Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see www.iso.org/patents).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation on the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the WTO principles in the Technical Barriers to Trade (TBT) see the following URL: Foreword - Supplementary information

The committee responsible for this document is ISO/TC 22, Road vehicles, Subcommittee SC 12, Passive safety crash protection systems.

This second edition cancels and replaces the first edition (ISO/TR 12350:2004), which has been technically revised.

Road vehicles — Injury risk curves for the evaluation of occupant protection in side impact tests

1 Scope

This Technical Report provides injury risk curves to assess occupant protection in side impact tests. The curves are given for the WorldSID 50th, a mid-size adult male side impact dummy. Injury risk curves for other side impact dummies could be added as soon as the necessary material is available and processed as described in this Technical Report. These dummies are used during tests carried out according to ISO 10997 or which are under investigation by regulatory bodies and consumer testing organizations.

2 Methodology

2.1 Selection of PMHS sample to be used for the construction of the injury risk curves

An in-depth review of the postmortem human subjects (PMHS) tests available in the literature and in the NHTSA database (http://www-nrd.nhtsa.dot.gov/database/aspx/biodb/querytesttable.aspx) was performed. The listed tests were analysed in order to determine if they could be accurately repeated with dummies and included in the construction of injury risk curves.

This clause summarizes the series of tests that were conducted by body region and type of loading. Reasons for including or excluding each particular test series are detailed. The PMHS characteristics are provided in the form of related electronic documents available through the ISO website and detailed in <u>Clause 4</u>. The detailed descriptions of the PMHS configurations allowing the reproduction of the test with a dummy are presented in <u>Annex A</u> to <u>Annex F</u>, as well as the reasons for inclusion or exclusion.

The rigid and padded head impactor tests conducted by Calspan^[18] were included and are detailed in Annex A. The head impactor tests of the Highway Safety Research Institute (HSRI)^[51] were excluded because the impact speeds were not known. The head impactor tests of the University of Michigan Transportation Research Institute (UMTRI) (NHTSA database) were excluded because the impactor characteristics were not known.

The whole body drop tests with head impact conducted by Wayne State University (WSU)[22], those conducted by the Association Peugeot-Renault (APR) without helmet, and the head drop tests conducted by Medical College of Wisconsin (MCW)[56] were included and are detailed in Annex A. The whole body drop tests with head impact conducted by APR with helmet were excluded because the helmet properties were unknown.

The shoulder impactor tests performed by APR[2], INRETS[14] [15] [17], and WSU[26] [30] were included. The shoulder impactor tests conducted by Ohio State University (OSU) on a rigid bench were also included[3] [4]. These configurations are detailed in Annex B. The oblique shoulder impactor tests performed by OSU on a 1996 Ford Taurus seat were excluded because the characteristics of the seat were unknown.

All, but one, of the thorax impactor tests conducted by HSRI[43] [44] [45] were included. The single-impact WSU thorax impactor test^[54] [55] was also included. The UMTRI[34] [35] and OSU[49] thorax impactor tests were included when the level of load was deemed to be below the threshold of rib fracture (700 N), such that the fractures could be attributed to the final high-speed impact. These test configurations are detailed in Annex C. The 76T038 HSRI test was excluded because the data were questionable. The HSRI tests 77T079 and 77T080 were excluded because it does not seem realistic to have 18 rib fractures for 2 165 N of impact force. All the WSU and INRETS[16] multi-impact tests, as well as some UMTRI tests (83E085, 83E086, 83E106, 83E107, 83E108) and OSU tests (0505OTH25L01, 0505LTH25R01, 0506OTH25R01, 0506LTH25L01, 0601LTH25L01, 0601OTH25R01), were excluded because it was not possible to determine which impact caused each injury.

ISO/TR 12350:2013(E)

Only one of the abdomen impactor tests performed by WSU[54] [55] (WSU063-34) was included because all the other subjects were impacted more than once in the abdomen and/or thorax. All the OSU abdomen impactor tests but two (93VRTAB08, 93VRTAB09) were included. These two tests were excluded because the abdomen deflection exceeded the target level of 16 % of the chest breadth. The test configurations are detailed in Annex D.

The Laboratory of Accidentology and Biomechanics (LAB) abdomen impactor tests [52] were excluded because a measurement system was positioned at the level of the liver and could have influenced the abdominal injuries.

Most of the reviewed pelvis impactor tests were multi-impact tests. The pelvis impactor tests performed by WSU[54] [55], UMTRI[33] [36], ONSER[11] [12], and INRETS[5] [6] were included when an increase in impactor speed was accompanied by an increase in energy for a given PMHS, as this was assumed to be an indication of no injury. The configurations are detailed in Annex E. Two UMTRI tests (83E087, 83E109) were conducted with an APR pad that is no longer available. The ONSER multi-impact tests C3, C4, D3, E2, F2, F3, H4, H5, I6, J2, J3, N7, S3, S4, X1, X2, Y2, Z1, and Z2 were excluded because there was a possible weakening of the pelvis bone.

APR conducted lateral drop tests with PMHS[2] [53]. A review of the films failed to confirm the position of the subjects' lower extremities and whether or not an impact surface was provided to catch the lower extremities. The test films revealed that some tests were conducted with the subjects' head, some were conducted without the head, and for the others, the film coverage did not reveal if the head was attached or removed. Some subjects were observed to rotate during the free fall. For these reasons, and because the APR padding cannot be reproduced, all of the whole body drop tests were excluded from the construction of injury risk curves for the thorax, abdomen, and pelvis.

Some sled tests performed by Heidelberg[25] [29], MCW/OSU[39] [40] [28] [27], and WSU[7] [8] [9] [10] [23] were included and are detailed in Annex F. Several checks were done to select the PMHS to be included in the construction of the injury risk curves. The checks are detailed in Annex G.

- The position of the PMHS at the time of impact was first checked. The Heidelberg tests (H82014, H82018, H82019, H82015) and MCW/OSU tests (SC126, SC105, SC131) were then excluded.
- The consistency between the thorax-pelvis transmissibility and the contact times of the thorax and pelvis plates were also checked. The Heidelberg tests (H82014, H82018, H82019, H82015) and MCW/OSU (SC126, SC105) were then excluded.
- The total momentum was checked. Tests for which the total momentum differed from other tests with the same impact wall configuration were excluded (MCW/OSU SC131).
- The absence of shoulder interaction with the wall was checked in the MCW/OSU configuration. Sled tests with PMHS seating height under 826 mm and shoulder interaction with the wall observed on the film were excluded from the shoulder, thorax, and abdomen injury risk curves (MCW/OSU SC137, SC138, SC119, 94LSI32P04, LSI32R08, SC30A102).
- PMHS characteristics were checked. The PMHS having sternotomy wires were excluded because the PMHS response and injuries were questionable (MCW/OSU SC122, SC132, LSI32P11, SC103, SC112, SC30A103, SC20A101).
- PMHS injuries were checked. PMHS from the MCW/OSU SC114 test with a right hemithorax, which could have resulted from secondary impact, was excluded.
- Some of the checks required the analysis of the wall plates loads. Some tests were excluded because the impact wall was not instrumented with load cells or because the data were questionable and then the checks could not be done. This was the case for the HSRI sled tests[31], the first test series conducted by WSU (NHTSA database), some Heidelberg tests (H82009, H80011, H80013, H80014, H80017, H80024, H81002, H81004, H81006, H81016, H81022, H81025, H81027, H82002, H82020, H80018, H80020, H80021, H80023, H81011, H81012, H81015, H81021, H83008, H83016, H83021, H83030, H83031), as well as some MCW/OSU sled tests (98LSI32R17, SC106, SC127, 96LSI32R07, SC123).

- Finally, sled tests for which the impact wall padding or the airbag was no longer available were excluded (Heidelberg tests H82008, H82021, H82022, H83008, H83016, H83021, H83030, H83031, H83011, H83020, H84008, H83010, H83012, HSRI tests 76T029, 76T034, 76T039, 76T042, MCW/OSU tests SAC 101, SAC 103, SAC 104, SAC 105, WSU 2nd test series SIC-09, SIC-10, SIC-11, SIC-12, SIC-13, SIC-14, SIC-15, SIC-16, SIC-17).
- The severity of PMHS injuries were coded according to the Abbreviated Injury Scale $2005^{[1]}$. Table 1 summarizes the body regions and injury severity levels for which PMHS data are available to construct injury risk curves. There were no AIS \geq 3 shoulder injuries from the PMHS tests. Therefore, injury risk curves for the shoulder can only be constructed for the AIS \geq 2 level of injury. For the thorax, abdomen, and pelvis, injury risk curves were constructed at the AIS \geq 3 injury level and either the AIS \geq 2 or AIS \geq 4 level if the PMHS injury/no injury results were better balanced at these AIS levels. Note that all rib fractures are coded in thoracic skeletal AIS, including those that resulted from abdominal impacts.

Table 1 — Body regions and AIS levels for which injury risk curves are constructed

| Body region | AIS levels used in the injury risk curve construction |
|----------------------|---|
| Head | AIS ≥ 3 |
| Shoulder | AIS ≥ 2 |
| Thorax (skeletal) | AIS ≥ 3 and AIS ≥ 4 |
| Thorax (soft tissue) | AIS ≥ 2 and AIS ≥ 3 |
| Abdomen | AIS ≥ 2 and AIS ≥ 3 |
| Pelvis | AIS ≥ 2 and AIS ≥ 3 |

2.2 Dummy data

Once the PMHS sample to build the injury risk curves is selected, the dummy results reproducing these PMHS test configurations are collected.

The injury risk curves are proposed in this Technical Report for a 50th percentile male dummy. Only WorldSID 50th percentile results are presented in the current version of this Technical Report. It is intended to add injury risk curves for the WorldSID 5th percentile adult female dummy to a future edition of the ISO/TR 12350. There are no plans to add injury risk curves for the ES-2 or ES-2re, and it is not appropriate to use the WorldSID injury risk curves with measures from either ES-2 or ES-2re.

The dummy test results reproducing the PMHS test configurations selected for the injury risk curve construction are presented in Annex H. The build level of the production version used was not provided with the results. It is to be noted that there was no head result available. Moreover, the shoulder deflection was only available for the impactor test and not for the sled test configurations.

The test results presented in Annex H are filtered data (according to Reference^[50] and according to filters indicated in Annex H) that have not been scaled and should not be used directly to construct dummy-specific injury risk curves.

The PMHS used in the biomechanical tests described in <u>Annex A</u> to <u>Annex F</u> were generally not mid-size adult males. Ideally, the test condition for the dummy tests should be scaled such that the test poses an equally severe impact as the individual PMHS test. However, many of the dummy tests used in this Technical Report were conducted at the same velocity and the same impactor mass as the PMHS tests. It is therefore necessary to scale the results of the dummy tests before they are paired with the PMHS injuries. The dummy data from impactor tests, drop tests, and sled tests were scaled using the formulae included in <u>Annex I</u>. The scaled dummy data are included in <u>Annex A</u> to <u>Annex F</u>.

2.3 Age adjustment

The injury risk curves are provided with age adjustment. It is out of the scope of this Technical Report to recommend an age to be used. The injury risk curves can be built for any age using the formulae included

ISO/TR 12350:2013(E)

in <u>Table 5</u>. However, the quality index cannot be computed from these formulae. As it was not possible to include the quality index for all ages, only two ages were considered. As indicated in Petitjean et al. (2009), the injury risk curves were constructed for a dummy representing a 45-year-old male, as this age has been used previously to represent the average age of an adult male in the field data. The injury risk curves were also constructed for median age of the PMHS included in the samples available for the construction of the WorldSID 50th injury risk curves (67 years old). This latest age was used because it provides the values with the higher confidence because the PMHS data are mostly around that age.

2.4 Statistical analysis

Guidelines for the construction of the injury risk curves were agreed on within ISO/TC 22/SC 12 (Resolution 2, N851).

The guidelines include several steps.

2.4.1 Step 1: Collect the relevant data

The first step is to collect the relevant data, including injuries and injury criterion.

According to the methodology developed in this Technical Report, relevant data corresponded to the paired PMHS injuries and scaled dummy measurements from tests performed in similar configurations.

Step 2: Assign the censoring status (left, right, interval censored, exact)

Once the biomechanical data were available, the censoring status was assigned (left, right, interval censored, exact). After this step, the dataset included one column with the injury criteria values associated with the censoring status indicated in a second column.

2.4.3 Step 3: Build the injury risk curve with the Consistent Threshold Estimate (CTE)[37] and check for dual injury mechanism

The step function was visually investigated in order to detect potential change in slope corresponding to different injury mechanisms.

2.4.4 Step 4:

- If there was an evidence of dual injury mechanism, the sample was separated into samples with single injury mechanism and Step 1 was performed.
- If there was no evidence of dual injury mechanism, the injury risk curve was built with the survival analysis according to the following steps.

2.4.5 Step 5: Estimate the parameters of the Weibull, log-normal, and log-logistic distributions with the survival analysis method

2.4.6 Step 6: Identify overly influential observations using the dfbetas statistics

The overly influential observations were identified using the dfbetas statistics.

Step 7: Check the distribution assumption graphically using a qq-plot or the CTE method 2.4.7

2.4.8 Step 8: Choose the distribution with the best fit, based on the Akaike information criterion (AIC)

The distribution with the lowest AIC among the three distributions was selected.

2.4.9 Step 9: Check the validity of the predictions against existing results (such as accidentology outcome), if available

2.4.10 Step 10:

- Step 10.1: The 95 % confidence intervals of the injury risk curve were calculated with the normal approximation of the error.
- Step 10.2: The relative sample size of the confidence interval was defined as the width of the 95 % confidence interval at a given risk relative to the value of the stimulus at this same risk. They were calculated at 5 %, 25 %, and 50 % risk.

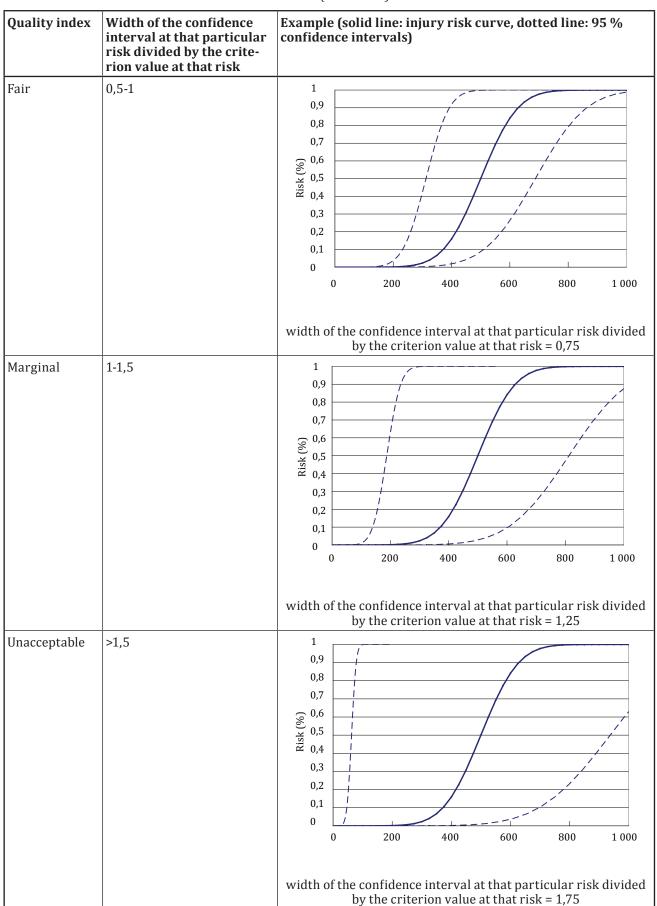

2.4.11 Step 11: Provide the injury risk curve associated with the quality index based on the relative sample size of the 95 % confidence interval

A scale of quality indexes based on the relative sample size was defined with four categories ("good" from 0 to 0,5, "fair" from 0,5 to 1, "marginal" from 1 to 1,5, "unacceptable" over 1,5). The injury risk curves associated with the quality indexes were provided. The scale was determined using biomechanical samples in order to distribute injury risk curves in the four categories. Illustrations for one example of each class of quality index are provided in <u>Table 2</u>.

Table 2 — Illustrations of the width of the 95 % confidence interval for an injury risk curve for each of the quality indexes

| Quality index | Width of the confidence interval at that particular risk divided by the criterion value at that risk | Example (solid line: injury risk curve, dotted line: 95 % confidence intervals) |
|---------------|--|---|
| Good | 0-0,5 | $ \begin{array}{c ccccccccccccccccccccccccccccccccccc$ |

Table 2 (continued)

2.4.12 Step 12: Recommend one curve per body region, injury type, and injury level

- <u>Step 12.1</u>: If several injury risk curves could be compared with the AIC and if the difference of the AIC was greater than 2, then the curve with the lowest AIC was recommended over the others.
- <u>Step 12.2</u>: If an injury risk curve had an "unacceptable" quality index, it should not be recommended.
- <u>Step 12.3</u>: If several injury risk curves were still available for a given injury type and level, engineering judgment was used to recommend one curve over another.

The recommended injury thresholds should be provided with their associated quality indexes.

3 Injury risk curves for the WorldSID 50th

The injury risk curves were constructed by correlating the dummy responses to the PMHS injuries in the same test configurations.

The injury risk curves were built with the following steps:

<u>Step 1</u>: Paired PMHS injuries and dummy measurements were collected, after having selected the PMHS sample and checking the dummy data.

<u>Step 2</u>: The censoring status was assigned to each pair depending on if it was left, right, interval censored, or exact. The WorldSID 50th injury risk curves were computed with the R software [$\frac{42}{2}$]. With the R software, the right, exact, left, and interval censored data are coded 0, 1, 2, and 3 respectively.

<u>Step 3</u>: The injury risk curve should be built with the Consistent Threshold Estimate (CTE)[37] in order to check for dual injury mechanism.

<u>Step 4</u>:

- If there was an evidence of dual injury mechanism, the sample was separated into samples with single injury mechanism and Step 1 was performed.
- If there was no evidence of dual injury mechanism, the injury risk curve was built with the survival analysis according to the following steps.

However, the injury risk curves here included the age as a covariable so it would be necessary to separate the sample into different classes of age before building the CTE injury risk curves. The resulting subsample was too small to build reliable injury risk curves so dual injury mechanisms were not checked for the WorldSID 50th.

<u>Step 5</u>: The parameters of the Weibull, log-normal, and log-logistic distributions with the survival analysis method were estimated (see <u>Table J.1</u>).

<u>Step 6</u>: The overly influential observations were identified with the dfbetas test (see <u>Table J.2</u> to <u>Table J.7</u>). These observations were checked for any specificity. As there was no evidence of difference between these observations and the others included in the sample, these observations were kept in the construction of the injury risk curve.

<u>Step 7</u>: The distribution assumption should be checked graphically using a qq-plot or the CTE method. However, the injury risk curves here included the age as a covariable so it would be necessary to separate the sample into age classes before building the CTE injury risk curves. The resulting sub-sample was too small to build reliable injury risk curves so distribution assumption was not checked in this Technical Report.

<u>Step 8</u>: The distribution with the best fit, based on the Akaike information criterion (AIC), was chosen (see <u>Table J.1</u> and <u>Table 3</u>).

<u>Step 9</u>: Check the validity of the predictions against existing results (such as accidentology), if available. In the case of the WorldSID 50th, there was no prediction to be validated.

Step 10: The 95 % confidence intervals were calculated, as well as the relative sample size of the confidence interval (width of the confidence intervals at 5 %, 25 %, and 50 % relative to the value of the stimulus at 5 %, 25 %, and 50 % of risk, respectively) (see Table I.8).

Step 11: The injury risk curves were provided with their associated quality indexes based on the relative sample size of the confidence interval (see <u>Table 4</u>).

Step 12: Recommend one curve per body region, injury type, and injury level.

Step 12.1: If several injury risk curves could be compared with the AIC and if the difference of the AIC was greater than 2, then the curve with the lowest AIC was recommended over the others.

The samples that could be compared were those with the same PMHS sample and the same level and type of injury. The AIC were then compared between:

- the skeletal risk AIS3+ as a function of the maximum thoracic rib deflection and viscous criterion;
- the skeletal risk AIS4+ as a function of the maximum thoracic rib deflection and viscous criterion;
- the abdomen risk AIS2+ as a function of the maximum abdomen rib deflection and viscous criterion, as well as of the lower spine Y acceleration 3 ms;
- the abdomen risk AIS3+ as a function of the maximum abdomen rib deflection and viscous criterion.

There was no comparison possible for the shoulder and pelvis injury risk curves.

Injury risk WorldSID measurement AIC Skeletal thoracic Maximum thoracic rib deflection (measured by 1D IR-TRACC) (mm) 24,8837 AIS3+ Maximum thoracic rib VC (measured by 1D IR-TRACC) (m/s) 29.6911 Maximum thoracic rib deflection (measured by 1D IR-TRACC) (mm) Skeletal thoracic 29,735 4 AIS4+ Maximum thoracic rib VC (measured by 1D IR-TRACC) (m/s) 30,6507 Abdomen AIS2+ Maximum abdomen rib deflection (measured by 1D IR TRACC) (mm) 14,988 9 Maximum abdomen rib VC (measured by 1D IR-TRACC)(m/s) 14.9777 Lower spine Y acceleration 3 ms (m/s^2) 27,5768 Abdomen AIS3+ Maximum abdomen rib deflection (measured by 1D IR-TRACC) (mm) 11,959 1 Maximum abdomen rib VC (measured by 1D IR-TRACC) (m/s) 11,8696

Table 3 — AIC values for the WorldSID 50th injury risk curves

Based on the comparison of the AIC values (see Table 3), the skeletal thoracic risks AIS3+ and AIS4+ were recommended to be predicted as a function of the maximum thoracic rib deflection rather than as a function of the maximum thoracic rib vital capacity (VC). The abdomen risks AIS2+ and AIS3+ were recommended to be predicted as a function of the maximum abdomen rib deflection or VC rather than as a function of the lower spine Y acceleration 3 ms.

Step 12.2: If an injury risk curve had an "unacceptable" quality index, it should not be recommended.

There was no "unacceptable" quality index for the shoulder, abdomen, and pelvis injury risk curves AIS2+ (see Table I.8). For the skeletal thoracic risk as a function of the maximum thoracic deflection, the 50 % AIS4+ risk for a 45-year-old occupant was "unacceptable". All the thoracic soft tissue injury risk curves were "unacceptable" at 5 % risk. All the abdomen injury risk curves AIS3+ were "unacceptable". This was probably due to the very limited number (only one) of AIS3+ cases. Among the pelvis injury risk curves AIS3+, the curve as a function of the pelvis Y acceleration 3 ms for a 45-year-old occupant was "unacceptable".

— <u>Step 12.3</u>: If several injury risk curves were still available for a given injury type and level, engineering judgment was used to recommend one curve over another.

The shoulder injury risk AIS2+ could still be predicted by the maximum shoulder rib deflection or by the maximum shoulder **Y** force. The available sample for the construction of the injury risk curve as a function of the maximum shoulder deflection was composed of impactor tests only. On the other side, the available sample for the construction of the injury risk curve as a function of the maximum shoulder **Y** force was composed of impactor tests, as well as sled tests. The injury risk curve as a function of the maximum shoulder **Y** force was recommended because the sample was composed of impactor tests, as well as sled tests.

The abdomen soft tissue injury risk AIS2+ could be predicted by the maximum abdomen rib deflection or by the maximum abdomen rib VC. The injury risk curve as a function of the maximum abdomen rib deflection was recommended as the quality indexes associated with this curve were better.

The pelvis injury risk AIS2+ could be predicted by the maximum pubic force or by the pelvis Y acceleration 3 ms. Most of the injuries observed in the PMHS tests used to build the injury risk curves were related to ilio-ischio rami and pubic symphysis. It was then recommended to predict the risk as a function of the pubic force, as this dummy measurement was the more closely related to these injuries.

The recommended injury thresholds should be provided with their associated quality indexes.

It is out of the scope of this Technical Report to recommend a probability of risk as a limit to be respected. However, the dummy measurement values corresponding to all the probabilities cannot be provided in a table. As a consequence, the dummy measurement values are given for a few levels of risk. The values at 5% risk are provided because the risk is close to the Injury Assessment Reference Values (IARV). It was also decided to provide the injury thresholds for the 25% and 50% risk because values used in regulations can reach those levels (as for example, the limit for the thorax compression criterion in the regulation ECE/R94). These injury thresholds associated with their quality indexes are provided in Table 4 for the WorldSID 50th. Other injury thresholds could be calculated using the estimated parameters of the survival analysis of the recommended injury risk curves given in Table 5.

Table 4 — WorldSID 50th recommended injury thresholds with its quality index

| | 5 % risk (quality index) | 25 % risk (quality index) | 50 % risk (quality index) | | | | | |
|-------------------|--|---|---------------------------|--|--|--|--|--|
| | Maximum shoulder force Y adjusted to 67 year old (N) | | | | | | | |
| shoulder AIS ≥ 2 | 1 594 (good) | 2 011 (good) | 2 265 (good) | | | | | |
| Silouldel AlS 2 2 | Maximum : | shoulder force Y adjusted to 45 | year old (N) | | | | | |
| | 1 799 (fair) | 2 270 (fair) | 2 556 (fair) | | | | | |
| | Maximum thoracic rib def | lection adjusted to 67 year old ((mm) | (measured by 1D IR-TRACC) | | | | | |
| Skeletal thoracic | 28,0 (fair) | 40,2 (good) | | | | | | |
| AIS≥3 | Maximum thoracic rib deflection adjusted to 45 year old (measured by 1D IR-TRACC) (mm) | | | | | | | |

The formulae of the injury risk curves are presented in <u>Table 5</u>.

The risk according to the Weibull distribution is

$$Risk(\%) = 1 - \exp \left[-\left(\frac{Dummy_measurement}{\exp(\text{int} + PMHS_age \times coef_age} \right)^{\frac{1}{\exp(\log_scale)}} \right]$$
(1)

The risk according to the log-normal distribution is

$$Risk(\%) = \log_{normal_distribution}[mean = int + age \times coef_age, std = exp(\log_{scale})]$$
(2)

The risk according to the log-logistic distribution is

$$Risk(\%) = \frac{1}{1 + \exp\left\{-\left[\ln(Dummy_measurement) - (\text{int} + age \times coef_age)\right] / \exp(\log_scale)\right\}}$$
(3)

where

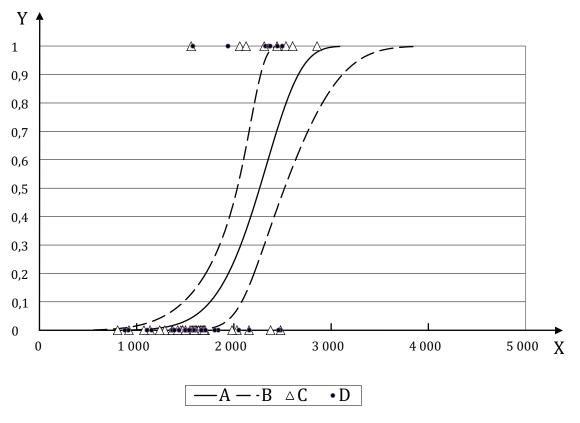

Dummy_measurement corresponds to the dummy measurement;

Table 5 — Formulae of the recommended WorldSID 50th injury risk curves built with the survival analysis

| Injury risk | Dummy measurement | Distribution | int | Coef_age | Log_scale |
|------------------------------|---|--------------|---------|----------|-----------|
| Shoulder AIS2+ | Maximum shoulder rib Y force (N) | Weibull | 8,143 5 | -0,005 5 | -2,0028 |
| Skeletal thoracic AIS3+ | Maximum thoracic rib deflection (measured by 1D IR-TRACC) mm) | Log-logistic | 4,669 9 | -0,014 6 | -2,094 5 |
| Abdomen soft tissue AIS2+ | Maximum abdomen rib deflection (measured by 1D IR-TRACC) (mm) | Weibull | 5,367 8 | -0,021 0 | -2,153 1 |
| Pelvis AIS2+ | Maximum pubic force (N) | Weibull | 8,774 8 | -0,013 9 | -1,525 9 |
| Pelvis AIS3+ | Maximum pubic force (N) | Weibull | 8,704 1 | -0,011 6 | -1,827 4 |

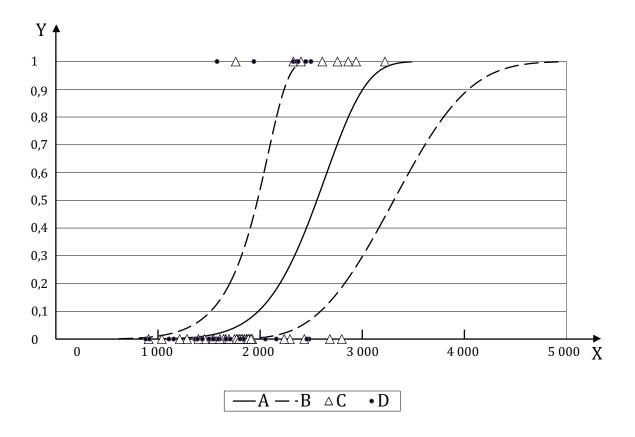

Injury risk curves for the WorldSID 50th percentile are given in Figures 1 to 10.

Figures 1 and 2 present the shoulder injury risk curves AIS \geq 2 as a function of the maximum shoulder Y force for the WorldSID 50th, with adjustment to 67 year old and 45 year old.

- X maximum shoulder Y force (N)
- Y shoulder injury risk AIS2+
- A 67 year old
- B 95 % confidence interval, 67 year old
- C data adjusted to 67 year old
- D data non-adjusted

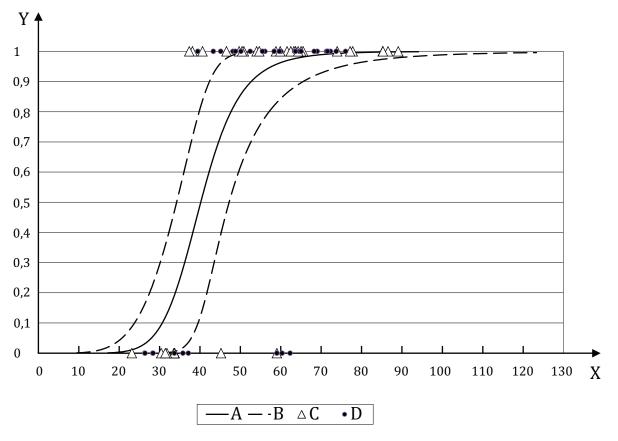

Figure 1 — Shoulder injury risk curve AIS ≥ 2 as a function of the maximum shoulder Y force adjusted to 67 year old for the WorldSID 50th

- X maximum shoulder Y force (N)
- shoulder injury risk AIS2+ Y
- 45 year old Α
- В 95% confidence interval, 45 year old
- C data adjusted to 45 year old
- D data non-adjusted

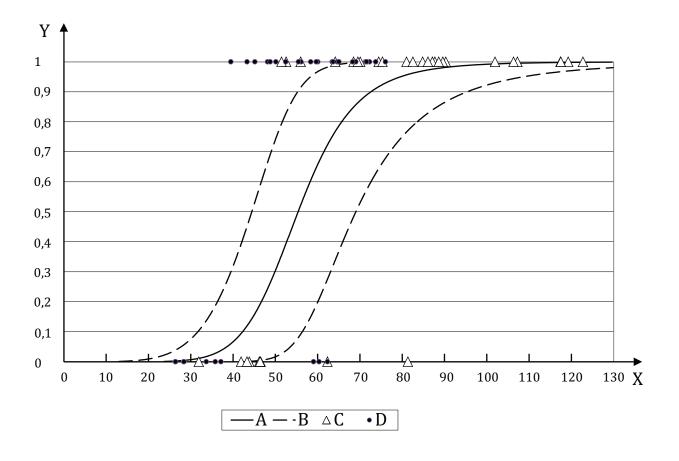

Figure 2 — Shoulder injury risk curve AIS ≥ 2 as a function of the maximum shoulder Y force adjusted to 45 year old for the WorldSID 50th

Figures 3 and 4 present the thoracic skeletal injury risk curves AIS \geq 3 as a function of the maximum thoracic rib deflection for the WorldSID 50th, with adjustment to 67 year old and 45 year old.

- X maximum thoracic rib deflection (mm)
- Y skeletal thoracic injury risk AIS3+
- A 67 year old
- B 95 % confidence interval, 67 year old
- C data adjusted to 67 year old
- D data non-adjusted

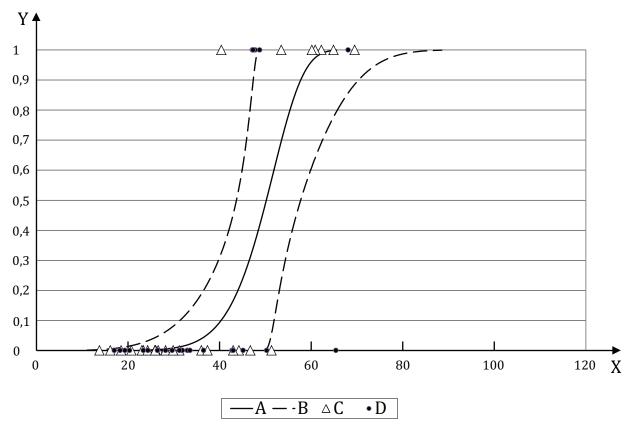

Figure 3 — Thoracic skeletal injury risk curve AIS ≥ 3 as a function of the maximum thoracic rib deflection adjusted to 67 year old for the WorldSID 50th

- X maximum thoracic rib deflection (mm)
- Y skeletal thoracic injury risk AIS3+
- A 45 year old
- B 95 % confidence interval, 45 year old
- C data adjusted to 45 year old
- D data non-adjusted

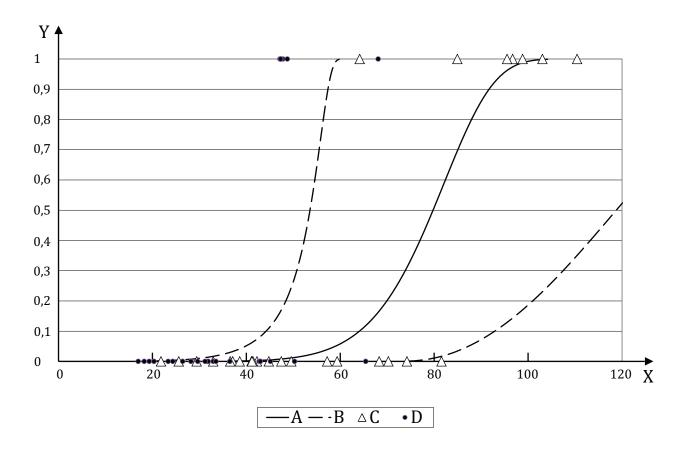

Figure 4 — Thoracic skeletal injury risk curve AIS ≥ 3 as a function of the maximum thoracic rib deflection adjusted to 45 year old for the WorldSID 50th

Figures 5 and 6 present the abdomen soft tissue injury risk curves AIS \geq 2 as a function of the maximum abdomen rib deflection with adjustment to 67 year old and 45 year old.

- X maximum abdomen rib deflection (mm)
- Y abdomen soft tissue injury risk AIS2+
- A 67 year old
- B 95 % confidence interval, 67 year old
- C data adjusted to 67 year old
- D data non-adjusted

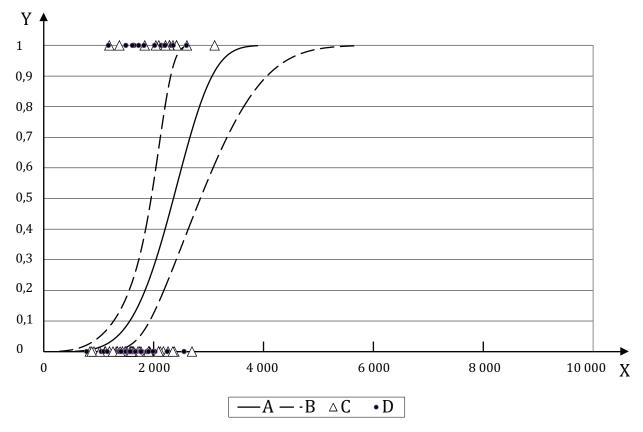

Figure 5 — Abdomen soft tissue injury risk curve AIS \geq 2 as a function of the maximum abdomen rib deflection adjusted to 67 year old for the WorldSID 50th

- X maximum abdomen rib deflection (mm)
- Y abdomen soft tissue injury risk AIS2+
- A 45 year old
- B 95 % confidence interval, 45 year old
- C data adjusted to 45 year old
- D data non-adjusted

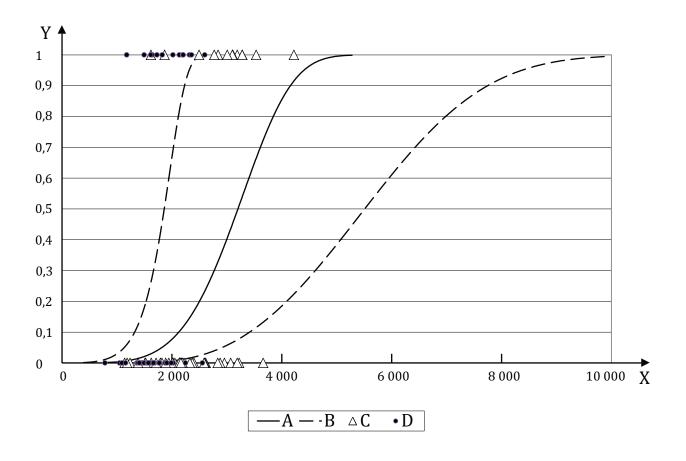

Figure 6 — Abdomen soft tissue injury risk curve AIS ≥ 2 as a function of the maximum abdomen rib deflection adjusted to 45 year old for the WorldSID 50th

Figures 7 and 10 present the pelvis injury risk curves AIS \geq 2 and AIS \geq 3 as a function of the maximum pubic force for the WorldSID 50th, with adjustment to 67 year old and 45 year old.

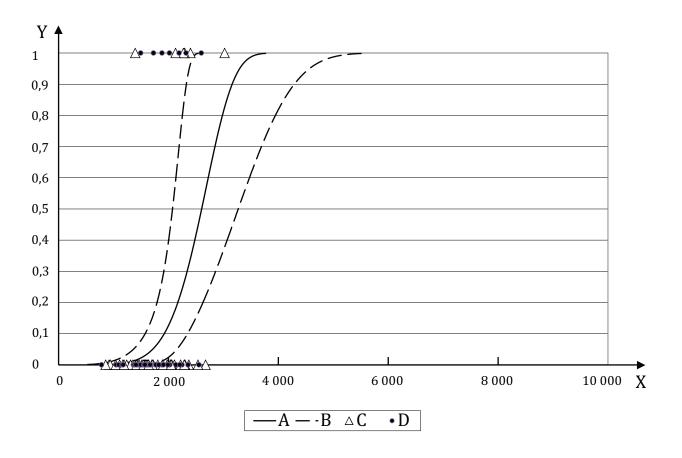

- X maximum pubic force (N)
- Y pelvis injury risk AIS2+
- A 67 year old
- B 95 % confidence interval, 67 year old
- C data adjusted to 67 year old
- D data non-adjusted

Figure 7 — Pelvis injury risk curve AIS \geq 2 as a function of the maximum pubic force adjusted to 67 year old WorldSID 50th

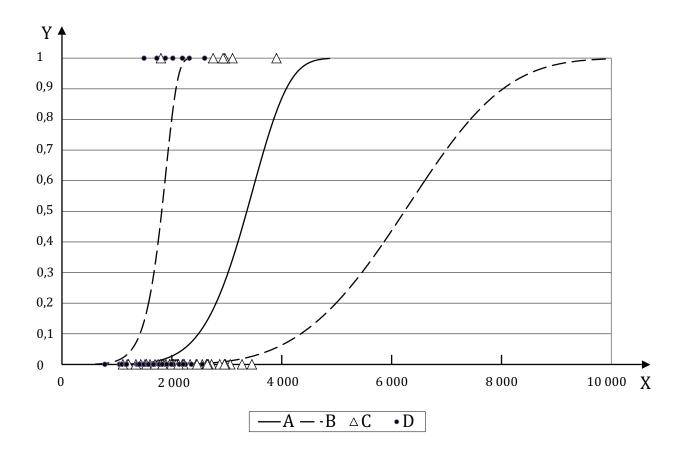

- maximum pubic force (N) X
- pelvis injury risk AIS2+ Y
- 45 year old Α
- 95 % confidence interval, 45 year old В
- data adjusted to 45 year old C
- D data non-adjusted

Figure 8 — Pelvis injury risk curve AIS ≥ 2 as a function of the maximum pubic force adjusted to 45 year old for the WorldSID 50th

- X maximum pubic force (N)
- Y pelvis injury risk AIS3+
- A 67 year old
- B 95 % confidence interval, 67 year old
- C data adjusted to 67 year old
- D data non-adjusted

Figure 9 — Pelvis injury risk curve AIS \geq 3 as a function of the maximum pubic force adjusted to 67 year old for the WorldSID 50th

Kev

- X maximum pubic force (N)
- Y pelvis injury risk AIS3+
- 45 year old Α
- 95 % confidence interval, 45 year old В
- data adjusted to 45 year old C
- data non-adjusted D

Figure 10 — Pelvis injury risk curve AIS ≥ 3 as a function of the maximum pubic force adjusted to 45 year old for the WorldSID 50th

Related electronic documents

The files providing the characteristics of the PMHS sample to be used for the construction of the injury risk curves, as well as the dummy responses, are gathered in related electronic documents posted on the ISO website at the following link: http://standards.iso.org/iso/tr/12350

- RED1: Head impactor and drop tests
- RED2: Shoulder impactor tests
- RED3: Thorax impactor tests
- RED4: Abdomen impactor tests
- RED5: Pelvis impactor tests
- RED6: Sled tests

Annex A (informative)

PMHS head test data

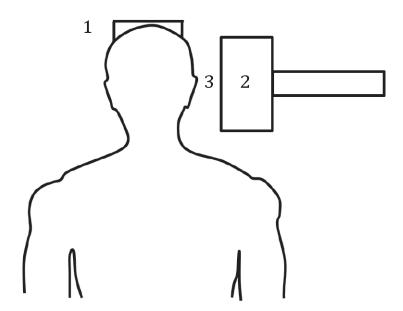

Annex A includes the description of the PMHS head impactor and drop tests used in the construction of the injury risk curves.

A.1 Head impactor tests

The Highway Safety Research Institute (HSRI) conducted a series of impactor tests to the heads of five PMHS[51]. The results of the HSRI impactor tests were excluded because the impact speeds are unknown. Therefore, the tests cannot be repeated with dummies.

The University of Michigan Transportation Research Institute (UMTRI) performed lateral impactor tests. The results of the UMTRI impactor tests were excluded because the impactor characteristics were not documented in the literature. Therefore, the tests cannot be repeated with dummies.

Calspan conducted a series of impactor tests to the heads of PMHS, as illustrated in Figure A.1 [18]. Each PMHS was seated in an upright posture, but the presence or absence of a back support was not documented. The position of the head was maintained by a chin strap that would break away upon impact. The impactor masses were 23,4 kg, 24,4 kg, and 25,3 kg. The impactor face was either rectangular (203 mm \times 254 mm or 171,5 mm \times 203 mm) or circular (152 mm diameter). The impactor face was either rigid or padded with a 213 foam (polyurethane) padding. The impactor face was centred on the level of the external auditory meatus.

Kev

- 2 impactor face
- 3 centreline of impactor at level of Frankfort plans and external auditory meatus

Figure A.1 — Impactor test configuration from the lateral head impacts conducted by Calspan (front view) $^{[18]}$

Table A.1 summarizes the Calspan PMHS tests that are included in constructing the injury risk curves for the head in lateral impact. The details of all the head impactor test configurations are provided in Table A.1 and in the related electronic document RED1. The padding used in dummy tests should be identical to the padding used in the original PMHS tests.

No WorldSID test results were available for these test conditions at the time when this Technical Report was published. This annex is kept for future use.

A.2 Head drop tests

The Association Peugeot-Renault (APR) conducted two series of whole body drop tests that involved impact to the temporoparietal region of the PMHS head[20] [21] [13]. The first series, illustrated in Figure A.2, strapped the torso into a cradle, with the head and upper torso protruding past the edge of the cradle. A device was used to maintain head alignment until impact. The second series suspended the body from several points, without the cradle. The subject was released from a height of 0,3 m to 3,0 m. The head impact surface was at an angle of 1° to 44° relative to horizontal and either rigid or padded. Both tests on a rigid impact surface were with bare heads. The height of the mattress was chosen to avoid neck kinematics that would cause cervical injuries.

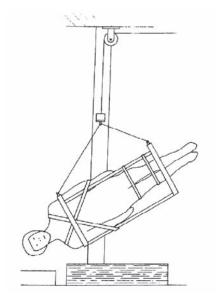

Figure A.2 — APR head lateral drop test configuration (front view)

Wayne State University (WSU) conducted whole body drop tests with head impact^[22]. In this series, the torso was strapped to a pallet that was free to pivot about one end. The PMHS head and neck were extended beyond the edge of the free end of the pallet. The pallet was rotated until the subject's head was positioned 0,46 m above the head impact surface. The impact surface was a rigid cylinder with a 1 inch radius. The pallet was released to produce the desired head impact.

The Medical College of Wisconsin (MCW) conducted lateral drop tests with heads, separated at the level of the occipital condyles[56]. Each head was dropped multiple times, from increasing heights (0,3 m to 3 m), until skull fracture was detected by a decrease in force associated with an increase in velocity. The head was oriented such that the temporoparietal region impacted either a flat or cylindrical impact surface, padded with 50 mm of rubber (either 40 durometer or 90 durometer), as illustrated in Figure A.3. Some tests were conducted with the brain intact and other tests were conducted with Sylgard gel in place of the brain.

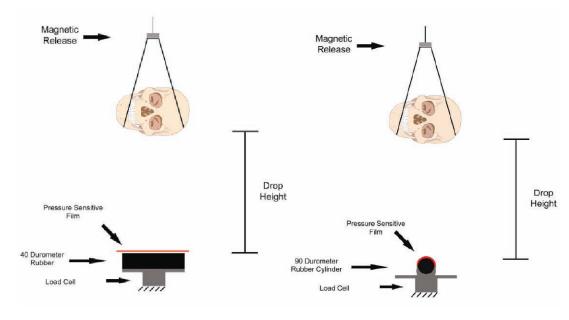

Figure A.3 — Impactor test configuration from the lateral head impacts conducted by MCW (front view)[56]

<u>Table A.2</u> summarizes the APR, WSU, and MCW PMHS tests that could be included in constructing injury risk curves for the head drop tests. The details of all the head drop test configurations are provided in <u>Table A.2</u> and the related electronic document RED1.

Angle A Resulting specimen orientation was such that the sagittal plane was rotated between −11° to −14° from horizontal about the X-axis and -1° to -4° from horizontal about the Z-axis

No WorldSID test results were available for these test conditions at the time when this Technical Report was published. This annex is kept for future use.

Annex B

(informative)

PMHS shoulder test data (shoulder impactor tests)

Annex B includes the description of the PMHS shoulder impactor tests used in the construction of the injury risk curves.

APR conducted a series of impactor tests to the shoulders of four PMHS[2]. Each PMHS was seated on a horizontal hardwood surface. The position of the head was maintained by taping it to a stick located behind the subject's back. The impactor mass was 23 kg and its flat circular impact face had a diameter of 150 mm. The impact face was centred at the shoulder level of each subject. Three subjects (MS202, MS203, and MS204) were impacted in a pure lateral direction and the fourth (MS201) was impacted at an angle of 15° forward of pure lateral. Each subject was impacted once.

INRETS conducted a series of shoulder impactor tests, as illustrated in Figure B.1 [14] [15] [17]. Each PMHS was seated upright, without back support. The 23,4 kg rigid impactor had a rectangular impact face (150 mm wide and 80 mm high) with rounded edges. The impactor face was centred on the glenohumeral joint. Each subject was impacted three times on the right shoulder (pure lateral, 15° rearward of lateral, and 15° forward of lateral) and once, at higher speed, on the left shoulder in the pure lateral direction.

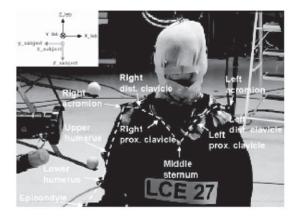

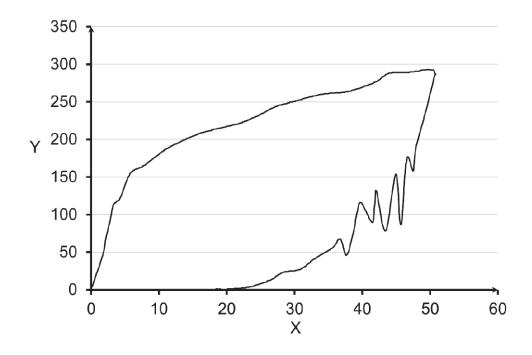

Figure B.1 — Impactor test configuration from the lateral and oblique-lateral shoulder impacts conducted by INRETS (front view)[14] [15] [17]

Ohio State University (OSU) conducted a series of shoulder impact tests[3] [4]. In the first test series, each PMHS was seated on a Teflon sheet on a rigid bench with backrest, as shown in Figure B.2. The 23 kg impactor had a rectangular impact face (203,2 mm wide and 152,4 mm high). The impactor face was padded with a 58-mm-thick piece of Arcel 310 foam (26,4 kg/m³ density). The characteristics of the padding are presented in Figure B.3.

Figure B.2 — Impactor test configuration from the lateral shoulder impacts conducted by OSU (front view)[3],[4]

Kev

- X compression in %
- pressure in kPa

Figure B.3 — Characteristic pressure versus compression curve for Arcel 310 padding tested at 6,0 m/s

The impactor face was centred on the glenohumeral joint. After the first impact, the shoulder was palpated for fractures. If a fracture was detected, the impact velocity for the opposite shoulder was reduced by 10 %. If no fracture was detected, then the impact velocity was increased by 10 %. Each subject was impacted once on each shoulder.

In the second test series of OSU tests (see Figure B.4), four subjects were tested on a rigid bench, in the pure lateral direction, with the same impactor configuration as the first series [4]. Supports were placed under the subject's elbows to position the acromion 25 mm above the spinous process of T1. The impactor face was centred 25 mm below the glenohumeral joint. Each subject was impacted once.

Figure B.4 — Impactor test configuration from the oblique-lateral shoulder impacts conducted by OSU^[4] (frontal and overhead views of a 30° impact to the left shoulder of a PMHS)

WSU conducted a series of impactor tests to the shoulder, as shown in Figure B.5 [26] [30]. Each PMHS was seated on a plastic sheet on a wooden seat, without back support. The position of the head was maintained by light tension to webbing that was taped to the subject's head. The webbing was attached to a ring that slid off of a hook during impact to minimize the effect on PMHS movement. The impactor mass was 23 kg and its flat, circular impact face had a diameter of 152,4 mm. The impact face was made of plywood and it was centred on the acromion of the subject. Each PMHS was impacted once in the pure lateral direction.

Figure B.5 — Impactor test configuration from the lateral shoulder impacts conducted by WSU (back view)[26] [30]

<u>Table B.1</u> summarizes the shoulder impact tests conducted by INRETS, OSU, and WSU that are included in constructing injury risk curves for the shoulder and details all the shoulder impactor test configurations. They are also provided in the related electronic document RED2. It includes the scaled WorldSID results.

Tests selected and for which no WorldSID test results are available for the construction of the injury risk curves are in bold.

Annex C (informative)

PMHS thorax test data (thorax impactor tests)

Annex C includes the description of the PMHS thoracic impactor tests used in the construction of the injury risk curves.

HSRI conducted a series of impactor tests to the thorax of PMHS, as shown in Figure C.1 [43][44] [45]. Each PMHS was seated upright, with the arms positioned above the shoulder and the hands above the head. The impactor was 23,4 kg and its flat circular impact face had a diameter of 152,4 mm. The impact face was aligned vertically at the junction of the fourth rib and the sternum. In the fore-aft direction, it was aligned midway between the front and the back of the subject. Each PMHS was impacted three times. The first two tests were either a frontal impactor test followed by a lateral impactor test or vice versa. The first two impacts were 0,9 m/s. The third test was either a lateral or a frontal impactor test at higher speed or a lateral sled test. Only one HSRI lateral test was excluded (76T038) due to questionable data.

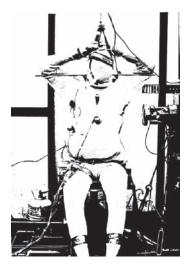

Figure C.1 — Impactor test configuration from the lateral thorax impacts conducted by HSRI (front view)[43] [44] [45]

WSU conducted a series of impactor tests to the thorax of PMHS, as illustrated in Figure C.2 [54] [55]. Each PMHS was suspended in a standing position, with the arms positioned above the shoulder and the hands above the head. The impactor mass was 23,4 kg and its flat circular impact face had a diameter of 152,4 mm and rounded edges. For the thorax impacts, the impact face was aligned vertically 75 mm below mid-sternum and struck at an angle of 30° forward of pure lateral. Only tests WSU935-4 and WSURNY1-3 were included because the injuries could be clearly attributed to the single test that each PMHS was subjected to.

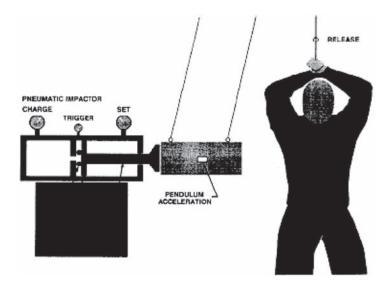

Figure C.2 — Impactor test configuration from the oblique-lateral thorax impacts conducted by WSU (front view)[54] [55]

UMTRI conducted a series of impactor tests to the thorax of PMHS, as illustrated in Figure C.3 [34] [35]. Each PMHS was suspended in a seated position, either with the arms positioned above the shoulder and the hands above the head or with the arms down. The impactor mass was 25 kg and its flat circular impact face had a diameter of 150 mm. The metal impact face had various materials affixed to it to produce different force-time histories and load distributions. The impact face was aligned mid-sternum in the vertical direction and midway between the front and the back of the subject in the fore-aft direction. Each subject was impacted multiple times. The tests at 2 m/s included a frontal impact, an impact at 45° forward of pure lateral, and up to three pure lateral impacts. The final test was a pure lateral impact at 8 m/s. The pure lateral test results were included if all low-speed impacts on a subject measured a peak force below 700 N. This level of load was deemed to be below the threshold of rib fracture and the fractures could be attributed to the final high-speed impact.

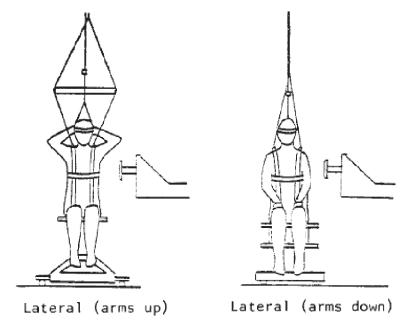

Figure C.3 — Impactor test configuration from the lateral thorax impacts conducted by UMTRI (front view)[34] [35]

ISO/TR 12350:2013(E)

OSU conducted a series of impactor tests to the thorax of PMHS, as illustrated in Figure C.4 [49]. Each PMHS was seated, with the arms horizontal and perpendicular to the torso and the forearms taped together on a horizontal support. The impactor mass was 23 kg and its flat circular impact face had a diameter of 152,4 mm, with an edge radius of 12,7 mm. The impact face was aligned vertically with the fourth interspace of the sternum. Each subject was impacted twice at a speed of approximately 2.5 m/s. One side of the subject was impacted in the pure lateral direction and the other side was impacted 30° forward of pure lateral. The order of the impacts was varied. The results were included if no fractures were found during autopsy or if the first impact on a subject measured a peak force below 700 N, both for the lateral and the oblique impacts. This level of load was deemed to be below the threshold of rib fracture and the fractures could be attributed to the second impact.

Figure C.4 — Impactor test configuration from the lateral and oblique-lateral thorax impacts conducted by OSU (front view)[49]

INRETS conducted a series of thorax impactor tests as illustrated in Figure B.1 [16]. The results of the INRETS tests were excluded because it was not possible to determine whether the fractures resulted from the shoulder impact or the thorax impact.

Table C.1 summarizes the HSRI, WSU, UMTRI, and OSU tests that are included in constructing injury risk curves for the thorax and details of all the thorax impactor test configurations. They are also provided in the related electronic document RED3. It includes the scaled WorldSID results.

Tests selected and for which no WorldSID test results are available for the construction of the injury risk curves are in bold.

Annex D (informative)

PMHS abdomen test data (abdomen impactor tests)

<u>Annex D</u> includes the description of the PMHS abdomen impactor tests used in the construction of the injury risk curves.

WSU conducted a series of impactor tests to the abdomen of PMHS [54] [55]. Only one test (WSU063-34) was included because all the other subjects were impacted more than once in the abdomen and/or thorax. The PMHS was suspended in a standing position, with the arms positioned above the shoulder and the hands above the head. The impactor mass was 23,4 kg and its flat, circular impact face had a diameter of 152,4 mm, with rounded edges. The impact face was aligned vertically 150 mm below midsternum and struck at an angle of 30° forward of pure lateral.

OSU conducted a series of abdomen impact tests [47]. Each PMHS was seated, with the arms positioned above the shoulder and the hands above the head, as shown in Figure D.1. The impactor mass was 9,1 kg and its flat, rectangular impact face was 200 mm wide and 150 mm high. The impactor face was padded with a 152,4-mm-thick piece of foam, either Arcel 310 (1,5 lb/f³), Ethafoam LC-200, or Arcel 310 (3 lb/f³). The impactor face was centred at the height of the lateral aspect of the eighth rib. Each subject was impacted once in the pure lateral direction. The impact speed was selected such that the abdomen deflection would not exceed 16 % of the PMHS chest breadth. The results from two subjects (93VRTAB08, 93VRTAB09) were excluded because the abdomen deflection exceeded the target level of 16 % of the chest breadth.

Figure D.1 — Impactor test configuration from the lateral abdomen impacts conducted by OSU (forward oblique view)[47]

The Laboratory of Accidentology and Biomechanics (LAB) conducted a series of impactor tests to the abdomen of PMHS^[52]. A measurement system was positioned at the level of the liver and could have influenced the abdominal injuries. Therefore, the results from this series were excluded.

Table D.1 summarizes the single WSU test and the OSU tests that are included in constructing injury risk curves for the abdomen and details of all the abdomen impactor test configurations. They are also provided in the related electronic document RED4. No WorldSID test results were available for these test conditions at the time when this Technical Report was published. This annex is kept for future use.

Annex E

(informative)

PMHS pelvis test data (pelvis impactor tests)

 $\underline{\text{Annex } E}$ includes the description of the PMHS pelvis impactor tests used in the construction of the injury risk curves.

WSU conducted a series of impactor tests to the pelvis of PMHS [54] [55]. Each PMHS was suspended in a standing position, with the arms positioned above the shoulder and the hands above the head. The impactor mass was 23,4 kg and its flat, circular impact face had a diameter of 152,4 mm, with rounded edges. For the pelvis impacts, the impact face was centred on the greater trochanter. Each subject was impacted up to three times in the pure lateral direction.

UMTRI conducted a series of impactor tests to the pelvis of PMHS, as illustrated in Figure E.1 [33] [36]. Each PMHS was suspended in a seated position and, for some of the tests, seated on a block of balsa wood upon a mobile table. The arms were down and the hands were positioned on the lap. The impactor mass was 20 kg, 25 kg, or 56 kg and its flat, circular impact face had a diameter of 150 mm. The metal impact face had various materials affixed to it to produce different force-time histories and load distributions. The impact face was aligned 80 mm anterior to the greater trochanter. Some subjects were impacted once or twice in the pure lateral direction, and others were subjected to a frontal impact to the knee prior to a pure lateral impact to the pelvis.

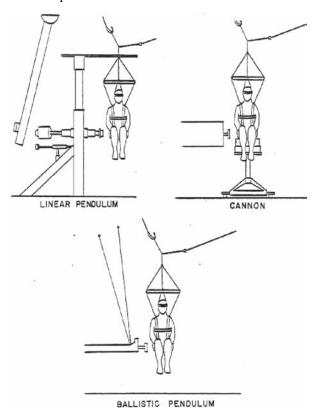

Figure E.1 — Impactor test configuration from the lateral pelvis impacts conducted by UMTRI (front view)[33] [36]

ONSER conducted a series of impactor tests to the pelvis of PMHS, as illustrated in Figure E.2 [11] [12]. Each PMHS was seated on a rigid seat. The arms were down and the hands were positioned on the lap.

The impactor mass was 17,3 kg. The impact face was a segment of a sphere (R=175 mm, r=60 mm) and it was either rigid or padded. The impact face was aligned on the greater trochanter. Each subject was impacted multiple times on the right side in a pure lateral direction. After each impact, x-ray was conducted to check for fractures. If the x-ray revealed no fractures, then the velocity was increased. If the x-ray revealed a fracture, then no additional tests were conducted on that subject.

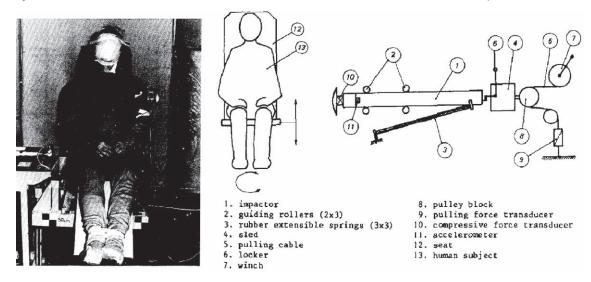

Figure E.2 — Impactor test configuration from the lateral pelvis impacts conducted by ONSER (front view)[11] [12]

INRETS conducted two series of pelvis impact tests^[5]. In the first series, each PMHS was seated on a Teflon sheet on a rigid seat. The impactor mass was 23,4 kg and its flat, rectangular impact face was 200 mm wide and 100 mm high. The impactor was centred on the greater trochanter. Each subject was impacted twice, on the same side, once at 3,5 m/s and once at 6,5 m/s. All of the results from INRETS first test series were included in the construction of injury risk curves for the pelvis.

In the second series of INRETS tests [6], the same test setup was used, but the impactor mass was either 12 kg or 16 kg and the impact speed was higher (9 m/s to 14 m/s). Each subject was impacted once. All of the results from INRETS second test series were included in the construction of injury risk curves for the pelvis.

The pelvis multi-impact tests were included when an increase in impactor speed was accompanied by an increase in energy, as this was assumed to be an indication of no injury.

Table E.1 summarizes the WSU, UMTRI, ONSER, and INRETS tests that could be included in constructing injury risk curves for the pelvis and details of all the pelvis impactor test configurations. They are also provided in the related electronic document RED5. It includes the scaled WorldSID results. No dummy tests were conducted with padding that was identical to that used in the PMHS tests.

Tests selected and for which no WorldSID test results are available for the construction of the injury risk curves are in bold.

Table E.1 — PMHS tests included in constructing injury risk curves for the pelvis

| Scaled pelvis acceleration 3 ms m/s² (CFC1000) | 444 | 565 | 340 | 640 | 338 | 338 | 631 | |

Annex F (informative)

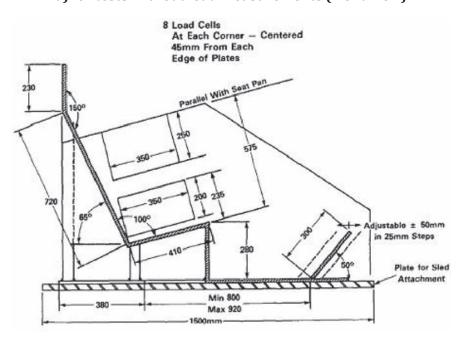

PMHS sled test data

<u>Annex F</u> includes the description of the PMHS sled tests used in the construction of the injury risk curves.

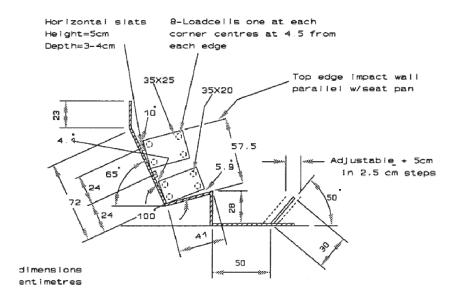

The University of Heidelberg conducted two series of whole body sled tests[25] [29]. In the first series of tests, shown in Figure F.1 a), the flat, rigid impact surface was tall enough that the subject's head impacted the wall. The impact wall was not instrumented in the first series of Heidelberg tests. In the second series of tests, illustrated in Figure F.1 b) or in Figure F.1 c), the impact wall consisted of separate instrumented plates that were impacted by the thorax and pelvis. The plates were either rigid or covered with blocks of APR pad. The second series had no impact surface for the head. The sled velocity ranged from 6,7 m/s to 12,7 m/s.

a) for tests without load measurements (front view)

b) for tests with load measurements according to [25][29] (side view)

c) for tests with load measurements according to [46] (side view)

Figure F.1 — Impact wall configuration from the lateral sled tests conducted by Heidelberg

HSRI conducted a series of whole body sled tests[31]. All of the HSRI sled tests were excluded because the impact wall was not instrumented with load cells.

MCW and OSU conducted a series of whole body sled tests[39] [40] [28] [27]. The impact wall configuration, illustrated in Figure F.2, was either flat, one plate was offset 110 mm closer to the subject, or the thorax and abdomen plates were angled, as shown in Figure F.3. The plates were either rigid, covered with 110-mm-thick Ethafoam LC-200, or covered with an airbag. The sled velocity ranged from 6,7 m/s to 8,9 m/s.

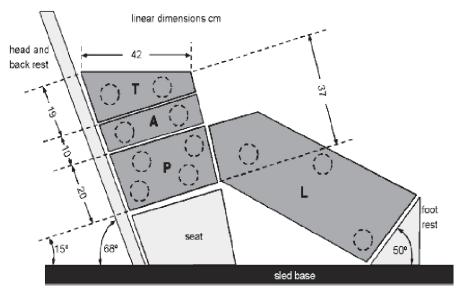

Figure F.2 — Impact wall configuration from the lateral sled tests conducted by MCW and OSU (side view)[39] [40] [28] [27]

Figure F.3 — Impact wall configuration from the lateral sled tests conducted by MCW for the angled thorax and abdomen plate tests (forward oblique view)[41]

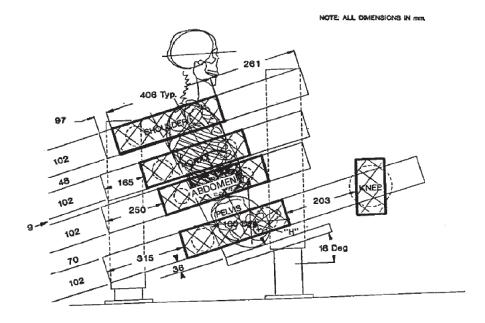

Figure F.4 — Impact wall configuration from the second series of lateral sled tests conducted by WSU (side view)[7] [8] [9] [10] [23]

Table F.1 summarizes the Heidelberg, HSRI, MCW, OSU, and WSU sled tests included in constructing injury risk curves and details all the sled test configurations. They are also provided in the related electronic document RED6. Table F.2 includes the scaled WorldSID results.

Tests selected and for which WorldSID test results are available for the construction of the injury risk curves are in bold.

Table F.1 — PMHS sled tests included in constructing injury risk curves

Annex G

(informative)

Assessment of the quality of the sled test results

Annex G details the description of analyses used to assess the quality of sled test results.

G.1 Momentum

Nusholtz et al.[38] proposed to use momentum for a data quality check. For a given test condition, the momentum for different PMHS should be consistent. Inconsistency in the momentum can be an indication of an instrumentation malfunction or improper calibration.

$$Momentum = \int_{0}^{T} F_{total_norm} dt$$
 (G.1)

where $F_{total\ norm}$ are the force measurements on the individual impact plates, normalized to a mid-size [19].

The integral is calculated from the time that the PMHS contact the first impact plate until the time that the PMHS is no longer contacting any of the impact plates.

The momentum for each test, with given impact wall configuration and impact velocity, should be consistent with all similar tests.

Momentum is also reported to a single sled velocity for a given test configuration to be able to compare momentum.

G.2 PMHS velocity at impact

For many tests, acceleration was measured at the PMHS (upper spine, lower spine, and pelvis). It is possible to calculate the velocity at each of these locations on the PMHS relative to the wall. If the PMHS is vertical when it strikes the impact wall, the velocity at these locations will be similar. If not, the PMHS was leaning, possibly due to friction of the pelvis on the bench.

The velocity at all locations of the spine and sacrum are compared at the time of contact with the first impact plate, regardless of the impact plate configuration.

G.3 PMHS leaning distance

Given the anthropometry of each PMHS, it is possible to calculate a theoretical distance that it is leaning at the time of contact with the impact wall. A theoretical difference between the time that the thorax plate is contacted and the time that the pelvis plate is contacted can be calculated.

[(pelvis breadth – shoulder breadth)/PMHS velocity relative to the wall]

The actual difference of time of contact with the thorax and pelvis plates can also be calculated. The time of contact was calculated, by using a modification of SAE J2052-Test Device Head Contact Duration Analysis (1997) (first time at which 5 % of the maximum plate force is reached, stepping backward in time from the time of maximum plate force).

The actual difference of contact time is then compared to the theoretical difference. The difference between the two contact times can be multiplied by the PMHS velocity relative to the wall to estimate the distance of leaning of the PMHS.

G.4 Transmissibility

The actual difference of contact time on the plate forces can also be compared to the transmissibility, the transmissibility being the time of maximum cross-correlation between two plate force measurements.

The cross-correlation consists in finding the time shift allowing the maximization of the sum of the product of the two signals considered on the whole time history.

$$C_{ab} = \sum_{t}^{t'} \mathbf{a}_i \cdot \mathbf{b}_i \tag{G.2}$$

where

 a_i is the standard alignment signal at the i^{th} time step;

 b_i is the signal to be aligned at the *i*th time step;

t is the beginning of the loading;

t' is the end of the loading.

The signals over the whole time history were used to calculate the time when the cross-correlation is maximum.

The comparison was performed between the thorax and pelvis load plates. If the transmissibility is not consistent with the actual difference of contact times, it means the considered test presents some irregularities.

G.5 Seating height

The MCW sled wall geometry was designed in order not to load the shoulder of the surrogate. The check for the shoulder interaction could have been done for all the tests looking at the high-speed videos. Unfortunately, all the films were not available. The use of the anthropometric measurements taken prior to the test was then chosen. The seated height of the occupant (SEATHT) was taken prior to the test with the test occupant sitting erect, looking straight ahead. It corresponded to the vertical distance from the sitting surface to the top of the head (see Figure G.1).

Figure G.1 — Illustration of the seated height (SEATHT), as defined in the MCW test reports

Schneider et al. (1985)^[48] provided some reference points specifying the anthropometry of the 50th and 95th male occupant. The top of the head was not included as a specific point. They also provided some drawings illustrating the anthropometry. The seating height were measured based on these drawings. The seating heights measured on the UMTRI drawings were 888 mm for the 50th male and 950 mm for the 95th male. The difference between the 50th and 95th seating height was 62 mm. The seating height of a 5th percentile male was then calculated by subtracting 62 mm from the seating height of the 50th

ISO/TR 12350:2013(E)

male, hypothesizing a normal distribution of this parameter. The seating height of a 5th percentile male was then found to be 826 mm.

It was proposed to exclude the PMHS with a seating height lower than 826 mm unless it was clear from the films that the shoulder did not interact with the wall, from the construction of the injury risk curves for the shoulder, thorax, and abdomen. These PMHS were not excluded from the construction of the pelvis injury risk curves because there was no evidence of the influence of the shoulder contact on the pelvis effective mass.

Annex H (informative)

WorldSID results

Annex H presents the WorldSID 50th test results corresponding to the PMHS configurations listed in Annex A to Annex F.

H.1 WorldSID head impactor test results

Table H.1 describes the dummy data available for head impactor tests.

Table H.1 — Dummy head impactor test results used for the construction of the injury risk curve

| PMHS test condition | Actual WorldSID impact speed m/s | WorldSID test number | WorldSID HIC |
|---|--|----------------------|--------------|
| Calspan 25,3 kg rigid impactor at 4 m/s (203 mm × 254 mm rectangular impact face) | NA | NA | NA |
| Calspan 23,4 kg rigid impactor at 4 m/s (152-mm-diameter circular impact face) | NA | NA | NA |
| Calspan 24,4 kg rigid impactor at 3 m/s (171,5 mm × 203 mm rectangular impact face) | NA | NA | NA |
| Calspan 24,4 kg impactor at 4 m/s (171,5mm × 203 mm rectangular impact face covered with 51 mm pad) | NA | NA | NA |

H.2 WorldSID head drop test results

Table H.2 describes the dummy data available for head drop tests.

Table H.2 — Dummy head drop test results used for the construction of the injury risk curve

Annex I

(informative)

Data scaling

<u>Annex I</u> describes the method used to scale the data before constructing the injury risk curves.

PMHS included in biomechanical studies present different characteristics (e.g. height, mass, mass distribution, bone strength) than an average mid-size adult male. It is therefore not correct to directly correlate the response of a mid-size male dummy to the injuries of a PMHS that is not a mid-size male. Each PMHS represents a different percentile. Each PMHS percentile is called "xxth percentile".

Scaling methods were developed in order to define injury risk curves for subjects of a given percentile using the injury risk curves of a different percentile. For example, the injury risk curves for a 5th percentile female or for a 95th male could be derived from injury risk curves defined for a 50th percentile male. Scaling factors were defined for each criterion in Reference^[32] and are presented for some criteria in Formula (I.1).

$$\lambda_d = \lambda_L \tag{I.1}$$

where λ_d is the ratio of deflection and λ_L is the ratio of a characteristic length of the PMHS.

The matter being only to scale each subject to a different size, their bone characteristics were kept constant ($\lambda_{\sigma f}$ =1 and λ_{E} =1, with $\lambda_{\sigma f}$ being the failure strength ratio and λ_{E} the Young's modulus ratio). Formula (I. 1) is then equivalent to Formula (I.2).

$$\lambda_{\mathcal{E}} = 1 \tag{I.2}$$

where λ_{ϵ} is the ratio of strain.

Strain can be defined in terms of deflection (*d*) and length (*L*) for each body region, therefore:

$$\frac{\lambda_d}{\lambda_L} = 1 \tag{I.3}$$

Formula (I.3) means that an *xxth* percentile PMHS will sustain the same injuries as a 50th percentile PMHS if each is compressed in proportion to the characteristic length, as written in Formula (I.4).

$$\frac{d_{xxth_PMHS}}{L_{xxth_PMHS}} = \frac{d_{50\text{th_}PMHS}}{L_{50\text{th_}PMHS}} \tag{I.4}$$

The use of a mass-spring-mass model, like in the normalization process, [24] allows for the calculation of a subject deflection as a function of the impactor mass and initial velocity, the subject mass, and the subject stiffness. By rearranging Formula (I.4), it is possible to calculate the impact velocity necessary to induce the same injuries on the 50th percentile PMHS as on the xxth percentile PMHS. This velocity is named V_0 50th PMHS.

This impact velocity $V_{0_50th_PMHS}$, however, does not correspond exactly to the impact velocity from the actual 50th percentile dummy tests. That is the reason why the actual 50th percentile dummy data responses need to be scaled to account for velocity differences relative to the target impact speed scaled for a 50th percentile PMHS $V_{0_50th_PMHS}$.

The principle of the scaling method is the same for the force, the acceleration, and the viscous criterion.

The following paragraphs explain in detail the calculation process done, first, to scale xxth percentile PMHS data to 50th percentile PMHS data, and second, to scale the dummy data to the relevant velocity $V_{0.50th~PMHS}$.

A mass-spring-mass model is considered. The impacting mass was equal to the impactor mass in the impactor tests and infinite in both the drop and sled tests. It can be noted that no scaling was necessary for the sled test configuration except the adjustment due to differences between the dummy impact speed and each PMHS impact speed.

Scaling factor for impactor test

I.1.1 Deflection

Since $\frac{\lambda_d}{\lambda_I} = 1$, the invariant parameter is compression.

In the data sample selected in the analysis, each PMHS represents a different percentile. Each PMHS percentile is called "xxth percentile".

Given the mass-spring-mass model in Reference^[24], the deflection and the compression for the xxth percentile PMHS are:

$$deflection_{xxth_PMHS} = V_{0_xxth_PMHS} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times \frac{1}{k_{xxth_PMHS}}$$

$$compression_{xxth_PMHS} = \frac{V_{0_xxth_PMHS}}{L_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times \frac{1}{k_{xxth_PMHS}}$$

$$(I.5)$$

$$compression_{xxth_PMHS} = \frac{V_{0_xxth_PMHS}}{L_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times \frac{1}{k_{xxth_PMHS}}$$
(I.6)

where

 $V_{0_xxth_PMHS}$ is the impact speed for the xxth percentile PMHS test;

is the stiffness of the body region considered of an *xxth* percentile PMHS: k_{xxth PMHS}

is the impactor mass (the same impactor mass is used for the xxth and the 50th per $m_{imp\ PMHS}$ centile PMHS);

is the effective mass of the body region considered of the xxth percentile PMHS; m_{xxth_PMHS}

is a characteristic length for the *xxth* PMHS. $L_{xxth\ PMHS}$

For a 50th percentile PMHS, the deflection and the compression are:

$$deflection_{50th_PMHS} = V_{0_50th_PMHS} \times \sqrt{\frac{m_{50th_PMHS} \times m_{imp_PMHS}}{m_{50th_PMHS} + m_{imp_PMHS}}} \times \frac{1}{k_{50th_PMHS}}$$
(I.7)

$$compression_{50th_PMHS} = \frac{V_{0_50th_PMHS}}{L_{50th_PMHS}} \times \sqrt{\frac{m_{50th_PMHS} \times m_{imp_PMHS}}{m_{50th_PMHS} + m_{imp_PMHS}}} \times \frac{1}{k_{50th_PMHS}}$$
(I.8)

where

 $V_{0_50th_PMHS}$ is the impact speed for the 50th percentile PMHS test;

is the stiffness of the body region considered of a 50th percentile PMHS; k_{50th PMHS}

is the effective mass of the body region considered of the 50th percentile PMHS (see m_{50th PMHS} Table I.1);

is a characteristic length for the 50th PMHS. $L_{50th\ PMHS}$

Since the invariant parameter is compression: $compression_{xxth\ PMHS} = compression_{50th\ PMHS}$, for a given injury assessment.

$$\frac{V_{0_xxth_PMHS}}{L_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times \frac{1}{k_{xxth_PMHS}} = \frac{V_{0_50th_PMHS}}{L_{50th_PMHS}} \times \sqrt{\frac{m_{50th_PMHS} \times m_{imp_PMHS}}{m_{50th_PMHS} + m_{imp_PMHS}}} \times \frac{1}{k_{50th_PMHS}} \times \frac{1}{k_{50th$$

If the same impactor mass is considered for the xxth percentile PMHS and the 50th percentile PMHS, the impact velocity for a 50th percentile PMHS allowing the same compression can be defined as follows:

$$V_{0_50th_PMHS} = \frac{V_{0_xxth_PMHS} \times L_{50th_PMHS}}{L_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times \frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{50th_PMHS} \times m_{imp_PMHS}} \times \frac{k_{50th_PMHS}}{k_{xxth_PMHS}} \times \frac{k_{50$$

Making the hypothesis of geometric similarity of the PMHS:

$$\lambda_k = \frac{k_{xxth_PMHS}}{k_{50th_PMHS}} = \lambda_m^{1/3} \tag{I.11}$$

$$\lambda_L = \frac{L_{xxth_PMHS}}{L_{50th_PMHS}} = \lambda_m^{1/3} \tag{I.12}$$

$$\lambda_m = \frac{m_{xxth_PMHS}}{m_{50th_PMHS}} \tag{I.13}$$

$$V_{0_50th_PMHS} = \frac{V_{0_xxth_PMHS}}{\lambda_m^{1/3}} \times \sqrt{\frac{\lambda_m}{\lambda_m^{1/3}}} \times \frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}$$
(I.14)

$$V_{0_50th_PMHS} = V_{0_xxth_PMHS} \times \sqrt{\frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}}$$
(I.15)

The ansat hat a 50th percentile PMHS should be impacted at $V_{0_50tl_PMHS}$ in order to have the same

It means that a 50th percentile PMHS should be impacted at $V_{0_50th_PMHS}$ in order to have the same compression as the xxth percentile PMHS and that the injury assessments for the 50th and xxth percentile PMHS will be the same.

Consequently, the 50th percentile dummy measurement to be associated with the PMHS injury assessment is the dummy measurement that would be found for an impact speed of $V_{0.50th\ PMHS}$.

However, dummy tests were only conducted at reference velocities, $V_{REF_0_50th_dummy}$. If $d_{REF_50th_dummy}$ is the deflection measured on the dummy at this reference velocity, then the dummy deflection at $V_{0_50th_PMHS}$, named $d_{scaled_50th_dummmy}$, would be the following:

$$d_{scaled_50th_dummmy} = d_{REF_50th_dummmy} \times \frac{V_{0_50th_PMHS}}{V_{REF_0_50th_dummmy}}$$
(I.16)

since for a given subject, deflection and impact velocity are proportional with the spring-mass model considered here.

Finally, it gives:

$$d_{scaled_50th_dummmy} = \frac{d_{REF_50th_dummmy}}{V_{REF_0_50th_dummmy}} \times V_{0_xxth_PMHS} \times \sqrt{\frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}}$$
(I.17)

Table I.1 — PMHS effective mass used for data scaling

| 50th male dummy | PMHS used to determine the mean % effective mass/total body mass | mean % effective mass/total body mass | m _{50th_PMHS} kg |
|-----------------------------|---|--|------------------------------|
| For shoulder impactor tests | LCE01, LCE02, LCE03, LCE04, LCE07, LCE08, LCE09, LCE10, LCE11, LCE12, LCE13, LCE14, LCE15, LCE16, LCE17, LCE18, LCE20, LCE21, LCE22, LCE23, LCE24, LCE25, LCE26, LCE27, LCE28, LCE29, LCE30, LCE31, LCE32, LCE33, LCE34, LCE35, LCE36, 02-UM29899, 04-UM29850, 05-UM29852, 06-UM29851, 07-WSU025, 09-WSU170, 10-WSU091, 11-WSU164, 12-UM30436 | 20,4 | 15,6 |
| For thorax impactor tests | 76T061, 76T062, 76T064, 76T065, 77T066, 77T070, 77T071, 77T073, 77T074, 77T076, 77T077, 77T081, 77T084, 77T088, 77T090, 77T091, 77T094, 77T097, 05030TH25L01, 0503LTH25R01, 0504LTH25L01, 0504OTH25R02, 0507LTH25R01, 0507OTH25L01, 0602LTH25R01, 0602OTH25L01 | 39,6 | 30,4 |
| For abdomen impactor tests | 93VRTAB01, 93VRTAB02, 93VRTAB03, 93VRTAB04, 93VRTAB05, 93VRTAB06, 93VRTAB07 | 50,4 | 38,4 |
| For pelvis impactor test | D1, D2, E1, H3, I1, I2, I3, I4, I5, J1, L1, L2, L3, L4, T2, V2, W2, MRB02, MRB03, MRB04, MRB06, MRB07, MRB08, MRB11, MRB12, MRB15, MRB16, MRB17, MRB18, MRB19 | 31,2 | 23,9 |

For each of the PMHS for which the effective mass was not available, the mean ratio of the effective mass out of the total body mass was multiplied by the total body mass of the PMHS considering a similar body posture, similar impact location on the body, similar impactor, similar impact angle, similar test velocity, etc. as those included in the PMHS sample used to compute the mean effective mass.

I.1.2 Force

Since $\frac{\lambda_F}{\lambda_S} = 1$, stress is the invariant parameter where λ_F is the ratio of force and λ_S is the ratio of surface.

In the data sample selected in the analysis, each PMHS represents a different percentile. Each PMHS percentile is called "xxth percentile".

Given the mass-spring-mass model in Reference [24], the force and the stress for the xxth percentile PMHS are:

$$Force_{xxth_PMHS} = V_{0_xxth_PMHS} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times k_{xxth_PMHS}}$$
 (I.18)

$$stress_{xxth_PMHS} = \frac{V_{0_xxth_PMHS}}{S_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times k_{xxth_PMHS}$$
(I.19)

where

 $V_{0_xxth_PMHS}$ is the impact speed for the xxth percentile PMHS test;

is the stiffness of the body region considered of a xxth percentile PMHS; k_{xxth PMHS}

is the impactor mass (the same impactor mass is used for the xxth and the 50th per m_{imp_PMHS} centile PMHS);

is the effective mass of the body region considered of the xxth percentile PMHS; $m_{xxth\ PMHS}$

is a characteristic section for the xxth PMHS (a characteristic section could be the $S_{xxth\ PMHS}$ area of a section of the ischio-ilio pubic ramus).

For a 50th percentile PMHS, the force and the stress are:

$$Force_{50th_PMHS} = V_{0_50th_PMHS} \times \sqrt{\frac{m_{50th_PMHS} \times m_{imp_PMHS}}{m_{50th_PMHS} + m_{imp_PMHS}}} \times k_{50th_PMHS}} \times k_{50th_PMHS}}$$

$$stress_{50th_PMHS} = \frac{V_{0_50th_PMHS}}{S_{50th_PMHS}} \times \sqrt{\frac{m_{50th_PMHS} \times m_{imp_PMHS}}{m_{50th_PMHS} + m_{imp_PMHS}}} \times k_{50th_PMHS}}{m_{50th_PMHS}}} \times k_{50th_PMHS}}$$
(I.21)

$$stress_{50th_PMHS} = \frac{V_{0_50th_PMHS}}{S_{50th_PMHS}} \times \sqrt{\frac{m_{50th_PMHS} \times m_{imp_PMHS}}{m_{50th_PMHS} + m_{imp_PMHS}}} \times k_{50th_PMHS}$$
(I.21)

where

 $V_{0_50th_PMHS}$ is the impact speed for the 50th percentile PMHS test;

is the stiffness of the thorax of a 50th percentile PMHS; k_{50th PMHS}

is the effective mass of the body region considered of the 50th percentile PMHS (see m_{50th_PMHS} Table I.1);

 $S_{50th\ PMHS}$ is the characteristic section for the 50th PMHS.

Since the invariant parameter is stress:
$$stress_{xxth_PMHS} = stress_{50th_PMHS}$$
, for a given injury assessment.
$$\frac{V_{0_50th_PMHS}}{S_{50th_PMHS}} \times \sqrt{\frac{m_{50th_PMHS} \times m_{imp_PMHS}}{m_{50th_PMHS} + m_{imp_PMHS}}} \times k_{50th_PMHS} = \frac{V_{0_xxth_PMHS}}{S_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times k_{xxth_PMHS}$$
(I.22)

If the same impactor mass is considered for the xxth percentile PMHS and the 50th percentile PMHS, the impact velocity for a 50th percentile allowing the same stress can be defined as follows:

$$V_{0_50th_PMHS} = V_{0_xxth_PMHS} \times \frac{S_{50th_PMHS}}{S_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times \frac{k_{xxth_PMHS}}{k_{50th_PMHS}} \times \frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{50th_PMHS} \times m_{imp_PMHS}} \times \frac{m_{50th_PMHS}}{m_{50th_PMHS}} \times \frac{m_{50$$

Making the hypothesis of geometric similarity of the PMHS:

$$\lambda_k = \frac{k_{xxth_PMHS}}{k_{50th_PMHS}} = \lambda_m^{1/3} \tag{I.24}$$

© ISO 2013 - All rights reserved

$$\lambda_S = \frac{S_{xxth_PMHS}}{S_{50th_PMHS}} = \lambda_m^{2/3} \tag{I.25}$$

$$\lambda_m = \frac{m_{xxth_PMHS}}{m_{50th_PMHS}} \tag{I.26}$$

$$V_{0_50th_PMHS} = \frac{V_{0_xxth_PMHS} \times L_{50th_PMHS}}{L_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times \frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{50th_PMHS} \times m_{imp_PMHS}} \times \frac{k_{50th_PMHS}}{k_{xxth_PMHS}} \times \frac{k_{50$$

$$V_{0_50th_PMHS} = V_{0_xxth_PMHS} \times \frac{1}{\lambda_m^{2/3}} \times \sqrt{\frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times \lambda_m^{4/3}$$
 (I.28)

$$V_{0_50th_PMHS} = V_{0_xxth_PMHS} \times \sqrt{\frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}}$$
(I.29)

It means that a 50th percentile PMHS should be impacted at $V_{0_50th_PMHS}$ in order to have the same stress as the *xxth* percentile PMHS and that the injury assessments for the 50th and *xxth* percentile PMHS will be the same.

Consequently, the 50th percentile dummy measurement to be associated with the PMHS injury assessment is the dummy measurement that would be found for an impact speed of $V_{0_50th_PMHS}$.

However, dummy tests were only conducted at reference velocities, $V_{REF_0_50th_dummy}$. If $F_{REF_50th_dummmy}$ is the force measured on the dummy at this reference velocity, then the dummy force at $V_{0_50th_PMHS}$, named $F_{scaled_50th_dummmy}$, would be the following:

$$F_{scaled_50th_dummmy} = F_{REF_50th_dummmy} \times \frac{V_{0_50th_PMHS}}{V_{REF_0_50th_dummmy}}$$
(I.30)

since for a given subject, force and impact velocity are proportional with the spring-mass model considered here.

$$F_{scaled_50th_dummmy} = \frac{F_{REF_50th_dummmy}}{V_{REF_0_50th_dummmy}} \times V_{0_xxth_PMHS} \times \sqrt{\frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}}$$
(I.31)

I.1.3 Acceleration

Since $\lambda_a \times \lambda_L = 1$, the invariant parameter is stress where λ_a is the ratio of acceleration.

In the data sample selected in the analysis, each PMHS represents a different percentile. Each PMHS percentile is called "xxth percentile".

Given the spring-mass model in Reference[24], the acceleration and stress for the *xxth* percentile PMHS are:

$$Acc_{xxth_PMHS} = \frac{V_{0_xxth_PMHS}}{m_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS}}} \times k_{xxth_PMHS}}$$

$$(I.32)$$

ISO/TR 12350:2013(E)

$$Stress_{xxth_PMHS} = \frac{V_{0_xxth_PMHS}}{m_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS}} + m_{imp_PMHS}}} \times k_{xxth_PMHS} \times \frac{m_{xxth_PMHS}}{S_{xxth_PMHS}}$$
(I.33)

where

 $V_{0_xxth_PMHS}$ is the impact speed for the xxth percentile PMHS test;

is the stiffness of the body region considered of a *xxth* percentile PMHS; k_{xxth PMHS}

is the impactor mass (the same impactor mass is used for the xxth and the 50th per m_{imp_PMHS} centile PMHS);

is the effective mass of the body region considered of the xxth percentile PMHS; $m_{xxth\ PMHS}$

is a characteristic section for the xxth PMHS. $S_{xxth\ PMHS}$

For a 50th percentile PMHS, the acceleration and stress are:

$$Acc_{50th_PMHS} = \frac{V_{0_50th_PMHS}}{m_{50th_PMHS}} \times \sqrt{\frac{m_{50th_PMHS} \times m_{imp_PMHS}}{m_{50th_PMHS} + m_{imp_PMHS}}} \times k_{50th_PMHS}}$$
(I.34)

$$Stress_{50th_PMHS} = \frac{V_{0_50th_PMHS}}{m_{50th_PMHS}} \times \sqrt{\frac{m_{50th_PMHS} \times m_{imp_PMHS}}{m_{50th_PMHS} + m_{imp_PMHS}}} \times k_{50th_PMHS} \times \frac{m_{50th_PMHS}}{S_{50th_PMHS}}$$
(I.35)

where

 $V_{0.50th\ PMHS}$ is the impact speed for the 50th percentile PMHS test;

is the stiffness of the body region considered of a 50th percentile PMHS; k_{50th PMHS}

is the effective mass of the body region considered of the 50th percentile PMHS (see m_{50th PMHS} Table I.1);

is a characteristic section for the 50th PMHS. $S_{50th\ PMHS}$

Since the invariant parameter is stress: $stress_{xxth}$ $_{PMHS} = stress_{50th}$ $_{PMHS}$, for a given injury assessment.

$$\frac{V_{0_50th_PMHS}}{m_{50th_PMHS}} \times \sqrt{\frac{m_{50th_PMHS} \times m_{imp_PMHS}}{m_{50th_PMHS} + m_{imp_PMHS}}} \times k_{50th_PMHS}}{k_{50th_PMHS}} \times \frac{m_{50th_PMHS}}{s_{50th_PMHS}} = \frac{V_{0_xxth_PMHS}}{m_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS}}} \times k_{xxth_PMHS}}{k_{xxth_PMHS}} \times \frac{m_{xxth_PMHS}}{s_{xxth_PMHS}} \times \frac{m_{xxth_PMHS}}{s_{x$$

If the same impactor mass is considered for the xxth percentile PMHS and the 50th percentile PMHS, the impact velocity for a 50th percentile PMHS allowing the same stress can be defined.

Making the hypothesis of geometric similarity of the PMHS:

$$\lambda_k = \frac{k_{xxth_PMHS}}{k_{50th_PMHS}} = \lambda_m^{1/3} \tag{I.37}$$

$$\lambda_S = \frac{S_{xxth_PMHS}}{S_{50th_PMHS}} = \lambda_m^{2/3} \tag{I.38}$$

$$\lambda_{m} = \frac{m_{xxth_PMHS}}{m_{50th_PMHS}}$$
 (I. 11, I. 12, I. 13) (I.39)

$$V_{0_50th_PMHS} = V_{0_xxth_PMHS} \times \sqrt{\frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}}$$
(I.40)

It means that a 50th percentile PMHS should be impacted at $V_{0_50th_PMHS}$ in order to have the same stress as the *xxth* percentile PMHS and that the injury assessments for the 50th and *xxth* percentile PMHS will be the same.

Consequently, the 50th percentile dummy measurement to be associated with the PMHS injury assessment is the dummy measurement that would be found for an impact speed of $V_{0.50th\ PMHS}$.

However, dummy tests were only conducted at reference velocities, $V_{REF_0_50th_dummy}$. If $Acc_{REF_50th_dummy}$ is the acceleration measured on the dummy at this reference velocity, then the dummy acceleration at $V_{0_50th_PMHS}$, named $Acc_{scaled_50th_dummy}$, would be the following:

$$Acc_{scaled_50th_dummmy} = Acc_{REF_50th_dummmy} \times \frac{V_{0_50th_PMHS}}{V_{REF_0_50th_dummmy}}$$
(I.41)

since for a given subject, acceleration and impact velocity are proportional with the spring-mass model considered here.

$$Acc_{scaled_50th_dummmy} = \frac{Acc_{REF_50th_dummmy}}{V_{REF_0_50th_dummmy}} \times V_{0_xxth_PMHS} \times \sqrt{\frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}}$$
(1.42)

I.1.4 Viscous criterion

Since $\lambda_V = 1$, the invariant parameter is PMHS velocity where λ_V is the ratio of velocity.

In the data sample selected in the analysis, each PMHS represents a different percentile. Each PMHS percentile is called "xxth percentile".

The deflection, deflection speed, and compression for the xxth percentile PMHS are:

$$deflection_{xxth_PMHS} = \frac{V_{0_xxth_PMHS}}{\omega} \times \sin(\omega t)$$
(I.43)

$$V_{xxth_PMHS} = V_{0_xxth_PMHS} \times \cos(\omega t) \tag{I.44}$$

$$C_{xxth_PMHS} = \frac{V_{0_xxth_PMHS}}{\omega} \times \sin(\omega t) \times \frac{1}{L_{xxth_PMHS}}$$
(I.45)

where

 $V_{0_xxth_PMHS}$ is the impact speed for the xxth percentile PMHS test;

 ω is pulsation;

 $L_{xxth\ PMHS}$ is the length for the xxth PMHS.

The VC for the *xxth* percentile PMHS is:

$$VC_{xxth_PMHS} = V_{0_xxth_PMHS} \times \cos(\omega t) \times \frac{V_{0_xxth_PMHS}}{\omega} \times \sin(\omega t) \times \frac{1}{L_{xxth_PMHS}}$$
(I.46)

$$VC_{xxth_PMHS} = V_{0_xxth_PMHS}^2 \times \cos(\omega t) \times \frac{1}{\omega} \times \sin(\omega t) \times \frac{1}{L_{xxth_PMHS}}$$
(I.47)

$$VC_{xxth_PMHS} = \sin(2\omega t) \times \frac{V_{0_xxth_PMHS}^2}{2 \times \omega \times L_{xxth_PMHS}}$$
(I.48)

The maximum for VC for the xxth percentile PMHS is:

$$VC_{xxth_PMHS_max} = \frac{V_{0_xxth_PMHS}^2}{2 \times L_{xxth_PMHS} \times \omega}$$
(I.49)

$$VC_{xxth_PMHS_max} = \frac{V_{0_xxth_PMHS}^2}{2L_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times \frac{1}{k_{xxth_PMHS}}$$
(I.50)

The maximum for VC for the 50th percentile PMHS is:

$$VC_{50th_PMHS_max} = \frac{V_{0_50th_PMHS}^{2}}{2L_{50th_PMHS}} \times \sqrt{\frac{m_{50th_PMHS} \times m_{imp_PMHS}}{m_{50th_PMHS} + m_{imp_PMHS}}} \times \frac{1}{k_{50th_PMHS}}$$
(I.51)

Since the invariant parameter is velocity: V_{xxth} $P_{MHS} = V_{50th}$ P_{MHS} , for a given injury assessment.

$$\frac{V_{0_50th_PMHS}^2}{2L_{50th_PMHS}} \times \sqrt{\frac{m_{50th_PMHS} \times m_{imp_PMHS}}{m_{50th_PMHS} + m_{imp_PMHS}}} \times \frac{1}{k_{50th_PMHS}} = \frac{V_{0_xxth_PMHS}^2}{2L_{xxth_PMHS}} \times \sqrt{\frac{m_{xxth_PMHS} \times m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}} \times \frac{1}{k_{xxth_PMHS}} \times \frac{1}{m_{xxth_PMHS}} \times \frac{1}{m$$

If the same impactor mass is considered for the xxth percentile PMHS and the 50th percentile PMHS, the impact velocity for a 50th percentile PMHS allowing the same velocity can be defined.

Making the hypothesis of geometric similarity of the PMHS:

$$\lambda_k = \frac{k_{xxth_PMHS}}{k_{50th_PMHS}} = \lambda_m^{1/3} \tag{I.53}$$

$$\lambda_L = \frac{L_{xxth_PMHS}}{L_{50th_PMHS}} = \lambda_m^{1/3} \tag{I.54}$$

$$\lambda_m = \frac{m_{xxth_PMHS}}{m_{50th_PMHS}} \tag{I.55}$$

$$V_{0_50th_PMHS} = V_{0_xxth_PMHS} \times \left(\frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}\right)^{1/4}$$
(I.56)

It means that a 50th percentile PMHS should be impacted at $V_{0.50th\ PMHS}$ in order to have the same maximum of VC as the xxth percentile PMHS and that the injury assessments for the 50th and xxth percentile PMHS will be the same.

Consequently, the 50th percentile dummy measurement to be associated with the PMHS injury assessment is the dummy measurement that would be found for an impact speed of $V_{0\ 50th\ PMHS}$.

However, dummy tests were only conducted at reference velocities, $V_{REF_0_50th_dummy}$. If $VC_{REF_max_50th_dummy}$ is the maximum VC measured on the dummy at this reference velocity, then the dummy maximum VC at $V_{0_50th_PMHS}$, named $VC_{max_scaled_50th_dummy}$, would be the following:

$$VC_{\text{max_scaled_50th_dummmy}} = VC_{REF_\text{max_50th_dummmy}} \times \left(\frac{V_{0_50th_PMHS}}{V_{REF_0_50th_dummmy}}\right)^{2}$$
(I.57)

since for a given subject, VC and impact velocity are square proportional with the spring-mass model considered here.

$$VC_{\max_scaled_50th_dummmy} = VC_{REF_\max_50th_dummmy} \times \left(\frac{V_{0_xxth_PMHS}}{V_{REF_0_50th_dummmy}}\right)^2 \times \sqrt{\frac{m_{50th_PMHS} + m_{imp_PMHS}}{m_{xxth_PMHS} + m_{imp_PMHS}}}$$
(I.58)

I.2 Scaling factor for sled and drop test

The same process is used as the one described above, replacing impactor mass by an infinite mass.

I.2.1 **Deflection**

$$d_{scaled_50th_dummmy} = d_{REF_50th_dummmy} \times \frac{V_{0_xxth_PMHS}}{V_{REF_0_50th_dummmy}}$$
(I.59)

I.2.2 **Force**

$$F_{scaled_50th_dummmy} = F_{REF_50th_dummmy} \times \frac{V_{0_xxth_PMHS}}{V_{REF_0_50th_dummmy}}$$
(I.60)

I.2.3 Acceleration

$$Acc_{scaled_50th_dummmy} = \frac{Acc_{REF_50th_dummmy}}{V_{REF_0_50th_dummmy}} \times V_{0_xxth_PMHS}$$
(I.61)

I.2.4 For viscous criterion

$$VC_{\text{max_scaled_50th_dummmy}} = VC_{REF_\text{max_50th_dummmy}} \times \left(\frac{V_{0_xxth_PMHS}}{V_{REF_0_50th_dummmy}}\right)^{2}$$
(I.62)

Hypothesis of geometric similarity **I.3**

The hypothesis of geometric similarity was made in the scaling process. The characteristic dimensions were indeed not available for the major part of the different series of PMHS tests. For example, the pelvis width was not available for the ONSER pelvis impactor tests. The ONSER pelvis impactor test sample represents half of the pelvis impactor tests used in this study (45 tests). Excluding these tests based on the fact that the characteristic dimension was not available would mean constructing the injury risk curves with small sample sizes and reduce the confidence in the results. Finally, it was preferred to keep a consistent way to calculate the stiffness and length ratio within the PMHS test samples. All the tests, including those for which the characteristic dimensions were available, were then analysed making the hypothesis of geometric similarity. Making the hypothesis of geometric similarity when no characteristic dimensions are available is a method that was already used in ISO/TR 9790.

Annex J (informative)

Steps to build injury risk curves dedicated to the WorldSID 50th

Annex J describes the different steps to be followed to build the injury risk curves for the WorldSID 50th dummy.

J.1 Estimation of the parameters

The risk according to the Weibull distribution is

$$Risk(\%) = 1 - \exp \left[-\left(\frac{Dummy_measurement}{\exp(\text{int} + PMHS_age \times coef_age} \right)^{\frac{1}{\exp(\log_scale)}} \right]$$
 (J.1)

The risk according to the log-normal distribution is

$$Risk(\%) = \log_n ormal_distribution[mean = int + age \times coef_age, std = exp(log_scale)]$$
 (J.2)

The risk according to the log-logistic distribution is

$$Risk(\%) = \frac{1}{1 + \exp\left\{-\left[\ln(Dummy_measurement) - \left(\text{int} + age \times coef_age\right)\right] / \exp(\log_scale)\right\}}$$
 (J.3)

when Dummy_measurement corresponds to the dummy measurement and PMHS_age corresponds to the PMHS age.

Table J.1 — Estimated parameters for the Weibull, log-normal, and log-logistic distributions for the survival analysis

| Injury risk | Dummy meas- urement | Distribution | int | Coef_age | Log_scale | AIC |
|-------------------------------|--|--------------|---------------|----------------|----------------|----------|
| Shoulder AIS2+ | Maximum shoul- der rib deflection (mm) | Weibull | 4,802 901 10 | -0,010 876 66 | -1,526 854 06 | 22,702 7 |
| | Maximum shoulder rib Y force (N) | Weibull | 8,143 520 261 | -0,005 505 064 | -2,002 759 491 | 28,680 4 |
| Skeletal thoracic AIS3+ | Maximum tho- racic rib deflec- tion (mm) | Log-logistic | 4,669 947 91 | -0,014 571 79 | -2,094 495 85 | 24,883 7 |
| | Maximum tho- racic rib VC (m/s) | Log-normal | 0,981 639 78 | -0,027 385 26 | -0,682 914 85 | 29,691 1 |
| Skeletal thoracic AIS4+ | Maximum tho- racic rib deflec- tion (mm) | Log-normal | 5,463 324 33 | -0,016 541 52 | -1,239 534 59 | 29,735 4 |
| | Maximum tho- racic rib VC (m/s) | Log-normal | 2,635 478 73 | -0,033 129 79 | -0,507 249 49 | 30,650 7 |

Table J.1 (continued)

| Injury risk | Dummy meas- urement | Distribution | int | Coef_age | Log_scale | AIC |
|----------------------------------|--|--------------|--------------|---------------|---------------|----------|
| Soft tissue thoracic AIS2+ | Maximum tho- racic rib VC (m/s) | Log-normal | 21,522 029 6 | -0,249 326 8 | 2,190 178 2 | 45,789 2 |
| Soft tissue thoracic AIS3+ | Maximum tho- racic rib VC (m/s) | Log-normal | 55,427 821 8 | -0,589 543 4 | 2,773 955 6 | 35,607 2 |
| Abdomen soft tissue AIS2+ | Maximum abdo- men rib deflec- tion (mm) | Weibull | 5,367 785 71 | -0,021 028 76 | -2,153 073 24 | 14,988 9 |
| | Maximum abdo- men rib VC (m/s) | Weibull | 1,990 103 19 | -0,034 274 53 | -1,678 603 32 | 14,977 7 |
| | Lower spine acceleration Y 3 ms (m/s ²) | Weibull | 7,226 378 56 | -0,012 791 82 | -1,860 358 41 | 27,576 8 |
| Abdomen soft tissue AIS3+ | Maximum abdo- men rib deflec- tion (mm) | Log-normal | 6,865 650 56 | -0,033 380 33 | -1,010 341 17 | 11,959 1 |
| | Maximum abdo- men rib VC (m/s) | Log-normal | 4,229 733 29 | -0,052 732 82 | -0,629 770 80 | 11,869 6 |
| 1.77 | Lower spine acceleration Y 3 ms (m/s ²) | | | | | / |
| Pelvis AIS2+ | Maximum pubic force (N) | Weibull | 8,774 827 06 | -0,013 855 68 | -1,525 878 36 | 64,005 2 |
| | Pelvis acceleration Y 3 ms (m/s ²) | Weibull | 7,848 665 45 | -0,017 648 48 | -1,271 622 71 | 81,179 1 |
| Pelvis AIS3+ | Maximum pubic force (N) | Weibull | 8,704 064 39 | -0,011 639 87 | -1,827 378 27 | 44,2048 |
| | Pelvis acceleration Y 3 ms (m/s ²) | Weibull | 8,776 559 53 | -0,027 097 67 | -1,317 818 37 | 54,890 5 |

Identification of the overly influential observations

The overly influential observations for the WorldSID 50th injury risk curves are specified in Tables J.2 to J.7.

Table J.2 — Overly influential observations for the shoulder AIS2+ risk as a function of the maximum shoulder rib deflection
