Designation: D6000/D6000M – 15$^{\varepsilon 1}$

Standard Guide for Presentation of Water-Level Information from Groundwater Sites[1]

This standard is issued under the fixed designation D6000/D6000M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε^1 NOTE—Editorially corrected designation to match units of measurement statement in September 2015.

1. Scope*

1.1 This guide covers and summarizes methods for the presentation of water-level data from groundwater sites.

1.2 The study of the water table in aquifers helps in the interpretation of the amount of water available for withdrawal, aquifer tests, movement of water through the aquifers, and the effects of natural and human-induced forces on the aquifers.

1.3 A single water level measured at a groundwater site gives the height of water at one vertical position in a well or borehole at a finite instant in time. This is information that can be used for preliminary planning in the construction of a well or other facilities, such as disposal pits. Hydraulic head can also be measured within a short time from a series of points, depths, or elevation at a common (single) horizontal location, for example, a specially constructed multi-level test well, indicates whether the vertical hydraulic gradient may be upward or downward within or between the aquifer.

NOTE 1—The phrases "short time period" and "finite instant in time" are used throughout this guide to describe the interval for measuring several project-related groundwater levels. Often the water levels of groundwater sites in an area of study do not change significantly in a short time, for example, a day or even a week. Unless continuous recorders are used to document water levels at every groundwater site of the project, the measurement at each site, for example, use of a steel tape, will be at a slightly different time (unless a large staff is available for a coordinated measurement). The judgment of what is a critical time period must be made by a project investigator who is familiar with the hydrology of the area.

1.4 Where hydraulic heads are measured in a short period of time, for example, a day, from each of several horizontal locations within a specified depth range, or hydrogeologic unit, or identified aquifer, a potentiometric surface can be drawn for that depth range, or unit, or aquifer. Water levels from different vertical sites at a single horizontal location may be averaged to a single value for the potentiometric surface when the vertical gradients are small compared to the horizontal gradients. The potentiometric surface assists in interpreting the gradient and horizontal direction of movement of water through the aquifer. Phenomena such as depressions or sinks caused by withdrawal of water from production areas and mounds caused by natural or artificial recharge are illustrated by these potentiometric maps.

1.5 Essentially all water levels, whether in confined or unconfined aquifers, fluctuate over time in response to natural- and human-induced forces. The fluctuation of the water table at a groundwater site is caused by several phenomena. An example is recharge to the aquifer from precipitation. Changes in barometric pressure cause the water table to fluctuate because of the variation of air pressure on the groundwater surface, open bore hole, or confining sediment. Withdrawal of water from or artificial recharge to the aquifer should cause the water table to fluctuate in response. Events such as rising or falling levels of surface water bodies (nearby streams and lakes), evapotranspiration induced by phreatophytic consumption, ocean tides, moon tides, earthquakes, and explosions cause fluctuation. Heavy physical objects that compress the surrounding sediments, for example, a passing train or car or even the sudden load effect of the starting of a nearby pump, can cause a fluctuation of the water table (**1**).[2]

1.6 This guide covers several techniques developed to assist in interpreting the water table within aquifers. Tables and graphs are included.

1.7 This guide includes methods to represent the water table at a single groundwater site for a finite or short period of time, a single site over an extended period, multiple sites for a finite or short period in time, and multiple sites over an extended period.

1.8 This guide does not include methods of calculating or estimating water levels by using mathematical models or determining the aquifer characteristics from data collected

[1] This guide is under the jurisdiction of ASTM Committee D18 on Soil and Rock and is the direct responsibility of Subcommittee D18.21 on Groundwater and Vadose Zone Investigations.

Current edition approved April 15, 2015. Published May 2015. Originally approved in 1996. Last previous edition approved in 2008 as D6000 – 96 (2008). DOI: 10.1520/D6000_D6000M-15E01.

[2] The boldface numbers in parentheses refer to a list of references at the end of this standard.

*A Summary of Changes section appears at the end of this standard during controlled aquifer tests. These methods are discussed in Guides D4043, D5447, and D5490, Test Methods D4044, D4050, D4104, D4105, D4106, D4630, D4631, D5269, D5270, D5472, and D5473.

1.9 Many of the diagrams illustrated in this guide include notations to help the reader in understanding how these diagrams were constructed. These notations would not be required on a diagram designed for inclusion in a project document.

1.10 This guide covers a series of options, but does not specify a course of action. It should not be used as the sole criterion or basis of comparison, and does not replace or relieve professional judgment.

1.11 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.12 *This guide offers an organized collection of information or a series of options and does not recommend a specific course of action. This document cannot replace education or experience and should be used in conjunction with professional judgment. Not all aspects of this guide may be applicable in all circumstances. This ASTM standard is not intended to represent or replace the standard of care by which the adequacy of a given professional service must be judged, nor should this document be applied without consideration of a project's many unique aspects. The word "Standard" in the title of this document means only that the document has been approved through the ASTM consensus process.*

3. Terminology

3.1 For common definitions of terms in this standard, refer to Terminology D653.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *groundwater site*—as used in this guide, a site is meant to be a single point, not a geographic area or property, located by an *X*, *Y*, and *Z* coordinate position with respect to land surface or a fixed datum. A groundwater site is defined as any source, location, or sampling station capable of producing water or hydrologic data from a natural stratum from below the surface of the earth. A source or facility can include a well, spring or seep, and drain or tunnel (nearly horizontal in orientation). Other sources, such as excavations, driven devices, bore holes, ponds, lakes, and sinkholes, which can be

[3] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

[4] The last approved version of this historical standard is referenced on www.astm.org.

shown to be hydraulically connected to the groundwater, are appropriate for the use intended.

3.2.2 *hydrograph, n*—for groundwater, a graph showing the water level or head with respect to time (**2**).

3.2.3 *water level, n*—for groundwater, the level of the water table surrounding a borehole or well. The groundwater level can be represented as an elevation or as a depth below a physical marker on the well casing.

4. Summary of Guide

4.1 The Significance and Use section presents the relevance of the tables and diagrams of the water table and related parameters.

4.2 A description is given of the selection process for data presentation along with a discussion on water level data preparation.

4.3 Tabular methods of presenting water-levels:
4.3.1 Tables with single water levels, and
4.3.2 Tables with multiple water levels (**3**).

4.4 Graphical methods for presenting water levels:
4.4.1 Vertical gradient at a single site,
4.4.2 Hydrographs,
4.4.3 Temporal trends in hydraulic head,
4.4.4 Potentiometric maps,
4.4.5 Change maps,
4.4.6 Water-table cross sections, and
4.4.7 Statistical comparisons of water levels.

4.5 Keywords.

4.6 A list of references is given for additional information.

5. Significance and Use

5.1 Determining the potentiometric surface of an area is essential for the preliminary planning of any type of construction, land use, environmental investigations, or remediation projects that may influence an aquifer.

5.1.1 The potentiometric surface in the proposed impacted aquifer must be known to properly plan for the construction of a water withdrawal or recharge facility, for example, a well. The method of construction of structures, such as buildings, can be controlled by the depth of the groundwater near the project. Other projects built below land surface, such as mines and tunnels, are influenced by the hydraulic head.

5.2 Monitoring the trend of the groundwater table in an aquifer over a period of time, whether for days or decades, is essential for any permanently constructed facility that directly influences the aquifer, for example, a waste disposal site or a production well.

5.2.1 Long-term monitoring helps interpret the direction and rate of movement of water and other fluids from recharge wells and pits or waste disposal sites. Monitoring also assists in determining the effects of withdrawals on the stored quantity of water in the aquifer, the trend of the water table throughout the aquifer, and the amount of natural recharge to the aquifer.

5.3 This guide describes the basic tabular and graphic methods of presenting groundwater levels for a single groundwater site and several sites over the area of a project. These methods were developed by hydrologists to assist in the interpretation of hydraulic-head data.

5.3.1 The tabular methods help in the comparison of raw data and modified numbers.

5.3.2 The graphical methods visually display seasonal trends controlled by precipitation, trends related to artificial withdrawals from or recharge to the aquifer, interrelationship of withdrawal and recharge sites, rate and direction of water movement in the aquifer, and other events influencing the aquifer.

5.4 Presentation techniques resulting from extensive computational methods, specifically the mathematical models and the determination of aquifer characteristics, are contained in the ASTM standards listed in Section 2.

6. Selection and Preparation of Water-Level Data

6.1 Measurement and recording of water levels should be subject to rigorous quality-control standards. Correct procedures must be followed and properly recorded in the field and the office in order for the water table to represent that in the aquifer.

6.1.1 Field quality controls include the use of an accurate and calibrated measuring device, a clearly marked and unchanging measuring point, an accurate determination of the altitude of the measuring point for relating this site to other sites or facilities in the project area, notation of climatic conditions at the time of measurement, such as barometric pressure or tide levels, a system of validating the water-level measurement, and a straightforward record keeping form or digital device.

6.1.2 Recording devices must be checked regularly to ensure that a malfunction has not occurred and that data is being accumulated and is in a usable form. Many permanently installed devices record water levels at fixed intervals, for example every 15 min. Unless the device is designed to be activated when sudden changes occur, events that cause an instantaneous and short term fluctuation in the water table may not be recorded, for example, earthquakes and explosions. Continuous recording analog devices are used to detect these types of events.

6.2 To interpret the significance of the raw water-level data, usually the information is prepared by adjusting to other values by using simple mathematics. For example, the water-level values in relationship to the measuring point are reduced to the altitude of the water table by subtracting the water level (+ or −) from the altitude of the measuring point. This procedure applied to all water levels from sites in the project area reduces these water levels to a common plane for comparison.

6.2.1 Preparation of water-level data for interpreting upward or downward trends over a period of time may require the use of simple regression or moving average/mean computations. A common analysis of the water-level data involves the selection of yearly highs and lows for use in computing high and low trends.

6.2.2 A technique of presenting water levels is to give the value as below or above land surface. This method requires that the numerical relationship of the measuring point and land surface be determined and the value of the measuring point be subtracted (+ or –) from the water-level measurement. This information gives the relationship of a single water level to the land surface at a finite instant in time. At a long-termed monitoring site the fluctuations and trends are shown. These water levels cannot be completely related to other sites in the area without additional computation (determining altitude of water level).

6.2.3 On occasion, the interpretations of human-induced water-table fluctuations at a site are masked by natural events, such as oscillations caused by barometric pressure or ocean tide. The magnitude and frequency of these fluctuations can be determined by monitoring the barometric pressure, ocean tide, and water levels in wells outside the radius of influence of the principal monitored site.

7. Presentation of Water-Level Information

7.1 *Tabular Methods of Presenting Water Levels*—Tables of groundwater levels in project reports vary from single measurements included in lists of related information, for example, well inventory data (Practice D5254, Guides D5408, D5409, D5410, and D5474), to tables that represent a long-term comprehensive record of the water levels at a site. The water levels can be presented as values in feet or metres as related to the altitude, elevation, NAVD88, or other common level reference. These values can be for a time-interval, for example, daily or weekly, giving the high, low, mean, or median water level for each period. Other methods include presenting water levels for a specific time, for example, noon or midnight (**3**).

NOTE 2—NAVD88 is the North American Vertical Datum of 1988 (NAVD88). It is the vertical control datum of orthometric height established for vertical control surveying in the United States of America based upon the General Adjustment of the North American Datum of 1988. NAVD88 was established in 1991 by the minimum-constraint adjustment f geodetic leveling observations in Canada, the United States, and Mexico. NAVD88 replaced the National Geodetic Vertical Datum of 1929 (NGVD29), previously known as the Sea Level Datum of 1929. Other Countries or jurisdictions may use other systems.

7.1.1 *Tables with Single Water Levels*—A single water level is normally included as one of the data items in a table entitled the "description of selected wells" or "groundwater site-inventory data" in many project reports. This table contains pertinent information from selected groundwater sites of the studied area. Table 1 is an abbreviated example of a "groundwater site-inventory data." The data included with the water level varies depending upon the priorities of the project, however, the site identification is standard information in most tables.

7.1.2 *Tables of Multiple Water Levels from Single Sites*—The following are common types of tables used to present groundwater levels from single sites. The format usually depends upon the method and frequency of data collection. Each individual table commonly includes a heading of information that describes the groundwater site. This heading normally contains the site location, owner, aquifer, site or well characteristics, instrumentation, datum and measuring point, relevant remarks, period of record, and extremes for the period of record.

7.1.2.1 *Tables of High and Low Water Levels for a Selected Period*—The water levels are retrieved from the continuous analog or digital recorders. The period for selecting the water levels can be of any length, for example, daily, weekly, monthly, seasonally, semiannually, yearly, and for the total period of record. For aquifer testing, for example, it can be for a background period and stress period separately. The table of water levels can be the high, low, or both values for the selected period of record (see Table 2).

7.1.2.2 *Mean Water Levels for a Selected Period*—The water levels are retrieved and the mean water levels determined for a specific period. The mean water level can be determined from the automatic data recorders or, with more difficulty, manually. The period for determining each water level may be daily, five-day, monthly, etc., and should be determined based on the objective of the project (see Table 3).

7.1.2.3 *Periodic Fixed-time Reading*—Periodic water levels can be selected from the records. The interval between each selected water level may be daily, every fifth day and end of month, weekly, or monthly, with the selected time-of-day constant, for example, the noon reading (see Table 4).

7.1.2.4 *Intermittent Water-level Measurements*—Water levels are considered intermittent when determined manually by instruments such as a steel tape or an electronic water-detection device. These measurements are usually collected by field personnel on a periodic time schedule at groundwater sites where there is no continuous recorder (see Table 5).

7.1.3 *Tables of Water Levels from Multiple Sites*—Tables that include water levels from more than one groundwater site allow for comparison of data from related locations (see Table 6).

7.2 *Graphical Methods of Presenting Water Levels*—Methods to represent water levels include those at a single groundwater site for a finite or short period of time, a single site over an extended period of time, multiple sites for a finite or short period in time, and multiple sites over an extended period of time. Multiple sites where groundwater levels are

measured by a continuous recorder or periodically by other methods are valuable for interpreting changes in aquifers caused by discharge and recharge events. These changes can be illustrated by maps and cross sections, and by the comparison of hydrographs.

7.2.1 The simplest category of the presentation of a water level is from a single groundwater site for a finite instant or short period in time. Water levels measured at a single groundwater site over a period of time give climatic trends and the effects of human and natural stresses on water in the aquifer. Water levels can be measured continuously by recorders and intermittently by a steel tape or electronic devices.

7.2.2 To interpret hydraulic-head data over the area of a project or political entity, multiple groundwater sites may need to be included in the analysis. These sites should be in the same aquifer, widely distributed, and the water levels measured during a short period.

7.2.3 *Vertical Gradient at a Single Site*—Multiple water levels can be measured within a short period of time from a series of vertical positions in different aquifers at a specially constructed groundwater site. The data gathered indicates the hydraulic gradient of the water. Examples of the three gradient possibilities from tightly spaced piezometers in a single unit (**4**) are given in Fig. 1. An example of a downward gradient in eight aquifers (**5**) is given in Fig. 2. An example of a specially constructed well is a test hole where the water level is measured at progressively deeper positions in the aquifer or a series of aquifers. The well is open to the aquifer at progressively deeper depths and each opening is uniquely accessible for measurement of the water level by a pipe to the surface, or several piezometers or wells that are tightly spaced and each open at a different depth in the aquifer.

7.2.4 *Hydrographs*—The hydrograph is used to illustrate the fluctuation of the hydraulic head over a period of time at a groundwater site. Interpolated lines (areas of missing or indeterminate record) on hydrographs should be clearly identified. The hydrograph is accompanied commonly with time-related phenomena to help in the interpretation of the

TABLE 4 Abbreviated Table—Noon Water Levels For A Site

374638087054101. Map number 1.
LOCATION.—Lat 37°46'38″, long 87°05'41″, Hydrologic Unit 05140201, County Code 059, Owensboro East quadrangle, at Owensboro Municipal Utilities water treatment plant, 100 ft (30 m) south of south bank of Ohio River, 0.1 ml (0.2 km) northeast of Davies County High School. 0.3 ml (0.5 km) north of U.S. Highway 60, in Owensboro, Daviess County, Kentucky. Owner: Owensboro Municipal Utilities.
AQUIFER.—Glacial sand and gravel of Quaternary age. Aquifer code: 112OTSH.
WELL CHARACTERISTICS.—Drilled unused water-table well, diameter 12 in. (0.30 m), depth 104 ft (32 m), screened 74–104 ft (22.6–31.7 m).
DATUM.—Altitude of land-surface datum (from topographic map) is about 405 ft (123 m). Measuring point: Floor of recorder shelter 4.33 ft (1.32 m) above land-surface datum.
REMARKS.—Water level affected by pumping from nearby wells.
PERIOD OF RECORD.—February 1951 to current year.
EXTREMES FOR PERIOD OF RECORD.—Highest water level, 18.16 ft (5.54 m) below land-surface datum, May 5, 1983; lowest, 63.21 ft (19.27 m) below land-surface datum, Sept. 17, 1970.

TABLE 5 Example Table—Intermittent Water Levels For A Site

424202087542301. Local Number, RA-03/22E/21-0005.
LOCATION.—Lat 42°42'02″, long 87°54'23″, Hydrologic Unit 04040002. Owner: Chicago, Milwaukee, St. Paul, and Pacific Railroad Co., Racine County, Wisconsin.
AQUIFER.—Sandstone.
WELL CHARACTERISTICS.—Drilled unused artesian well, diameter 12 in. (0.30 m), depth 1,176 ft (358 m), cased to 586 ft (179 m), 10 in. (0.25 m) liner 976-1083 ft (297–330 m).
DATUM.—Altitude of land-surface is 730 ft (225 m) National Geodetic Vertical Datum of 1929. Measuring point: top of casing, 1.00 ft (0.30 m) above land-surface datum.
REMARKS.—Water level affected by regional pumping of wells.
PERIOD OF RECORD.—July 1946 to current year.
EXTREMES FOR PERIOD OF RECORD.—Highest water level measured, 109.00 ft (33.25 m) below land-surface datum, July 29, 1946; lowest water level measured, 264.70 ft (80.68 m) below land-surface datum, Mar. 3, 1981.

Water Level, in Feet Below Land-Surface Datum, Water Year October 1980 to September 1981

DATE	WATER LEVEL	DATE	WATER LEVEL	DATE	WATER LEVEL	DATE	WATER LEVEL	DATE	WATER LEVEL	DATE	WATER LEVEL

MAR 3	264.70	APR 6	257.40								

TABLE 6 Abbreviated Table—Water Levels From Multiple Sites

LOCATION.—State of Nevada.
WELL DEPTH.—Depths are referenced to Land-surface Datum (LSD).
PERIOD OF RECORD.—Interval shown spans period from earliest measurement to latest measurement, and may include intervals with no record.
WATER LEVELS.—Levels above LSD are listed as negative values.

Site ID	Well Depth (Ft)	Period of Record	Water Levels (Feet Below Land Surface)

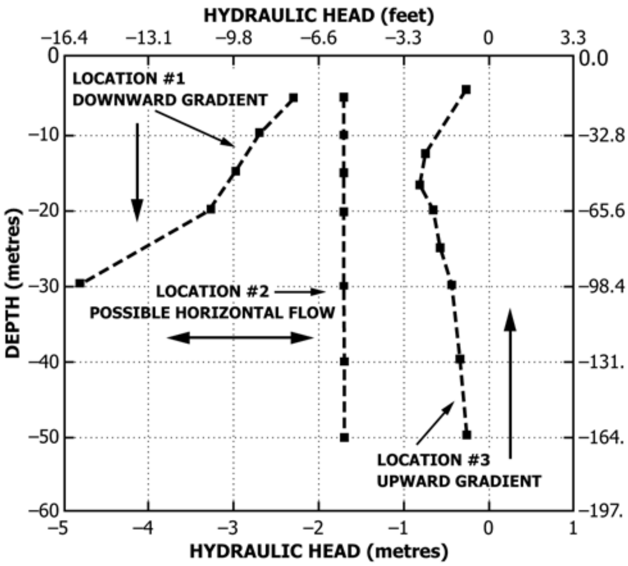
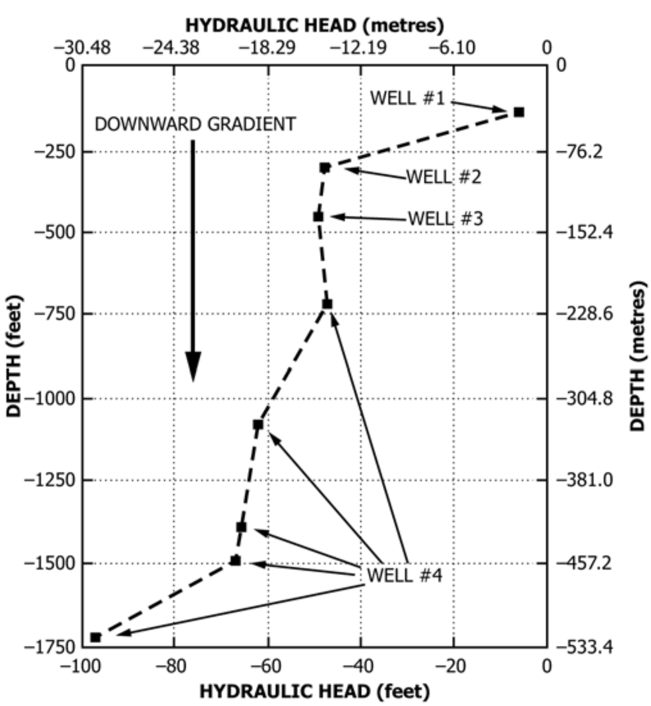
fluctuations, for example, precipitation. Recession curves of surface-water hydrographs are used to determine groundwater baseflow in the streams. Some examples of the hydrographs and combined phenomena for a groundwater site follow.



NOTE 1—Location No. 2 is fabricated to simulate horizontal flow.

FIG. 1 Hydraulic Gradient at Three Groundwater Locations (adapted from Ref (5))



NOTE 1—In this figure, water levels at 143 ft (43.58 m), 305 ft (92.96 m), and 460 ft (140.21 m) were measured in 1961, others in 1959. These data are from an area where little development had taken place at the time of the water-level measurements.

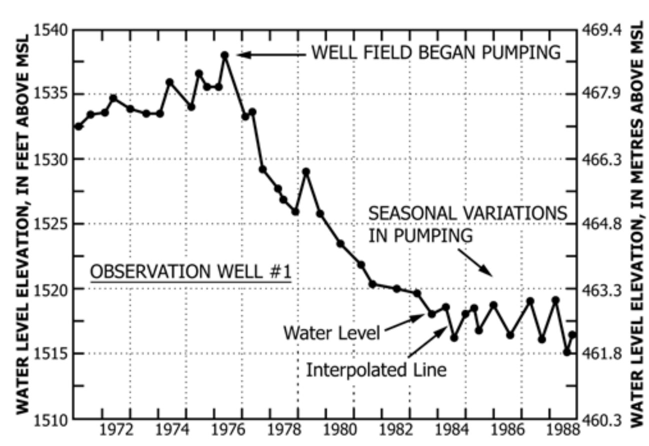
FIG. 2 Hydraulic Gradient at a Groundwater Location (data from four wells) (adapted from Ref (6))

7.2.4.1 *Simple Hydrograph*—The basic hydrograph of the water table at a groundwater site displays the natural and human-induced fluctuations over a period of time. The example hydrograph shows fluctuations controlled by natural conditions from 1971 to 1976, those resulting from pumping withdrawals that began in 1976, and those caused by seasonal variations in pumping that are apparent from 1984 to 1988 (see Fig. 3) (**6**).

7.2.4.2 *Hydrograph Compared with Precipitation that Results in Natural Recharge*—Precipitation that results in recharge to an unconfined aquifer can be analyzed by comparison of the timing and amount of rainfall with the hydrographs of shallow wells in the area. A method of displaying this relationship is by combining a water-table graph and a precipitation line or bar plot onto a single illustration. The time scales for the two sets of data are equal, and the water-table and precipitation data are scaled to emphasize the relationship of the values (see Fig. 4) (**1**). Rapid response to recharge events is evident where the travel path from the land surface to the aquifer is short or unrestricted, for example, a shallow sand formation or a karst topography. Heavy rainstorms can cause entrapment of air between the recharge water at the surface and a shallow water table. This recharge surge can increase the pressure of the trapped air creating a rapid decline in the water table and a resultant rise of water in open observation wells. The water table will rise when the entrapped air escapes by breaching the recharged water and continue to rise as the recharge water reaches the water table. In aquifers where restrictions occur, for example, intermediate clay layers or aquitards, the response can be dampened or delayed because of a much longer travel time.

7.2.4.3 *Hydrograph Compared with Artificial Recharge to the Aquifer*—Artificial recharge to aquifers can occur from methods that spread water on the land's surface, for example, irrigation, or from techniques that direct the water below the land's surface, for example, recharge wells and pits. This type of recharge can be monitored by wells in the area and illustrated by hydrographs (see Fig. 5).

7.2.4.4 *Hydrograph Compared with Barometric Pressure*—A change in barometric pressure causes water levels to fluctuate in open wells. The effects of barometric pressure often mask other influences that cause fluctuations of the water table. By plotting the hydrograph and barometric pressure on an



NOTE 1—The water level measurements in Fig. 3 average two values per year. These intermittent values are connected by interpolated lines to simulate a continuous hydrograph. Water levels determined by a nearly continuous digital recorder would result in a continuous hydrograph.

FIG. 3 Example of Simple Hydrograph (adapted from Ref (7))

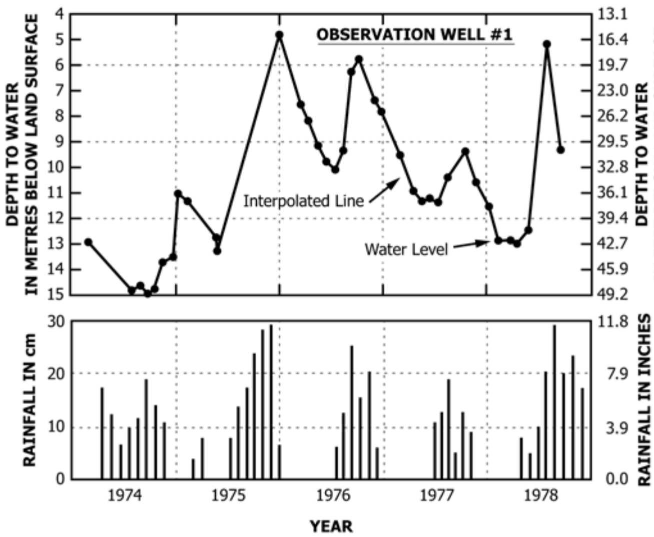


FIG. 4 Hydrograph and Precipitation Plot (adapted from Ref (8))

equal time scale, the correlation of oscillations can be demonstrated (see Fig. 6) (**10–11**).

7.2.4.5 *Hydrograph Compared with Withdrawals from the Aquifer*—Water withdrawals from an aquifer can result in the fluctuation and decline of the hydraulic head. The hydraulic head fluctuates depending upon the periodic oscillation in the amount of water withdrawn and decline when the water removed is more than water recharged to the aquifer. A hydrograph from a groundwater site compared with the withdrawal amounts displays the effect on the hydraulic head in the aquifer (see Fig. 7) (**10–12**).

7.2.4.6 *Hydrograph Compared with Tidal Effects*—The hydraulic head fluctuates semidiurnally in response to tides in the solid earth and in large bodies of surface water. The tides are caused by the gravitational attraction of the moon and sun upon the earth (see Fig. 8) (**13**). Fluctuations are obvious in confined aquifers that are next to an ocean where a rising tide compresses the underlying sediments (rising hydraulic head) and a falling tide allows the underlying sediments to expand (falling hydraulic head). The water table in unconfined aquifers near large surface water bodies fluctuates caused by the actual movement of water in the aquifer. Fluctuations caused by earth tides are obscure, but can be detected in confined aquifers of inland areas by mathematically removing the influence of other causes of hydraulic-head oscillations, such as the barometric pressure.

7.2.4.7 *Hydrograph Compared Earthquakes, Explosions, and Loading Effects*—Shock waves radiating out from earthquakes and explosions travel through the earth and along the earth's surface causing the elastic crust to compress and expand, resulting in a fluctuation of the hydraulic head (see Fig. 9). Loading effects on underlying sediments, for example, a train that moves through the area, can cause the hydraulic head to oscillate in response (**14**).

7.2.4.8 *Hydrograph Compared with Water Quality Parameters*—The fluctuation of the hydraulic head in an aquifer can indicate the movement of water containing natural- and human-induced chemical constituents toward an area of lower hydraulic pressure. A comparison of the hydrograph and a time-plot of the chemical constituents at a groundwater site can help in the interpretation of the origin and rate of movement of these constituents (see Fig. 10) (**9, 15**). Some of the constituents in the groundwater can originate from natural leaching because of recharge oscillations caused by climatic cycles. Artificial recharge of water from surface spreading or injection by pits or wells can leach or induce ions into the groundwater. Water that has a high concentration of dissolved solids, for example, seawater, is denser than fresh water and, therefore, will have a slight difference in the water table when compared to bordering fresh water.

7.2.4.9 *Hydrograph Compared with Surface Stream*—The water table in unconfined aquifers that are next to and interconnected with streams and lakes, react rapidly to changes in the surface-water stage. The amount of fluctuation in the surface-water stage and the groundwater table is similar if the observation well is close to the stream (see Fig. 11). These fluctuations are dampened if the observation well is at some greater distance from the surface-water body. Oscillations in confined aquifers are caused by the loading effect of rising and falling surface-water stages (see 7.2.4.6 on tidal effects) (**16**).

7.2.4.10 *Hydrograph Compared with Air Temperature*—The water table in unconfined aquifers that are a few feet or metres below lands surface fluctuate in response to the thermal gradient between the mean air and groundwater temperatures, in that the capillary moisture and soil vapor move toward the medium having the lowest temperature (see Fig. 12) (**1, 17**). When the mean daily air temperature remains below freezing over time, the upward moving water freezes in the near surface soil material, forming a frost layer. Because of this water transfer, the groundwater table declines. Soon after the mean daily temperature rises above freezing, melted water from the frost layer moves downward as recharge causing a rise in the groundwater table. During the spring and summer months, evapotranspiration causes diurnal fluctuations of the shallow water table. If no recharge occurs during this period, the general trend of the water table will be downward.

7.2.4.11 *Hydrograph with Fluctuations Caused by Unusual Phenomenon*—The sudden rise of a hydraulic head may be a clue to a problem that has affected the aquifer, for example, a defective casing of a gas well that has allowed natural gas to escape into the aquifer (see Fig. 13). An undefined change of the hydraulic head may indicate a movement of water from one aquifer to another having a lower water table, perhaps from a failed casing or improperly constructed well (**18**).

7.2.4.12 *Hydrograph with Boxplots of Water Levels, Precipitation, Surface Water, and Evaporation*—An association of groundwater, surface water, and precipitation time-series graphs with statistical boxplots offers a useful combination for data interpretation. The boxplots concisely illustrate the median, 25th percentile, 75th percentile, skewness, and the outside and far-outside values for each of those data sets (see Fig. 14) (**19**).

7.2.4.13 *Multiple Hydrographs*—Hydrographs from multiple groundwater sites of an area can be compared to interpret the rate of water movement in an aquifer and between several aquifers (see Fig. 15) (**20–21**). Hydrographs from precisely

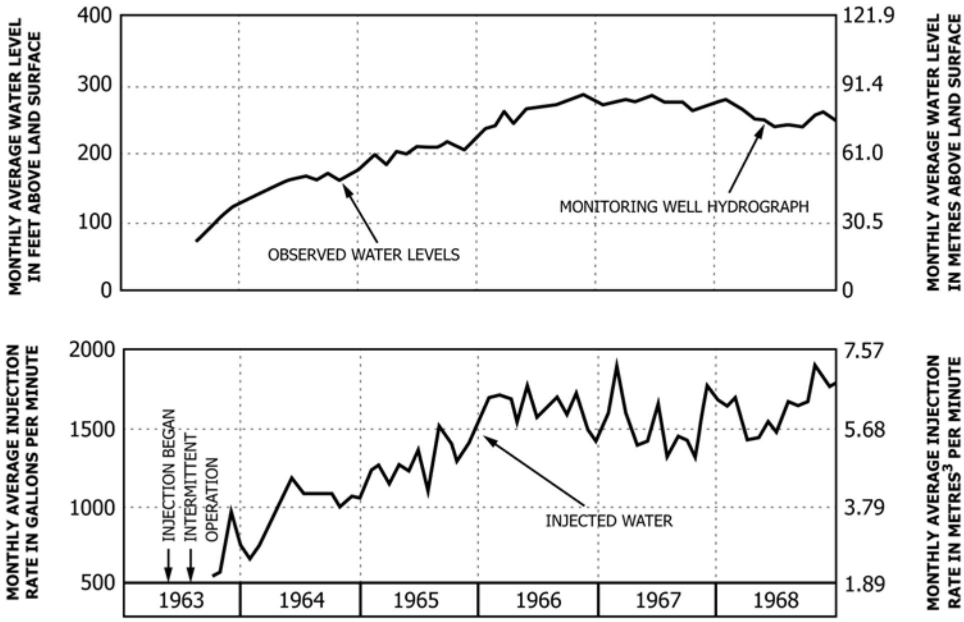

FIG. 5 Hydrograph Showing Effects of Artificial Recharge by Injection Well (adapted from Ref (9))

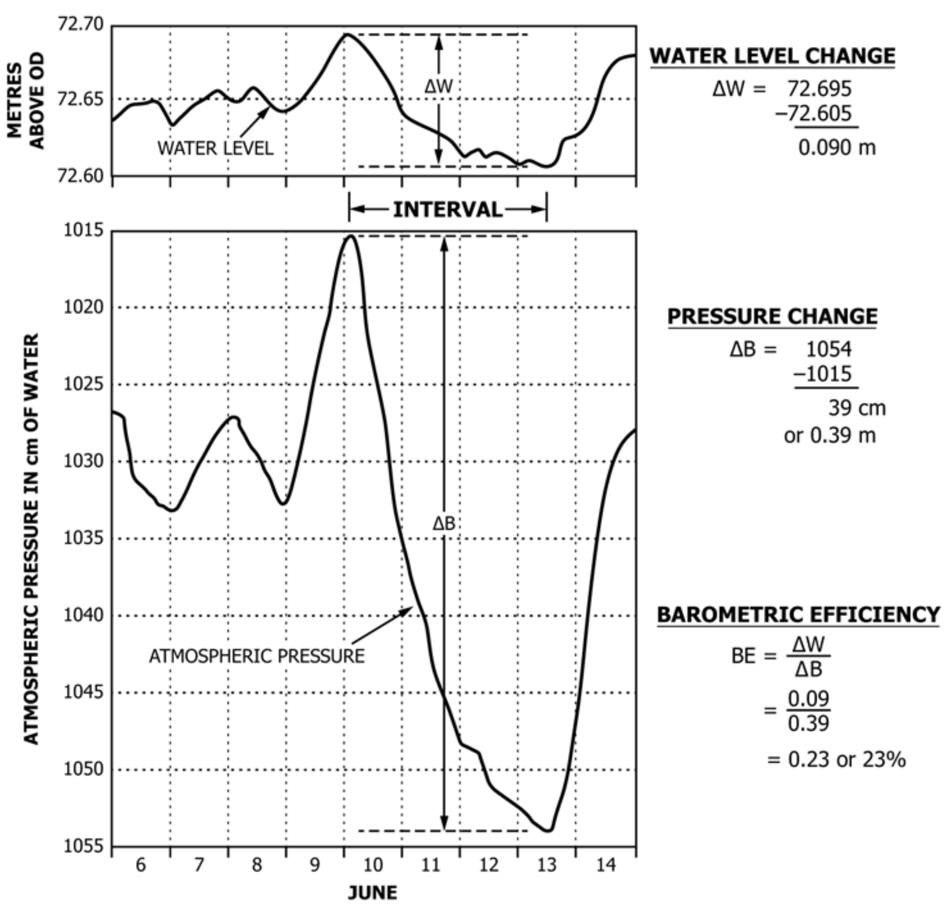
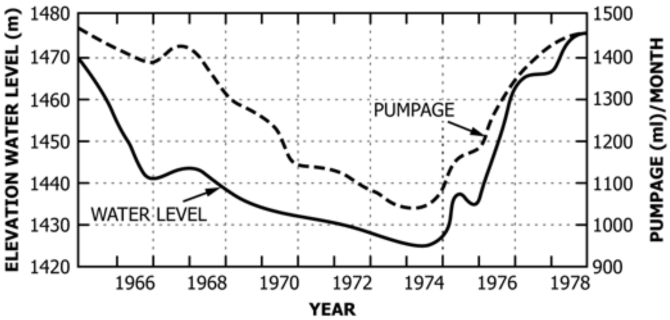


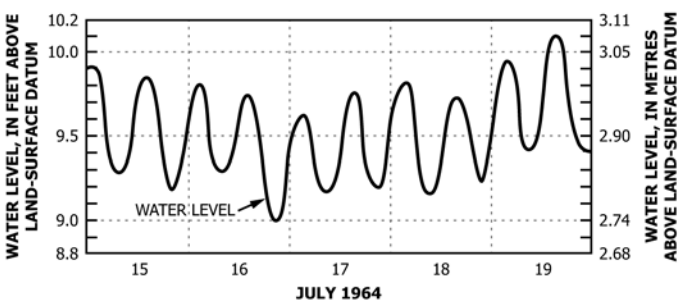
NOTE 1—The effect of barometric pressure can be removed from the water-table fluctuations by subtracting the value determined from multiplying the "barometric efficiency" (BE) times the amount of water-table fluctuation. The BE is a decimal number determined by dividing the change in water level (ΔW) by the change in barometric pressure (ΔB) over an interval of time ($BE = \Delta W/\Delta B$). These two values must be in the same units to calculate the *BE*, for example, if the water levels are in metres, then convert the barometric pressure to metres of water at 4°C (1000 millibars pressure = 10.197 m of water at 4°C).

FIG. 6 Hydrograph with Barometric Efficiency



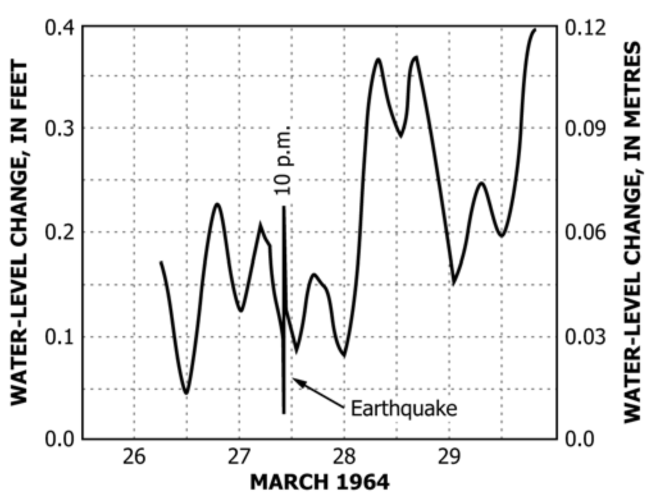
NOTE 1—This is a mined area where pumpage is for dewartering the mine. Pumpage exceeded recharge before 1975 resulting in a decline of the water level. Abnormally high rainfall beginning in 1975 resulted in increase recharge and a rise of the water level. Pumpage was increased to control the rise of the water level.

FIG. 7 Hydrograph with Pumpage (adapted from Ref (12))



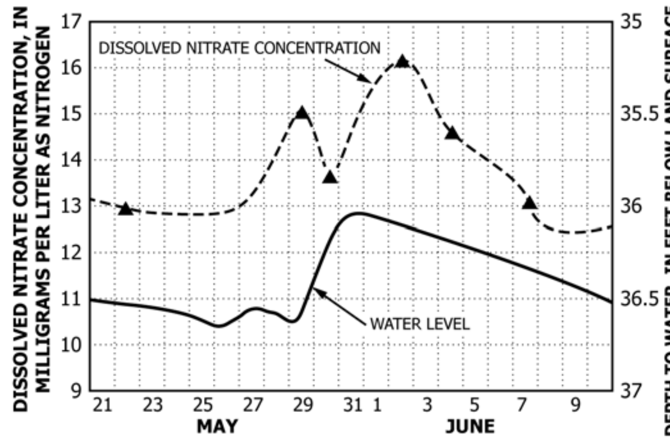
NOTE 1—This is an artesian aquifer.

FIG. 8 Hydrograph Showing Tidal Effects (adapted from Ref (13))



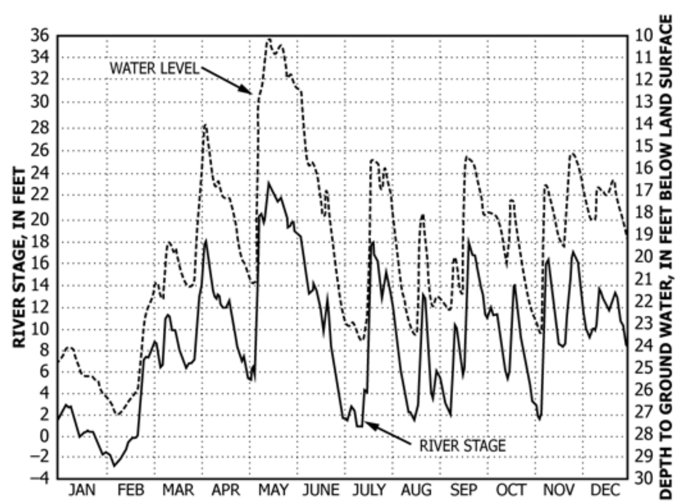
NOTE 1—March 27, 1964 Alaskan earthquake, well at Vincent Dome, Iowa.

FIG. 9 Hydrograph With Seismic Fluctuation (adapted from Ref (14))



NOTE 1—The rise in water level and nitrate concentration is the result of a storm. Graph lines are interpolated. To convert to metres, multiply feet value times 0.3048. ▲ = Analysed dissolved nitrate concentration.

FIG. 10 Hydrograph and Graph of Dissolved Nitrate Concentration (adapted from Ref (15))



NOTE 1—Well, screened in alluvium, is 1700 ft from the river. To convert to metres, multiply feet value times 0.3048.

FIG. 11 Hydrographs of River Stage and Water Levels in a Well (adapted from Ref (16))

positioned groundwater sites in an aquifer of a project area can be compared to determine the effect of distance from an impacted locality on the water table, for example, the water levels of monitoring wells for a recharge pit. The elapse-time effects of natural or artificial recharge can be evaluated by comparing hydrographs from a shallow and the underlying aquifers. The effects of distance from fluctuating surface-water bodies on adjacent aquifers can be shown by comparing the hydrographs

7.2.5 *Temporal Trends in Hydraulic Head*—The temporal trend of hydraulic head is dictated by many factors that contribute to the stress of an aquifer, for example, recharge of water to and discharge of water from the aquifer. All longer-term hydrographs exhibit a trend, either downward, level, upward, or cyclical.

7.2.5.1 *Trend Hydrograph*—At groundwater sites where the water level is measured by a continuous recorder, the trend can be determined by selecting the high, computing the mean, or selecting the low water level from a fixed period, for example, a day, week, month, or year, and plotting these values as a hydrograph. At groundwater sites where water levels are measured intermittently, the trend can be determined by selecting water levels from the same yearly period, for

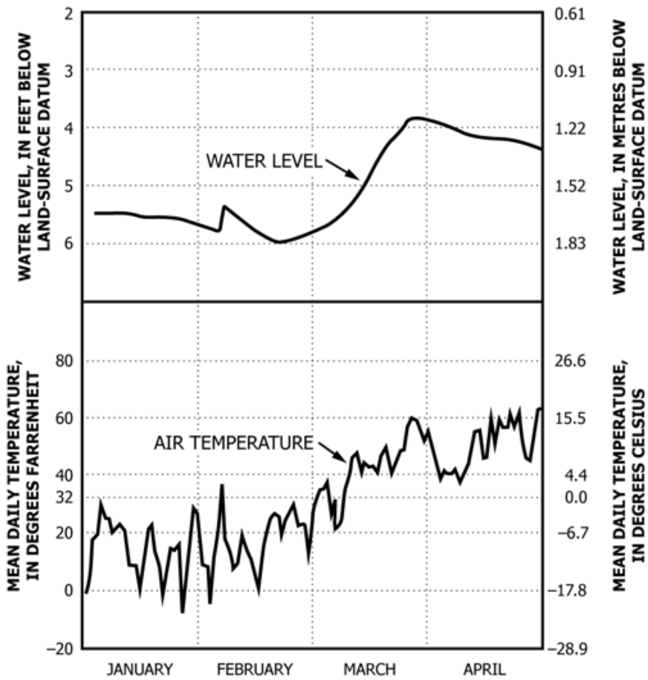


FIG. 12 Water Levels and Air Temperatures (adapted from Ref (17))

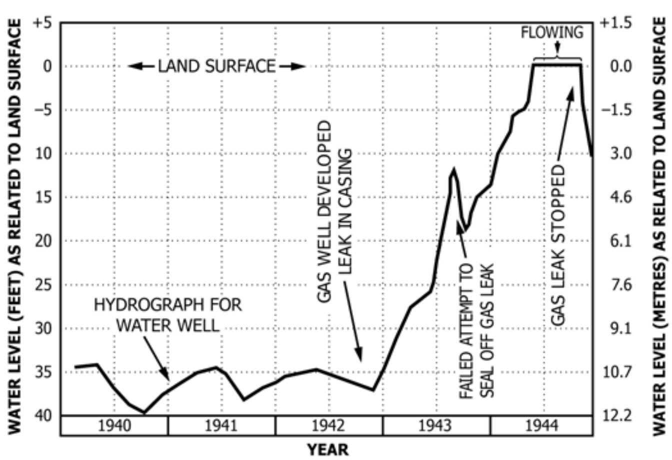

Note 1—Gas well was located five miles from water well.

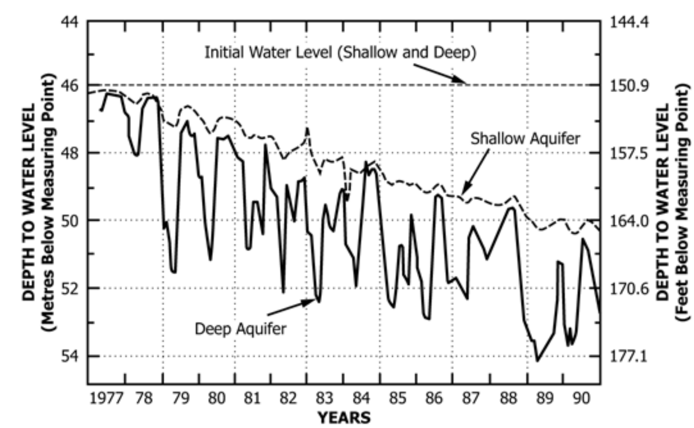

FIG. 15 Multiple Hydrographs Comparing Shallow and Deep Aquifers (adapted from Ref (21))

example, January or June, and plotting these values as a hydrograph (see Fig. 16) (**3, 22**).

7.2.6 *Potentiometric Maps*—Maps that illustrate the potentiometric surface commonly show the altitude of the hydraulic head as related to mean sea level (msl) or a fixed level in the vicinity of the project (see Fig. 17) (**6, 24, 25**). Potentiometric maps help in the interpretation of the hydraulic gradient, direction of water movement, and losing and gaining of surface-water bodies. The water levels used on the map need to be measured in a short-time period. These plots can be drawn on topographic maps or aerial photos to show the relationship of the hydraulic head to surface topography and cultural features (**26**). Often Potentiomnetric maps include not only the location of the wells, but include the well identifier, water levels or contaminant levels for ease of review

Note 3—In addition to the consideration of QA/QC items discussed in Section 6, some factors that must be avoided in constructing potentiometric maps include:

(1) Contouring of water levels from wells screened at different depths in aquifers with vertical hydraulic gradients,

(2) Over-simplified contours, for example, straight-line,

(3) Over-interpreted contours, for example, more curves than justified by number of data points,

(4) Extrapolation of contours well beyond data points,

(5) Contouring of data values from substantially different time periods,

(6) Contours adjusted to "fit" the contaminant plume as a means of justifying a contaminant pathway, and

(7) Contouring of water levels impacted by liquid phase contaminants without proper adjustment of the contours.

7.2.7 *Depth to Water Maps*—Maps that illustrate the depth of water below the land surface are useful for construction projects where the concern is intersecting the unconfined water surface, for example, by basements, disposal pits, or mines. These maps can also provide information about natural

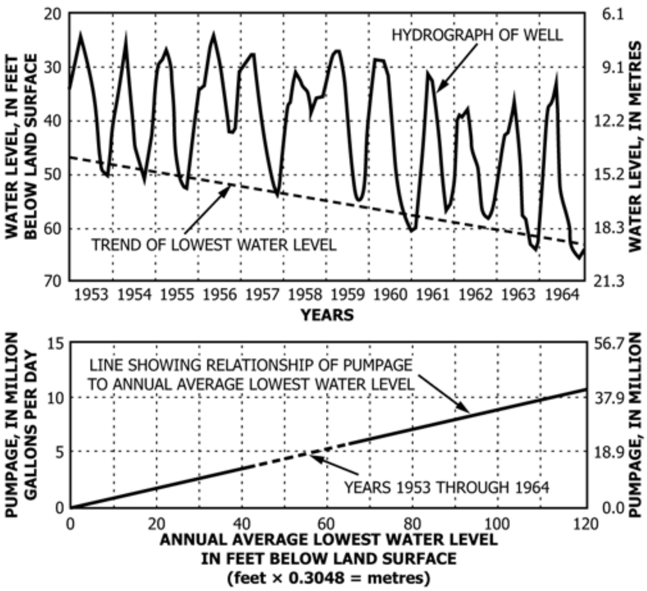

FIG. 16 Hydrograph Showing Water Level Trend and Graph Showing Relationship of Trend to Pumpage (adapted from Ref (23))

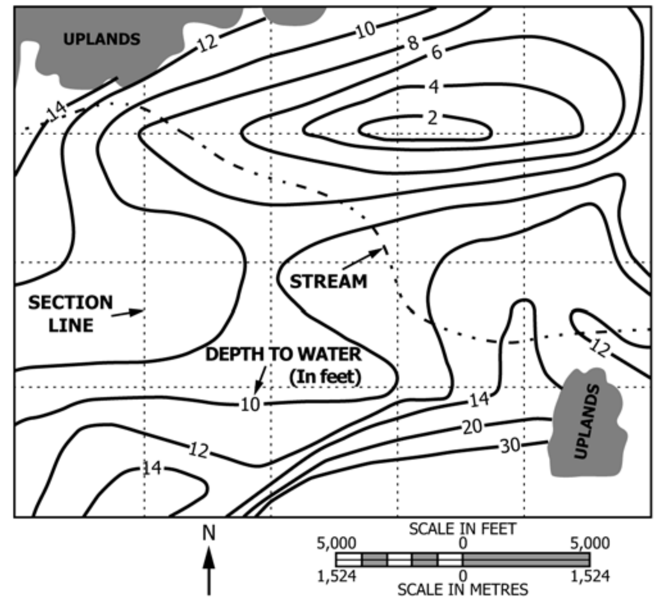

FIG. 18 Map Showing Depth to Water Below Land Surface (adapted from Ref (28))

7.2.8 *Change Maps*—The change of the potentiometric surface over time, for example, one or ten years, helps in the interpretation of the effects of natural- and human-induced stresses on the aquifer (see Fig. 19) (**11**,**27**, **28**). The change map (Fig. 19) is a plot of the difference in the hydraulic head of an area over a period of one year. The map is constructed by subtracting the water levels from a potentiometric surface of the later time from those of the earlier time (1 year). Positive plotted values on the change map show a rising hydraulic head (indicating recharge) and negative values show a falling hydraulic head (indicating discharge).

7.2.9 *Water-table Cross Sections*—A vertically oriented cross-section through several sites shows an exaggerated shape of the aquifers, the groundwater table, and the hydraulic gradient as they relate to land surface features (see Fig. 20) features, including the relationship of surface-water bodies and wetland areas to the groundwater table (see Fig. 18) (**27**).

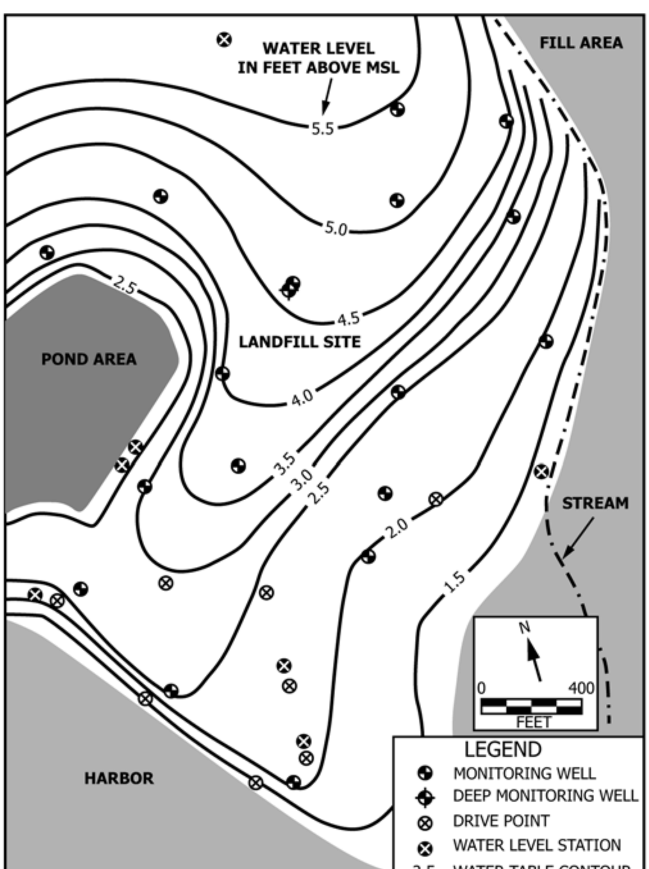

FIG. 17 Potentiometric Map at Landfill Facility (adapted from Ref (24))

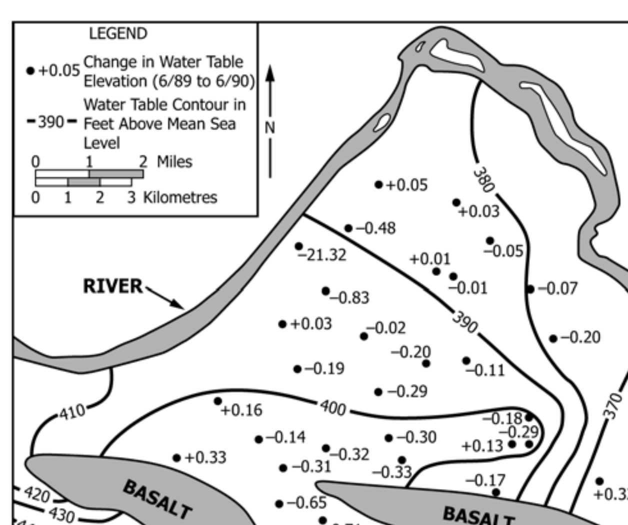

FIG. 19 Water Level Change Map and Potentiometric Surface (adapted from Ref (29))

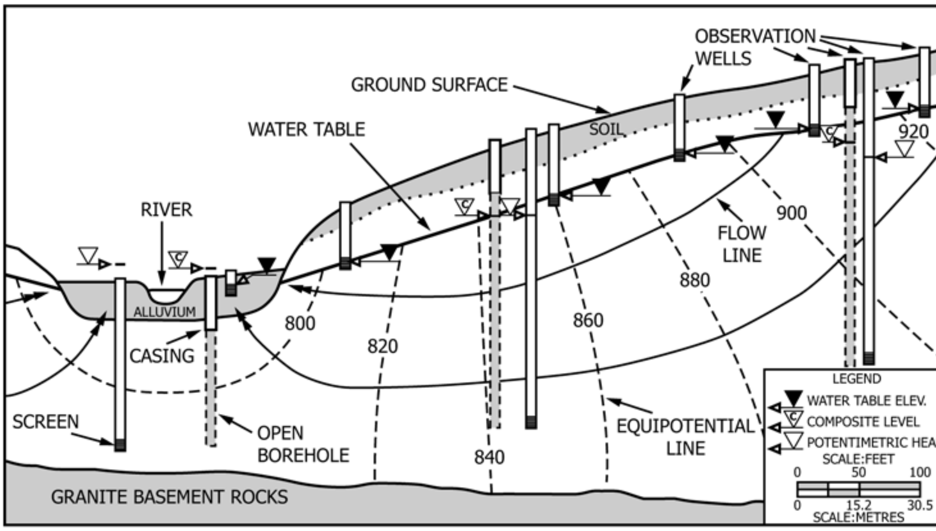

FIG. 20 Water-level Cross Section (adapted from Ref (25))

(5,6,10,27). Cross-sections of unconfined aquifers commonly show the relationship of surface features, for example, pits, lakes, streams, and cultural structures, with the sub-surface materials, for example, aquifer configuration, depth and gradient of water surface, groundwater flow net, location and construction features of wells, and chemical characteristics of the water (10). Cross-sections of confined aquifers tend to place less emphasis on the surface features that have little effect on conditions in the aquifer. These diagrams can be misleading as it includes flow-lines that appear perpendicular to the equipotentials on a diagram with exaggerated vertical scales.

7.2.10 *Statistical Comparisons of Water Levels*—Groundwater table data can be analyzed by many common statistical methods to determine trends and to correlate these data with related natural and human-caused factors (see Fig. 21) (3,11,30–31). Basic statistics for example, mean, median, high, and low values are commonly used to determine the long-term trends of the hydraulic head. A long-term average hydrograph, for example, from 20 wells, can be determined for a project area or these same water levels can be shown on a hydrograph for a single year (31). Probability plots for minimum spring time or differences between springtime minimum and fall-time maximum water table can be determined from long-term records (30). Cumulative departures in pumpage and precipitation rates versus average water table can be plotted to compare interdependence of the data (32). Correlation analyses between water table fluctuations and related data, for example, river stages, precipitation, or barometric pressure, can be valuable in detecting the cause of the fluctuations (11). Maps showing the seasonal deviation of the water table from the long-term mean of selected shallow wells can indicate areas of drought and above normal precipitation conditions, for example, for a state (3).

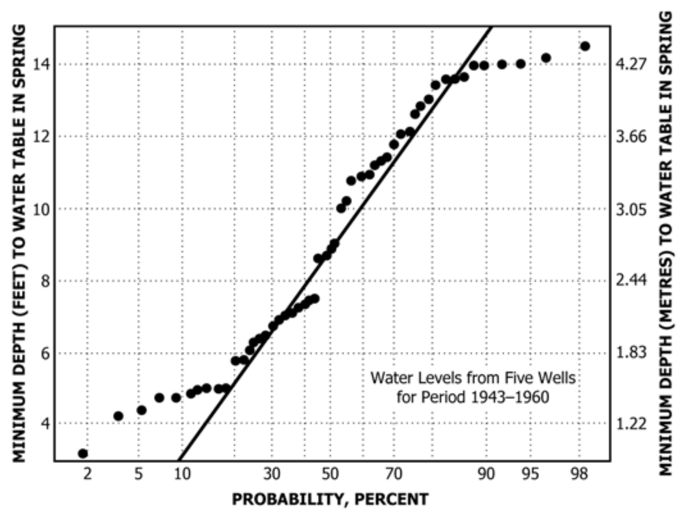

FIG. 21 Probability of Spring Minimum Depths to Water Table (adapted from Ref (32))

8. Automated Procedures for Water-Level and Hydraulic Head Graphics

8.1 Information concerning the availability of computer software for displaying water level and hydraulic head data in a tabular and graphic format can be obtained from scientific software clearing houses.

8.1.1 Commercially available software is available for plotting graphs, contour maps, and cross-section of groundwater.

9. Keywords

9.1 aquifer; confined aquifer; groundwater; hydraulic head; hydrograph; potentiometric surface; unconfined aquifer; water level; water table

SUMMARY OF CHANGES

In accordance with Committee D18 policy, this section identifies the location of changes to this standard since the last edition (1996(2008)) that may impact the use of this standard.

(1) Moved information from most notes into the body of the text.
(2) Deleted withdrawn ASTM standards and references to them in the body.
(3) Moved contents of Note 1 into Section 3 definitions.
(4) Removed company names in Section 8 and references, and replaced with generic information.
(5) Removed unneeded references.
