greater flexibility than traditional government agencies that are supposedly hamstrung by red tape, civil service regulations, and bidding requirements. Rather than being an argument in favor of OBEs, however, such claims are a clarion call for the reform of bureaucratic red tape and regulations. If regulations and red tape hamper government operations without compensating benefits, reform is essential. Much closer to the truth is that OBEs offer politicians greater opportunities for nepotism and favoritism in rewarding their supporters than does onbudget government agencies where freedom-of-information legislation typically mandates an openness and transparency from which OBEs are exempted as "private" corporations.

Third, a persuasive argument can be made that OBEs should be disbanded and their actitivities turned over to

	State debt		Local government debt		Total	
Year	Full faith and credit	Nonguaranteed	Full faith and credit	Nonguaranteed	Full faith and credit	Nonguaranteed
1942 ^a	\$2,641	\$455	b	b	b	b
1952	\$4,926	\$1,714	\$17,510	\$4,571	\$22,436	\$6,285
1960	\$8,912	\$9,216	\$32,738	\$15,938	\$41,650	\$25,154
1970	\$17,736	\$21,167	\$57,601	\$34,911	\$75,337	\$56,078
1980	\$49,364	\$70,457	\$100,439	\$102,196	\$149,803	\$172,653

private firms. OBEs obtain revenues from providing goods or services, so the eclusivity criterion so crucial to the concept of public goods is not applicable. In short, those who do not pay for the electric service or the highway tolls, for example, can easily be denied such services. Thus, virtually all of the activities of OBEs could be conducted by private firms, even if government subsidies were required (as might be the case for mass transit). A large and growing literature on *privatization of public services* shows unequivocally that private provision is typically far more efficient than government provision, so taxpayers would benefit from higher quality services at less cost.

Finally, scholars and researchers should be aware that the public sector, particularly at the state and local level of government in the United States, is much larger in terms of revenues, expenditures, and employment than is generally reported — OBEs are extensions of government. In terms of both numbers and outstanding debt, OBEs are clearly important components of the public enterprise broadly conceived. Off-budget enterprises are not unique to the United States by any means, but exist in Britain and other countries where they are called "quangos," an acronym for quasi-autonomous nongovernmental organizations. Underground government and off-the-books operations are prominent features of the political landscape that benefit politicians more than their constituents.

V

THE VALUE OF VOTING RIGHTS

In almost all democratic national elections an individual vote matters only in highly unlikely situations. It can be said that it is more likely to win the jack pot of a national state lottery than to become once the decisive voter in a lifetime, or to be hit in a thunderstorm than to change the voting results. Thus, it can be said that individual voters generally cannot alter such an election result regardless of whether they vote or not and how they vote. The fact that nevertheless many individuals voluntarily participate in such elections suggests that people care about democracy as such.

In public choice theory it is assumed that individuals as voters act rationally, i.e., by their voting behavior they try to maximise their own benefits. The rational voter theory was first developed by Downs (1957), Tullock (1967), Riker and Ordeshook (1968), and it is summarized e.g., by Mueller (1989, Chap. 18), Struthers and Young (1989), and Schram (1991). Given the fact that voting means to invest some effort (gathering and evaluating information, going to the polling booth or asking for the ballot-papers for postal vote), the extremely low probability for one's own vote being decisive makes voting apparently irrational. Because of this conclusion it is often asked why people vote, and many scholars have tried to give reasons in order to explain the discrepancy between the theoretical prediction and empirical observations refered to as "vote participation paradox."

According to public choice theory, voters' decision to participate in a vote is driven by individual costs and benefits involved. The typical reason given by public choice theorists why benefits should be close to zero is the extremely low probability that the own vote is decisive (Mueller, 1989; Struthers and Young, 1989). Besides the low probability justification for not voting ("my vote won't matter"), the costs of voting offer another justification. These costs include the necessary preparations (one needs the voting card or, as in the United States, is not even registered automatically by the authorities but has to take the initiative oneself) as well as the costs of information, i.e., in the case at hand the costs of making up one's mind which party one should vote for. A clear-cut position about the support for one party or another is usually the result of gathering information and reevaluating, reinterpreting or even neglecting facts. By deciding not to vote, all these mental efforts can be avoided. Furthermore, important costs of voting are, of course, the opportunity costs in terms of lost working or leisure time.

The rational voter theory as applied in the literature on political support functions (for a survey see Nannestad and Paldam, 1994) somehow neglects the low probability argument for not voting and claims that people decide in public elections as in economic situations. In other words: a voter chooses that party or coalition whose program or expected policy is best for him or herself personally. According to such a view, parties are nothing more than competing firms trying to satisfy the voters' demands (given a perfect competitive political system).

To justify such an approach one has to argue why the low probability-argument does not apply. One way would be that most voters' subjective probabilities for being decisive are rather unrelated to the objective probabilities (for a discussion see Struthers and Young, 1989; a related argument referring to self-deception and diagnostic voting is given by Quattrone and Tversky, 1985). In the minimaxregret model of Ferejohn and Fiorina (1974) voting is interpreted as a decision under uncertainty, i.e., voters are unable to estimate the probabilities of the alternative outcomes and, consequently, neglect them by concentrating on the outcomes themselves.

The theory of low-cost decisions, on the other hand, is serious about the low-probability argument. Voting decisions are identified as situations where the individual decision is irrelevant for the individuals themselves and for all other individuals, though the collective decision is relevant for all individuals (Kirchgässner, 1992). The decision takes place behind a "veil of insignificance" (Kliemt, 1986) resulting in "wrong" decisions being without significant consequences for the decision-makers. One important aspect in this context is whether voters decide rationally between the alternatives, once they have decided to participate in the vote (Brennan and Buchanan, 1994 or Kliemt, 1986). The other dimension is to decide whether or not to vote. The theory of low-cost decisions suggests that because hard (economic) incentives are missing, soft incentives like those created by moral rules or psychic costs can exert a strong impact for such decisions. Consequently, the main difference between economic and voting decisions is that costs of following social (moral) rules are usually high in economic decisions but rather low in voting decisions.

As already Riker and Ordeshook (1968) argued, citizens may receive some utility from their act of voting independent of the outcome. Citizens may enjoy the act of voting because participating in democratic elections awakens political interests and thereby all the fun and inspirations induced by more or less active participation in political debates. Voters may also be concerned to maintain democracy (Downs, 1957) or derive some sort of satisfaction from complying with the ethic of voting or with "civic duty." According to this view, the rewards of voting are considered to be twofold: voting is not exclusively instrumental to determine the winning party or coalition, but also is a private consumption act from which benefits accrue independent of the outcome of the election. The distinction made is between the investment and consumption value of voting (e.g., Stigler, 1972 or Guttman et al., 1994) or between instrumental and expressive voting (Fiorina, 1976).

In empirical studies there is quite a lot of evidence that changes in the relevant variables, as e.g., in expected closeness, cause changes in the turnout rate (e.g., Kirchgässner and Schimmelpfennig, 1992). For an explanantion of the high turnout level, however, other variables turn out to be relevant like the sense of duty, inter- and intragroup relations or respondent's level of political interest (see, for instance, Blais et al., 2000 for an empirical study conducted during the 1993 Canadian federal election campaign, or Schram and Sonnemans (1996) for evidence from a participation game experiment).

In an experiment Güth and Weck-Hannemann (1997) investigate the value of democratic voting rights by providing the participants the chance to sell them. More specifically, an incentive compatible mechanism was used to elicit the (willingness-to-accept) value of the voting right in the election of the German Bundestag in October, 1994. Moreover, a postexperimental questionnaire made it possible to assess the relative importance of answers to the question "why do people vote?"

The results are striking though consistent with observed turnout levels: Most of the participants did not want to sell their voting right even at the top price offered; only a small minority of participants would have sold their voting right for any positive price, i.e., only very few people view their individual voting power as inessential as suggested by the "why do people vote?" paradoxon; and another intermediate group was willing to sell their voting right for substantial prices, but refused to do so at very low prices.

The bids which, from a normative point of view, should reveal the true values for one's voting right thus show a strong non-willingness to sell one's voting right. Furthermore, the group of voters who hardly assign any positive value to their voting right is close to being negligible. Among the reasons why to vote most subjects viewed voting as a civic duty or as a possibility to state one's opinion as the most important for their own decision. In total, one may conclude (following Blais, 2000 as well as Kirchgässner and Pommerehne, 1993) that the rational choice model of voter participation is useful, but only in explaining behavior at the margins of social norms and other-regarding behavior, and that the importance and impact of low-cost decisions have to be fully recognized and more carefully studied in the future in public choice analysis.

VOTES FOR WOMEN

In the United States, Wyoming and Utah were the first states to grant women the right to vote, in 1869 and 1870, respectively. They were followed over two decades later by Colorado in 1893 and Idaho in 1896. The list of states approving female suffrage then grew steadily from 1910 to 1920, when the 19th Amendment to the U.S. Constitution expanding the voting franchise to women was ratified.

It took many more years for female suffrage to spread around the world. Finland granted women the right to vote in 1906 and was followed over the next quarter century by many European countries. It was not until 1929 that the first Latin American and Asian countries — Ecuador and India — allowed women to vote. Expansion of women's suffrage continued across these continents through the late 1950s. Moslem countries were among the last to grant women the right to vote, many doing so between 1949 and 1963. In 1971, Switzerland became the last major developed country to allow women to vote.

There are several interesting questions involving women's suffrage that have been addressed in public choice research. What factors played a role in determining support for women's suffrage and its early adoption? How long did it take for women to fully respond to their new voting privilege? What impact did the resulting shift in the composition of voters have on government policies?

There has been very little research on the sources of political support for women's suffrage. Jones (1991) explains voting behavior in the U.S. House and Senate on a constitutional amendment giving women the right to vote, and Kenny (2002) studies the timing of U.S. states approving women's suffrage provisions. Not surprisingly, Jones finds that legislators from states that had granted women the right to vote supported amending the U.S. Constitution to expand the voting franchise to women across the country.

More fundamentally, support for women's suffrage depended on the ratio of women to men and on the fraction

of women who were married. Granting women the right to vote was less costly to men in states where there were fewer women and thus a smaller change in the equilibrium due to suffrage. The scarcity of women in frontier states should have given women a greater share of marital income (Becker, 1981), and thus more privileges. Furthermore, having women's suffrage may have helped states with few women attract more women, which would be valued by single males in these states. Consistent with this reasoning, legislators from states with relatively few women were more likely to support the 19th Amendment (Jones, 1991), and states with few women granted women the right to vote earlier (Kenny, 2002). Similarly, granting women the right to vote should have had a smaller impact on political outcomes in states in which more women were married, and thus internalizing in their marriage the gains from marital specialization and from efficient statistical discrimination in the labor market (Hunt and Rubin, 1980). As predicted, Kenny finds that states with a larger fraction of women married adopted women's suffrage sooner.

The greater difficulty that women in rural states faced in organizing a successful grass roots movement hampered their success in obtaining the right to vote. Kenny's finding that the adoption of women's suffrage occurred later in more rural states is consistent with Stigler's (1971) evidence that occupations obtained licensure later in less urbanized states.

How long did it take for women to fully utilize their newly obtained voting privilege? For many individuals, the various benefits from voting appear to barely cover the cost of voting. But some political capital is needed to be able to select the candidate or policy that is best for a citizen. Lott and Kenny (1999) argue that the acquisition of this political capital, and the voter participation that it facilitates, is unlikely to be profitable for an older person who has just been given the right to vote but should be beneficial for a newly enfranchised 25 year old. As time passes, older cohorts of women who did not take advantage of their new right to vote are replaced by young cohorts of women who, with a lifetime of voting ahead of them, find it worthwhile to vote. This process of cohort replacement thus results in higher voter turnout. There is, however, very little evidence on how long it takes for voter turnout to fully respond to a major change in the voting franchise.

Lott and Kenny estimate the impact of giving women the right to vote on voter turnout in gubernatorial races in 1870–1940. Approximately half the ultimate increase in turnout occurs immediately. As time passes since women obtained the voting franchise, turnout continues to rise but at a decreasing rate. Under a spline specification, after nine years have passed the rate of increase in turnout as time passes falls to one third the initial rate of increase. Under a quadratic specification, turnout is estimated to increase until 54 years have passed since women were granted the right to vote. Both results suggest that it takes a very long time for the full effects of granting women the right to vote to be observed.

Other evidence is consistent with it taking a generation before turnout fully responds to a sharp rise in the incentive to vote, due to the repeal of a poll tax. Filer et al. (1991) find that the poll tax, which was repealed in 1964 by the 24th Amendment, was still depressing turnout 16 years later. Lott and Kenny (1999) estimate that it took at least 20 years for voter turnout to fully recover after the poll tax was removed.

Adding women to the ranks of voters is hypothesized to have resulted in higher government spending. Divorced women often have been unable to obtain full compensation for their family-specific investments through alimony. And programs that favor the poor are more valued by women, who tend to have lower incomes than men. Thus women who are single or concerned about becoming single may prefer government programs that transfer resources to the poor over uncertain alimony payments. Lott and Kenny (1999) use the estimated growth in turnout due to granting women the right to vote, which was described above, to measure the growing importance of women in the ranks of those who vote. Allowing women to vote is estimated to have raised state spending by 14 percent immediately, by 21 percent after 25 years, and by 28 percent after 45 years. The growth in spending that is attributed to women's suffrage accounts for approximately 16 percent of the 88 percent growth in real per capita state spending between 1913 and 1922. Lott and Kenny's other finding that state congressional delegations became more liberal after women were allowed to vote also is consistent with suffrage leading to greater government spending.

Women in Switzerland obtained the right to vote in 1971, at least 25 years after women in neighboring France, Germany, and Italy had started to vote. Abrams and Settle (1999) take advantage of this natural experiment to estimate the impact on government spending of women participating in elections. Enfranchising women is hypothesised to result in a new decisive voter who is poorer. According to Meltzer and Richard's (1981) model, this should lead to a rise in pure redistributive government spending. Abrams and Settle provide support for this prediction. They find that social welfare spending rose 28 percent. Husted and Kenny (1997) show that spending on government services falls if the income effect associated with the new decisive voter being poorer is greater than the substitution effect due to this voter facing a lower price for government services. Abrams and Settle find that government spending on final goods and services fell by 6 percent as a result of women being granted the right to vote, which is consistent with the empirical generalisation that the income elasticity for government services typically exceeds the price elasticity (Husted and Kenny, 1997, p. 55).

There also is some evidence that the legal and regulatory structure became more favorable to women after they were given the right to vote. Lott and Kenny (1999) report that states that had approved women's suffrage laws were more likely to pass legislation that restricted alimony to women and allowed alimony to be granted permanently. Women played a dominant role in the temperance movement. Lott and Kenny find that states were more likely to pass state laws banning the consumption of alcohol once women started voting. Similarly, the 18th Amendment to the U.S. Constitution establishing Prohibition received more support in state houses and senates in states that had given women the right to vote (Munger and Schaller,1997).

To summarize, states with relatively few women and in which most women were married were among the first to grant women the right to vote. It took several decades for turnout to fully respond to this expansion of the voting franchise. As women began to vote and then turned out in greater numbers, state congressional delegations became more liberal, state spending increased, and state divorce laws became more favorable to women. State legislatures also responded to the influence of female voters by outlawing the consumption of alcohol in the state and supporting a constitutional ban on alcohol for the nation.

VOTING EQUIPMENT, MINORITIES AND THE POOR

"... the old and cheap, outdated machinery is usually found in areas with populations that are of lower income people, minorities, and seniors on fixed incomes." (Al Gore, November 28, 2000)

"... everybody knows that the worst voting machinery is concentrated in poor areas." (*The Economist*, June 9, 2001)

In the aftermath of the 2000 Presidential election and the disputed vote in Florida, controversy arose over the previously obscure issue of differences in voting equipment across jurisdictions. The American public became acquainted with the potential for punch card voting mechanisms to produce large numbers of invalidated ballots. A widespread perception emerged among politicians and in the news media that the use of punch cards, and of antiquated voting machinery more generally, was more common in counties with a greater percentage of minorities and poor people. A series of editorials and op-ed articles in the Washington Post claimed that "it is mainly affluent counties that have switched" from punch cards to more modern equipment while "poor and minority voters tend to be stuck with less accurate machines," that African Americans "were far more likely to be stuck with the lousy machines than were affluent whites," and that "the most error-prone machines tend to be in the poorest counties."

This conventional wisdom that emerged so rapidly in late 2000 was superficially plausible for two reasons. First, the proportion of ballots for which no valid presidential choice was registered was much higher in areas heavily populated by minorities and the poor than elsewhere. Second, income and ethnicity are often strongly related to the quality of other public services, such as education. It seems reasonable to assume that where incomes and local tax revenues are low, election administration would be less well funded, and inferior voting technology — namely, punch card equipment — would still be in use.

There are several flaws in this logic, however. First, although there were several previous local elections in which incompletely punched-out chad produced controversial recounts, there was no universal consensus among election administrators that they produced the highest rates of voter error. The drawbacks of punch cards are now well known: voters often punch the holes in the wrong places, or apply insufficient force so that incompletely-removed chad results in undervotes; because no candidate information is printed directly on the cards, it is difficult for voters to discern mistakes by examining their cards. However, technical studies of voting equipment (e.g., Saltman (1988), have also documented problems with lever machines, optical scan systems, and direct electronic recording (DRE) systems (which use touch screens, push buttons or keyboards). In fact, empirical analyses find virtually no difference overall in the rates of invalidated ballots produced by DRE and punch card systems (Caltech/MIT, 2001; Knack and Kropf, 2002a).

Second, minimizing invalidated ballots is only one of several criteria by which election administrators have typically assessed the performance of voting technology. Although the media now revile any technology that appears to produce voter error, until after the 2000 election the media's interest was only in producing quick vote totals on election night — and by that criterion, punch card systems performed far better than optical scan systems, particularly for large jurisdictions such as Los Angeles County.

Third, election administration, and voting equipment more specifically, represents only a tiny fraction of any county's budget, regardless of the type of voting equipment it uses. (In most states, elections are administered by county governments.) Moreover, it had never been a salient issue, or a visible item in county budgets. In counties with high income levels, with strong tastes for education, public parks and other services, election administration may receive as little public attention and as little funding as in a poorer county. For example, the only county in Maryland still using punch cards in 2000 (Montgomery) has the wealthiest, best-educated population in the state, and spends more per capita on education, parks and other services than almost any county in the nation.

Historical and idiosyncratic factors appear to be influential determinants of voting equipment in use. In the early 1960s, hand-counted paper ballots were used in most small counties, while lever machines were used in large counties. As many of the smaller counties have grown, they purchased optical scanning equipment, which use ballots very similar to the hand-counted ballots. Many lever machine counties switched to punch cards beginning in 1964; others retained lever machines until DREs became available more recently, while others still use the lever machines. Because so few people within county government know much about voting equipment, election administrators often have a high level of discretion in choosing equipment type, and their choices are likely to reflect their own experiences, and those of their colleagues in other counties. Some election administrators are likely to be highly risk averse, and unwilling to adopt a system not already in wide use elsewhere. Some of them may have budgets allowing them to attend conferences and learn what has worked well and what has failed in other counties.

To the extent that cost does matter, income per capita may not predict quality as well as county size. Volume discounts from vendors, and economies of scale in setting up new systems, favor larger counties. As noted in FEC (1982: 11):

New voting systems are, typically, first adopted by large metropolitan jurisdictions where the complexity of the ballots and the volume of voters create pressures for improved vote recording and tabulating techniques. Such jurisdictions are also blessed with the fiscal, technical, and managerial resources equal to the challenge. Only when new devices are tested and debugged in this way are they normally then adopted by intermediatesized jurisdictions.

Minorities tend to live in larger counties, so may benefit from more modern voting equipment, to the degree that cost matters. Tennessee is an illustrative case. In 1998, fewer than one fifth of all the state's counties had electronic voting systems. However, these included the three largest counties of Shelby (Memphis), Davidson (Nashville), and Knox, which account for a disproportionate share of the state's poor, minorities, and Democratic voters. Shelby County alone is home to nearly one half of the state's African Americans, but just over one tenth of its whites.

Statistical analyses reported in Knack and Kropf (2002b) overwhelmingly reject the conventional wisdom that minorities and the poor disproportionately reside in areas using punch card and other inferior voting equipment. They combined county-level data on voting equipment in use in 1998 with U.S. Census data on minority and poor populations, county size, income levels, and property tax revenues per capita. For the U.S. overall, black-white differences in punch card use were negligible: 31.9% for whites and 31.4% of African Americans live in counties using this voting technology. Hispanics were much more likely to live in punch card counties than either whites or blacks. However, this difference was entirely attributable to Los Angeles County, where nearly one in seven Hispanics in the country reside. (About 1 in 10 voters using punch card equipment in 1998 lived in L.A. County.) Whites (27.7%) were more likely than blacks (21.8%) to live in optical scanning counties, but blacks (37.8%) were much

more likely than whites (26%) to live in counties using either of the technologies for which "overvoting" is impossible if machines are programmed correctly: DRE and lever machines.

In Florida, African Americans were only slightly more likely than whites to live in punch card counties. The notable difference again was for Hispanics, 84% of whom live in punch card counties, compared to just over 60% for whites and African Americans. This difference is entirely attributable to the use of punch card voting in Miami-Dade County, home of more than one half of Florida's Hispanics, but fewer than one in seven whites and fewer than one in five African Americans.

Findings are similar when looking at voting equipment used by the poor (persons living below the poverty level) and non-poor. The poor are slightly more likely (33.4% compared to 31.8%) to live in punch card counties than the non-poor nationwide, but they are also slightly more likely (9.8% to 8.6%) to use the most modern technology (DRE).

These comparisons were also conducted on a stateby-state basis, for the 29 states in which some but not all counties used punch card technology. In 18 of the 29 states, whites were more likely than African Americans to live in punch card counties. Whites were more likely than Hispanics to live in punch card counties in 21 of the 29 states. In 21 states, the non-poor are more likely than the poor to reside in counties using punch card voting equipment.

Other results in Knack and Kropf (2002b) provide little evidence for the importance of "affordability," as measured by county size, per capita income, or property tax revenues per capita. Punch card counties in Florida are much larger, wealthier, and more revenue-rich than counties using any other type of voting equipment. Similarly, for the U.S. as a whole, punch card counties are larger and wealthier on average than those using any other voting system. Counties using electronic voting constitute the group with the lowest incomes on average, and — by a wide margin — the lowest property tax revenues per capita.

Similar findings are produced by state-by-state comparisons across counties for the 28 states in which some counties use punch cards while others use modern (optical scanning or electronic voting) equipment. In 17 of the 28 states, punch card counties tend to be larger than counties with modern equipment. In 17 (but not the same 17 as in the case of county size) of the 28 states, punch card counties tend to have higher average incomes. Similarly, in 17 of the 28 states, punch card counties on average had higher property tax revenues per capita. Florida fits these general patterns. Population, income and tax revenues were all significantly higher in its 15 counties using punch cards in 1998 than in its 24 optical scan counties (electronic voting had not yet been approved for use in Florida).

Higher rates of invalidated ballots in heavily-minority areas cannot, therefore, be attributed to a greater likelihood that minorities must vote using punch card equipment. Controlling for the type of voting equipment in use, invalidated ballots remain higher in counties with more African Americans, Hispanics, and poor persons (Knack and Kropf, 2002b). However, although voting equipment is distributed in a race-neutral way, it may have effects that are not race-neutral. Several studies have found, using both precinct-level and county-level data, that the association between invalidated ballots and African American population is particularly strong where punch cards are used, but disappears where voting technology is used that can be programmed to prevent overvoting (Herron and Sekhon, 2001; Kimball et al., 2001; Tomz and Van Houweling, 2001; Knack and Kropf, 2002a).

The explanation for this pattern is not obvious. Survey data indicate that differences in deliberate undervoting between whites and blacks are fairly small, and there is little reason to expect these differences to vary much with the types of voting technology used. It is not the case that, within punch card counties, the oldest and most errorprone punch card devices are likely to be placed in the heavily-minority precincts: in most counties, the devices are stored in a central location between elections and are not earmarked for particular precincts, and they are assembled in a central location weeks prior to the election by a small number of elections administration staff (not by poll workers within the precinct). It is conceivable that African American voters are less likely than whites to request assistance from poll workers, or that poll workers in minority precincts are less able or willing to provide useful assistance. Although these studies control for educational level and voter experience to the extent allowed by the available data, they cannot control effectively for differences in education quality (as distinct from years of schooling completed), or for experience in undertaking unfamiliar administrative and bureaucratic tasks. In the absence of data to test such ideas, they must remain purely conjectural.

VOTING IN U.S. PRESIDENTIAL ELECTIONS

1. Introduction: The Electoral College

The United States elects its presidents through an indirect mechanism called the Electoral College, which has its roots in the U.S. Constitution (Article II, Section 1 and the 12th Amendment). There are various intricacies and details about the evolution and functioning of the Electoral College, but for present purposes, a short explanation will suffice.

Rather than allowing the popular vote to determine the winner of a presidential election, the U.S. Constitution set up an Electoral College wherein each state is given a number of Electors equal to the number of U.S. Senators (2) plus the number of its U.S. Representatives. The latter number changes after every Census (each 10 years) as the number of Representatives is reapportioned according to population. Rather than voting for a presidential candidate, voters cast their ballots for a slate of Electors representing their choice for president and vice-president. By the rules of the Electoral College, the candidate with the most votes in a state wins all of that state's electors. In other words, the system is a "winner-take-all" procedure (with some minor exceptions in Maine and Nebraska where two electors are chosen by statewide popular vote and the rest by popular vote in each Congressional district).

This is a sketch of how the Electoral College system generally works. It should be kept in mind that individual states and the electors have considerable discretion in this process. States can make their own rules about how many electors are allocated to each candidate. And, electors are technically free to vote for whomever they choose. For example, as noted below, one elector chose to abstain in the 2000 presidential election.

Ultimately, however, the Electors vote, and the candidate with the most electoral votes, provided it is more than one-half of the total, is declared president. The present magic number of electoral votes is 270. If no one obtains an absolute majority of electoral votes, the U.S. House of Representatives chooses the president from among the top three vote-getters in a process, with each state casting only one vote and an absolute majority of states being required to elect.

The current arithmetic of the Electoral College by state is listed in Table 1. Note that this will change in favor of states that gained population after the U.S. House districts are redrawn with respect to the results of the 2000 Census.

All of this, of course, is much better known and appreciated after the incredibly close and contested 2000 presidential election in the United States between Gore and Bush. Although Gore won more popular votes than Bush (500,000 plus), Bush ultimately won the hotly contested 25 electoral votes in Florida to achieve a victory in the Electoral College (271 to 266 with 1 abstention). Thus, a rare outcome was recorded when the popular vote winner lost in the Electoral College.

Much earlier, in 1824, Andrew Jackson won the popular vote and the electoral vote, but no candidate received a majority of electoral votes. Under the provisions of the 12th Amendment, the House voted for President (each state having one vote), and elected John Q. Adams. The 1876 election between Hayes and Tilden was also disputed with Tilden winning the popular vote, but Hayes was ultimately declared to have more electoral votes and to be president.

2. The U.S. Presidency from a Public Choice Perspective

With a few key exceptions covered below, public choice theory has not given much attention to the role of the executive branch in the determination of political outcomes. The bulk of public choice research has been on the legislative branch of government, with some attention also given to the judiciary by scholars in law and economics. This is unfortunate to say the least since the chief executive is a key political actor in a democratic setting. Nonetheless, confining attention to the United States, the presence of the Table 1: Distribution of electoral votes totalelectoral vote: 538 needed to elect: 270

Electoral College, as outlined above, opens the door for a vote-maximizing theory of executive behavior.

Previous work on the U.S. presidency examined the president's formal and informal powers. Neustadt (1960) focused on the president's informal power and his ability to persuade or bargain with Congress in an institutional setting which places the two branches in conflict. The formal powers of the president (vetoes and appointments) have been examined using the structure induced-equilibrium (SIE) models introduced by Shepsle and Weingast (1981).

Although economists and political scientists have derived equilibrium results from the bargaining game and SIE models by including a presidential preference set, the content of this preference set remains a black box. Since these models do not specify the policies preferred by the president, few predictions can be made about the bills the president will veto, the budget he will propose, the people he will appoint, or the regulations he will promulgate and enforce.

The few works that have advanced positive theories of presidential behavior make the essential point that U. S. president is not a popular vote maximizer but an electoral vote maximizer. Wright (1974), in an important early paper, showed that New Deal spending in the 1930's could be explained as a function of a measure of electoral votes across states. Anderson and Tollison (1991a) found this same result while controlling for measures of congressional influence. Couch and Shughart (1998) provide a summary and extension of this work on New Deal Spending. The basic point of this research was to show that New Deal spending was not so much a public relief program as a political program designed to buy votes with the public purse. Electoral votes, not "need," drove the allocation of New Deal spending across states.

Building on Wright's approach. Anderson and Tollison (1991b) examine the allocation of Civil War causalities across the Northern states. Given that the Northern troops were organized by states and that President Lincoln sought to be reelected, these authors found that Northern causalities were partly determined by electoral votes in 1864. Troops from close states were much less likely to suffer causalities. In other words, dead men cannot vote.

A third application of the electoral vote model to presidential behavior concerns the use of the executive veto. Grier et al. (1995) argue that winner-take-all voting in states and the unequal distribution of electoral votes across states in presidential elections makes incumbent presidents rationally place more weight on the preference of voters in closely contested, larger states when making policy decisions. They tested this hypothesis by examining whether presidential veto decisions are influenced by the floor votes of Senators from these electorally crucial states. In a pooled sample of 325 individual bills from 1970 through 1988, they found significant evidence of this behavior by incumbent presidents. That is, the more Senators from electorally important states oppose a bill, the more likely the president is to veto it, even when controlling for a wide variety of conditioning variables, including the overall vote on the bill.

Finally, Brams and Davis (1974) present a theoretical model of presidential campaign resource allocation that predicts candidates will spend resources in each state proportionally to the state's electoral votes raised to the 1.5 power, or the so-called 3/2's rule. Colantoni et al. (1975) confirmed the existence of a large state bias, but argued that the level of electoral competition (closeness) in states will also affect resource allocation. They also generally argued against the specific 3/2's rule. The evidence used in this debate was data on campaign appearances (by state) by presidential candidates in four elections (1964 through 1972).

2.1. Presidential Politics

Several basic points should be kept in mind here. First, the behavior of the executive branch of government is among the least studied parts of modern public choice analysis. This literature is in its infancy. Second, more so than other areas, this literature is tied exclusively to U.S. political institutions, namely, the Electoral College system of electing presidents. Third, the literature is rife with measurement issues. Some authors use electoral votes per capita, some use raw electoral votes (a proxy for population), and some use closeness weighted electoral votes (either per capita or raw).

Nonetheless, in keeping with the central tenet of public choice theory, presidential behavior in this approach is modeled as maximizing electoral votes subject to constraints. Essentially, the president is analyzed as a careful shopper for electoral votes in his effort to be elected or reelected. States in which the incumbent president or candidate expects to win or lose by a wide margin can safely be ignored in this process. States that are predicted to be close will be the recipients of presidential largesse and visits. The constraints on this activity include time, campaign resources, congressional influences over federal pork, and so on. Even where the president cannot run for reelection, this approach presumes that he behaves as if he were running. Such a model has thus far provided a strong predictive theory of presidential behavior in a variety of areas, as outlined above.

An economic model of presidential and presidential candidate behavior maps into this situation easily. When

faced with a choice among states with respect, for example, to new funding initiatives, the president will estimate the probability that he will win the state times the number of electoral votes. States with higher expected values will receive the funding, following an equi—marginal rule of funding allocation. States that are not expected to be close (win or lose) or small states are left out in the cold in this calculation. Obviously, all forms of presidential behavior and not simply funding can be analyzed with this model. The relevant constraints on the president are the obvious ones — time and money.

3. Concluding Remarks

The electoral vote approach has been successfully employed, as noted above, to explain the allocation of New Deal spending across states, presidential vetoes, campaign stops by presidential candidates, and still other aspects of presidential decision making. Though still in its infancy, this approach, at least for the United States, has the potential to fill in the black box of presidential preferences and to offer a positive economic explanation of presidential behavior. It also clearly finds its roots in the basic economic methodology of maximizing expected value subject to constraints. Presidential aspirants, whether they know it or not, are rational economic actors when it comes to shopping for electoral votes.

VOTING PARADOXES IN LIST SYSTEMS OF PROPORTIONAL REPRESENTATION

Social scientists have increasingly become aware of the possibility that individual preferences may not necessarily translate easily into meaningful collective choices, and that the methods by which the preferences are aggregated may exert significant influence upon the outcomes (Black, 1948; Black, [1958] 1998; Arrow, [1951] 1963; Riker, 1982, 1986). So far, the theoretical analysis has primarily dealt with Anglo-American electoral and parliamentary institutions and has only infrequently been applied to, e.g., proportional systems of representation such as found in the majority of electoral systems used in the world, and whereas the extent of formal social choice theorizing has been extensive, the examination of the possible empirical occurrence of voting paradoxes has been relatively modest (cf., e.g., Rasch, 1995; Van Deemen, 1998; Kurrild-Klitgaard, 2001).

Nonetheless, voting paradoxes may occur also in proportional systems and would seem to do so occasionally. The fundamental insight of social choice analysis is that whenever more than two persons are to choose between more than two issues certain paradoxical results may occur. The classical illustration is the so-called Condorcet Paradox, which depicts a situation of social choice where no unique majority winner exists, i.e., where no alternative is preferred more than all other alternatives when compared in pair wise contests. The paradox is usually illustrated by considering a hypothetical example with three voters contained in the nonempty and finite set N = $\{i_1, i_2, i_3\}$, who are faced with the three alternatives contained in the nonempty and finite set $M = \{x_1, x_2, x_3\},\$ and where each voter $i \in N$ has a preference ordering, P_i , over the alternatives in M, which follows the standard formal assumptions about preferences (completeness, transitivity, asymmetry and irreflexivity). If we assume that the "relation" means "preferred at least as much as," " $x_{1 N} x_{2}$ " means that x_1 is preferred at least as much as x_2 by N. We may hypothesize a situation, where the preferences are such, that they can be represented by a profile of individual preference orderings:

 $\begin{array}{l} P_1: \, x_1 \, x_2 \, x_3 \\ P_2: \, x_2 \, x_3 \, x_1 \\ P_3: \, x_3 \, x_1 \, x_2 \end{array}$

Given such preferences, and if the procedure for choosing is pair-wise comparisons, the collective preference ordering (or social ordering) of the group N may be said to be "cyclical":

 $P_N: x_1 x_2 x_3 x_1$

In this case it is impossible to construct a transitive collective preference ordering, and there is no so-called "Condorcet winner," i.e., no stable equilibrium outcome exists that cannot be beaten by (at least) one other alternative. No matter what of the three alternatives is selected, another can beat it in a pair-wise comparison. One majority (i_1 and i_3) prefers x_1 to x_2 , while another (i_1 and i_2) prefers x_2 to x_3 , and a third (i_2 and i_3) prefers x_3 to x_1 . This is a non-trivial paradox, because there would seem to be an obvious discrepancy between what is the actual observation and what would usually be the intuitive or common sense expectation: That if something is a democratic decision, it is reasonable to assume that one alternative would be preferred.

Traditionally social choice scholars have, in theoretical and empirical studies alike, tended to focus on choicesettings involving choices between, e.g., competing policies or candidates, and where the aggregation method is one of plurality. Paradoxes of social choice may, however, also occur in electoral systems with party lists and proportional representation, i.e., as found in most Western democracies. In such systems votes are not cast solely for individual candidates (as with the first-past-the-post systems of, e.g., the United Kingdom and the United States), but for candidates appearing on party lists and/or the party itself, and where the votes subsequently are converted into seats allocated to parties through the use of some vote-seat conversion method aiming at proportionality (e.g., the d'Hondt or Saint Laguë formulas).

To see this, let us assume that we identify the voters as those contained in the nonempty and finite set $N = \{i_1, ..., i_n\}$, that these are confronted with the choice between political parties included in the nonempty and finite set $M = \{x_1, ..., x_m\}$. Furthermore let $s(x_i)$ be the number of seats *s* allocated in an electoral system to a political party *i*. We may identify the following paradoxes of voting, which may occur in democracies with list-systems of proportional representation (Van Deemen, 1993; Van Deemen and Vergunst, 1998: 239ff):

 The Condorcet Paradox: Where a party x₁ is preferred to a party x₂ by a majority of the voters (x_{1 N} x₂), and where party x₂ in turn is preferred to a party x₃ by a majority (x_{2 N} x₃) by a majority, but where it is also the case that party x₃ is preferred to party x₁ (x_{3 N} x₁), i.e., that the social ordering is the intransitive ordering x_{1 N} x_{2 N} x_{3 N} x₁.

- 2. *The More-Preferred-Less-Seats Paradox*: Where a party x_1 is preferred to a party x_2 by a majority of the voters $(x_1 \ N \ x_2)$, but where party x_1 receives less seats than party x_2 , i.e., $s(x_1) < s(x_2)$.
- 3. *The Condorcet-Winner-Turns-Loser Paradox*: Where a party x_1 is the Condorcet winner and thus can beat any party in pair-wise comparisons $(x_1 \ N \ (x_2, \ ..., \ x_m))$, but where the party receives less seats than a party x_2 , i.e., $s(x_1) < s(x_2)$, or even no seats at all.
- 4. *The Majority-Reversal Paradox*: Where a majority relation for an election (e.g., $x_1 \ N \ x_2 \ N \ x_3$) may be exactly the reversal of the ranking of the parties in correspondence with their number of seats as assigned by the system of proportional representation, i.e., $s(x_3) > s(x_2) > s(x_1)$.

It has been demonstrated that such paradoxes may in principle occur in proportional systems such as those used in a majority of democracies (Van Deemen, 1993) and that at least some of these paradoxes occur in practice (Van Deemen and Vergunst, 1998). In order to do the latter, it is necessary to have data from a relatively large number of voters and have information on their preference rankings. This may be done, e.g., if the analyst has access to "thermometer" evaluation, where respondents have been asked to assign points to alternatives on a scale ranging from the most positive to the most negative. In order to turn the "thermometer" values into Condorcet comparisons, we let $\Delta_i(x_1)$ stand for the points assigned by individual *i* to alternative x_1 . We may thus assume that if a respondent assigns more points to x_1 than to x_2 , then he strictly prefers x_1 to x_2 , i.e., if $\Delta_i(x_1) > \Delta_i(x_2)$: $x_{1,i} x_2$, and that if an individual assigns the same number of points to x_1 and x_2 , he is indifferent between the two, i.e., if $\Delta_i(x_1) = \Delta_i(x_2)$: $x_1 \sim_i x_2$. When the voter preferences over the alternatives have been constructed as such, these may be aggregated by majority rule, so that alternative x_1 is majority preferred to alternative x_2 , if the number of voters who prefer x_1 to x_2 is larger than the number of voters who prefer x_2 to x_1 . If we let N represent the group of voters in question, we may express this as if $N(x_{1 i} x_2) > N(x_{2 i} x_1)$: $x_{1 N} x_2$, and if $N(x_{1 i} x_2) =$ $N(x_{2i}, x_1): x_1 \sim_N x_2$. We may thus also say that an alternative x_1 is a Condorcet winner if and only if it is the case that for all other alternatives x it is the case that $x_{1 N} x_{2}$.

We may illustrate this with data derived from the Danish Election Survey Project (1973, 1994, 1998). Table 1 summarizes the results of the Condorcet comparisons for the three elections and contains the majority relation for the voters in each of the three elections (MR) as well as the order of the parties according to the number of seats allocated to them under proportional representation (PR).

Table 1: Social orderings and seats of political parties, Danish election surveys and parliamentary elections, 1973, 1994, 1998. Majority relations (MR) and seats according to proportional representation (PR)

Sources: Actual election results, with the number of seats received by the party given in brackets.

Abbreviations: MR: Majority Relation (i.e., ranking according to results of pair-wise Condorcet comparisons); PR: Proportional Representation (i.e., ranking according to proportions of votes in the election); A: Social Democratic Party; B: Radical Liberal Party; C: Conservative People's Party; D/M: Center-Democrats; E: Justice Party; F: Socialist People's Party; Indp: Jacob Haugaard, elected as an independent, was not included in the party survey; K: Danish Communist Party; Q: Christian People's Party; O: Danish People's Party; U: Democratic Renewal; V: Danish Liberal Party; Y: Left Socialists; Z: Progress Party; Ø: Socialist Unity List.

There were no examples in any of the three elections of the Condorcet Paradox (i.e., of a cycle involving all the alternatives) or of intransitivity more generally speaking (e.g., with a cycle among a sub-set of alternatives). Compared to the theoretical literature, these findings are somewhat surprising, i.e., much of social choice theory has predicted that intransitivity should be widespread in collective preferences. But compared to previous empirical findings, the present results are less surprising: With a few notable exceptions (Niemi, 1970; Kurrild-Klitgaard, 2001), social choice theorists have, so far, not been able to detect any examples of the full-fledged Condorcet Paradox in larger electorates and only relatively few examples of other forms of intransitivity. Specifically, the result is similar to a study of four Dutch election surveys, which found no examples of intransitivity in the preferences of voters over parties (Van Deemen and Vergunst, 1998).

Investigations such as these should, however, be accompanied by some reservations. First, since the election surveys are based on samples, it is impossible to be sure that the collective preference orderings found necessarily can be generalized to be representative of all the voters. This has some specific consequences. In all three elections considered there are several pair-wise comparisons for which the most preferred alternative cannot be inferred with certainty if, e.g., a 99 pct. confidence interval is applied to the results of the pair-wise comparisons. For example, in the 1994 election this was the case with the differences between the Social Democrats and the Liberals, the Social Democrats and the Conservatives, the Liberals and the Conservatives, and the Socialist People's Party and the Center-Democrats, thus making it possible that there may in fact have been a cycle among the top-ranked alternatives.

In order to establish whether any of the other social choice paradoxes identified here were present in the preferences of the Danish voters, we must compare the social ordering according to the majority-relation with the actual results of the three elections. It is evident from the data in Table 1 that two of the paradoxes seem to be absent in the three elections. The Condorcet-Winner-Turns-Looser Paradox is not present in any of the elections; indeed the Condorcet winner is in all three elections also the party, which receives most seats, namely the Social Democrats. This is in contrast to the investigation of four Dutch election surveys, which found two examples of this paradox. This result would, due to the logical character of the paradox, stand for the sample as well as for the electorate as a whole; we can, however, not say at a 99 pct. confidence level that the Social Democrats in fact was the Condorcet winner for the electorate in 1994, and so the Condorcet-Winner-Turns-Loser Paradox may have been present in the preferences of the electorate as a whole. Given the absence of the Condorcet-Winner-Turns-Loser Paradox in the sample of voters, the Majority-Reversal Paradox is not present either. This was not found in the investigation of the four Dutch election surveys either. This result too would stand for the sample as well as for the electorate as a whole.

In contrast, the More-Preferred-Less-Seats Paradox is abundantly present in Danish elections, or at least all three elections considered here. It was present in the 1973 election, where only two of the eleven parties, the Social Democrats and the Liberals, had the same place in the social ordering and in terms of the allocation of seats. Most significantly, the Progress Party received more seats than no less than six other parties ranked higher in the social ordering. In the 1994 election the same three parties were top-ranked with the two different methods, but beyond this the orderings were quite different. For example, the Progress Party and the Socialist Unity List both received more seats than the Christian People's Party, which did not receive any seats at all despite beating both these parties in pair-wise comparisons. In 1998 a quite similar picture emerged as in 1994.

We can thus with some safety conclude that the More-Preferred-Less-Seats Paradox seems to occur quite frequently in list systems of proportional representation. But how 'much' does it occur? Van Deemen and Vergunst (1998: 484–485) calculated the robustness of the orderings by using Kendall's τ , which may be seen as a good indicator of the number of reversals; the smaller the difference between the rankings, the larger the Kendall's τ coefficient. For the four Dutch elections they found coefficients between 0.641 and 0.944 and with an average of 0.752. In the case of the Danish elections considered here, the coefficients were 1973: 0.491; 1994: 0.611; 1998: 0.745 and with an average of 0.615.

It is thus clear that a number of paradoxes of voting may and do occur not only in first-past-the-post systems but also in proportional representation systems. The analysis conducted so far suggests that one social choice paradox is present in virtually all elections using list-systems with proportional representation, albeit to different extents, namely the More-Preferred-Less-Seats Paradox. Two other paradoxes, the Condorcet-Winner-Turns-Loser Paradox and the Majority-Reversal Paradox, are occasionally, but rarely, present, while the fourth and most infamous, the Condorcet Paradox, is not found in any samples of voters, although its existence cannot be completely ruled out for the electorates.

The widespread presence of the More-Preferred-Less-Seats Paradox, i.e., that the proportional system entails a significant number of reversals vis-à-vis the majority relation, raises an interesting question, namely if the discrepancy between the two may be seen as an indication of a more fundamental instability in the political system, or perhaps as a cause of it? A preliminary analysis of the results suggests that it is relatively more "extremist" parties, which receive more seats under proportional representation than is consistent with their rank in the social ordering according to the majority-relation. In contrast, the "losers" to these parties would seem almost consistently to be small, centrist parties. More generally the presence of the paradox would seem to contradict a premise underlying much of contemporary democratic debate, namely that if more people prefer one party than another, then it would be wrong for the latter party to receive more seats. Proportional representation obviously adds pluralism to a party system compared to, e.g., the first-past-the-post system, but it would also seem not only to do so by benefiting some parties at the cost of others but also to do so in direct opposition to the majority principle and thus to fly in the face of much of what underlies the general view of democracy.

W

THE WAR ON DRUGS

The first nation-wide shot in the "war on drugs" in the United States was the 1914 Harrison Narcotics Act. This war was escalated by the 1937 Marijuana Tax Act, which effectively outlawed cannabis and hashish. Since then, this war has waxed and waned repeatedly, although for the past thirty years it has largely accelerated.

By "war on drugs" I mean government's active prohibition of the production, distribution, possession, and use of certain mind- and mood-altering natural and chemical substances — a policy for which police, military, judicial, and penal forces all are employed toward the ostensible goal of minimizing the use of such substances in America. The "war," therefore, is more accurately described as a war on people who are either suppliers or buyers of outlawed drugs. It is, in short, a policy of prohibition. This policy is identical in all essential respects to the national prohibition of alcohol from 1920 to 1934. For the sake of accuracy, I will from here on in refer to the "war on drugs" as "drug prohibition."

Debate over the wisdom of drug prohibition typically focuses on its morality or its effectiveness. Neither of these issues turns principally on public-choice considerations. Nevertheless, drug prohibition has several public-choice aspects, although space permits only a handful to be reviewed here.

1. Bootleggers and Baptists

While the existence of rent-seeking special interest groups alone might often generate sufficient pressure on the legislature to enact statutes creating rents for these interest groups, Bruce Yandle (1983) argues that legislation benefiting a rent-seeking special interest group is more likely to be enacted if that legislation also is supported by a group whose motives are not (or not obviously) pecuniary. In Yandle's useful terminology and example, the legislature is more likely to outlaw alcohol if the "bootleggers" who stand to gain monetarily from this prohibition can rely upon the "Baptists" — people sincerely seeking to reduce alcohol consumption for religious reasons — to add pressure on the legislature and to take the lead in making the public case for prohibition. Drug prohibition seems clearly to be a product of a "bootleggers and Baptists" phenomenon. The "Baptists" are the large number of Americans who are sincerely convinced that prohibition is in the public interest. But a conviction can be sincere without being deep or fundamental. Contrary to popular perception, the public's demand for drug prohibition seems not to originate with the public. Instead, it seems to be the product of interest-group efforts.

Bruce Benson and David Rasmussen (1997: 202–205) report evidence that public support for drug prohibition is, in large part, a *result* of a policy of prohibition. Building on the model of Breton and Wintrobe (1982) — in which regulators can release both true and false information and, thus, distort the public's perception of reality — Benson and Rasmussen (1997: 205) argue that such information distortion "has clearly been the case in the evolution of drug policy." (See also Twight, 2002: 19–53.) As an example, these scholars offer

the bureaucratic campaigns leading up to the 1937 marijuana legislation [which] 'included remarkable distortions of the evidence of harm caused by marijuana, ignoring the findings of empirical inquiries' [Richards, 164]. The 'reefer madness' scare can be traced to the misinformation propagated by the Narcotics Bureau. Marijuana was alleged to cause insanity, to incite rape, and to trigger delirious rages in users making them irresponsible and prone to commit violent crimes. Factual distortions did not stop there, however. For instance, the bill was represented as one that was largely symbolic in that it would require no additional enforcement expenditures. (Benson and Rasmussen, 1997: 205)

Benson and Rasmussen (1997: 202–207) contend that the same process whereby rent-seeking interest groups bootleggers — actively worked to create public hostility toward marijuana in 1937 was also at work throughout the entire U.S. experience with drug prohibition. In short, when it comes to illegal drugs, the bootleggers seem to play a prominent role in creating the Baptists.

2. Drugs and Crime

The most prominent justification for drug prohibition is its alleged promise to reduce crime rates (Miron, 1998: 648). Illegal drugs are thought to make their users more likely to commit crimes. Therefore, by raising the cost of drugs and, hence, reducing the quantity demanded, prohibition allegedly reduces crime rates.

Although not without some intuitive appeal, this argument suffers from several weaknesses. Most notably, while there is a connection between crime and the supply and use of currently illegal drugs, much of this crime is an artifact of prohibition. First and most obviously, because the distribution, possession, and use of substances such as marijuana and cocaine are *defined* as criminal activities, crime statistics will show that sellers and users of these substances are criminals.

Second, because the illegal-drug trade necessarily takes place outside of the law, illegal-drug sellers and buyers have no access to formal institutions — such as courts, credit-rating agencies, and trade associations — that minimize conflict and help to settle disputes peaceably. In such a setting, violence enjoys a comparative advantage at dispute resolution.

Third and relatedly, the concern for reputation that plays a powerful role in promoting proper and honorable behavior (Klein, 1997) is enfeebled in those who deal in illegal drugs. One reason is that the more likely someone is to be guided by a concern to maintain a good reputation, the less likely he is to enter an enterprise popularly regarded as criminal, even if he himself finds nothing intrinsically wrong with it. Therefore, illegal activities — including the illegal-drug trade - will be dominated by people who are less apt than ordinary people to care about their good reputations. They are people who generally pay less heed to the counsel of Adam Smith's Impartial Spectator. Another reason is that, once a person is perceived as being a criminal, the marginal psychic cost to him of acting in ways that further diminish his reputation are low. He will, therefore, engage in more dishonorable activities. (That is, suppose someone keenly interested in his reputation nevertheless is attracted to the illegal-drug trade. Once in this trade, the big blow to his reputation has already been felt; his good reputation is already sacrificed. Once this good reputation is gone, concern for it is unlikely to restrain him from further acts of deceit, dishonesty, and, perhaps, even cruelty.)

Fourth, resources used to combat the distribution and use of illegal drugs are diverted from policing directly against crimes, such as murder and theft, that violate the rights of innocent people. Of course, it is an empirical question whether this diversion of criminal-justice resources from fighting crime directly to fighting it indirectly (by attempting to reduce drug use) increases, decreases, or leaves unchanged the rate of crime against innocent people and their property.

What evidence there is suggests that drug prohibition promotes rather than discourages crimes against persons and property. Again, much of the pioneering research on this question was done by Bruce Benson and his coauthors. Benson et al. (1995: 26) report that "[t]here is no evidence that increasing use of law enforcement resources to combat drugs has reduced other crime...Indeed, in sharp contrast to the political rhetoric, it seems that drug enforcement causes property crime." (See also Benson and Rasmussen, 1991.)

3. Asset Forfeiture

Many of the reasons that drug prohibition enhances rather than discourages non-drug crimes of the sort that people legitimately fear are revealed in an analysis of civil asset forfeiture. Asset forfeiture is now one of most widely used weapons of drug-prohibition enforcers, with the federal government seizing about \$450 million annually and state governments seizing at least that much (Rising, 1999; Wollstein, 2001).

Asset-forfeiture statutes permit law-enforcement agents to seize and take title to property and cash reasonably suspected of being involved in illegal activities. Owners of the assets need not ever be convicted of, or even charged with, criminal wrongdoing. All that is needed by enforcement authorities is a reasonable suspicion that the assets have either been used to facilitate criminal behavior or are the proceeds of such behavior.

Some states and the federal government allow innocentowner defenses: that is, if the owner is innocent of the wrongdoing, his property must be returned to him. However, such a defense is not constitutionally required some states in some cases provide no innocent-owner defense — and oftentimes the property owner bears the burden of proving his innocence rather than enjoying a presumption of innocence. (This was the case under federal law until 2000, when Congress changed its forfeiture statutes to give owners of seized properties a presumption of innocence for purposes of the innocent-owner defense under federal asset-seizure law.)

Law-enforcement authorities justify asset forfeiture as a vital tool to fight drug distribution and use. Their argument is simple: civil forfeiture is a tax on the drug trade that simultaneously raises dealers' costs and increases the incentives of enforcement officials to hunt down and destroy illegal drugs.

But matters are not this straightforward. Consider a politician's choice between prohibition and taxation. Why would he ever vote to prohibit the possession and use of goods demanded by large numbers of people? The answer, of course, is that influential interest groups (likely bootleggers and Baptists) demand such prohibition. If prohibition succeeds, politicians gain votes by removing from the street goods intensely disliked by politically influential groups and/or a sufficiently large bloc of voters. But even if prohibition is ineffective, voters might still be swayed by the posturing of politicians stumbling over each other to display how tough they are on crime. Political benefits, however, are never free. Prohibition prevents tax revenues from being collected on the outlawed substances. But asset forfeiture solves this problem for politicians. Because the government keeps the value of forfeited assets, forfeiture surreptitiously taxes prohibited substances.

As a form of taxation, though, asset forfeiture poses specific and troubling problems. They emerge from the following facts:

- Law-enforcement agencies keep part of the proceeds from forfeiture.
- Asset-forfeiture proceeds are collected only from a small and politically unorganized subgroup of the population.
- Constitutional protections against government abuses are often rejected by courts when asset forfeiture is used.

As a consequence of allowing law-enforcement officials to keep some of the proceeds from asset-forfeiture actions, these officials coalesce into an interest group supporting asset forfeiture. Empirical studies of the effect of asset forfeiture upon the size of enforcement-agencies' budgets indicate that forfeitures "have a significant positive impact on non-capital expenditures by police agencies" (Benson et al., 1995: 22). That is, asset forfeitures increase lawenforcement agencies' discretionary budgets.

Moreover, as a means of taxation, asset forfeiture is inequitable. Because of their civil-law (rather than criminallaw) nature, asset-forfeiture statutes permit government to confiscate assets without abiding by constitutional rules designed to guarantee a strong likelihood that persons convicted of criminal wrongdoing actually are guilty of criminal wrongdoing. Thus, government has a much easier time getting these assets than it has of convicting people of crimes. The wide discretionary scope that asset-forfeiture actions give to governments, therefore, almost surely results in too many innocent people losing their properties in assetforfeiture actions, making a mockery of the claim that asset forfeiture is necessary in order to punish actual criminals.

In short, a large element of randomness mars assetforfeiture actions (at least if the benchmark is the accuracy of actually convicting genuine criminals of their offenses). And random enforcement is unlikely to be effective enforcement. Also, the random manner in which asset-forfeiture taxes are levied hides from taxpayers a part of the cost of government operations. A disproportionate share of this cost is foisted upon owners whose properties are suspected of being used to commit drug offenses. This group — largely because of the randomness of the enforcement effort — is politically unorganized. Therefore, its members generally cannot adequately defend themselves in the political arena against the much more cohesive and self-aware law-enforcement officials who benefit materially from asset forfeiture.

The potential loss of property due to forfeiture is typically a one-time, low-probability event for each property owner. Thus, they have little incentive to form or to join lobbying groups pressing to rein in asset-forfeiture powers (Pritchard, 1991).

The perverse incentives created by asset forfeiture are even greater at the level of law-enforcement agencies that are able to keep all or part of the proceeds seized in forfeiture actions. To see why, consider briefly some basic economics of law enforcement.

The optimal level of deterrence for any particular crime — say, drug enforcement — is the level at which the marginal benefit of deterrence equals its marginal cost. If deterrence is less than that level, the benefit of spending an extra dollar on deterrence is greater than the cost of doing so. Deterrence efforts should be increased. If, in contrast, deterrence is at a super-optimal level, the value of spending an extra dollar on deterrence yields benefits less than the attendant costs. Deterrence efforts should be reduced.

A more precise way to make this point is to say that one necessary condition for the optimal level of deterrence is that the net benefit of spending a dollar of resources on deterrence of each of the several types of crime be equal. That is, if the last dollar spent investigating murder nets murder deterrence worth \$15, while the last dollar spent investigating burglary nets burglary deterrence worth \$25, resources should be shifted from murder investigations to burglary investigations until these net benefits are equal to each other.

The practice of asset forfeiture likely prevents the attainment of optimal levels of deterrence. The reason is that law-enforcement officials will adjust their enforcement efforts to maximize revenues from asset forfeitures rather than to achieve the optimal level of crime deterrence (Boudreaux and Pritchard, 1997: 352-355). And there is no reason to expect that the level of drug enforcement that vields maximum forfeiture revenues is also that enforcement level at which the marginal benefit of enforcement equals its marginal cost. Indeed, because the bulk of the cost of forfeitures is borne by people who are politically unorganized — and because the benefits of forfeiture actions are concentrated disproportionately on enforcement agencies — efforts to enforce drug prohibition using asset-forfeiture powers are likely to be excessive. Too many law-enforcement resources will be devoted to enforcing drug-prohibition statutes and, hence, too few resources will be devoted to enforcing laws against violence and theft.

This conclusion is strengthened by the recognition that forfeiture actions are generally less risky and more lucrative for law-enforcement agents than are efforts to hunt and capture violent criminals. Suppose that, from society's standpoint, extra man-hours and resources are better spent pursuing violent offenders rather than enforcing drug prohibitions. Unlike seeking out valuable properties whose owners fit a broad profile of drug trader or user, pursuing and capturing, say, murderers puts the agents' lives at some significant risk and, even if successful, probably does not pay to the law-enforcement agency a handsome monetary return.

The availability of asset forfeiture, therefore, likely tempts self-interested law-enforcement agencies to overenforce drug prohibitions and under-enforce other criminal laws.

4. Conclusion

Other public-choice problems contaminate drug-prohibition efforts. For example, because there are seldom any victims to complain about drug transactions, enforcement authorities must often engage in sting operations that rely for their justification on the word of the enforcement agencies themselves. In addition, bribery of law-enforcement officials is an ever-present temptation, not only because of the large sums of money involved in the illegal-drug trade but also because the victimless nature of drug crimes means that fewer third-parties are available to detect evidence of bribery.

No evidence shows that drug prohibition works, and much evidence shows that drug prohibition has several perverse and unintended consequences. Regardless of the nobility of the notion of a nation free of drugs, prudence suggests that the best course of action is to end drug prohibition just as alcohol prohibition was ended seventy years ago. As with alcohol, the effects of ending the futile attempt to prevent people from enjoying intoxicants of their choosing likely will reduce crime and, at the same time, reduce the political pressures to ignore important provisions of the Constitution.

WELFARE ECONOMICS AND PUBLIC CHOICE

Welfare economics provides the basis for judging the achievements of markets and policy makers in allocating resources. Its most powerful conceptual tool is the utility possibility frontier. This defines the set of utility allocations that can be achieved in a society subject to the constraints of tastes and technologies. Any allocation on the frontier cannot be Pareto dominated and hence would satisfy a rather minimal condition for it to be socially desirable.

Distributional judgements about points on the Pareto frontier are typically embodied in a social welfare function. The social choice literature, beginning with Arrow (1951), has demonstrated the difficulties of *deriving* such a function from citizens' underlying preferences over social alternatives without making interpersonal comparisons of utility. By postulating a social welfare function for pedagogical purposes, the analyst is implicitly assuming that interpersonal comparisons of utility can be made and has adopted a position on how society should weigh such comparisons (Sen, 1977).

The analysis of competitive markets culminated in the fundamental theorems of welfare economics which elucidated the (restrictive) conditions under which resource allocation by markets would achieve Pareto efficiency. The first fundamental theorem says that all perfectly competitive equilibria with complete markets (to deal with externalities and uncertainty) are Pareto efficient. The second fundamental theorem says that any Pareto efficient allocation might be decentralized by suitable choice of lump-sum transfers.

Modern welfare economics builds on this by putting incentive constraints at centre stage. Among the seminal contributions are Mirrlees (1971) and Hammond (1979). This analysis dispenses with the assumption that lump-sum transfers are feasible because of the incentive problems that they create. The appropriate benchmark for government is second best Pareto efficiency, taking into account appropriate restrictions on policy instruments. A whole tradition of policy analysis in this vein has been developed (see, e.g., Atkinson and Stiglitz, 1980).

Welfare economic approaches to the policy process have been criticized by those operating in the public choice tradition, for failing to consider how actual policy choices are made. Thus, even if we were able to understand what optimal policies are, there is no guarantee that the kinds of decision making institutions that we observe in reality will bring them about. The *public choice critique of welfare economics* says that, by failing to model government, it provides a misleading view of the appropriate role for government. (See Buchanan, 1972) for a forceful plea for a level playing field.)

To see the logic of the critique, consider the argument that the government should intervene to fix a market failure, say by introducing a Pigouvian tax. Then, the welfare economist will select the tax, and other policy instruments, to maximize some social welfare objective. There is no reason at all to expect the political process to yield this outcome. Even if the tax is chosen to be second best Pareto efficient, the distributional outcome selected by the political process need not match that of the "social planner." While this may suggest that a public choice approach has to be more conservative, this is only true when equilibrium effects on other policy instruments are ignored. As argued in Besley and Coate (2003), it is possible for these other policy instruments to be changed in a welfare improving direction.

Many models in the public choice literature lead to efficient policies which fail to maximize social welfare. A good example is the Leviathan approach of Brennan and Buchanan (1980). In this case politicians extract resources for themselves at the expense of voters. Proponents of probabilistic voting models have sometimes suggested that particular social welfare functions are maximized in political equilibrium. (See Coughlin, 1992 for a discussion.) However, they rest on strong assumptions and it appears unlikely that technological assumptions are at the heart of the distributional conflict implicit in political competition.

Some economists use the benchmark of social surplus to judge political outcomes. However, this is conceptually problematic and is even (misleadingly) labeled as an efficiency criterion. The notion of surplus is only defined under restrictive assumptions about preferences. Moreover, the criterion really only makes if (i) there are lump-sum transfers and (ii) social preferences weight a dollar in every citizen's hands equally. This would be fine if both the political process and the planner were able to use lump-sum transfers. However, even then, the exact allocation of transfers would enter the calculus of whether the intervention is justified unless (ii) also holds. But the latter is only one particular distributional preference and not an efficiency criterion.

Policies chosen by the political process may fail to be efficient using second-best efficiency as a benchmark. Besley and Coate (1998) define a welfare economic definition of political failure in this way. To motivate this, consider the textbook analysis of market efficiency. First, the set of efficient allocations is characterized (graphically, the utility possibility frontier). This is a purely technological notion of efficiency, since the frontier depends only on the tastes and technologies of the economy. The second step requires a model, such as that developed by Arrow-Debreu, to specify how markets allocate resources. The idea of market failure, then comes from observing that, under certain conditions, markets do not result in allocations that are on the frontier. The term "failure" is justified by the observation that, in principle, all citizens could be made better off. A parallel notion of political failure arises when resources used to determine policy fail to produce a selection from the second-best Pareto frontier so that, in principle, all citizens can be made better off.

This welfare economic notion of political failure should be contrasted with the standard approach to political failure rooted in the work of Wicksell. He argued that government intervention is legitimate only if government dominates a status quo point where government is absent. Then a political failure is defined when government fails to select a Pareto dominant point.

The welfare economic approach and Wicksellian approach are distinct. To see this, consider the comparison between the outcome attained from a political process to a policy vector x_0 which is the outcome that would prevail with no government intervention. A *Wicksellian political failure* is now defined as a situation in which the political process selects a policy outcome which does not Pareto dominate x_0 (See Figure 1). Let *A* denote the utility

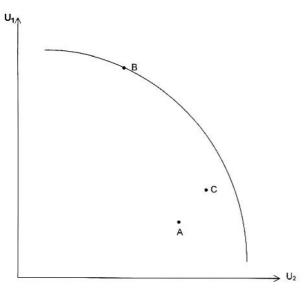

Figure 1

allocation associated with x_0 . By fixing market failures, we suppose that (in-line with the welfare economic approach) the government can, in principle, shift out the Pareto frontier. Let x_0 be the new policy vector and consider possible utility outcomes associated with it. Point B which is on a higher Pareto frontier and hence is (second best) efficient. However, this point is not a Pareto improvement over point A. Hence, if chosen by government, it would constitute a Wicksellian political failure. However, it would not be a political failure according to the definition above as it is on the Pareto frontier and there is no scope for improving government efficiency. Now consider point C. According to the Wicksellian definition, it is not a political failure as it is a Pareto improvement relative to A. However, the definition based on second-best Pareto efficiency would regard it as a political failure. It is possible to make all citizens better off beginning from this point.

Wicksell's definition of political failure embodies an important distributional judgement which outlaws any pure redistribution of resources around point A except in so far as this is justified on citizens' underlying preferences for redistribution. A government can intervene efficiently in the welfare economic sense and yet still create a political failure. Moreover, the scope for political failure on this definition is vast, depending on the status quo point x_0 being posited.

Are there good reasons to believe that governments chose inefficient policies using second best Pareto efficiency as the criterion? In answering this, it is essential that the same set of instruments that a welfare economist would allow the government to use should be available in the political process. Claims about the inefficiency of outcomes associated with the median voter often miss this point. Consider the claim that the median voter fails to provide public goods efficiently. While it is true that, in general, the Lindahl-Samuelson rule does not yield the same outcome as the median voter rule, this has nothing to do with political inefficiency. The Lindahl-Samuelson rule requires that lump-sum transfer are feasible while the median voter model usually works with a more restrictive tax system. The former achieves first best efficiency while the latter a very constrained form of second best efficiency.

Why then does this kind of claim persist? The difficulty lies in the need to make sufficient restrictions on the model of political resource allocation to get an equilibrium to exist. These often exclude the rich policy space studied in welfare economics. However, the failing is on the side of economists not governments — the latter struggling with a satisfactory theory of public choice. If the theory of market failure had proceeded in this way, it would have lead to many strange conclusions. Suppose that economists were limited in their ability to study multi-product pricing by firms. Then, we would conclude that there is always a market failure when the government can make these choices instead! This critique of the literature was raised in an important article by Wittman (1989).

In a static model of policy choice where rulers choose policy in their own interests (no matter how narrow), there is a presumption of second-best efficiency (Besley and Coate, 1997). A good example of this is the Leviathan model. There is no reason for Leviathan to extract resources from citizens in an inefficient way. However, there are potential sources of second-best Pareto inefficiency: the use of influence activities, legislative inefficiencies, coordination problems and strategic use of policies in a dynamic setting. We now discuss each of these briefly in turn.

There is a vast literature on why the policy process may be subject to influence activities — rent-seeking or lobbying. The literature on rent-seeking originating with Tullock (1967) and Krueger (1974) studied how private actions influence policy. Formal analysis has focused mostly on modelling competition among individuals or groups to obtain an indivisible policy favor, the aim being to characterize the aggregate expenditure on rent-seeking activities (see, e.g., Baye et al. (1994) and the references therein).

Whether this activity is inefficient depends critically on the form that it takes. Cash transfers, as modeled by Grossman and Helpman (1994) yield movements around the Pareto frontier. However, examples such as campaign finance as modeled in Grossman and Helpman (1996) yield real resource misallocation. For this to be second-best inefficient (i.e., a political failure), there must exist is a way of re-organizing the influence game so that all players (including those involved in the influence process) can be better off. An example along these lines is studied in Besley and Coate (2001). But why might political favors not be granted in the most efficient way? An intriguing answer is given in Coate and Morris (1995). If voters fail to re-elect politicians who engage in such behavior that disguised forms of transfer may be preferred to keep voters in the dark.

Political failure may also occur because of coordination difficulties among voters. Consider a world where there are both competent and incompetent candidates — the latter defined as candidates who (for fixed ideological preferences) can generate a potential Pareto improvement. Then, it is possible to construct a political equilibrium between two incompetent and one competent candidate of different ideologies where voters fail to coordinate on the competent candidate who therefore loses (Besley and Coate, 1997).

Legislative policy making is also a potential source of political failure — with important insights going back to the seminal work by Buchanan and Tullock (1957). However, for a legislature to pick a Pareto dominated point, it must be that there is some failure in the bargaining procedure used to make decisions — either limits on transfers or the credibility of promises.

In dynamic models, examples of political failure are created principally by the strategic use of policy. One of the earliest examples to illustrate this is the work of Persson and Svensson (1989) and Tabellini and Alesina (1990). They show that governments will have an incentive to run deficits to reduce the policy flexibility of future incumbents. Aghion and Bolton (1990) and Milesi-Ferretti and Spaolore (1994) show that strategic policy choice can also lead to changes in who is elected. This too may lead to policies being selected that are inefficient. Privatization decisions may be a key practical instance of this (Biais and Perrotti, 2002). Many governments underpriced privatizations to create a class of stakeholders committed to voting in favor of particular kinds of governments. This could explain privatization even without appealing to economic gains. Besley and Coate (1998) pulls this ideas together to give a unified definition of political failure in dynamic models where the criterion is second best Pareto efficiency.

So what do we learn from this pathology? In cases of true political failure, there should be unanimous consent that something should be done (provided that the failure results in a truly Pareto dominant outcome). In all the above cases, there are important and interesting questions about institutions can be redesigned to mitigate the political failure. This is similar in spirit to the notion, in traditional public choice writings, that there should be a focus on designing a fiscal and procedural constitution (Brennan and Buchanan, 1985). In practice, it is likely that progress will come from piece-meal analysis of specific institutional variations.

The juxtaposition of welfare economic and public choice approaches to the role of government is frequently overstated. There are as strong reasons for public choice economists to study welfare economics and optimal policy. Similarly, welfare economists need to understand public choice. Societies frequently have make choices about how to govern their affairs which have both efficiency and distributional implications. The role of welfare economics in a world of public choice is to provide an analysis of this.

WELFARE ECONOMICS AND THE THEORY OF THE STATE¹

The most general attribute that distinguishes government from other organizations is its coercive role, circumscribing the activities of all of its citizens and the other inhabitants of its territories. Laws and their enforcement require members of the public to behave in certain way and preclude them from engaging in actions that some of them would otherwise undertake. Explicitly in a democracy and implicitly in any government that operates under some sort of social contract, this means that the governed must have chosen voluntarily to be subjected to coercion that prevents them from behaving as they would otherwise choose to do. Such a paradoxical arrangement nevertheless can constitute rational behavior on the part of the public. The theory of the state, in essence, entails resolution of this paradox. It will be shown that welfare economics deals with an entirely parallel issue. Indeed, the policy measures that welfare theory suggests are particular examples of coercive public sector acts that it would serve the interests of the public to support and accept voluntarily. The logic of the analysis applies to issues as varied as taxation, finance of national defense, counter-cyclical measures and programs to counteract congestion problems in road traffic and urban dwellings, among many others.

1. How Acceptance of Government Coercion can Serve the Interests of the Coerced

Acceptance of government coercion by the coerced can serve the self interest of the latter in only one of two circumstances: (1) where the coerced fear that they will not otherwise make decisions that really serve their best interests and (2) where acceptance by the individuals of rules circumscribing their own conduct is a prerequisite for adoption of rules coercing others. The first has been illustrated by Ulysses' request to be tied to the mast of his ship to prevent him from succumbing to the Sirens' song. Individuals may feel that they lack the strength of character to undertake an act that denies them an immediate pleasure but will be very beneficial to themselves later. Compulsory saving for retirement, as imposed by social security laws, are a clear example. This role of government, then, is recourse by citizens to the paternalism of government, with the latter assigned to make decisions for the individuals that are superior for their welfare than the decisions they would make themselves. Seat belt laws for automobile passengers, laws against consumption of narcotics or dangerous foods and taxes on cigarettes are all illustrations.

What is noteworthy here is that all of these are examples of a type of market failure that is usually omitted from the standard listings (see, e.g., Bator, 1958). In all of these cases, the reason the free market does not work is that individuals can sometimes be guided by transitory or illusory incentives to make decisions that do not really serve their interests and that, in many cases, even they themselves would concede to be self damaging. In such cases the market will sometimes compound the imperfection by offering rewards to those who tempt people to act self destructively, for example, via the profits that can be earned by the supply of tobacco products or drugs. But this brings us to a second category of coercive government acts that it may serve the self interest of the individual to accept.

This second category, which it will be convenient to divide further into two subcases, arguably encompasses the major tasks of government. These are cases in which the individual, A, would be better off if left free to make her own decisions, but in which no constraining rule will be applied to others unless it also holds for individual A as well. That is, the individual in principle is faced with three levels of welfare, $w_1 < w_2 < w_3$, with the last of these obtainable only if everyone else in the world is subject to some constraining rules but A is exempted from them. Welfare level w₂ is attainable if the rules are uniformly applied to everyone, while the absence of the constraining rules yields only welfare level w₁. As a practical matter, the w₃-yielding option is not really available, so the individual must choose between only the other two. In that case the reason for agreeing to be coerced is clear, at least in the abstract terms so far considered. It is convenient to refer to this situation as one that entails beneficial nondiscriminatory coercion.

The most widely recognized nondiscriminatory subcase entails protection of the individual from actions by others that damage the individual's interest. Laws against burglary, false advertising and monopolistic behavior are clear illustrations and other examples are easily cited. Most but not all² of these involve redistributive activities in which an agent seeks to benefit at the expense of others. Most often, this involves an attempt by the former to take away income, wealth or property of others, without compensation.

In many such cases it is not clear that the individual would benefit if that person alone were exempted from the constraining rules. Few of us would be likely to pursue the profits of bank robbery if the rules against this activity became inapplicable to us. But that is, arguably, because we live in a society in which it has become customary to deplore acts of violence and to take measures against them. History suggests, however, that in a society where there is little or no legal constraint upon violent behavior, it becomes not only acceptable but actually honorific, with status conferred upon those who are most successful in such activities. In any event, the point is that in these cases, at worst, the individual does not lose by being included among the universally coerced, and benefits to the extent that protection of private holdings against arbitrary takings is beneficial to all.

2. Generalized Externalities and the Theory of the State

The third and very significant category of circumstances in which self interest dictates acceptance of coercion is a generalization of the externalities phenomenon that plays a critical role in welfare economics (Pigou, 1932; Buchanan and Stubblebine, 1962). The issue arises when the individual's immediate self interest is served by a course of action that has more than offsetting effects upon others, so that if all individuals are left free to act in accord with their immediate interests there will be a net reduction in the product of the economy or the benefits of any sort available in the society, with the possibility that each and every person will end up worse off. This is not a matter of redistribution, as when a pickpocket obtains someone's wallet. Rather, it is a situation in which the entire inventory of benefits that is available for the members of the society to share is reduced by the self-interested actions of every individual.

What is critical here is the fact that such damaging actions do not constitute irrational behavior on the part of the individual. In the absence of a rule that precludes everyone from the socially damaging behavior in question, the best course open to each and every individual is to behave in such a detrimental fashion.

A standard example will make this clear. Consider the case of automotive emissions that are very harmful to health, and suppose that they can be avoided if an expensive suppression device, costing D dollars, is installed on every vehicle. In a city with 2 million autos the contribution of any one of them to deterioration of air quality is negligible. If no other person installs an emission suppressor, it would be a quixotic act of some one person to spend the D dollars to install the suppressor on his own vehicle, since this would make no discernable difference to air quality. Moreover, even if a law requiring suppressors on all vehicles were adopted and enforced, any one car owner could benefit by being granted a special and unique exemption, since his emissions would hardly affect the purity of the air. Yet, if the additional medical bills and cleaning cost resulting from failure to suppress everyone's emissions add up to more than D dollars per vehicle owner, failure to adopt the coercive suppressor installation law will clearly be damaging to all. There is no redistribution issue here. No one is in need of protection from the predation of others. Nor is any individual protected from inability to make rational decisions. Rather, it is only the community as a whole that effectively has the option of choosing between rational and irrational behavior, that is, behavior whose consequences the individual herself considers to be undesirable.

It is important to recognize, as is emphasized in the economic literature, that externalities can be as damaging to the interests of society when the affected activities are themselves beneficial as when they are detrimental. The example just discussed involves pollution emissions that are inherently damaging to others, and the problem is that, though some level of emissions is unavoidable, or further suppression beyond some low level is impractical, in the absence of rules individuals will end up emitting far more than is consistent with the public interest. The opposite result occurs where the externality-generating activity is beneficial. Here society's interests will be harmed because without coercion too little of such an activity will be undertaken.

A clear and important example is expenditure on the R&D that is plainly of crucial importance for economic growth. It has long been observed that much of the benefit from innovative activities goes to persons other than the inventors or those who invested in the process. This beneficial externality may, indeed, be far greater than generally recognized. If the bulk of the more than 10-fold rise in per capita GDP in the U.S. and much of Western Europe since the beginning of the industrial revolution is attributable to innovation, and one can estimate that less that 10 percent of GDP goes to persons who participate in the innovation process, it follows that the bulk of the beneficial externalities deriving from the efforts of the latter ultimately go to others. This means, and many studies confirm, that the incentives for innovative activity provided by the market are likely to be inadequate to induce a voluntary level of investment in innovation that is optimal in terms of the social interest.³ This suggests that coercive collection of taxes by government to provide additional resources for innovation facilitating activities, such as basic research, can be beneficial to the entire community, particularly in the long run.

3. Size of the Community and Private Steps to Deal with Externality Issues

In a classic article, Ronald Coase (1960) shows, among other things, that where only a small number of decision makers is involved, a process of voluntary bargaining and compensatory payments by those affected by an externality may be able to provide an optimal result. In effect the "victim" of a detrimental externality can bribe its generator to cease and desist, or at least to cut back on the damaging activity to an optimal degree. Here, because only a few persons are involved, the need for governmental coercion patently is limited, and may even prove to be too much of a good thing.

That numbers make the difference for the rationality of voluntarily accepted coercion has long been recognized. For example, more than two centuries ago Hume, with his powerful insight wrote

Two neighbors may agree to drain a meadow, which they possess in common; because it is easy for them to know each other's mind; and each must perceive that the immediate consequence of his failing in his part, is the abandonment of the whole project. But it is very difficult, and indeed impossible, that a thousand persons should agree in any such action; it being difficult for them to concert so complicated a design and still more difficult for them to execute it; while each seeks a pretext to free himself of the trouble and expense, and would lay the whole burden on others. Political society easily remedies both these inconveniences...⁴

In these few words, Hume lays out much of the welfare economics that underlies the theory of the state, and brings out the importance of the presence of a substantial number of inhabitants for its rationale.

4. Government Activities that Fall into the Category of Externalities

Economic externalities are widespread, indeed arguably ubiquitous. The literature of welfare economics provides a profusion of illustrations. However, here it is more to the point to offer several examples in areas not usually cited in this arena. The illustrations are inflation, recession and unemployment and defense against terrorism.

Hyper inflation brings the point out most dramatically. When inflation proceeds at the fantastic rates experienced in Germany after the First Word War or, more recently, in Latin America and Israel, clearly money loses its value as it is being pocketed by the recipient. In such an economy, in the absence of governmental intervention, it is plainly in the interest of the recipient of any cash to spend it as quickly as it can be get rid of, before it becomes virtually worthless. But that is precisely the pattern of behavior most likely to exacerbate the inflation. And no one individual can afford to do otherwise or can achieve anything by doing so. Only strong and essentially coercive governmental action can bring the explosion of prices to an end, and has repeatedly done so in the past. This is clearly an example in which voluntary acceptance of coercion may be the only rational response by members of the public. Any one individual would be irrational to undertake unilaterally to curb hasty spending, yet it would be perfectly rational to vote for a government that coerces that person, along with everyone else, to do so.

The opposite argument clearly applies to an effort to counteract recession and unemployment. The enhanced risk of loss of jobs and investments in such circumstances provides a powerful incentive for the individual to curb spending and save as much as possible for the imminent rainy day. But, at least from the point of view of a Keynesian, this is the reverse of what the situation requires. By taking such defensive measures the individuals collectively do as much as they can to bring upon themselves the very problems against which they seek protection. Acting individually, they can do nothing to help bring the problem to an end. But if they vote support for a government that adopts appropriate and universally applied coercive measures they can achieve what unconstrained behavior makes impossible for them.

Finally, it is appropriate to end with an issue that is entirely removed from economics and that thereby underscores the broad pertinence of the externalities analysis. This is the issue of defense expenditure, in particular in its most recent form, defense against the threat of terrorism. Economists recognize the role of externalities here, and refer to such defense preparation as a public good, meaning that if it protects the society it protects all of its members, without an increase in cost resulting from an expansion in the number of recipients of its benefits. Once again, the individual is powerless to act effectively in this arena, and an isolated outlay by the individual for this purpose cannot be expected to achieve anything. Only by agreeing to use of the coercive powers of government to collect the required resources can the public obtain the benefit that it may value far higher than the cost.

5. Conclusion

The essential feature that defines a democratic government is voluntary agreement by the members of the public to subject themselves to its coercion. As is true of any paradox, despite its appearance there are good and logical reasons for them to do so. The logic of externalities analysis that is provided by the economics of welfare is a critical component of that explanation. Moreover, the phenomena to which this explanation applies are neither rare nor unimportant. Military defense, measures to counteract inflation and recession and the encouragement of innovation are hardly minor issues, and there are many more, including environmental protection, congestion in transportation and residences and a host of others. If this is not the full story of the logic of intervention by the state, it certainly is a good part of the tale.

WILLIAM J. BAUMOL

NOTES

- 1. On the general subject see (Baumol, 1952), (Downs, 1957), (Buchanan and Tullock, 1962) and (Olson, 1965).
- 2. Protection of the law against random and irrational violence is an example in which redistribution is not involved.
- 3. The market, however, does provide a higher share of the rewards to innovators than this suggests. A very substantial number of firms, many of them major enterprises, engage voluntarily in licensing and trading of their privately owned technology, thereby internalizing at least part of the externality. For example, newspaper reports suggest that in 2001

approximately 20 percent of IBM's net profits derived from technology license fees. On this subject see Baumol (2002 chapters 6 and 7).

4. (Hume, 1739). Olson (1965) also brings out the importance of the number of the governed.

WHY GOVERNMENT SUCCEEDS

Government accomplishes some ambitious goals but fails miserably in meeting others. If government can send a man to the moon, why can it not eliminate poverty? If government can bomb the Taliban with deadly precision, why can it not control medical costs?

1. Special Interests

Most explanations for such differences focus on the explicitly political, highlighting two related themes:

(1) A policy succeeds only if government officials really want a program to attain its stated goals. Policy fails when the goals of politicians differ from those formally stated. The intent behind pork barrel projects, for example, may be to spend money in a legislative district, rather than to control floods or to protect the environment. (2) Interest groups mold policy in ways that defeat the purpose of the program. Economic regulation is the classic example, but the deflection of goals by organized interests has also been claimed to undermine everything from social initiatives (Lowi, 1979) to economic growth (Olson, 1982).

This last idea has been extended in several ways. When voters are uncertain about who will lose and who will gain from a policy, a majority of voters may oppose a policy that, were it implemented, would benefit a majority (Fernandez and Rodrik, 1991; Glazer and Konrad, 1993). And even when voters unanimously prefer a policy over the status quo, the attempt by different groups to gain at the expense of others can lead them to delay adoption of the policy; such delay may be an effective way of showing that the benefits of the policy for that group are low and therefore that gaining its support requires giving it greater benefits (see Alesina and Drazen, 1991).

The influence of special interests is also a central element of the Transaction Costs explanation for government failure (Dixit, 1996, who views politics as constrained by asymmetric information and by limited commitment possibilities).

Implicit in these analyses is the belief that government could implement beneficial policies if politicians had the right incentives and if special interests were weaker.

2. Characteristics of Problems

But the features of the problems government addresses, and the innate characteristics of policy, may also explain some of the successes and failures. Some problems may be difficult to solve even for a government with the best intentions, because economic conditions and behavior create constraints which make policy ineffective in many areas.

Four elements appear to be prominent in explaining the success or failures of policies that are adopted (see Glazer and Rothenberg, 2001).

2.1. Credibility

Credibility requires officials to persuade others that government will follow through on the actions promised. Credibility will be especially important when the success of a policy requires government to induce firms and individuals to make costly, irreversible, investments. But an elected government can be thrown out of office and lacks many commitment methods (such as contracts enforceable by the courts) available to firms or consumers, making credibility problematic. These constraints have been especially well studied in macroeconomics (for surveys see Persson, 1988; Persson and Tabellini, 1990; Cukierman, 1992; for a more political perspective, see Alesina and Rosenthal, 1995 and Keech, 1995). Dixit (1996) discusses the difficulty that government has in committing to future policies and the consequences of that difficulty. One way commitment problems are overcome is by an external agency: the IMF and the World Bank have played this role, although their motives and achievements are subject to controversy.

Sometimes public policies that are the least credible may be the most effective. For example, when future income is thought to be guaranteed, redistribution may be undermined by reduced work effort or savings by the beneficiaries. Redistributive policy may therefore be more effective if its continuance is in doubt.

2.2. Rational Expectations

Rational expectations refer to the collection of, and the sophisticated response to, information by decision makers. In general, policies readily anticipated and easily counteracted by economic agents are most likely to fail.

For example, rational consumers who foresee future taxes may increase savings if government increases its budget deficit, thereby negating the stumulative effects of fiscal policy (see Barro, 1989). Or rational workers who expect the central bank to stimulate the economy by expanding the money supply may anticipate inflation, demand higher wages, and thus negate the monetary stimulus. Similarly, offsetting behavior by consumers may negate the aims of regulations.

2.3. Crowding Out / Crowding In

Crowding out or, alternatively, crowding in, appears when the consumption or production of a good varies with the amount other firms or persons consume and produce. With crowding out, activity is reduced (e.g., when governmental subsidies to the arts, to medical research, or to universities, reduce private contributions). With crowding in, activity is increased (for instance, with fad behavior, where the participation by some in an activity makes it attractive to others). Depending upon whether the activity in question eases or obstructs the achievement of government goals, crowding out or crowding in may have different effects on what government can accomplish.

Regulation of personal behavior is especially constrained by crowding out. Consider the use of seatbelts in automobiles. The consensus is that offsetting behavior is substantial and that the increase in reckless driving has endangered pedestrians (Peltzman, 1975; Blomquist, 1988; Keeler, 1994). Similarly, some evidence suggests that air bags have reduced injuries less than hoped. The evidence, analogous to the findings for seat belts, shows that air bags cause more reckless driving (Peterson et al., 1995).

2.4. Multiple Equilibria

The idea of multiple equilibria refers to the theoretical and empirical possibility for different outcomes to be produced by the same circumstances. The important point is that on some issues government may determine which equilibrium is brought about. Thus, some government policy can be viewed as an attempt to nudge behavior towards a particular equilibrium. Though the existence of multiple equilibria does not guarantee the success of policy, it can provide opportunities for success, since government policy can induce a switch from chaos to a coordinated equilibrium, or from a bad to a good equilibrium.

Coordination problems are important instances where policy can be effective. Traffic laws (it is in my interest to stop at a red light because I expect the other drivers facing a green light to proceed), and daylight saving time are good examples of this.

But multiple equilibria are not limited to coordination problems. For example, policies aimed at reducing cigarette smoking appear to have been effective by inducing a shift from one equilibrium to another, where multiple equilibria can appear because an individual's propensity to smoke can vary with the number of other smokers.

2.5. Interaction of Features

The factors discussed above are inter-related. Often the beliefs of firms and consumers about what government will do, and the reactions of economic actors to the policies, are based on a rational analysis of what incentives or pressures government will face or what changes will occur (for example, through elections). Therefore, estimating the credibility of a policy often requires considering rational expectations of future policy. And to determine the effects of a credible policy it is also necessary to consider the behavior of economic actors in response to the policy, which can depend in part on what people expect the effects to be. Similarly, issues of crowding can be prominent, as when a change in the behavior of some people induces others to react in the same way (perhaps changing political pressures and expectations about policy along the way), thereby weakening or strengthening credibility. Under some, but not all, conditions

these updated expectations can reinforce the private behavior that government desires. Multiple equilibria can thus arise when one actor's behavior can affect the behavior of others, with the special characteristic that it allows a temporary policy to have permanent effects.

When the desired behavior by individuals or firms generates crowding in of that behavior, when people anticipate such crowding in, and when they believe that government is committed to pursuing the policy, they become yet more willing to engage in that behavior, thus making the policy self-sustaining. Crowding in may be sufficiently powerful to move the economy from one equilibrium to another, with individuals and firms continuing to behave in the manner that government desired even after government ends the policy. When some or all of these conditions are absent, a policy can be self-defeating, making success unlikely.

3. Example of Success

These features may explain the regulatory success in reducing chlorofluoro-carbon (CFC) production. The policies affected firms which produced inputs for firms in other industries and the actions of one set of firms undermined the ability of the other set of firms to hold out and violate regulatory standards.

Believing that the long-term prospects for the chemical's production were slim, manufacturers of products that used CFCs invested in technology to allow substitutes (Benedick, 1991). This undermined claims that firms using CFCs had no alternative. Given reduced demand for their product and an incentive to invest in goods that manufacturers wanted, CFC capacity and opposition to regulations also declined. Production of CFCs fell from about 1 million tons in 1986 to about 200,000 tons in 1995. Thus, one equilibrium may have had no investment in CFC substitutes and its continued production and use; the other equilibrium had investment in the production of less harmful chemicals and a drastic reduction in CFC use. The absence of vertical integration induced firms to invest, and allowed government to achieve its regulatory goals.
